Picture the belt/chain around the large wheel that is turning slowly and then the belt/chain extending down to the smaller wheel which then must turn quickly to keep up with the speed of the belt. The shaft of the smaller wheel can have on it another somewhat larger wheel that will then be turning at the same faster speed of the smaller wheel and a chain/belt from that larger wheel to still another smaller wheel on another shaft will repeat the principle with this second smaller wheel going faster still. The process can be repeated a number of times so that while the first wheel may have been turning only a few revolutions per minute - we can arrive at a wheel turning thousands of revolutions per minute - if that is our goal and PROVIDING that the first wheel has enough torque (combination of weight/mass and energy/momentum) to sustain the drag of the added gears or pulleys.

The reverse principles can be used to make a fast moving small wheel turn more slowly a large wheel, but it is more likely that in our application we are going to need to use the method given in the example. Adding the weight or drag of the belt/chain slows down the big wheel and our problem is that usually we cannot make it go fast enough to overcome the drag that we wish to add to it.

Using a slow waterwheel to run a faster generator

In our above horizontal waterwheel we would have the water hitting the paddles of the the wheel from several sides of the wheel. As an analogy, think of the old playground merry-go-round. Children stand around the outside adding to the speed of the spin. Each one pushing on a bar as it goes by. Eventually they cannot push very much on the merry-go-round because it comes by too fast for them to get a hold on it. Each child is not adding much energy to the wheel as it goes past. Each child's energy potential is being

wasted.

The same thing happens when our waterwheel is coming past the nozzels too fast. The water from the nozzel does not get to hit the blade for very long - so its energy is wasted. The thing to do is to slow down the wheel. We do this by putting more weight on it. Now more energy will go into the wheel at each nozzel. With the merry-go-round there would be more children on the wheel and those standing and pushing would have longer to push the bar in front of them. We use the same principle to capture more of the speed of the water in our nozzels and to change it to torque in the waterwheel. We simply add weight and that slows down the wheel and allows us to capture more energy from the speed and force of the water.

A merry-go-round with few children on it is much easier to stop than another one moving at the same speed with many children on it. That is the effect of mass on torque. A body in motion tends to stay in motion and the heavier the body in motion - the harder it is to stop. This is one of the reasons why we like heavy flywheels in our system.

The Drawback to Flywheels

The DRAWBACK to flywheels is that there is ALWAYS a loss of energy in conversion so ideally we would instead like for our initial wheel to be moving at the end desired speed with the maximum torque it that can master. Because it is difficult, with low head sources, to actually get up to 1800 rpm it is more optimal to use low rpm generators and so consequently our target is more in the area of 400 rpm. The question then becomes one of how much torque (mass/weight - moving at 400 rpm) can we develop from our blade/paddle and nozzel system. We are not wanting to just keep adding weight to the wheel until it slows down to 400 rpm because while it would have good momentum and torque - that is to say it would be difficult to slow down - that weight we added would be just dead weight and the energy (work) that we were using to move it around would be just useless work.

The weight that we want to add as directly as we can to the waterwheel is the weight or energy requirement of turning our generator at 400 rpm. If the waterwheel has the capacity to turn our generator at twice that speed then that is great because we can then let it turn two generators at the same time and we will get twice the electrical output. Conversely, if our waterwheel while initially turning at 400 rpm slows down to half that speed when we add the weight of turning the generator - then perhaps we need a smaller generator or two waterwheels to turn the generator, or a bigger faster waterwheel, or some other combination.

Waterwheel Variables

There are many variables that we can perhaps adjust. The size and weight of the waterwheel, the gear/pulley ratio of the drive to the generator, the number, angle and closeness of the nozzels shooting water onto the paddle/blades and the volume and speed of the water coming through the nozzels. There will undoubtedly be much skill involved in maximizing the adjustments. But no matter - with some reasonable application of the principles involved and some reasonable resources as to waterhead and volume and the components I have described - one should be able to produce some amount of electrical energy. Hopefully

an amount that will make the effort worthwhile.

I would liked to have carried this idea beyond theory, but The Powers That Be would not let me proceed with my experiments. We will have to make do with what we have available but we would particularly have liked to have worked further on the design of the nozzels - an art in itself.

Nozzels

I called around North America and talked with a number of nozzle design engineers and went and visited a couple. Basically what we concluded was that the antique fire hose nozzle of old was the best that we could do. It is long tapered and pointy (at least on the inside). This is somewhat difficult to machine but that is the ideal. One starts with a long bar of steel, (or plastic - if that is what you have and can handle), cut it up into appropriate nozzle lengths and then mill down into the inside.

We have bought all the components for the number (twenty-four) that we think that we will need at our two sites. Connectors, valves, makings for the nozzels, and lots of hose.

In the picture I am holding one of the assembled nozzels. We have also gone ahead and put in place the power house and have acquired the big batteries for the system but we have gone as far as the government will permit us to go.

As I have said - it would have been much better to get our home waterpower system working ahead of time and to prove out the design - but we have gone about as far as the government will permit us to go. We are also considering an altogether different approach for the large waterfall and that is a large pump which we would use as a turbine. But that subject is covered in its own place.

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Energy Types](#)

Making Pumps into Electrical Generators

It is unlikely that after a nuclear holocaust you will be able to find a suitable turbine even if you do find a high head water source but here is a solution that has been tried and said to work even in pre-holocaust time.

[How to do it: Using a pump as a turbine](#)

This 38 page .pdf file gives you a lot information about the process. It is however copyrighted and will have to remain locked until after the nuclear war.

Unfortunately, because of government bureaucray we were not able to go ahead and do a demonstration implementation of the solution - still we did do the the engineering studies.

Large pumps are to be found, even now, in ship and oil field salvage yards. They may have been used to pump oil or some chemical so that you would not want to use them to pump drinking water - but that is okay because you are just using them to create power.

Here is a picture of the type of pump that we are talking about:

It is big (stands about 3 and a half feet high), heavy, and dirty - but once it is cleaned up it will probably work just fine. Moreover, you can very possibly use the attached motor, as explained in an earlier webpage, to run backwards and be the generator.

If you don't have a single large enough volume of water - or sufficient pressure in the water to run the pump then

you may be able to use the approach that I suggest on our home waterfall website and that is to cut holes in the casing and aim nozzels in at the blades, so that you are striking them at more than one location.

Don't forget - your goal is not to move the water (which is the original design purpose of the pump) but rather to take the energy out of the flowing water and transfer it to the wheel inside the pump. For this reason - once you have received the energy, the water is really just in the way and you are now having to use energy to get rid of it. Therefore, what you can do is cut other holes in the casing for the water to escape through - because you just want it to leave.

Another point. If you aren't getting enough energy from the wheel to run the motor backward at a sufficient speed to generate electricity you can also substitute a low rpm generator for the motor.

Overall the concepts here should have application for numbers of potential situations. And don't forget the idea of possibly adding a heavy flywheel to add to the torque and smooth out the operation, but also consider the disadvantage of flywheels as discussed under our home falls generating system.

Below is an engineering study on the expected performance of the pump at our large falls location.:

L
 12 x 14-14
 DV

4000 / 51' @ 1200 RPM \equiv 3933 / 49.3' @ 1180 RPM

IMPELLER SHOULD BE TRIMMED TO APPROXIMATELY 13 1/4" ϕ

AT THIS SIZE, THIS PUMP WILL FLOW 4756 GPM @ 60' AND PRODUCE 45.7 KW
 1200 RPM GENERATOR REQ'D

From the above chart, done by US engineers, you can see that it was expected that we would get over 45KW given a flow of 4756 gallons per minute and using a 1200 rpm generator. Twenty four hours per day with no additional energy input it would be the neatest thing we would have going. Then or now.

The following chart, done by Canadian Engineers, shows the site flow expectations in cubed meters per second. I have not yet been able to convert between American gallons per minute and Canadian cubed meters per second to reconcile the two sets of numbers.

Figure No. 1 Flow Duration Curve Horning's Mills

The following chart shows revenue expectations assuming that we could sell the electricity back to the grid under the "green program" which was legislated many years ago and has been talked about endlessly but I know of no one who has personally made it through the bureaucratic hoops. This chart shows a substantial seasonal difference in water flow and while I have seen BIG differences as the result of a storm - I haven't personally noted there to be that kind of seasonal difference. It makes me wonder if the engineers took some seasonal charts rather than considering the actual underground source from which our stream is fed.

				350,000	\$8,517	\$9,333

Below is the summary engineering study showing, that given the terms of the current "green power" legislation, that the project is financially feasible. Electricity prices have increased since the study was done and as they continue to increase - the case justification of course just gets better and better.

However, the PTB have frustrated all attempts for implementation - not just for us, but also for many others. There has been talk, talk, talk about "green power" and the environment - but it is just talk and impossible hurdles by very antagonistic low level bureaucrats are placed in anyone's way who tries to do anything about it. When my wife and I showed our case to my attorney - he simply replied, "Ah! You are planning to put my children through college!"

After a

nuclear war the practicality - nay the dire necessity of such sources as this will become apparent and so I continue to study and prepare for that eventuality.

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Energy Types](#)

Making Motors into Electrical Generators

Here is another interesting idea for generating electricity. Using an electrical motor and running it backwards. There will probably be lots of good motors with their bearings and windings intact, after a nuclear war. It will be just a matter of matching it up to a wind, water, bicycle, small engine or other driving source.

[How to do it: Using motors as generators](#)

This 49 page .pdf file gives you a lot information about the process. It is however copyrighted and will have to remain locked until after the nuclear war.

Below is another method of getting electricity out of motors, but one that requires magnets. Finding the magnets to make the modifications will probably be the greater challenge. Still, there will be magnets out there also. One good source would be old speakers. Another is computer harddrives. The magnets can be taken from them and sawed into the shapes desired. I have sawed some magnets, and that can be a bit tricky too, without a diamond saw or disk. However, there will be all sorts of challenges - and ingenuity can overcome many of them. In sawing magnets you don't want to overheat them or they will splinter and crack. They need to be kept cool by water during the process. Odd shaped magnets can be cut into smaller shapes and then reassembled into the desired shape. They will self-adhere but a glue or adhesive can be used for integrity.

A magnet sawed in half cannot have the two part joined back together - the way they came apart. They will then repel each other. Amazing! And I am not sure that even physicists understand why. I have asked several. There is SO much that I DON'T understand about magnets. I spent many bucks and hours developing a lathe to shape magnets. Unsuccessfully. Had the input and assistance of a number of capable tool makers, and still couldn't get it to work.

Not all our experiments are succesful. Indeed, many (most) are not - or certainly have to be greatly modified from our original design plans. We have had GREAT failures with many things that we have tried - all the way from hydroponics, to ships, submarines and robots. With inputs of enough time, money and engineering many things can be accomplished. The problem is that as individuals we are often very limited in all those inputs. The limitations will probably only increase after a nuclear war. That is why I so greatly appreciate hearing about designs that have been tested and proven.

We have also had some exceptional successes, as evidenced by my marketing of my patents and some other, what I think are, notable accomplishments. What I try try to share in many of these pages is not so much "how to do" as an attitude about "trying to do" because I think it is the latter that is going to be very important during nuclear recovery.

[Motor 2: Supplementing motors with magnets to make generators](#)

This idea from Force Field seems to be relatively simply done - if you can find the magnets.

[SEALED: Supplementing motors with magnets to make generators](#)

This is this SEALED mirrored site that won't be opened until after The Great Catastrophe.

[Motor 3: Tape Drive Motors as Generators](#)

Force Field has lots of experience with low rpm generators. Here is an example from them of a motor being used as a generator without any modification.

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Energy Types](#)

Diesel and Gasoline Generators

Diesel and gasoline powered generators are an excellent source of electrical power, but of course the problem is finding fuel for them. Every drop of fuel will undoubtedly be scavenged from abandoned vehicles and old storage tanks. Diesels run equally well on furnace heating oil. It is really nothing other than diesel sold under a different taxing system and perhaps with a coloring added to it.

A longer term solution for diesels is the growing and distilling of one's own biofuels. This subject is covered elsewhere in our series of web pages.

It is very beneficial to have storage battery systems associated with diesel and gasoline generating systems. These very often are larger generators that put out way more power than one wishes to consume at the moment that they are running, so it is by far more fuel efficient to store the excess power.

HOWEVER, it is more efficient still to use the power directly without first storing it because about 20% of the energy is lost in the conversion process. For this reason, where it is possible, it is best to bunch up or save up the tasks that require a lot of power until such time as the generator will be running, so that the power can be used directly.

[The Diesels at Ark Two](#)

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Energy Types](#)

Batteries and Inverters

Batteries are an important part of alternative electrical systems for two reasons.

First, because the systems often produce so little power, it is important to capture all the power they do produce so that one can have it available at a later time if it is not needed at the moment it is produced.

Secondly, so little power is sometimes produced it is necessary to store it up until one has sufficient to use for the task they wish to undertake.

Banks of large batteries may be difficult to come by but there may be large quantities of automobile batteries about.

[SEALED: The Complete Battery Book](#)

This 98 page .pdf document gives essential information about the care and usage of these batteries and may be very useful information to have. Automobile Batteries will perhaps be the most available.

[Testing: Ammeter.](#)

Forcefield explains how to build and use an ammeter.

[SEALED: Forcefield Ammeter design.](#)

The SEALED version of the Forcefield explanation of how to build and use an ammeter. This file will not be opened until after the nuclear war.

Below is a friend's large battery bank. In actuality he has a half dozen storage sheds with battery banks like this. The batteries require considerable maintenance, the water and acid levels needing to be checked and their charge needing to be replenished, even if they are just kept on standby.

A friend's large battery bank

Inverters

Batteries can be configured for different voltages depending on how they are wired together. It is possible to string out enough to get 110 volts off of them but generally they are used to run 12 volt systems. There are many twelve volt appliances about. They can be found in camping trailers and elsewhere. Also automobiles have a variety of twelve volt motors and devices that can be gotten out of them. The headlights, radios and so forth in automobiles can be used with any sufficiently large twelve volt battery system.

When it is absolutely necessary to convert from 12 to another voltage the device used is called an "inverter". The most common ones convert the power to 110 volts. The problem is that most of the smaller ones, the ones that are most available, and which are relatively inexpensive - costing presently in the one to two hundred dollar range, cannot deliver enough wattage to start pumps or run many household appliances.

Still, if one is fortunate to have an inverter they will probably find many uses that they can put it to. Otherwise, it is best to try to develop things like lighting systems by cannibalizing vehicles for twelve volt sockets and bulbs that one can string together.

Bicycle Power

Bicycles are an important source of transportation that is largely overlooked in North America. I used to oftentime see Mormon Missionaries riding them, and in some areas the Amish. Bicycle paths are becoming more common in many large cities but still it was in China that I realized how under-utilized they are in North America. There in China I traveled through a sea of thousands, more like tens of thousands of them, perhaps even hundreds of thousands while on auto trips. I could see them moving like a mighty river from my high hotel room window.

Bikes were/are used to transport things there that I would have thought unimaginable. I have literally seen a rider with a piano strapped on his back although I do not know if it contained all its guts. Nevertheless, bikes piled high with cabbages, several feet higher than the rider - were a common sight. Bike (or really trike) rick-a-shaws were another common sight. We just don't use the bike anywhere near to that extent in North America. Or we didn't. After the war we may change our attitude about it.

We have used bicycles at Ark Two for many purposes. We use them to mechanically run air blowers, grind wheat, and they can be used for many mechanical purposes such as running a small printing press. Below you see pictures of a bicycle attached to a blower. And we use them for generating electricity.

[Bike 1: Not just for riding \(SEALED\)](#)

This SEALED 144 page .pdf document gives a great amount of valuable information on how to apply bike power to many different kinds of machines. It is a copyrighted document and won't be opened here until after the nuclear war.

Bicycle Power for Generation of Electricity

While I have read lots of articles by people theorizing about using bicycles for electric power generation and I have actually pedaled several ones in the Science Museum and at science demonstrations the three presented here are the best actual bicycle experiments that I am aware of.

Here I am in our garage workshop, pedaling away on our first bike powered generator. Hung around behind me are 8 twelve volt florescent lights which I am lighting by pedaling on the bike.

This generator is hooked to one of several old exercise bikes we have but we also have ten old multispeed bikes waiting down at the shelter. We also have air blowers and wheat grinding mills that we can hook up to them.

We have the system set up so that the florescent lights come on only if the bike is being pedaled. I am lighting all eight lights that you see (plus one more 50 watt Halogen that you can't see) to take the picture. The only light used for the picture was that which I was pedaling. No, I wasn't lighting the heater! That is on a separate circuit.

Ed fixed up a neat system so that any extra power that I pump will go into a battery and not blow up the florescent lights. But the battery doesn't light the lamps.

This is Ed in our garage. Ed has been a major expert on getting all this going.

In the background are the clear basswood boards that I had cut and kilned this summer in preparation for making the blades for windmill propellers. And behind the bike you can see stacked up a number of the brakedrums we were working on.

After we got all ten of the brakedrum generators completed and tested we took one of them to the WLP Picnic to run the sound system amplifiers. The best way to work any of these systems is to pump the power into the batteries so that it will be available whenever you want it - but sometimes we ran the sound system directly off the bike just to show that we could do it.

On the previous low RPM generator web page I link to other pages with more detail about building the brakedrum generators and other low RPM generators and there are lots more detailed pictures of the generators themselves.

[Bike 2: The David Butcher Pedal Powered Generator](#)

The central idea that you want to get from this presentation is the value of a heavy flywheel to smooth out the generation and ease the operation. David also gives a lot of other good information about expected performance.

1. WHAT IS A WOOD GAS GENERATOR AND HOW DOES IT WORK?

This report is one in a series of emergency technology assessments sponsored by the Federal Emergency Management Agency (FEMA). The purpose of this report is to develop detailed, illustrated instructions for the fabrication, installation, and operation of a biomass gasifier unit (i.e., a "producer gas" generator, also called a 'wood gas' generator) that is capable of providing emergency fuel for vehicles, such as tractors and trucks, in the event that normal petroleum sources were severely disrupted for an extended period of time. These instructions have been prepared as a manual for use by any mechanic who is reasonably proficient in metal fabrication or engine repair.

1.1 INTRODUCTION

Fuel gas, produced by the reduction of coal and peat, was used for heating, as early as 1840 in Europe, and by 1884 it had been adapted to fuel engines in England. Before 1940, gas generator units were a familiar, but not extensively utilized, technology. However, petroleum shortages during World War II led to widespread gas generator applications in the transportation industries of Western Europe. (Charcoal-burning taxis, a related application, were still common in Korea as late as 1970.) The United States, never faced with such prolonged or severe oil shortages, has lagged far behind Europe and the Orient in familiarity with and application of this technology; however, a catastrophe could so severely disrupt the supply of petroleum in this country that this technology might be critical in meeting the energy needs of some essential economic activities, such as the production and distribution of food.

This report attempts to preserve the knowledge about wood gasification as put into practical use during World War II. Detailed, step-by-step procedures are presented in this report for constructing a simplified version of the World War II, Imbert wood gas generator. This simple, stratified, downdraft gasifier unit can be constructed from materials that would be widely available in the United States in a prolonged petroleum crisis. For example, the body of the unit consists of a galvanized metal garbage can atop a small metal drum; common plumbing fittings throughout; and a large, stainless steel mixing bowl for the grate. A prototype gasifier unit was fabricated from these instructions. This unit was then mounted onto the front of a gasoline-engine farm tractor and successfully field tested, using wood chips as the only fuel; see [Fig. 1-1](#) (all figures and tables are presented at the end of their respective sections).

Photographic documentation of the actual assembly of the unit, as well as its operational field test, is included in this report.

The use of wood gas generators need not be limited to transportation applications. Stationary engines can also be fueled by wood gasifiers to run electric generators, pumps, and industrial equipment. In fact, the use of wood gas as a fuel is not even restricted to gasoline engines; if a small amount of diesel fuel is

used for ignition, a properly adjusted diesel engine can be operated primarily on wood gas introduced through the intake manifold. However, this report is concerned with the operation of four-cylinder gasoline engines rated from 10 to 150 horsepower. If more information is needed about operating gasifiers on other fuels (such as coal, charcoal, peat, sawdust or seaweed), a list of relevant literature is contained in the Bibliography at the end of this report.

The goal of this report is to furnish information for building a homemade wood gas generator made out of ordinary, available hardware, in order to get tractors, trucks, and other vehicles operating without delay, if a severe liquid fuel emergency should arise. Section 1 describes gasification principles and wood gas generators, in general, and gives some historical background about their operation and effectiveness. Section 2 contains detailed step-by-step instructions for constructing your own wood gas generator unit; illustrations and photographs are included to prevent confusion. Section 3 contains information on operating, maintaining, and trouble-shooting your wood gas generator; also included are some very important guidelines on safety when using your gasifier system.

The wood gasifier design presented in this report has as its origin the proven technology used in World War II during actual shortages of gasoline and diesel fuel. It should be acknowledged that there are alternate technologies (such as methane production or use of alcohol fuels) for keeping internal combustion engines in operation during a prolonged petroleum crisis; the wood gasifier unit described in this report represents only one solution to the problem.

1.2 PRINCIPLES OF SOLID FUEL GASIFICATION

All internal combustion engines actually run on vapor, not liquid. The liquid fuels used in gasoline engines are vaporized before they enter the combustion chamber above the pistons. In diesel engines, the fuel is sprayed into the combustion chamber as fine droplets which burn as they vaporize. The purpose of a gasifier, then, is to transform solid fuels into gaseous ones and to keep the gas free of harmful constituents. A gas generator unit is, simultaneously, an energy converter and a filter. In these twin tasks lie its advantages and its difficulties.

The first question many people ask about gasifiers is, 'Where does the combustible gas come from?' Light a wooden match; hold it in a horizontal position; and notice that while the wood becomes charcoal, it is not actually burning but is releasing a gas that begins to burn brightly a short distance away from the matchstick. Notice the gap between the matchstick and the luminous flame; this gap contains the wood gas which starts burning only when properly mixed with air (which contains oxygen). By weight, this gas (wood gas) from the charring wood contains approximately 20% hydrogen (H_2), 20% carbon monoxide (CO), and small amounts of methane, all of which are combustible, plus 50 to 60% nitrogen (N_2). The nitrogen is not combustible; however, it does occupy volume and dilutes the wood gas as it enters and burns in an engine. As the wood gas burns, the products of combustion are carbon dioxide (CO_2) and water vapor (H_2O).

The same chemical laws which govern combustion processes also apply to gasification. The solid, biomass fuels suitable for gasification cover a wide range, from wood and paper to peat, lignite, and coal, including coke derived from coal. All of these solid fuels are composed primarily of carbon with varying amounts of hydrogen, oxygen, and impurities, such as sulfur, ash, and moisture. Thus, the aim of gasification is the almost complete transformation of these constituents into gaseous form so that only the ashes and inert materials remain.

In a sense, gasification is a form of incomplete combustion; heat from the burning solid fuel creates gases which are unable to burn completely, due to insufficient amounts of oxygen from the available supply of air. In the matchstick example above, as the wood was burned and pyrolyzed into charcoal, wood gas was created, but the gas was also consumed by combustion (since there was an enormous supply of air in the room). In creating wood gas for fueling internal combustion engines, it is important that the gas not only be properly produced, but also preserved and not consumed until it is introduced into the engine where it may be appropriately burned.

Gasification is a physiochemical process in which chemical transformations occur along with the conversion of energy. The chemical reactions and thermochemical conversions which occur inside a wood gas generator are too long and too complicated to be covered here. Such knowledge is not necessary for constructing and operating a wood gasifier. Books with such information are listed in the Reference Section (see, for example, Reed 1979, Vol. II; or Reed and Das 1988).

1.3 BACKGROUND INFORMATION

The use of wood to provide heat is as old as mankind; but by burning the wood we only utilize about one-third of its energy. Two-thirds is lost into the environment with the smoke. Gasification is a method of collecting the smoke and its combustible components. Making a combustible gas from coal and wood began around 1790 in Europe. Such manufactured gas was used for street lights and was piped into houses for heating, lighting, and cooking. Factories used it for steam boilers, and farmers operated their machinery on wood gas and coal gas. After the discovery of large petroleum reserves in Pennsylvania in 1859, the entire world changed to oil - a cheaper and more convenient fuel. Thousands of gas works all over the world were eventually dismantled.

Wood gas generators are not technological marvels that can totally eliminate our current dependence on oil, reduce the impacts of an energy crunch, or produce long-term economic relief from high fossil fuel prices, but they are a proven emergency solution when such fuels become unobtainable in case of war, civil upheaval, or natural disaster. In fact, many people can recall a widespread use of wood gas generators during World War II, when petroleum products were not available for the civilian populations in many countries. Naturally, the people most affected by oil and petroleum scarcity made the greatest advancements in wood gas generator technology.

In occupied Denmark during World War II, 95% of all mobile farm machinery, tractors, trucks, stationary engines, fishing and ferry boats were powered by wood gas generators. Even in neutral

Sweden, 40% of all motor traffic operated on gas derived from wood or charcoal (Reed and Jantzen 1979). All over Europe, Asia, and Australia, millions of gas generators were in operation between 1940 and 1946. Because of the wood gasifier's somewhat low efficiency, the inconvenience of operation, and the potential health risks from toxic fumes, most of such units were abandoned when oil again became available in 1945. Except for the technology of producing alternate fuels, such as methane or alcohol, the only solution for operating existing internal combustion engines, when oil and petroleum products are not available, has been these simple, inexpensive gasifier units.

1.3.1 The World War II, Imbert Gasifier

The basic operation of two gasifiers is described in this and the following section. Their operating advantages and disadvantages will also be discussed. This information is included for the technically interested reader only; it is intended to give the reader more insight into the subtleties of the operating principles of the wood gas generator described in this manual. Those readers who are anxious to begin construction of their own wood gas generator may skip the material below and proceed directly to [Sect. 2](#) without any loss of continuity.

The constricted hearth, downdraft gasifier shown in [Fig. 1-2](#) is sometimes called the 'Imbert' gasifier after its inventor, Jacques Imbert; although, it has been commercially manufactured under various names. Such units were mass produced during World War II by many European automotive companies, including General Motors, Ford, and Mercedes-Benz. These units cost about \$1500 (1985 evaluation) each. However, after World War II began in 1939, it took six to eight months before factory-made gasifiers were generally available. Thousands of Europeans were saved from certain starvation by home-built, simple gasifier units made from washing machine tubs, old water heaters, and metal gas or oxygen cylinders. Surprisingly, the operation of these units was nearly as efficient as the factory-made units; however, the homemade units lasted for only about 20000 miles with many repairs, while the factory-made units operated, with few repairs, up to 100,000 miles.

In [Fig. 1-2](#), the upper cylindrical portion of the gasifier unit is simply a storage bin or hopper for wood chips or other biomass fuel. During operation, this chamber is filled every few hours as needed. The spring-loaded, airtight cover must be opened to refill the fuel hopper; it must remain closed and sealed during gasifier operation. The spring permits the cover to function as a safety valve because it will pop open in case of any excessive internal gas pressure.

About one-third of the way up from the bottom of the gasifier unit, there is a set of radically directed air nozzles; these allow air to be injected into the wood as it moves downward to be gasified. In a gas generator for vehicle use, the downstroke of the engine's pistons creates the suction force which moves the air into and through the gasifier unit; during startup of the gasifier, a blower is used to create the proper airflow. The gas is introduced into the engine and consumed a few seconds after it is made. This gasification method is called "producer gas generation," because no storage system is used; only that amount of gas demanded by the engine is produced. When the, engine is shut off, the production of gas stops.

During normal operation, the incoming air burns and pyrolyzes some of the wood, most of the tars and oils, and some of the charcoal that fills the constricted area below the nozzles. Most of the fuel mass is converted to gas within this combustion zone. The Imbert gasifier is, in many ways, self-adjusting. If there is insufficient charcoal at the air nozzles, more wood is burned and pyrolyzed to make more charcoal. If too much charcoal forms, then the charcoal level rises above the nozzles, and the incoming air burns the charcoal. Thus, the combustion zone is maintained very close to the nozzles.

Below this combustion zone, the resulting hot combustion gases - carbon dioxide (CO_2) and water vapor (H_2O) - pass into the hot charcoal where they are chemically reduced to combustible fuel gases: carbon monoxide (CO) and hydrogen (H_2). The hearth constriction causes all gases to pass through the reaction zone, thus giving maximum mixing and minimum heat loss. The highest temperatures are reached in this region.

Fine char and ash dust can eventually clog the charcoal bed and will reduce the gas flow unless the dust is removed. The charcoal is supported by a movable grate which can be shaken at intervals. Ash buildup below the grate can be removed during cleaning operations. Usually, wood contains less than 1% ash (by weight). However, as the charcoal is consumed, it eventually collapses to form a powdery charcoal/ash mixture which may represent 2 to 10% (by weight) of the total fuel mass.

The cooling unit required for the Imbert gasifier consists of a water filled precipitating tank and an automotive radiator type gas cooler. The precipitating tank removes all unacceptable tars and most of the fine ash from the gas flow, while the radiator further cools the gas. A second filter unit, containing a fine mesh filtration material, is used to remove the last traces of any ash or dust that may have survived passage through the cooling unit. Once out of the filter unit, the wood gas is mixed with air in the vehicle's carburetor and is then introduced directly into the engine's intake manifold.

The World War II, Imbert gasifier requires wood with a low moisture content (less than 20% by weight) and a uniform, blocky fuel in order to allow easy gravity feed through the constricted hearth. Twigs, sticks, and bark shreds cannot be used. The constriction at the hearth and the protruding air nozzles present obstructions to the passage of the fuel and may create bridging and channeling followed by poor quality gas output, as unpyrolyzed fuel falls into the reaction zone. The vehicle units of the World War II era had ample vibration to jar the carefully sized wood blocks through the gasifier. In fact, an entire industry emerged for preparing wood for use in vehicles at that time (Reed and Jantzen 1979). However, the constricted hearth design seriously limits the range of wood fuel shapes that can be successfully gasified without expensive cubing or pelletizing pretreatment. It is this limitation that makes the Imbert gasifier less flexible for emergency use.

In summary, the World War II Imbert gasifier design has stood the test of time and has successfully been mass produced. It is relatively inexpensive, uses simple construction materials, is easy to fabricate, and can be operated by motorists with a minimum amount of training.

1.3.2 The Stratified, Downdraft Gasifier

Until the early 1980's, wood gasifiers all over the world (including the World War II designs) operated on the principle that both the fuel hopper and the combustion unit be airtight; the hopper was sealed with a top or lid that had to be opened every time wood was added. Smoke and gas vented into the atmosphere while new wood was being loaded; the operator had to be careful not to breathe the unpleasant smoke and toxic fumes.

Over the last few years, a new gasifier design has been developed through cooperative efforts among researchers at the Solar Energy Research Institute in Colorado, the University of California in Davis, the Open University in London, the Buck Rogers Company in Kansas, and the Biomass Energy Foundation, Inc., in Florida (Reed and Das 1988). This simplified design employs a balanced, negative-pressure concept in which the old type of sealed fuel hopper is no longer necessary. A closure is only used to preserve the fuel when the engine is stopped. This new technology has several popular names, including 'stratified, downdraft gasification' and 'open top gasification.' Two years of laboratory and field testing have indicated that such simple, inexpensive gasifiers can be built from existing hardware and will perform very well as emergency units.

A schematic diagram of the stratified, downdraft gasifier is shown in [Fig. 1-3](#). During operation of this gasifier, air passes uniformly downward through four zones, hence the name 'stratified:'

1. The uppermost zone contains unreacted fuel through which air and oxygen enter. This region serves the same function as the fuel hopper in the Imbert design.
2. In the second zone, the wood fuel reacts with oxygen during pyrolysis. Most of the volatile components of the fuel are burned in this zone and provide heat for continued pyrolysis reactions. At the bottom of this zone, all of the available oxygen from the air has completely reacted. The open top design ensures uniform access of air to the pyrolysis region.
3. The third zone is made up of charcoal from the second zone. Hot combustion gases from the pyrolysis region react with the charcoal to convert the carbon dioxide and water vapor into carbon monoxide and hydrogen.
4. The inert char and ash, which constitute the fourth zone, are normally too cool to cause further reactions; however, since the fourth zone is available to absorb heat or oxygen as conditions change, it serves both as a buffer and as a charcoal storage region. Below this zone is the grate. The presence of char and ash serves to protect the grate from excessive temperatures.

The stratified, downdraft design has a number of advantages over the World War II, Imbert gasifier. The open top permits fuel to be fed more easily and allows easy access. The cylindrical shape is easy to fabricate and permits continuous flow of fuel. No special fuel shape or pretreatment is necessary; any blocky fuel can be used.

The foremost question about the operation of the stratified, downdraft gasifier concerns char and ash removal. As the charcoal reacts with the combustion gases, it eventually reaches a very low density and

breaks up into a dust containing all of the ash as well as a percentage of the original carbon. This dust may be partially carried away by the gas; however, it might eventually begin to plug the gasifier, and so it must be removed by shaking or agitation. Both the Imbert gasifiers and the stratified concept have a provision for shaking the grate; when they are used to power vehicles, they are automatically shaken by the vehicle's motion.

An important issue in the design of the stratified, downdraft gasifier is the prevention of fuel bridging and channeling. High-grade biomass fuels such as wood blocks or chips will flow down through the gasifier under the influence of gravity, and downdraft air flow. However, other fuels (such as shredded wood, sawdust, and bark) can form a bridge that will prevent continuous flow and cause very high temperatures. Obviously, it is desirable to use these widely available biomass residues. Bridging can be prevented by stirring, shaking, or by agitating the grate or by having it agitated by the vehicle's movement. For prolonged idling, a hand-operated shaker has been included in the design.

A prototype design of the stratified, downdraft gasifier design has been developed. The detailed but simple design is described and illustrated in Section 2 (see Table of Contents), however, it has not been widely tested at this time. The reader is urged to use his ingenuity and initiative in constructing his own wood gas generator. As long as the principle of airtightness in the combustion regions, in the connecting piping, and in the filter units is followed, the form, shape, and method of assembly is not important.

INTRODUCTION TO 2nd EDITION

This construction manual was prepared by my friend and colleague, Harry LaFontaine for the Federal Emergency Management Agency, FEMA, assisted by F.P. Zimmerman at the Oak Ridge national Laboratory. The justification for writing this report was that in the event of a war or natural emergency, when liquid fuel supplies were interrupted, individuals could build gasifiers to run engines for transport and power. The manual was originally distributed by FEMA. This edition is the first edition by the Biomass Energy Foundation Press.

Harry was uniquely qualified to write this manual because he built and operated gasifiers during World War II during the daytime as a cover for his Danish Underground activities at night. Harry was also very ingenious in working with the people and materials at hand, so that this is a very practical manual. However, in the intervening years he also came to appreciate the fundamentals of gasification and he also explains these here.

It has been a pleasure to know and work with Harry. He was the founder of the Biomass Energy Foundation in 1983. The BEF is a 501 3C not for profit organization established to promote the use of Biomass.

It grieves me to say that Harry died (while still in the midst of many projects) on April 12, 1994. However, this report lives on as a very useful memorial to his life and experience.

Thomas B. Reed

Executive summary

This report is one in a series of emergency technology assessments sponsored by the Federal Emergency Management Agency (FEMA). The purpose of this report is to develop detailed, illustrated instructions for the fabrication, installation, and operation of a biomass gasifier unit (i.e. a "producer gas" generator, also called a "wood gas" generator) which is capable of providing emergency fuel for vehicles, such as tractors and trucks, should normal petroleum sources be severely disrupted for an extended period of time. These instructions have been prepared as a manual for use by any mechanic who is reasonably proficient in metal fabrication or engine repair.

Fuel gas, produced by the reduction of coal and peat, was used for heating as early as 1840 in Europe and by 1884 had been adapted to fuel engines in England. Prior to 1940, gas generator units were a familiar, but not extensively utilized, technology. However, petroleum shortages during World War II led to widespread gas generator applications in the transportation industries of Western Europe. (Charcoal burning taxis, a related application, were still common in Korea as late as 1970.) The United States, never faced with such prolonged or severe oil shortages, has lagged far behind Europe and the Orient in familiarity with and application of this technology. However, a catastrophic event could disrupt the supply of petroleum in this country so severely that this technology might be critical in meeting the energy needs of some essential economic activities, such as the production and distribution of food.

In occupied Denmark during World War II, 95% of all mobile farm machinery, tractors, trucks, stationary engines, and fishing and ferry boats were powered by wood gas generator units. Even in neutral Sweden, 40% of all motor traffic operated on gas derived from wood or charcoal. All over Europe, Asia, and Australia, millions of gas generators were in operation between 1940f and 1946. Because of the wood gasifier's health risks from toxic fumes, most of such units were abandoned when it again became available in 1945. Except for the technology of producing alternate fuels, such as methane or alcohol, the only solution for operating existing internal combustion engines, when oil and petroleum products are not available, has been these simple, inexpensive gasifiers units.

This report attempts to preserve the knowledge about wood gasification that was put into practical use during World War II. In this report, detailed step-by-step procedures are presented for constructing a simplified version of the WWII wood gas generator; this simple, stratified, downdraft gasifier unit (shown schematically in [Fig. S-1](#)) can be constructed from materials which would be widely available in the United States in a prolonged petroleum crisis. For example, the body of the unit consists of a galvanized metal garbage can atop a small metal drum; common plumbing fittings are used throughout; and a large, stainless steel mixing bowl is used for the grate. A prototype gasifier unit was fabricated from these instructions (see [Fig. S-2](#)); this unit was then mounted onto the front of a farm tractor and successfully field tested, using wood chips as the only fuel (see [Fig. S-3](#)). Photographic documentation of the actual assembly of the unit, as well as its operational field test, is included in the body of this report.

The use of wood gas generators need not be limited to transportation applications. Stationary engines can also be fueled by wood gasifiers to run electric generators, pumps, and industrial equipment. In fact, the use of wood gas as a fuel is not even restricted to gasoline engines; if a small amount of diesel fuel is used for ignition, a properly adjusted diesel engine can be operated primarily on wood gas introduced through the intake manifold.

S.1 Principles of solid fuel gasification

All internal combustion engines actually run on vapor, not liquid. The liquid fuels used by gasoline engines are vaporized before they enter the combustion chamber above the pistons. In diesel engines, the fuel is sprayed into the combustion chamber as fine droplets which burn as they vaporize. The purpose of a gasifier, then, is to transform solid fuels into gaseous ones and to keep the gas free of harmful constituents. A gas generator unit is simultaneously an energy converter and a filter. In these twin tasks lie its advantages and its difficulties.

In a sense, gasification is a form of incomplete combustion-heat from the burning solid fuel creates gases which are unable to burn completely because of the insufficient amounts of oxygen from the available supply of air. The same chemical laws which govern combustion processes also apply to gasification. There are many solid biomass fuels suitable for gasification - from wood and paper to peat, lignite, and coal, including coke derived from coal. All of these solid fuels are composed primarily of carbon with varying amounts of hydrogen, oxygen, and impurities, such as sulfur, ash, and moisture. Thus, the aim of gasification is the almost complete transformation of these constituents into gaseous form so that only the ashes and inert materials remain. In creating wood gas for fueling internal combustion engines, it is important that the gas not only be properly produced, but also preserved and not consumed until it is introduced into the engine where it may be appropriately burned.

Gasification is a physiochemical process in which chemical transformations occur along with the conversion of energy. The chemical reactions and thermochemical conversions which occur inside a wood gas generator are too long and too complicated to be covered here; however, such knowledge is not necessary for constructing and operating a wood gasifier. By weight, gas (wood gas) produced in a gasifier unit contains approximately 20% hydrogen (H_2), 20% carbon monoxide (CO), and small amounts of methane, all of which are combustible, plus 50 to 60% nitrogen (N_2). The nitrogen is not combustible; however, it does occupy volume and dilutes the wood gas as it enters and burns in an engine. As the wood gas burns, the products of combustion are carbon dioxide (CO_2) and water vapor (H_2O).

One of the by-products of wood gasification is carbon monoxide, a poisonous gas. The toxic hazards associated with breathing this gas should be avoided during refueling operations or prolonged idling, particularly in inadequately ventilated areas. Except for the obvious fire hazard resulting from the combustion processes inside the unit, carbon monoxide poisoning is the major potential hazard during

normal operation of these simplified gasifier units.

S.2. THE STRATIFIED DOWNDRAFT GASIFIER

Until the early 1980s, wood gasifiers all over the world (including the World War II designs) operated on the principle that both the fuel hopper and the combustion unit be absolutely airtight; the hopper was sealed with a top or lid which had to be opened every time wood was added. Smoke and gas vented into the atmosphere while wood was being loaded; the operator had to be careful not to breathe the unpleasant smoke and toxic fumes.

Over the last few years, a new gasifier design has been developed through cooperative efforts among researchers at the Solar Energy Research Institute in Colorado, the University of California in Davis, the Open University in London, the Buck Rogers Company in Kansas, and the Biomass Energy Foundation, Inc., in Florida. This simplified design employs a balanced, negative-pressure concept in which the old type of sealed fuel hopper is no longer necessary. A closure is only used to preserve the fuel when the engine is stopped. This new technology has several popular names, including "stratified, downdraft gasification" and "open top gasification." Several years of laboratory and field testing have indicated that such simple, inexpensive gasifiers can be built from existing hardware and will perform very well as emergency units.

A schematic diagram of the stratified, downdraft gasifier is shown in [Fig. S-1](#). During operation of this gasifier, air passes uniformly downward through four zones, hence the name stratified:

1. The uppermost zone contains unreacted fuel through which air and oxygen enter. This region serves the same function as the fuel hopper in the older, World War II designs.
2. In the second zone, the wood fuel reacts with oxygen during pyrolysis. Most of the volatile components of the fuel are burned in this zone and provide heat for continued pyrolysis reactions. At the bottom of this zone, all of the available oxygen from the air should be completely reacted. The open top design ensures uniform access of air to the pyrolysis region.
3. The third zone is made up of charcoal from the second zone. Hot combustion gases from the pyrolysis region react with the charcoal to convert the carbon dioxide and water vapor into carbon monoxide and hydrogen.
4. The inert char and ash, which constitute the fourth zone, are normally too cool to cause further reactions; however, because the fourth zone is available to absorb heat or oxygen as conditions change, it serves both as a buffer and as a charcoal storage region. Below this zone is the grate. The presence of char and ash serves to protect the grate from excessive temperatures.

The stratified, downdraft design has a number of advantages over the World War II gasifier designs. The

open top permits fuel to be fed more easily and allows easy access. The cylindrical shape is easy to fabricate and permits continuous flow of fuel. No special fuel shape or pretreatment is necessary; any blocky fuel can be used.

The foremost question about the operation of the stratified, downdraft gasifier concerns char and ash removal. As the charcoal reacts with the combustion gases, it eventually reaches a very low density and breaks up into a dust containing all of the ash as well as a percentage of the original carbon. This dust may be partially carried away by the gas and might eventually begin to plug the gasifier. Hence, it must be removed by shaking or agitation. When the stratified gasifier unit is used to power vehicles, it is automatically shaken by the vehicle's motion.

An important issue in the design of the stratified, downdraft gasifier is the prevention of fuel bridging and channeling. High grade biomass fuels, such as wood blocks or chips, will flow down through the gasifier because of gravity and downdraft air flow. However, other fuels (such as shredded chips, sawdust, and bark) can form a bridge, which will obstruct continuous flow and cause very high temperatures. Bridging can be prevented by stirring, shaking, or by agitating the grate or by having it agitated by the vehicle's movement. For prolonged idling, a hand-operated shaker has been included in the design in this report.

A prototype unit of the stratified, downdraft gasifier design (se Figs. [S-2](#) and [S-3](#)) has been fabricated according to the instructions in this report; however, it has not been widely tested at this time. The reader is urged to use his ingenuity and initiative in the construction of his own wood gas generator. As long as the principle of airtightness in the combustion regions, in the connecting piping, and in the filter units is followed, the form, shape, and method of assembly is not important.

The wood gasifier design presented in this report has as its origin the proven technology used in World War II during actual shortages of gasoline and diesel fuel. It should be acknowledged that there are alternate technologies (such as methane production or use of alcohol fuels) for keeping internal combustion engines in operation during a prolonged petroleum crisis; the wood gasifier unit described in this report represents only one solution to the problem.

CONVERSION FACTORS FOR SI UNITS

English units have been retained in the body of this report. The report refers to commercially available materials and sizes which are commonly expressed in English units. The conversion factors for SI (Standard International - metric) units are given below:

To convert from	TO	Multiply by
cubic feet (ft.)	cubic meters (m ³)	0.0283
cubic yards (yd.)	cubic meters (m ³)	0.7646
Fahrenheit degrees (OF)	Kelvin degrees (K)	(see Note 1)
foot (ft)	meter (m)	0.3048
gallon (gal)	cubic meters (m ³)	3.785 * 10 ⁻³
horsepower (hp)	watt (W)	745.7
inch (in.)	meter (m)	0.0254
pound (lb.)	kilogram (kg)	0.4536
quart (qt.)	cubic meters (m ³)	9.464 * 10 ⁻⁴

Note I: To convert temperatures, use the following equation,

$$K = 273 + 0.5556 X (F - 32),$$

where F is the temperature in Fahrenheit degrees, and K is the temperature in Kelvin degrees.

Table 2-1. List of materials for the gasifier unit and the wood fuel hopper

Item	Quantity	Description
1A	1	Metal pipe, tube, or other, open-ended metal cylinder; diameter and length from Table 2-2; minimum wall thickness of 1/4 in.
2A	1	Circular metal plate with thickness of 1/8 in.; diameter equal to outside diameter of Item 1A.
3A	1	30-gal metal oil drum or metal container with approximate dimensions of 18 in. (diameter) by 29 in. (height); container must have a bottom.
4A	1	10-quart stainless steel mixing bowl, container, or other stainless steel bowl with approximately 14-in. diameter and 6-in. depth.
5A	1	2-in. metal U-bolt.
6A	1	3/16-in. metal chain with 1-in. links; 7 ft total length.
7A	3	1/4-in. eyebolts, 3 in. length with two nuts for each eyebolt.
8A	1	4-in. metal pipe nipple.
9A	1	Metal pipe, cap for Item 8A.
10A	2	3-in. metal pipe nipple.
11A	2	Metal pipe cap for Item 10A.
12A		Shaker assembly; see Fig. 2-8 .
1AA	1	Metal 1/2-in. pipe; 6 in. length.
2AA	1	Iron bar stock; square or round, 1/2 in.; 6 in. length.
3AA	1	1/2-in. bolt; 8 in. long.
4AA	1	Iron bar stock; rectangular, 1/4 by 1 in.; 10 in. length.
5AA	1	1/2-in. flat washer.
6AA	2	1/2-in. nuts.
7AA	1	Metal pipe cap or bushing for Item 1AA.
13A	1	Iron bar stock; rectangular, 1/4 by 2 in.; 10 ft length.
14A	25	1/4-in. bolts; 314 in. length; with nuts.
15A	1	20-gal metal garbage can or metal container with approximate dimensions of 18 in. (top diameter) by 24 in. (height); bottom is not required.
16A	1	Lid for 20-gal garbage can.
17A	1	Garden hose; 1/2 to 5/8 in. diameter; length equal to circumference of Item 15A.
18A	1	Foam weather stripping with adhesive backing; 1/4 by 1 in.; length equal to circumference of Item 15A.

19A	1	Iron bar stock; rectangular, 1/4 by 2 in.; 10 ft length.
20A	12	1/4-in. bolts; 3/4 in. length; with nuts.
21A	4	Metal triangles; 2 by 2.5 in., 1/8 to 1/4 in. thick.
22A	2	Metal eye hook.
23A	2	Screen door spring, 14 in. length.
24A	1	Lock ring for 30-gal (or larger) oil drum.
25A	4	Metal squares; 2 by 2 in., 1/4 in. thick.
26A	4	3/8-in. bolts; 3 in. length.
27A	1	Tube. of high temperature silicone or liquid high temperature gasket material.
28A	1	60-lb. sack of hydraulic or other waterproof cement [such as SEC-PLUG (tm), which is manufactured by the Atlas Chemical Company, Miami, FL].
29A	1	2-in. pipe, electrical conduit, flexible automobile exhaust pipe, or other metal tubing; 6-ft minimum length. Pipe must be able to withstand temperatures of 400°F.

Table 2-2. Fire tube dimensions

Inside diameter (inches)	Minimum length (inches)	Engine power (hp)	Typical engine displacement (cubic inches)
2-	16	5	10
4-	16	15	30
6	16	30	60
7	18	40	80
8	20	50	100
9	22	65	130
10	24	80	160
11	26	100	200
12	28	120	240
13	30	140	280
14	32	160	320

*A fire tube with an inside diameter of less than. 6 in. would create bridging problems with wood chips and blocks. If the engine is rated at or below 15 horsepower, use a 6-in. minimum fire tube diameter and create a throat restriction in the bottom of the tube corresponding to the diameter entered in the above table.

NOTES: For engines with displacement rated in liters, the conversion factor is 1 liter = 61.02 cubic inches.

The horsepower listed above is the SAE net brake horsepower as measured at the rear of the transmission with standard accessories operating. Since the figures vary when a given engine is installed and used for different purposes, such figures are representative rather than exact. The above horsepower ratings are given at the engine's highest operating speed.

Table 2-3. List of materials for the primary filter unit

Item	Quantity	Description
1B	1	5-gal metal can or other metal container with minimum dimensions of 11.5-in. diameter and 13 in. tall.
2B	1	Circular metal plate; diameter equal to 1/2 in. smaller than inside diameter of Item 1B; thickness of 1/8 in.
3B	3	3/8-in. bolts; 3 in. length with two nuts for each bolt.
4B	1	Rectangular metal plate; width equal to 1/4 in. smaller than inside diameter of Item 1B; height equal to 2.5 in. smaller than internal height of Item 1B; 1/8 in. thick.
5B	1	High-temperature hose, 3/8 to 5/8 in. diameter; length equal to circumference of Item 1B.
6B	1	Circular metal plate; diameter equal to outside diameter of Item 1B; thickness of 1/8 in.
7B	1	12-volt blower (automotive heater type); case and fan must be all metal.
8B	1	Metal extension pipe for blower outlet, including elbows and connections for vertical orientation; 1 ft. minimum length.
9B	1	Cap for Item 8B; plastic is acceptable.
10B	1	1.25-in. metal pipe, electrical conduit, automotive exhaust pipe, or other metal tubing; 2 ft minimum length.
11B	3	Metal latch for securely connecting Items 1B and 6B together. Such devices as suitcase or luggage catches, bail-type latches, window sash catches (with strike), or wing-nut latches are acceptable.
12B	1	High-temperature hose, 3/8 to 5/8 in. diameter; length equal to three times the height of Item 4B.
13B	1	Metal 1/2-in. pipe, threaded on one end; 8 in. length.
14B	1	Metal pipe cap for Item 13B.

Table 2-4.

List of materials for the carbureting unit

Item	Quantity	Description
1C	1	1.25-in. closet flange.
2C	1	1.25-in. male-to-female 45° pipe elbow.
3C		Butterfly valve; see Fig. 2-23 .
1CC	2	1.25-in. pipe nipple or threaded length of pipe, 3-in. length.
2CC	2	Oval metal plate; 1/16 in. thick; short dimension equal to inside diameter of Item 1CC; long dimension equal to 1.02 times the short dimension.
3CC	2	3/8-in. diameter rod; 2.5 in. length.
4CC	4	3/16-in. screws; 3/16 in. length.
3CC	2	Flat bar stock; rectangular 1/2 by 3 in.; 1/8 in. thick.
6CC	1	7/16-in. nut.
7CC	1	1/8-in. set screw.
4C	1	1.25-in. tee with all female threads.
5C	1	1.25-in. pipe nipple or threaded length of pipe, 3 in. length.
6C	1	1.25-in. pipe or hose.
7C	1	Gasket material; sized to cover Item 1C.
8C	1	Tube of pipe compound or Teflon tape for sealing threaded assemblies.

Table 3-1.

Trouble-shooting your wood gas generator

Trouble	Cause	Remedy
Start up takes too long	Dirty system or clogged pipes.	Clean the gasifier unit and all the connecting piping.
	Blower is too weak	Check the blower and the battery's charge.
	Wet or poor quality charcoal	Check charcoal and replace or refill to proper level.
	Wood fuel bridges in the fire tube.	Lightly tamp down the wood fuel in the hopper and fire tube or replace the fuel with smaller-sized chips.
Engine will not start.	Insufficient gas	Use the blower longer during start up.
	Wet wood fuel.	Vent steam and smoke through the fire tube and fuel hopper for several minutes.
	Incorrect fuel-air mixture.	Regulate the carburetor's air control for proper mixing
Engine starts, but soon dies	Not enough gas has been produced.	Use low RPM while starting engine and do not rev engine for several minutes.
	Air channels through fire tube.	Tamp down wood fuel lightly in hopper. <u>Do not</u> crush charcoal above the grate.
Engine loses power under load.	Restricted gas flow in piping.	Reduce air mixture valve setting. Check for partial blockage of unit or piping.
	Leaks in system.	Check all covers and pipes for air tightness

Table 3-2.

Effect of breathing carbon monoxide

Carbon monoxide content of inhaled air (%)	Physiological effects
0.020	Possible mild frontal headache after two to three hours
0.040	Frontal headache and nausea after one to two hours; occipital (rear of head) headache after 2.5 to 3.5 hours.
0.080	Headache, dizziness, and nausea in 45 min; collapse and possible unconsciousness in who hours.
0.160	Headache, dizziness, and nausea inn 45 min; collapse and possible unconsciousness in two hours.
0.320	Headache and dizziness in 5 to 10 min; unconsciousness and danger of death in 30 min.
0.640	Headache and dizziness in 1 to 2 min; unconsciousness and danger of death in 10 to 15 min.
1.280	Immediate physiological effect; unconsciousness and danger of death in 1 to 3 min.

CONSTRUCTION OF A SIMPLIFIED WOOD GAS GENERATOR FOR FUELING INTERNAL COMBUSTION ENGINES IN A PETROLEUM EMERGENCY

H. LaFontaine G. P. Zimmerman

ABSTRACT

This report is one in a series of emergency technology assessments sponsored by the Federal Emergency Management Agency (FEMA). The purpose of this report is to develop detailed, illustrated instructions for the fabrication, installation, and operation of a biomass gasifier unit (i.e., a 'producer gas' generator, also called a "wood gas" generator) that is capable of providing emergency fuel for vehicles, such as tractors and trucks, in the event that normal petroleum sources were severely disrupted for an extended period of time. These instructions have been prepared as a manual for use by any mechanic who is reasonably proficient in metal fabrication or engine repair.

This report attempts to preserve the knowledge about wood gasification that was put into practical use during World War II. Detailed, step-by-step fabrication procedures are presented for a simplified version of the World War II, Imbert wood gas generator. This simple, stratified, downdraft gasifier unit can be constructed from materials that would be widely available in the United States in a prolonged petroleum crisis. For example, the body of the unit consists of a galvanized metal garbage can atop a small metal drum; common plumbing fittings throughout; and a large, stainless steel mixing bowl for the grate. The entire compact unit was mounted onto the front of a farm tractor and successfully field tested, using wood chips as the only fuel. Photographic documentation of the actual assembly of the unit as well as its operation is included.

1. WHAT IS A WOOD GAS GENERATOR AND HOW DOES IT WORK?

This report is one in a series of emergency technology assessments sponsored by the Federal Emergency Management Agency (FEMA). The purpose of this report is to develop detailed, illustrated instructions for the fabrication, installation, and operation of a biomass gasifier unit (i.e., a "producer gas" generator, also called a 'wood gas' generator) that is capable of providing emergency fuel for vehicles, such as tractors and trucks, in the event that normal petroleum sources were severely disrupted for an extended period of time. These instructions have been prepared as a manual for use by any mechanic who is reasonably proficient in metal fabrication or engine repair.

1.1 INTRODUCTION

Fuel gas, produced by the reduction of coal and peat, was used for heating, as early as 1840 in Europe, and by 1884 it had been adapted to fuel engines in England. Before 1940, gas generator units were a familiar, but not extensively utilized, technology. However, petroleum shortages during World War II led to widespread gas generator applications in the transportation industries of Western Europe. (Charcoal-burning taxis, a related application, were still common in Korea as late as 1970.) The United States, never faced with such prolonged or severe oil shortages, has lagged far behind Europe and the Orient in familiarity with and application of this technology; however, a catastrophe could so severely disrupt the supply of petroleum in this country that this technology might be critical in meeting the energy needs of some essential economic activities, such as the production and distribution of food.

This report attempts to preserve the knowledge about wood gasification as put into practical use during World War II. Detailed, step-by-step procedures are presented in this report for constructing a simplified version of the World War II, Imbert wood gas generator. This simple, stratified, downdraft gasifier unit can be constructed from materials that would be widely available in the United States in a prolonged petroleum crisis. For example, the body of the unit consists of a galvanized metal garbage can atop a small metal drum; common plumbing fittings throughout; and a large, stainless steel mixing bowl for the grate. A prototype gasifier unit was fabricated from these instructions. This unit was then mounted onto the front of a gasoline-engine farm tractor and successfully field tested, using wood chips as the only fuel; see [Fig. 1-1](#) (all figures and tables are presented at the end of their respective sections).

Photographic documentation of the actual assembly of the unit, as well as its operational field test, is included in this report.

The use of wood gas generators need not be limited to transportation applications. Stationary engines can also be fueled by wood gasifiers to run electric generators, pumps, and industrial equipment. In fact, the use of wood gas as a fuel is not even restricted to gasoline engines; if a small amount of diesel fuel is

used for ignition, a properly adjusted diesel engine can be operated primarily on wood gas introduced through the intake manifold. However, this report is concerned with the operation of four-cylinder gasoline engines rated from 10 to 150 horsepower. If more information is needed about operating gasifiers on other fuels (such as coal, charcoal, peat, sawdust or seaweed), a list of relevant literature is contained in the Bibliography at the end of this report.

The goal of this report is to furnish information for building a homemade wood gas generator made out of ordinary, available hardware, in order to get tractors, trucks, and other vehicles operating without delay, if a severe liquid fuel emergency should arise. Section 1 describes gasification principles and wood gas generators, in general, and gives some historical background about their operation and effectiveness. Section 2 contains detailed step-by-step instructions for constructing your own wood gas generator unit; illustrations and photographs are included to prevent confusion. Section 3 contains information on operating, maintaining, and trouble-shooting your wood gas generator; also included are some very important guidelines on safety when using your gasifier system.

The wood gasifier design presented in this report has as its origin the proven technology used in World War II during actual shortages of gasoline and diesel fuel. It should be acknowledged that there are alternate technologies (such as methane production or use of alcohol fuels) for keeping internal combustion engines in operation during a prolonged petroleum crisis; the wood gasifier unit described in this report represents only one solution to the problem.

1.2 PRINCIPLES OF SOLID FUEL GASIFICATION

All internal combustion engines actually run on vapor, not liquid. The liquid fuels used in gasoline engines are vaporized before they enter the combustion chamber above the pistons. In diesel engines, the fuel is sprayed into the combustion chamber as fine droplets which burn as they vaporize. The purpose of a gasifier, then, is to transform solid fuels into gaseous ones and to keep the gas free of harmful constituents. A gas generator unit is, simultaneously, an energy converter and a filter. In these twin tasks lie its advantages and its difficulties.

The first question many people ask about gasifiers is, 'Where does the combustible gas come from?' Light a wooden match; hold it in a horizontal position; and notice that while the wood becomes charcoal, it is not actually burning but is releasing a gas that begins to burn brightly a short distance away from the matchstick. Notice the gap between the matchstick and the luminous flame; this gap contains the wood gas which starts burning only when properly mixed with air (which contains oxygen). By weight, this gas (wood gas) from the charring wood contains approximately 20% hydrogen (H_2), 20% carbon monoxide (CO), and small amounts of methane, all of which are combustible, plus 50 to 60% nitrogen (N_2). The nitrogen is not combustible; however, it does occupy volume and dilutes the wood gas as it enters and burns in an engine. As the wood gas burns, the products of combustion are carbon dioxide (CO_2) and water vapor (H_2O).

The same chemical laws which govern combustion processes also apply to gasification. The solid, biomass fuels suitable for gasification cover a wide range, from wood and paper to peat, lignite, and coal, including coke derived from coal. All of these solid fuels are composed primarily of carbon with varying amounts of hydrogen, oxygen, and impurities, such as sulfur, ash, and moisture. Thus, the aim of gasification is the almost complete transformation of these constituents into gaseous form so that only the ashes and inert materials remain.

In a sense, gasification is a form of incomplete combustion; heat from the burning solid fuel creates gases which are unable to burn completely, due to insufficient amounts of oxygen from the available supply of air. In the matchstick example above, as the wood was burned and pyrolyzed into charcoal, wood gas was created, but the gas was also consumed by combustion (since there was an enormous supply of air in the room). In creating wood gas for fueling internal combustion engines, it is important that the gas not only be properly produced, but also preserved and not consumed until it is introduced into the engine where it may be appropriately burned.

Gasification is a physiochemical process in which chemical transformations occur along with the conversion of energy. The chemical reactions and thermochemical conversions which occur inside a wood gas generator are too long and too complicated to be covered here. Such knowledge is not necessary for constructing and operating a wood gasifier. Books with such information are listed in the Reference Section (see, for example, Reed 1979, Vol. II; or Reed and Das 1988).

1.3 BACKGROUND INFORMATION

The use of wood to provide heat is as old as mankind; but by burning the wood we only utilize about one-third of its energy. Two-thirds is lost into the environment with the smoke. Gasification is a method of collecting the smoke and its combustible components. Making a combustible gas from coal and wood began around 1790 in Europe. Such manufactured gas was used for street lights and was piped into houses for heating, lighting, and cooking. Factories used it for steam boilers, and farmers operated their machinery on wood gas and coal gas. After the discovery of large petroleum reserves in Pennsylvania in 1859, the entire world changed to oil - a cheaper and more convenient fuel. Thousands of gas works all over the world were eventually dismantled.

Wood gas generators are not technological marvels that can totally eliminate our current dependence on oil, reduce the impacts of an energy crunch, or produce long-term economic relief from high fossil fuel prices, but they are a proven emergency solution when such fuels become unobtainable in case of war, civil upheaval, or natural disaster. In fact, many people can recall a widespread use of wood gas generators during World War II, when petroleum products were not available for the civilian populations in many countries. Naturally, the people most affected by oil and petroleum scarcity made the greatest advancements in wood gas generator technology.

In occupied Denmark during World War II, 95% of all mobile farm machinery, tractors, trucks, stationary engines, fishing and ferry boats were powered by wood gas generators. Even in neutral

Sweden, 40% of all motor traffic operated on gas derived from wood or charcoal (Reed and Jantzen 1979). All over Europe, Asia, and Australia, millions of gas generators were in operation between 1940 and 1946. Because of the wood gasifier's somewhat low efficiency, the inconvenience of operation, and the potential health risks from toxic fumes, most of such units were abandoned when oil again became available in 1945. Except for the technology of producing alternate fuels, such as methane or alcohol, the only solution for operating existing internal combustion engines, when oil and petroleum products are not available, has been these simple, inexpensive gasifier units.

1.3.1 The World War II, Imbert Gasifier

The basic operation of two gasifiers is described in this and the following section. Their operating advantages and disadvantages will also be discussed. This information is included for the technically interested reader only; it is intended to give the reader more insight into the subtleties of the operating principles of the wood gas generator described in this manual. Those readers who are anxious to begin construction of their own wood gas generator may skip the material below and proceed directly to [Sect. 2](#) without any loss of continuity.

The constricted hearth, downdraft gasifier shown in [Fig. 1-2](#) is sometimes called the 'Imbert' gasifier after its inventor, Jacques Imbert; although, it has been commercially manufactured under various names. Such units were mass produced during World War II by many European automotive companies, including General Motors, Ford, and Mercedes-Benz. These units cost about \$1500 (1985 evaluation) each. However, after World War II began in 1939, it took six to eight months before factory-made gasifiers were generally available. Thousands of Europeans were saved from certain starvation by home-built, simple gasifier units made from washing machine tubs, old water heaters, and metal gas or oxygen cylinders. Surprisingly, the operation of these units was nearly as efficient as the factory-made units; however, the homemade units lasted for only about 20000 miles with many repairs, while the factory-made units operated, with few repairs, up to 100,000 miles.

In [Fig. 1-2](#), the upper cylindrical portion of the gasifier unit is simply a storage bin or hopper for wood chips or other biomass fuel. During operation, this chamber is filled every few hours as needed. The spring-loaded, airtight cover must be opened to refill the fuel hopper; it must remain closed and sealed during gasifier operation. The spring permits the cover to function as a safety valve because it will pop open in case of any excessive internal gas pressure.

About one-third of the way up from the bottom of the gasifier unit, there is a set of radially directed air nozzles; these allow air to be injected into the wood as it moves downward to be gasified. In a gas generator for vehicle use, the downstroke of the engine's pistons creates the suction force which moves the air into and through the gasifier unit; during startup of the gasifier, a blower is used to create the proper airflow. The gas is introduced into the engine and consumed a few seconds after it is made. This gasification method is called "producer gas generation," because no storage system is used; only that amount of gas demanded by the engine is produced. When the, engine is shut off, the production of gas stops.

During normal operation, the incoming air burns and pyrolyzes some of the wood, most of the tars and oils, and some of the charcoal that fills the constricted area below the nozzles. Most of the fuel mass is converted to gas within this combustion zone. The Imbert gasifier is, in many ways, self-adjusting. If there is insufficient charcoal at the air nozzles, more wood is burned and pyrolyzed to make more charcoal. If too much charcoal forms, then the charcoal level rises above the nozzles, and the incoming air burns the charcoal. Thus, the combustion zone is maintained very close to the nozzles.

Below this combustion zone, the resulting hot combustion gases - carbon dioxide (CO_2) and water vapor (H_2O) - pass into the hot charcoal where they are chemically reduced to combustible fuel gases: carbon monoxide (CO) and hydrogen (H_2). The hearth constriction causes all gases to pass through the reaction zone, thus giving maximum mixing and minimum heat loss. The highest temperatures are reached in this region.

Fine char and ash dust can eventually clog the charcoal bed and will reduce the gas flow unless the dust is removed. The charcoal is supported by a movable grate which can be shaken at intervals. Ash buildup below the grate can be removed during cleaning operations. Usually, wood contains less than 1% ash (by weight). However, as the charcoal is consumed, it eventually collapses to form a powdery charcoal/ash mixture which may represent 2 to 10% (by weight) of the total fuel mass.

The cooling unit required for the Imbert gasifier consists of a water filled precipitating tank and an automotive radiator type gas cooler. The precipitating tank removes all unacceptable tars and most of the fine ash from the gas flow, while the radiator further cools the gas. A second filter unit, containing a fine mesh filtration material, is used to remove the last traces of any ash or dust that may have survived passage through the cooling unit. Once out of the filter unit, the wood gas is mixed with air in the vehicle's carburetor and is then introduced directly into the engine's intake manifold.

The World War II, Imbert gasifier requires wood with a low moisture content (less than 20% by weight) and a uniform, blocky fuel in order to allow easy gravity feed through the constricted hearth. Twigs, sticks, and bark shreds cannot be used. The constriction at the hearth and the protruding air nozzles present obstructions to the passage of the fuel and may create bridging and channeling followed by poor quality gas output, as unpyrolyzed fuel falls into the reaction zone. The vehicle units of the World War II era had ample vibration to jar the carefully sized wood blocks through the gasifier. In fact, an entire industry emerged for preparing wood for use in vehicles at that time (Reed and Jantzen 1979). However, the constricted hearth design seriously limits the range of wood fuel shapes that can be successfully gasified without expensive cubing or pelletizing pretreatment. It is this limitation that makes the Imbert gasifier less flexible for emergency use.

In summary, the World War II Imbert gasifier design has stood the test of time and has successfully been mass produced. It is relatively inexpensive, uses simple construction materials, is easy to fabricate, and can be operated by motorists with a minimum amount of training.

1.3.2 The Stratified, Downdraft Gasifier

Until the early 1980's, wood gasifiers all over the world (including the World War II designs) operated on the principle that both the fuel hopper and the combustion unit be airtight; the hopper was sealed with a top or lid that had to be opened every time wood was added. Smoke and gas vented into the atmosphere while new wood was being loaded; the operator had to be careful not to breathe the unpleasant smoke and toxic fumes.

Over the last few years, a new gasifier design has been developed through cooperative efforts among researchers at the Solar Energy Research Institute in Colorado, the University of California in Davis, the Open University in London, the Buck Rogers Company in Kansas, and the Biomass Energy Foundation, Inc., in Florida (Reed and Das 1988). This simplified design employs a balanced, negative-pressure concept in which the old type of sealed fuel hopper is no longer necessary. A closure is only used to preserve the fuel when the engine is stopped. This new technology has several popular names, including 'stratified, downdraft gasification' and 'open top gasification.' Two years of laboratory and field testing have indicated that such simple, inexpensive gasifiers can be built from existing hardware and will perform very well as emergency units.

A schematic diagram of the stratified, downdraft gasifier is shown in [Fig. 1-3](#). During operation of this gasifier, air passes uniformly downward through four zones, hence the name 'stratified:'

1. The uppermost zone contains unreacted fuel through which air and oxygen enter. This region serves the same function as the fuel hopper in the Imbert design.
2. In the second zone, the wood fuel reacts with oxygen during pyrolysis. Most of the volatile components of the fuel are burned in this zone and provide heat for continued pyrolysis reactions. At the bottom of this zone, all of the available oxygen from the air has completely reacted. The open top design ensures uniform access of air to the pyrolysis region.
3. The third zone is made up of charcoal from the second zone. Hot combustion gases from the pyrolysis region react with the charcoal to convert the carbon dioxide and water vapor into carbon monoxide and hydrogen.
4. The inert char and ash, which constitute the fourth zone, are normally too cool to cause further reactions; however, since the fourth zone is available to absorb heat or oxygen as conditions change, it serves both as a buffer and as a charcoal storage region. Below this zone is the grate. The presence of char and ash serves to protect the grate from excessive temperatures.

The stratified, downdraft design has a number of advantages over the World War II, Imbert gasifier. The open top permits fuel to be fed more easily and allows easy access. The cylindrical shape is easy to fabricate and permits continuous flow of fuel. No special fuel shape or pretreatment is necessary; any blocky fuel can be used.

The foremost question about the operation of the stratified, downdraft gasifier concerns char and ash removal. As the charcoal reacts with the combustion gases, it eventually reaches a very low density and

breaks up into a dust containing all of the ash as well as a percentage of the original carbon. This dust may be partially carried away by the gas; however, it might eventually begin to plug the gasifier, and so it must be removed by shaking or agitation. Both the Imbert gasifiers and the stratified concept have a provision for shaking the grate; when they are used to power vehicles, they are automatically shaken by the vehicle's motion.

An important issue in the design of the stratified, downdraft gasifier is the prevention of fuel bridging and channeling. High-grade biomass fuels such as wood blocks or chips will flow down through the gasifier under the influence of gravity, and downdraft air flow. However, other fuels (such as shredded wood, sawdust, and bark) can form a bridge that will prevent continuous flow and cause very high temperatures. Obviously, it is desirable to use these widely available biomass residues. Bridging can be prevented by stirring, shaking, or by agitating the grate or by having it agitated by the vehicle's movement. For prolonged idling, a hand-operated shaker has been included in the design.

A prototype design of the stratified, downdraft gasifier design has been developed. The detailed but simple design is described and illustrated in Section 2 (see Table of Contents), however, it has not been widely tested at this time. The reader is urged to use his ingenuity and initiative in constructing his own wood gas generator. As long as the principle of airtightness in the combustion regions, in the connecting piping, and in the filter units is followed, the form, shape, and method of assembly is not important.

2. BUILDING YOUR OWN WOOD GAS GENERATOR

The following fabrication instructions, parts lists, and illustrations describe the prototype gasifier unit shown schematically in [Fig. 1-3](#). These instructions are simple and easy to follow. The dimensions in the following plans are given in inches rather than in millimeters to make construction easier for those who might be unfamiliar with the metric system and to allow the builder to take advantage of available, alternate construction materials. It will be obvious to the experienced engineer, mechanic, or builder that most of the dimensions (for example, plate thicknesses and cleanout diameters) are not critical to the acceptable performance of the finished gasifier unit.

The prototype gasifier unit described in the following text was actually constructed and field tested on a gasoline engine farm tractor (a 35-hp, John Deere 1010 Special); see [Fig. 2-1](#). The unit operated very well, and on par with the European, World War II designs, but it has not had the test of time nor the millions of operating hours like the older Imbert design. This new stratified design was developed for the construction of simple, inexpensive emergency wood gas generator units. The prototype design below should be considered to be the absolute minimum in regard to materials, piping and filter arrangement, and carburetor system connections.

The gasifier unit, as described below, is designed to maintain proper cooling, even at moderate vehicle speeds. If this unit is to be used on stationary engines or on slow-moving vehicles, a gas cooler and a secondary filter must be placed in the piping system between the generator unit and the carburetor. The ideal temperature for the wood gas at the inlet to the carburetor manifold would be 70°F, with acceptable peaks of 140 to 160°F. For every 10 degrees above 70°F, an estimated 1% horsepower is lost. Cooler gas has higher density and, therefore, contains more combustible components per unit volume.

The millions of wood gasifiers built during World War II proved that shape, form, and construction material had little or no effect on the performance of the unit. Judicious substitution or the use of scavenged parts is, therefore, quite acceptable. What is important is that:

1. the fire tube dimensions (inside diameter and length) must be correctly selected to match the rated horsepower of particular engine which is to be fueled,
2. airtightness of the gas generator unit and all connecting piping must be maintained at all times, and
3. unnecessary friction should be eliminated in all of the air and gas passages by avoiding sharp bends in the piping and by using piping sizes which are not too small.

2.1. BUILDING THE GAS GENERATOR UNIT AND THE FUEL HOPPER

[Figure 2-2](#) shows an exploded view of the gas generator unit and the fuel hopper; the list of materials is

given in [Table 2-1](#) (all figures and tables mentioned in Sect. 2 are presented at the end of Sect. 2). Only the dimensions of the fire tube (Item 1A) must be reasonably close; all other dimensions and materials can be substituted as long as complete airtightness is maintained. In the following instructions, all item numbers refer both to [Fig. 2-2](#) and to [Table 2-1](#).

The prototype unit described in this report was constructed for use with a 35-hp gasoline engine; the unit has a fire tube diameter of 6 in. (as determined from [Table 2-2](#)). A gas generator unit containing a fire tube up to 9-in. diameter (i.e., a gasifier unit for fueling engines up to about 65 hp) can be constructed from the following instructions. If your engine requires a fire tube diameter of 10 in. or more, use a 55-gal drum for the gas unit and another 55-gal drum for the fuel hopper.

The following fabrication procedure is very general and can be applied to the construction of gas generator units of any size; however, the specific dimensions which are given in the parts list and in the instructions below are for this particular prototype unit. All accompanying photographs were taken during the actual assembly of the prototype unit. The fabrication procedure is as follows:

1. Using the displacement or horsepower rating of the engine to be fueled by the gasifier unit, determine the dimensions (inside diameter and length) of the fire tube (Item 1A) from [Table 2-2](#). Fabricate a cylindrical tube or cut a length of correctly sized pipe to match the dimensions from [Table 2-2](#). (For the prototype gasifier unit illustrated in this report, a 6-in.-diam firetube was used; its length was 19 in.)
2. The circular top plate (Item 2A) should be cut to a diameter equal to the outside diameter of the gasifier housing drum (Item 3A) at its top. A circular hole should then be cut in the center of the top plate; the diameter of this hole must be equal to the outside diameter of the fire tube. The fire tube (Item 1A) should then be welded at a right angle to the top plate (Item 2A) as shown in [Fig. 2-3](#).
3. The grate (Item 4A) should be made from a stainless steel mixing bowl or colander. Approximately 125 holes with diameters of 1/2 in. should be drilled in the bottom and up the sides of the mixing bowl; see [Fig. 2-4](#). A U-bolt (Item 5A) should be welded horizontally to the side of the grate, 2 in. from its bottom. This U-bolt will be interlocked with the shaker mechanism (Item 12A) in a later step.
4. The support chains (Item 6A) are to be attached to the grate in three evenly spaced holes drilled under the lip of the mixing bowl or colander; see [Fig. 2-5](#). These chains are to be connected to the top plate (Item 2A) with eyebolts (Item 7A), as shown in [Fig. 2-6](#). Each eyebolt should have two nuts, one on each side of the top plate, so that the eyebolts can be adjusted to the proper length. When assembled, the bottom of the firetube should be 1.25 in. above the bottom of the mixing bowl.

5. A hole equal to the outside diameter of the ash cleanout port (Item 8A) should be cut into the side of the gasifier housing drum (Item 3A); the bottom edge of this hole should be about 1/2 in. from the bottom of the drum. Because of the thin wall thickness of oil drums and garbage cans, welding is not recommended; brazing such parts to the drums or cans will ensure both strength and airtightness (see [Fig. 2-7](#)).
6. Two holes, equal to the outside diameters of the ignition ports (Item 10A), are to be cut with their centers at a distance from the top of the housing drum (Item 3A) equal to the firetube length less 7 in. (19 in. less 7 in. equals 12 in. for this prototype unit); the holes should be placed opposite each other as shown in [Fig. 2-2](#). The ignition ports should be attached to the wall of the housing drum by brazing.
7. When the ash cleanout port (Item 8A) and the ignition ports (Item 10A) have been attached to the wall of the gasifier housing drum (Item 3A), they should then be closed with pipe caps, Items 9A and 11A respectively. The threads of the pipe caps should be first coated with high temperature silicone (Item 27A) to ensure airtightness. An optional steel crossbar welded to the pipe cap will reduce the effort required to open these caps later.
8. The shaker assembly (Item 12A) is shown in [Fig. 2-8](#). The 1/2-in. pipe (Item 1AA) should be brazed into the side of the housing drum (Item 3A), 1.5 inches from the bottom of the drum; the length of this pipe which protrudes into the drum must be chosen so that the upright bar (Item 2AA) is in line with the U-bolt (Item 5A) on the grate. Likewise, the length of the upright bar must be selected so as to connect into the U-bolt.
9. Weld the upright bar (Item 2AA) to the head of the bolt (Item 3AA). The threaded end of the bolt should be ground down or flattened on one side, as shown in [Fig. 2-9](#), to positively interlock with a slot to be drilled and filed in the handle (Item 4AA). The handle can be formed or bent into any desired or convenient shape.
10. A hole should be drilled in the pipe cap (Item 7AA) so that there is a close fit between this hole and the bolt (Item 3AA). The close fit will help to ensure airtightness.
11. Before assembling the shaker, as shown in [Fig. 2-8](#), coat the bolt (Item 3AA) with a small amount of grease. Before inserting the bolt, fill the pipe (Item 1AA) with high temperature silicone (Item 27A) to ensure airtightness. Tighten the nuts (Item 6AA) so that the position of the handle (Item 4AA) is maintained by friction, yet is capable of being turned and agitated during cleanout or stationary operation.
12. Fabricate the supports (Item 13A) for the gasifier unit housing drum (Item 3A) out of rectangular, iron bar stock. The shape and height of the support flanges must be determined by the frame of the vehicle to which the gasifier is to be mounted. The supports can either be bolted to the bottom and side with the 1/4-in. bolts (Item 14A) or can be brazed directly to the drum; see [Fig. 2-10](#).

Remember to seal all bolt holes for airtightness.

13. Completely cover the bottom of the housing drum (Item 3A) with 1/2 in. of hydraulic cement (Item 28A). The cement should also be applied to the inside of the drum for about 5 in. up the inside walls near the bottom. All edges should be rounded for easy ash removal.
14. The fuel hopper (Item 15A) is to be made from a second container with its bottom up as shown in [Fig. 2-11](#). Remove the bottom, leaving a 1/4-in. lip around the circumference.
15. A garden hose (Item 17A) should be cut to a length equal to the circumference of the fuel hopper (Item 15A) and should then be, slit along its entire length. It should be placed over the edge of the fuel hopper from which the bottom was removed. This will prevent injury to the operator when adding wood fuel to the unit. To insure close fit of the garbage can lid (Item 16A), a piece of weather stripping (Item 18A) should be attached under the lid where it makes contact with the fuel hopper.
16. Cut four support bars (Item 19A) to lengths 2.5 in. longer than the height of the fuel hopper (Item 15A). Drill a 3/8-in. hole in each end of all four support bars; these holes should be centered 3/4 in. from the ends. Bend 2 in. of each end of these support bars over at a right angle; then, mount them evenly spaced around the fuel hopper (Item 15A) with 1/4-in. bolts (Item 20A). One of the bends on each support bar should be as close to the lower edge of the fuel hopper as possible.
17. Cut four metal triangular standoffs (Item 21A) and braze, weld, or rivet them flat against the edge of the garbage can lid (Item 16A) as shown in [Fig. 2-12](#); they must be aligned with the four support bars (Item 19A) attached to the fuel hopper. During operation, the garbage can lid must have a minimum 3/4-in. opening for air passage; the standoffs should provide this clearance, where they are engaged into the holes in the top edges of the support bars (Item 19A); see [Fig. 2-13](#).
18. Two eye hooks (Item 22A) should be attached to opposite sides of the garbage can lid (Item 16A). Two screen door springs (Item 23A) should be attached to the garbage can handle-s and used under tension to keep the top lid (Item 16A) either open or closed.
19. Cut the oil drum lock ring (Item 24A) to the exact circumference of the top plate (Item 2A) so that it will fit snugly around the gasifier unit housing drum (Item 3A).
20. Cut four 2 by 2 by 1/4-in. tabs (Item 25A); then, braze these tabs to the lock ring (Item 24A), evenly spaced and in alignment with the support bars (Item 19A) on the fuel hopper. Drill a 3/8-in. hole in each tab to align with the holes in the fuel hopper support bars (Item 19A). The lock ring is shown in [Fig. 2-14](#).
21. The connecting pipe (Item 29A) between the gasifier unit and the filter unit should be attached to the gasifier housing drum (Item 3A) at a point 6 in. below the top of the drum. This pipe must be a

minimum of 2-in. in diameter and should be at least 6 ft long for cooling purposes. At least one of the ends of this pipe must be removable for cleaning and maintenance. On this prototype unit, an airtight electrical conduit connector was used; this connection is visible in [Fig. 2-1](#). Many similar plumbing devices are available and can be used if they are suitable for operation at 400°F and above. The pipe can also be welded or brazed directly to the housing drum.

22. When assembling the gasifier unit, the upright bar (Item 2AA) on the shaker assembly must be placed inside the U-bolt (Item 5A) on the grate.
23. The lock ring will then clamp the gasifier unit housing drum (Item 3A) and the top plate (Item 2A) together. The fuel hopper support bars (Item 19A) must be attached to the tabs (Item 25A) on the lock ring with bolts (Item 26A). High temperature silicone (Item 27A) should be applied to all edges to make an airtight connection. The lock ring connections are shown in the lower portion of [Fig. 2-13](#).

2.2 BUILDING THE PRIMARY FILTER UNIT

[Figures 2-15](#) and [2-16](#) show exploded views of the primary filter unit; the list of materials is given in [Table 2-3](#) (all figures and tables mentioned in Sect. 2 listed in the figure and table files). In the following instructions, all item numbers refer to either [Fig. 2-15](#) or [2-16](#) and to [Table 2-3](#).

The prototype primary filter unit was made from a 5-gal paint can. That size seems to be sufficient for gasifiers with fire tubes up to 10 in. in diameter. If a fire tube diameter of more than 10 in. is required, then a 20-gal garbage can or a 30-gal oil drum should be used. The Filter unit could be fabricated in any shape or form as long as airtightness and unobstructed flow of gas are provided. If a 5-gal container is used, it must be clean and free of any chemical residue. The top edge must be straight and without any indentations. If an alternate container can be found or fabricated, a larger diameter will permit longer operation between cleanings.

The piping (Item 29A in [Figs. 2-2](#) and [2-15](#)) which connects the gas generator unit to the primary filter should be considered to be a necessary part of the cooling system and should never have an inside diameter less than 2 in. A flexible automotive exhaust pipe was used on the prototype filter unit described below; it was shaped into a semicircular arc so that increased length would achieve a greater cooling effect. The fabrication procedure for the filter unit follows:

1. A hole equal to the outside diameter of the drain tube (Item 13B in [Fig. 2-15](#)) should be cut into the side of the filter container (Item 1B); the bottom edge of this hole should be about 1/2 in. from the inside bottom of the container.
2. The drain tube (Item 13B) should be inserted into the previously cut hole in the filter container and should be positioned so that its nonthreaded end is near the center of the container and is about 1/2

- in. off the bottom. Once this position has been ensured, braze (do not weld) the drain pipe into the side of the filter container. Close the threaded, exterior end of the drain pipe with the pipe cap (Item 14B).
3. Coat the bottom of the filter container (Item 1B) with a 1/2-in. layer of hydraulic cement (Item 28A), taking care not to plug or obstruct the end of the drain tube (Item 13B) with cement (i.e., fill the drain tube with a paper, styrofoam, or other easily removable, but rigid material). The cement should also be applied for about 1.5 in. up the inside walls of the container near its bottom. Round the edges slightly; the cement is to provide a pathway for any liquid condensate to drain out through the drain tube. The cement must be allowed to harden before proceeding with the fabrication steps below. Remove the filler material from the drain tube when the cement has hardened.
 4. A circular bottom plate (Item 2B) should be cut to a diameter 1/2 in. smaller than the inside diameter of the filter container (Item 1B). This will allow for heat expansion and easy removal for cleaning. This bottom plate should be drilled with as many 3/4-in. holes as are practical for the size of the plate. Three evenly spaced 3/8-in. holes should also be drilled around the edge of the bottom plate for the spacer bolts (Item 3B).
 5. [Fig. 2-16](#) shows the detail of using three bolts (Item 3B) as spacers for the bottom plate (Item 2B). The length of the bolts should be adjusted to provide a clearance of about 2-in. between the layer of cement in the bottom of the container (Item 1B) and the bottom plate (Item 2B).
 6. A rectangular divider plate (Item 4B) should be cut to a width 1/4 in. less than the inside diameter of the filter container (Item 1B) and to a height 2.5 in. less than the inside height of the container. This divider plate should then be welded at a right angle to the centerline of the bottom plate (Item 2B) as shown in [Fig. 2-17](#).
 7. Cut a piece of high-temperature hydraulic hose (Item 5B) to a length equal to the circumference of the filter container. It should be slit along its entire length and then placed over the top edge of the filter container (Item 1B) to ensure airtightness.
 8. A circular lid (Item 6B) should be cut equal to the outside diameter of the filter container (Item 1B). Three holes should be cut into this lid for the exhaust pipe (Item 29A) from the gasifier unit, the blower (Item 7B), and the filter exhaust pipe (Item 10B) to the engine manifold. Note the arrangement of these holes: the pipe (Item 29A) from the gasifier unit must enter the lid on one side of the divider plate (Item 4B); the blower (Item 7B) and the filter exhaust pipe (Item 10B) to the engine manifold must be located on the other side of the divider plate. This arrangement can be seen in [Fig. 2-18](#).
 9. The connecting pipe (Item 29A) between the gasifier unit and the filter unit should be attached to the lid (Item 5B) of the filter container. At least one of the ends of the connecting pipe (Item 29A)

must be removable for cleaning and maintenance. On this prototype unit, an airtight electrical conduit connector was used. Many similar plumbing devices are available and can be used if they are suitable for operation at 400°F and above. The pipe can also be welded or brazed directly to the lid.

10. Attach the blower (Item 7B) to the filter container lid (Item 6B). On the prototype gasifier illustrated in this report, a heater blower from a Volkswagen automobile was used. Connections for a vertical extension tube (Item SB) will have to be fabricated as shown in [Fig. 2-19](#). A closing cap (Item 9B) is required for the blower exhaust tube. A plumbing cap of steel or plastic with a close fit can be used or fabricated to fit. The vertical extension and the closing cap are visible in [Fig. 2-1](#).
11. The gas outlet (Item 10B) to the carbureting unit on the engine should be 1.25 in. minimum diameter. In fabricating this connection, all abrupt bends should be avoided to ensure free flow of gas. Using plumbing elbows is one solution. The gas outlet (Item 10B) can either be welded or brazed to the lid (Item 6B) of the filter container or an airtight, electrical conduit connector can be used.
12. Latching devices (Item 11B) should be welded or brazed to the lid (see [Fig. 2-20](#)) and to the sides (see [Fig. 2-21](#)) of the filter container. An air tight connection between the lid and the filter container must be maintained.
13. Cut two lengths of high-temperature hydraulic hose (Item 12B) equal to the height of the divider plate (Item 4B); cut a third length of hose equal to the width of the divider plate. Slit each hose along its entire length. Place the first two hoses on each side of the divider plate, and place the third hose along the top edge of the divider plate as shown in [Fig. 2-17](#).
14. Insert the divider plate (Item 4B) into the filter container (Item 1B), making sure that the hoses (Item 12B) create an airtight seal along all sides. By changing the length of the spacer bolts (Item 3B), adjust the height of the divider plate so that it is exactly flush with the top of the filter container. Make sure that the lid (Item 5B) will seat flatly and tightly against the top edge of the divider plate.
15. Fill the filter container (Item 1B) on-both sides of the divider plate with wood chips, the same kind as would be used for fuel in the gasifier unit. After carefully packing and leveling these wood chips, place the lid (Item 6B) on the filter container, and close the latches tightly.

2.3. BUILDING THE CARBURETING UNIT WITH THE AIR AND THROTTLE CONTROLS

[Figures 2-22](#) and [2-23](#) show exploded views of the carbureting unit; the list of materials is given in [Table 2-4](#) (all figures and tables mentioned in Sect. 2 are presented at the end of Sect. 2). In the following

instruction's, all item numbers refer both to [Figs. 2-22](#) and [2-23](#) and to [Table 2-4](#). The following is a simple and easy way to assemble a carburetor to achieve both air mixture and throttle control. It can be mounted to either updraft or downdraft manifolds by simply turning the unit over. Most of the fabrication procedure below is devoted to the assembly of two butterfly valves: one for the throttle valve and one for the air mixture valve. The remainder of the carburetor unit can be assembled from ordinary, threaded plumbing parts.

The inside diameter of the piping used in the carburetor unit must be related to the size of the engine and should never be smaller than the intake opening on the engine manifold. If in doubt on the inside diameter for the pipe and/or hose sizes, always go with a larger diameter. This will reduce friction losses and will give longer operating hours between cleanings.

When the wood gas leaves the filter unit it should normally be below 180°F. About 2 ft from the filter container, an automotive water hose can be connected to the pipe on the carbureting unit. This rubber hose will keep engine vibration from creating air leaks in the filter unit or in the connecting piping. The hose must be a fairly new item; such hoses have a steel spring inside to keep them from collapsing when negative pressure is applied. The spring will soon rust if it has first been subjected to water and then to the hot wood gas enriched with hydrogen. The fabrication procedure for the assembly of two butterfly valves follows:

1. The manifold adapter (Item 1C in [Fig. 2-22](#)) must be fitted with bolts and/or holes for mounting onto the engine's existing intake manifold. Because gasoline engines are produced with so many different types of intake manifolds, ingenuity and common sense must be used to modify the manifold adapter (Item 1C) for each different engine to be operated on wood gas. A gasket (Item 7C) should be cut to match the shape of the engine intake fitting.
2. The butterfly valve (Item 3C) is shown in [Figs. 2-24](#) and [2-25](#); two such valves are required. A 3/8-in. hole should be drilled through the diameter of each valve body (Item 1CC) at the midpoint of its length.
3. The valve plate (Item 2CC) must be oval in shape with the dimensions given in [Table 2-4](#). An oval valve plate must be used so that, in the closed position, the valve will be about 10° off center. This will ensure that the valve will come to a complete stop in the closed position.
4. The edges of the valve plate (Item 2CC), around the longer diameter of the oval, should be beveled to provide a positive, airtight closure. Two evenly spaced, 1/4-in. holes should be drilled along the shorter diameter of the oval plate.
5. The valve support rod (Item 3CC) should be filed or ground flat on one side as shown in [Fig. 2-24](#); the flat area must begin 1/4 in. from one end and must continue for a distance equal to the inside diameter of the valve body (Item 1CC).

6. Two 3/16-in. holes should be drilled into the flat area of the valve support rod (Item 3CC); these holes must align with the holes in the valve plate (Item 2CC). They must also be tapped (with threads) to accept the valve plate screws (Item 4CC).
7. The butterfly valve (Item 3C) should be assembled by first placing the valve support rod (Item 3CC) through the hole in the valve body (Item 1CC). The valve plate (Item 2CC) should be dropped into one end of the valve body and then inserted into the flat area of the valve support rod. The two screws (Item 4CC) should be used to attach the valve plate to the support rod. Check to see that the assembled valve plate rotates freely and seats completely in the closed position.
8. A nut (Item 6CC) should be welded flat against one side of the throttle arm (Item 5CC) near its end. A 1/8-in. hole should be drilled into the side of the nut and must be threaded to accept the set screw (Item 7CC). At least one hole should be drilled into the throttle arm for attachment of the engine throttle control or air control linkages.
9. Place the nut (Item 6CC) on the throttle arm over the end of the valve support rod (Item 3CC) and use the set screw (Item 7CC) to secure the assembly. The throttle arm can be placed in any convenient orientation. Assembled butterfly valves are shown in [Fig. 2-26](#).
10. The remaining parts of the carburetor assembly should be screwed together as shown in [Fig. 2-27](#). Pipe thread compound should be used to make airtight connections. The assembled carburetor unit should be attached to the engine's intake manifold as shown in [Fig. 2-28](#)
11. This prototype gasifier was designed to operate if gasoline were unavailable; but, if dual operation on wood and gasoline is desired, the elbow (Item 2C) could be replaced with a tee, allowing a gasoline carburetor to also be mounted.
12. The arm on the butterfly valve (Item 3C) which is closest to the elbow (Item 2C) is to be connected to the foot- (or, on tractors, hand-) operated accelerator. The other butterfly valve is to be used as the air mixture control valve and can be operated with a manual choke cable. If the engine has an automatic choking device, then a hand operated choke cable should be installed. Both butterfly valves and their connecting control linkages must operate smoothly with the ability to adjust the valve yet keep it stationary in the selected position during operation. The linkages must close the valves airtight when the engine is off.
13. The air inlet (Item 6C) should be connected by an extension hose or pipe, either iron or plastic, to the existing engine's air filter in order to prevent road dust or agricultural residue from entering the engine.
14. The wood gas inlet (Item 5C) is to be connected to the outlet piping (Item 10B as shown in [Fig. 2-15](#)) from the wood gas filter unit. Part of this connection should be a high-temperature rubber or neoprene hose to absorb engine vibration.

3. OPERATING AND MAINTAINING YOUR WOOD GAS GENERATOR

3.1 USING WOOD AS A FUEL

Because wood was used extensively as generator fuel during World War II, and since it is plentiful in most parts of the populated United States, it merits particular attention for use as an emergency source of energy. When used in gas generators, about 20 lb. of wood have the energy equivalence of one gallon of gasoline.

Wood consists of carbon, oxygen, hydrogen, and a small amount of nitrogen. As a gas generator fuel, wood has several advantages. The ash content is quite low, only 0.5 to 2% (by weight), depending on the species and upon the presence of bark. Wood is free of sulfur, a contaminant that easily forms sulfuric acid which can cause corrosion damage to both the engine and the gas generator. Wood is easily ignited a definite virtue for the operation of any gas generator unit.

The main disadvantages for wood as a fuel are its bulkiness and its moisture content. As it is a relatively light material, one cubic yard of wood produces only 500 to 600 lb. of gas generator fuel. Moisture content is notoriously high in wood fuels, and it must be brought below 20% (by weight) before it can be used in a gas generator unit. By weight, the moisture in green wood runs from 25 to 60%, in air-dried wood from 12 to 15%, and in kiln-dried wood about 8%. Moisture content can be measured quite easily by carefully weighing a specimen of the wood, placing it in an oven at 220° F for thirty minutes, reweighing the specimen, and reheating it until its weight decreases to a constant value. The original moisture content is equivalent to the weight lost.

The prototype unit in this manual (with an 6-in.-diam firetube) operated well on both wood chips (minimum size: 3/4 by 3/4 by 1/4 in.) and blocks (up to 2-in. cubes); see [Fig. 3-1](#) (all figures and tables mentioned in Sect. 3 are presented at the end of Sect. 3). Larger sizes could be used, if the firetube diameter is increased to prevent bridging of the individual pieces of wood; of course, a throat restriction would then have to be added to the bottom of the firetube so as to satisfy the dimensions in [Table 2-2](#) in Sect. 2.

3.2 SPECIAL CONSIDERATIONS AND ENGINE MODIFICATIONS

To start the fire in the gasifier, the blower must be used to create a suction airflow through the wood in the hopper and downward in the firetube. If an especially high horse power engine is to be fueled by the gasifier unit, then it might be necessary to install two such blowers and run them simultaneously during start-up.

When the wood gas leaves the gasifier unit, all the oxygen pulled down with the air through the firetube has been chemically converted and is contained in carbon monoxide (CO) and water (H₂O). The wood gas is unable to burn without being mixed with the proper amount of additional oxygen. If an air leak develops below the grate area, the hot gas will burn while consuming the available oxygen and will create heat; this will almost certainly destroy the gasifier unit if it is not detected soon. If an air leak develops in the filter unit or in the connecting piping, the gas will become saturated with improper amounts of oxygen and will become too dilute to power the engine. Therefore airtightness from the gasifier unit to the engine is absolutely essential.

Ideally, as the wood gas enters the engine manifold it should be mixed with air in a ratio of 1:1 or 1.1:1 (air to gas) by volume. The carburetion system described in this report will provide this mixture with a minimum of friction losses in the piping. The throttle control valve and the air control valve must be operable from the driver's seat of the vehicle. The engine's spark plug gaps should be adjusted to between 0.012 and 0.015 in.; the ignition timing should be adjusted to 'early.'

3.3 INITIAL START-UP PROCEDURE

Initially, you will need to add charcoal to the grate below the firetube. Subsequent operation will already have the grate full of charcoal which has been left over from the previous operating period.

Fill the firetube with charcoal to a level 4 in. above the grate. Fill the hopper with air-dried wood; then, proceed with the routine start-up directions below.

Charcoal produced for outdoor barbecue grills is not well suited for gas generator use. To produce a better grade of charcoal, place a rag soaked in alcohol on the grate, or place 3 to 5 pages of newspaper on the grate, then fill the fire tube to a height of 10 to 12 in. with well-dried wood. Have all the valves closed and let the Fire tube act as a chimney until the wood is converted to charcoal.

3.4 ROUTINE START-UP PROCEDURE

1. Agitate the grate shaker handle for at least twenty seconds to shake down the Charcoal from the previous operating period.
2. Open the ash cleanout port and remove the ashes from the generator housing drum. Lubricate the threads of the cleanout port with high-temperature silicone, and close the cover of the cleanout port so that it is airtight.

3. Fill the hopper with wood fuel, and tamp the fuel down lightly. Either leave the lid completely off the fuel hopper, or adjust the opening around the lid to a 3/4-in. (or larger) clearance.
4. Close the carburetor's air control valve and remove the cover from the blower exhaust on top of the filter unit. Start the blower, and let it run for thirty seconds to avoid explosion of residual gas in the system. Then, with the blower still operating, proceed with the next step.
5. Open the ignition port, and ignite a 12- by 12-in. piece of newspaper; with a long stick or wire, push the burning sheet of newspaper into the grate; see [Fig. 3-2](#). Close the ignition port. If no smoke appears at the blower's exhaust port, repeat the start-up sequence from Step (5). If repeated attempts fail, new charcoal should be added to the unit as described in Sect. 3.3, above, and the start-up ignition sequence should be repeated.
6. After a few minutes of smoky exhaust, test the gas at the, blower exhaust by safely and carefully attempting to ignite it, see [Fig. 3-3](#). When the gas burns consistently well, stop the blower and replace the cover on the blower exhaust.
7. Open the carburetor's air control valve, adjust the engine's accelerator, and start the engine in a normal manner. Let the engine warm up slowly (two to five minutes). If the engine fails to start or dies repeatedly, restart the blower and repeat the ignition sequence from Step (4).

3.5 DRIVING AND NORMAL OPERATION

Shift gears so as to keep the engine speed (rpm) high at all times. Remember that it is the vacuum created by the pistons that provides the force which moves the gas from the gasifier unit into the engine.

Refill the hopper with wood (as shown in [Fig. 3-4](#)) before it is completely empty, but avoid refilling just before the end of engine operation. Periodically shake down the ashes from the grate. If your system is equipped with a gas cooler, drain water from the cooler from time to time.

Under operation in dry weather, the gasifier can be operated without the lid on the fuel hopper. However, when the gasifier unit is shut down the hopper must be covered to prevent air from continuing to burn the wood in the hopper. Under wet-weather operation, the cover must be placed on the fuel hopper, and then lifted up and rotated about 2 in. until the triangular pieces line up with the holes in the support bars. The tension of the screen door springs will then hold the lid closed. See [Fig. 3-5](#) for clarification.

3.6 SHUTTING DOWN THE GASIFIER UNIT

When shutting down the gasifier unit, turn off the ignition switch and open the carburetor's air control valve for ten seconds to relieve any pressure from within the system. Then, completely close the air control valve, and place the cover tightly on the fuel hopper. When restarting after a short stopover, let the engine warm up briefly. After longer stops (up to one hour), tamp down the wood lightly and try to use the blower for restarting without relighting the wood fuel. After very long stops (over two hours) the charcoal must be ignited again.

3.7 ROUTINE MAINTENANCE

Periodically check all nuts on the gasifier unit, the fuel hopper, the filter unit, and the carburetor for snugness; check all penetrations and fittings for airtightness. In addition, perform the following maintenance activities as scheduled:

3.7.1 Daily Maintenance

Open the ash cleanout port of the gasifier housing drum and remove the ashes after shaking the grate for at least thirty seconds. Replace the cover of the port after coating the threads with high-temperature silicone to ensure airtightness. Open the drain tube, at the bottom of the filter container and allow any liquid condensate to drain out; remember to close the drain tube when finished.

3.7.2 Weekly Maintenance (or every 15 hours of operation)

Clean out the gasifier housing drum, the fuel hopper, and the filter. Rinse out the piping and connections to and from the filter. Replace the wood chips inside the filter, (The used wood chips from the filter can be dumped into the fuel hopper and burned to produce wood gas.) Use high-temperature silicone on all pipe connections and on the filter lid to ensure airtightness.

3.7.3 Biweekly Maintenance (or every 30 hours of operation)

Make sure that all pipe connections are secure and airtight. Check and tighten all mounting connections to the vehicle chassis. Check for rust on the outside of the gas generator housing drum, especially on the lower region. Coat with high-temperature protective paint as necessary.

3.8 OPERATING PROBLEMS AND TROUBLE-SHOOTING

A discussion of problems and their related causes and cures is contained in the trouble-shooting guide of [Table 3-1](#). Many operational problems can be traced to failure to maintain the airtightness of all piping connections and fittings; the piping should be routinely checked to prevent such problems.

3.9 HAZARDS ASSOCIATED WITH GASIFIER OPERATION

Unfortunately, gas generator operation involves certain problems, such as toxic hazards and fire hazards.

These hazards should not be treated lightly; their inclusion here, at the end of this report, does not mean that these hazards are unimportant. The reader should not underestimate the dangerous nature of these hazards.

3.9.1 Toxic Hazards

Many deaths in Europe during World War II were attributed to poisoning from wood gas generators. The danger of 'generator gas poisoning' was one of the reasons that such gasifiers were readily abandoned at the end of World War II. It is important to emphasize that generator gas poisoning' is carbon monoxide (CO) poisoning. Acute 'generator gas poisoning' is identical with the symptoms that may develop if a heating stove damper is closed too early, or if a gasoline vehicle is allowed to idle in a poorly ventilated garage.;[Table 3-2](#) shows how poisoning symptoms develop according to the concentration of carbon monoxide in breathable air. It is important to note that rather brief exposures to very small concentrations of carbon monoxide result in undesirable physiological effects.

In case of carbon monoxide poisoning, first aid should consist of the following procedures:

1. Move the victim quickly out into the open air or to a room with fresh air and good ventilation. All physical exertion on the part of the victim must be avoided.
2. If the victim is unconscious, every second is valuable. Loosen any tight clothing around the neck. If breathing has stopped, remove foreign objects from the mouth (false teeth, chewing gum, etc.) and immediately give artificial respiration.
3. Keep the victim warm.
4. Always call a physician.
5. In case of mild carbon monoxide poisoning without unconsciousness, the victim should be given oxygen if possible.

3.9.2 Technical Aspects of 'Generator Gas Poisoning'

Generator gas poisoning is often caused by technical defects in the functioning of the gas generator unit. When the engine is running, independent of the starting blower, the entire system is under negative pressure created by the engine's pistons; the risk of poisoning through leakage is therefore minimal. However, when the engine is shut off, formation of wood gas continues, causing an increase of pressure inside the generator unit. This pressure increase lasts for approximately 20 minutes after the engine is shut off. For this reason, it is not advisable to stay in the vehicle during this period. Also, the gas generator unit should be allowed to cool for at least 20 minutes before the vehicle is placed in an enclosed garage connected with living quarters. It should be emphasized that the gas formed during the

shutdown period has a carbon monoxide content of 23 to 27% and is thus very toxic.

3.9.3 Fire Hazard

The outside of a gas generator housing drum may reach the same temperature as a catalytic converter on today's automobiles. Care should be taken when operating in areas where dry grass or combustible material can come into contact with the housing drum of the gas generator unit. If a gas generator unit is mounted on a personal car, bus, van or truck, a minimum 6-in. clearance must be maintained around the unit. Disposal of ashes must only be attempted after the unit has cooled down (to below 150°F). Such residue must be placed away from any combustible material and preferably be hosed down with water for absolute safety.

EXECUTIVE SUMMARY

This report is one in a series of emergency technology assessments sponsored by the Federal Emergency Management Agency (FEMA). The purpose of this report is to develop detailed, illustrated instructions for the fabrication, installation, and operation of a biomass gasifier unit (i.e., a "producer gas" generator, also called a "wood gas" generator) which is capable of providing emergency fuel for vehicles, such as tractors and trucks, should normal petroleum sources be severely disrupted for an extended period of time. These instructions have been prepared as a manual for use by any mechanic who is reasonably proficient in metal fabrication or engine repair.

Fuel gas, produced by the reduction of coal and peat, was used for heating as early as 1840 in Europe and by 1884 had been adapted to fuel engines in England. Prior to 1940, gas generator units were a familiar, but not extensively utilized, technology. However, petroleum shortages during World War II led to widespread gas generator applications in the transportation industries of Western Europe. (Charcoal-burning taxis, a related application, were still common in Korea as late as 1970.) The United States, never faced with such prolonged or severe oil shortages, has lagged far behind Europe and the Orient in familiarity with and application of this technology. However, a catastrophic event could disrupt the supply of petroleum in this country so severely that this technology might be critical in meeting the energy needs of some essential economic activities, such as the production and distribution of food.

In occupied Denmark during World War II, 95% of all mobile farm machinery, tractors, trucks, stationary engines, and fishing and ferry boats were powered by wood gas generator units. Even in neutral Sweden, 40% of all motor traffic operated on gas derived from wood or charcoal. All over Europe, Asia, and Australia, millions of gas generators were in operation between 1940 and 1946. Because of the wood gasifier's somewhat low efficiency, the inconvenience of operation, and the potential health risks from toxic fumes, most of such units were abandoned when oil again became available in 1945. Except for the technology of producing alternate fuels, such as methane or alcohol, the only solution for operating existing internal combustion engines, when oil and petroleum products are not available, has been these simple, inexpensive gasifier units.

This report attempts to preserve the knowledge about wood gasification that was put into practical use during World War II. In this report, detailed step-by-step procedures are presented for constructing a simplified version of the World War II wood gas generator; this simple, stratified, downdraft gasifier unit (shown schematically in Fig. S-1) can be constructed from materials which would be widely available in the United States in a prolonged petroleum crisis. For example, the body of the unit consists of a galvanized metal garbage can atop a small metal drum; common plumbing fittings are used throughout; and a large, stainless steel mixing bowl is used for the grate. A prototype gasifier unit was fabricated from these instructions (see Fig. S-2); this unit was then mounted onto the front of a farm tractor and successfully field tested, using wood chips as the only fuel (see Fig. S-3). Photographic documentation of the actual assembly of the unit, as well as its operational field test, is included in the body of this report.

The use of wood gas generators need not be limited to transportation applications. Stationary engines can also be fueled by wood gasifiers to run electric generators, pumps, and industrial equipment. In fact, the use of wood gas as a fuel is not even restricted to

gasoline engines; if a small amount of diesel fuel is used for ignition, a properly adjusted diesel engine can be operated primarily on wood gas introduced through the intake manifold.

S.1. PRINCIPLES OF SOLID FUEL GASIFICATION

All internal combustion engines actually run on vapor, not liquid. The liquid fuels used by gasoline engines are vaporized before they enter the combustion chamber above the pistons. In diesel engines, the fuel is sprayed into the combustion chamber as fine droplets which burn as they vaporize. The purpose of a gasifier, then, is to transform solid fuels into gaseous ones and to keep the gas free of harmful constituents. A gas generator unit is simultaneously an energy converter and a filter. In these twin tasks lie its advantages and its difficulties.

In a sense, gasification is a form of incomplete combustion—heat from the burning solid fuel creates gases which are unable to burn completely because of the insufficient amounts of oxygen from the available supply of air. The same chemical laws which govern combustion processes also apply to gasification. There are many solid biomass fuels suitable for gasification—from wood and paper to peat, lignite, and coal, including coke derived from coal. All of these solid fuels are composed primarily of carbon with varying amounts of hydrogen, oxygen, and impurities, such as sulphur, ash, and moisture. Thus, the aim of gasification is the almost complete transformation of these constituents into gaseous form so that only the ashes and inert materials remain. In creating wood gas for fueling internal combustion engines, it is important that the gas not only be properly produced, but also preserved and not consumed until it is introduced into the engine where it may be appropriately burned.

Gasification is a physiochemical process in which chemical transformations occur along with the conversion of energy. The chemical reactions and thermochemical conversions which occur inside a wood gas generator are too long and too complicated to be covered here; however, such knowledge is not necessary for constructing and operating a wood gasifier. By weight, gas (wood gas) produced in a gasifier unit contains approximately 20% hydrogen (H_2), 20% carbon monoxide (CO), and small amounts of methane, all of which are combustible, plus 50 to 60% nitrogen (N_2). The nitrogen is not combustible; however, it does occupy volume and dilutes the wood gas as it enters and burns in an engine. As the wood gas burns, the products of combustion are carbon dioxide (CO_2) and water vapor (H_2O).

One of the by-products of wood gasification is carbon monoxide, a poisonous gas. The toxic hazards associated with breathing this gas should be avoided during refueling operations or prolonged idling, particularly in inadequately ventilated areas. Except for the obvious fire hazard resulting from the combustion processes inside the unit, carbon monoxide poisoning is the major potential hazard during normal operation of these simplified gasifier units.

S.2. THE STRATIFIED, DOWNDRAFT GASIFIER

Until the early 1980s, wood gasifiers all over the world (including the World War II designs) operated on the principle that both the fuel hopper and the combustion unit be absolutely airtight; the hopper was sealed with a top or lid which had to be opened every time wood was added. Smoke and gas vented into the atmosphere while wood was being loaded; the operator had to be careful not to breathe the unpleasant smoke and toxic fumes.

Over the last few years, a new gasifier design has been developed through cooperative efforts among researchers at the Solar Energy Research Institute in Colorado, the University of California in Davis, the Open University in London, the Buck Rogers Company in Kansas, and the Biomass Energy Foundation, Inc., in Florida. This simplified design employs a balanced, negative-pressure concept in which the old type of sealed fuel hopper is no longer necessary. A closure is only used to preserve the fuel when the engine is stopped. This new technology has several popular names, including "stratified, downdraft gasification" and "open top gasification." Several years of laboratory and field testing have indicated that such simple, inexpensive gasifiers can be built from existing hardware and will perform very well as emergency units.

A schematic diagram of the stratified, downdraft gasifier is shown in Fig. S-1. During operation of this gasifier, air passes uniformly downward through four zones, hence the name "stratified:"

1. The uppermost zone contains unreacted fuel through which air and oxygen enter. This region serves the same function as the fuel hopper in the older, World War II designs.
2. In the second zone, the wood fuel reacts with oxygen during pyrolysis. Most of the volatile components of the fuel are burned in this zone and provide heat for continued pyrolysis reactions. At the bottom of this zone, all of the available oxygen from the air should be completely reacted. The open top design ensures uniform access of air to the pyrolysis region.
3. The third zone is made up of charcoal from the second zone. Hot combustion gases from the pyrolysis region react with the charcoal to convert the carbon dioxide and water vapor into carbon monoxide and hydrogen.
4. The inert char and ash, which constitute the fourth zone, are normally too cool to cause further reactions; however, because the fourth zone is available to absorb heat or oxygen as conditions change, it serves both as a buffer and as a charcoal storage region. Below this zone is the grate. The presence of char and ash serves to protect the grate from excessive temperatures.

The stratified, downdraft design has a number of advantages over the World War II gasifier designs. The open top permits fuel to be fed more easily and allows easy access. The cylindrical shape is easy to fabricate and permits continuous flow of fuel. No special fuel shape or pretreatment is necessary; any blocky fuel can be used.

The foremost question about the operation of the stratified, downdraft gasifier concerns char and ash removal. As the charcoal reacts with the combustion gases, it eventually reaches a very low density and breaks up into a dust containing all of the ash as well as a percentage of the original carbon. This dust may be partially carried away by the gas and might eventually begin to plug the gasifier. Hence, it must be removed by shaking or agitation. When the stratified gasifier unit is used to power vehicles, it is automatically shaken by the vehicle's motion.

An important issue in the design of the stratified, downdraft gasifier is the prevention of fuel bridging and channeling. High-grade biomass fuels, such as wood blocks or chips, will flow down through the gasifier because of gravity and downdraft air flow. However, other fuels (such as shredded chips, sawdust, and bark) can form a bridge, which will obstruct

continuous flow and cause very high temperatures. Bridging can be prevented by stirring, shaking, or by agitating the grate or by having it agitated by the vehicle's movement. For prolonged idling, a hand-operated shaker has been included in the design in this report.

A prototype unit of the stratified, downdraft gasifier design (see Figs. S-2 and S-3) has been fabricated according to the instructions in this report; however, it has not been widely tested at this time. The reader is urged to use his ingenuity and initiative in constructing his own wood gas generator. As long as the principle of airtightness in the combustion regions, in the connecting piping, and in the filter units is followed, the form, shape, and method of assembly is not important.

The wood gasifier design presented in this report has as its origin the proven technology used in World War II during actual shortages of gasoline and diesel fuel. It should be acknowledged that there are alternate technologies (such as methane production or use of alcohol fuels) for keeping internal combustion engines in operation during a prolonged petroleum crisis; the wood gasifier unit described in this report represents only one solution to the problem.

CONVERSION FACTORS FOR SI UNITS

English units have been retained in the body of this report. The report refers to commercially available materials and sizes which are commonly expressed in English units. The conversion factors for SI units are given below:

<u>To convert from</u>	<u>To</u>	<u>Multiply by</u>
cubic feet (ft ³)	cubic meters (m ³)	0.0283
cubic yards (yd ³)	cubic meters (m ³)	0.7646
Fahrenheit degrees (°F)	Kelvin degrees (°K)	(see Note 1)
foot (ft)	meter (m)	0.3048
gallon (gal)	cubic meters (m ³)	3.785 X 10 ⁻³
horsepower (hp)	watt (W)	745.7
inch (in.)	meter (m)	0.0254
pound (lb)	kilogram (kg)	0.4536
quart (qt.)	cubic meters (m ³)	9.464 X 10 ⁻⁴

Note 1: To convert temperatures, use the following equation,

$$K = 273 + 0.5556 \times (F - 32) ,$$

where

F is the temperature in Fahrenheit degrees, and

K is the temperature in Kelvin degrees.

**CONSTRUCTION OF A SIMPLIFIED WOOD GAS GENERATOR
FOR FUELING INTERNAL COMBUSTION ENGINES
IN A PETROLEUM EMERGENCY**

H. LaFontaine
G. P. Zimmerman

ABSTRACT

This report is one in a series of emergency technology assessments sponsored by the Federal Emergency Management Agency (FEMA). The purpose of this report is to develop detailed, illustrated instructions for the fabrication, installation, and operation of a biomass gasifier unit (i.e., a "producer gas" generator, also called a "wood gas" generator) that is capable of providing emergency fuel for vehicles, such as tractors and trucks, in the event that normal petroleum sources were severely disrupted for an extended period of time. These instructions have been prepared as a manual for use by any mechanic who is reasonably proficient in metal fabrication or engine repair.

This report attempts to preserve the knowledge about wood gasification that was put into practical use during World War II. Detailed, step-by-step fabrication procedures are presented for a simplified version of the World War II, Imbert wood gas generator. This simple, stratified, downdraft gasifier unit can be constructed from materials that would be widely available in the United States in a prolonged petroleum crisis. For example, the body of the unit consists of a galvanized metal garbage can atop a small metal drum; common plumbing fittings throughout; and a large, stainless steel mixing bowl for the grate. The entire compact unit was mounted onto the front of a farm tractor and successfully field tested, using wood chips as the only fuel. Photographic documentation of the actual assembly of the unit as well as its operation is included.

1. WHAT IS A WOOD GAS GENERATOR AND HOW DOES IT WORK?

This report is one in a series of emergency technology assessments sponsored by the Federal Emergency Management Agency (FEMA). The purpose of this report is to develop detailed, illustrated instructions for the fabrication, installation, and operation of a biomass gasifier unit (i.e., a "producer gas" generator, also called a "wood gas" generator) that is capable of providing emergency fuel for vehicles, such as tractors and trucks, in the event that normal petroleum sources were severely disrupted for an extended period of time. These instructions have been prepared as a manual for use by any mechanic who is reasonably proficient in metal fabrication or engine repair.

1.1 INTRODUCTION

Fuel gas, produced by the reduction of coal and peat, was used for heating, as early as 1840 in Europe, and by 1884 it had been adapted to fuel engines in England. Before 1940, gas generator units were a familiar, but not extensively utilized, technology. However, petroleum shortages during World War II led to widespread gas generator applications in the transportation industries of Western Europe. (Charcoal-burning taxis, a related application, were still common in Korea as late as 1970.) The United States, never faced with such prolonged or severe oil shortages, has lagged far behind Europe and the Orient in familiarity with and application of this technology; however, a catastrophe could so severely disrupt the supply of petroleum in this country that this technology might be critical in meeting the energy needs of some essential economic activities, such as the production and distribution of food.

This report attempts to preserve the knowledge about wood gasification as put into practical use during World War II. Detailed, step-by-step procedures are presented in this report for constructing a simplified version of the World War II, Imbert wood gas generator. This simple, stratified, downdraft gasifier unit can be constructed from materials that would be widely available in the United States in a prolonged petroleum crisis. For example, the body of the unit consists of a galvanized metal garbage can atop a small metal drum; common plumbing fittings throughout; and a large, stainless steel mixing bowl for the grate. A prototype gasifier unit was fabricated from these instructions. This unit was then mounted onto the front of a gasoline-engine farm tractor and successfully field tested, using wood chips as the only fuel; see Fig. 1-1 (all figures and tables are presented at the end of their respective sections). Photographic documentation of the actual assembly of the unit, as well as its operational field test, is included in this report.

The use of wood gas generators need not be limited to transportation applications. Stationary engines can also be fueled by wood gasifiers to run electric generators, pumps, and industrial equipment. In fact, the use of wood gas as a fuel is not even restricted to gasoline engines; if a small amount of diesel fuel is used for ignition, a properly adjusted diesel engine can be operated primarily on wood gas introduced through the intake manifold. However, this report is concerned with the operation of four-cycle gasoline engines rated from 10 to 150 horsepower. If more information is needed about operating gasifiers on other

fuels (such as coal, charcoal, peat, sawdust or seaweed), a list of relevant literature is contained in the Bibliography at the end of this report.

The goal of this report is to furnish information for building a homemade wood gas generator made out of ordinary, available hardware, in order to get tractors, trucks, and other vehicles operating without delay, if a severe liquid fuel emergency should arise. Section 1 describes gasification principles and wood gas generators, in general, and gives some historical background about their operation and effectiveness. Section 2 contains detailed step-by-step instructions for constructing your own wood gas generator unit; illustrations and photographs are included to prevent confusion. Section 3 contains information on operating, maintaining, and trouble-shooting your wood gas generator; also included are some very important guidelines on safety when using your gasifier system.

The wood gasifier design presented in this report has as its origin the proven technology used in World War II during actual shortages of gasoline and diesel fuel. It should be acknowledged that there are alternate technologies (such as methane production or use of alcohol fuels) for keeping internal combustion engines in operation during a prolonged petroleum crisis; the wood gasifier unit described in this report represents only one solution to the problem.

1.2 PRINCIPLES OF SOLID FUEL GASIFICATION

All internal combustion engines actually run on vapor, not liquid. The liquid fuels used in gasoline engines are vaporized before they enter the combustion chamber above the pistons. In diesel engines, the fuel is sprayed into the combustion chamber as fine droplets which burn as they vaporize. The purpose of a gasifier, then, is to transform solid fuels into gaseous ones and to keep the gas free of harmful constituents. A gas generator unit is, simultaneously, an energy converter and a filter. In these twin tasks lie its advantages and its difficulties.

The first question many people ask about gasifiers is, "Where does the combustible gas come from?" Light a wooden match; hold it in a horizontal position; and notice that while the wood becomes charcoal, it is not actually burning but is releasing a gas that begins to burn brightly a short distance away from the matchstick. Notice the gap between the matchstick and the luminous flame; this gap contains the wood gas which starts burning only when properly mixed with air (which contains oxygen). By weight, this gas (wood gas) from the charring wood contains approximately 20% hydrogen (H_2), 20% carbon monoxide (CO), and small amounts of methane, all of which are combustible, plus 50 to 60% nitrogen (N_2). The nitrogen is not combustible; however, it does occupy volume and dilutes the wood gas as it enters and burns in an engine. As the wood gas burns, the products of combustion are carbon dioxide (CO_2) and water vapor (H_2O).

The same chemical laws which govern combustion processes also apply to gasification. The solid, biomass fuels suitable for gasification cover a wide range, from wood and paper to peat, lignite, and coal, including coke derived from coal. All of these solid fuels are composed primarily of carbon with varying amounts of hydrogen, oxygen, and impurities, such as sulphur, ash, and moisture. Thus, the aim of gasification is the almost complete transformation of these constituents into gaseous form so that only the ashes and inert materials remain.

In a sense, gasification is a form of incomplete combustion; heat from the burning solid fuel creates gases which are unable to burn completely, due to insufficient amounts of

oxygen from the available supply of air. In the matchstick example above, as the wood was burned and pyrolyzed into charcoal, wood gas was created, but the gas was also consumed by combustion (since there was an enormous supply of air in the room). In creating wood gas for fueling internal combustion engines, it is important that the gas not only be properly produced, but also preserved and not consumed until it is introduced into the engine where it may be appropriately burned.

Gasification is a physiochemical process in which chemical transformations occur along with the conversion of energy. The chemical reactions and thermochemical conversions which occur inside a wood gas generator are too long and too complicated to be covered here. Such knowledge is not necessary for constructing and operating a wood gasifier. Books with such information are listed in the Reference Section (see, for example, Reed 1979, Vol. II; or Reed and Das 1988).

1.3 BACKGROUND INFORMATION

The use of wood to provide heat is as old as mankind; but by burning the wood we only utilize about one-third of its energy. Two-thirds is lost into the environment with the smoke. Gasification is a method of collecting the smoke and its combustible components. Making a combustible gas from coal and wood began around 1790 in Europe. Such manufactured gas was used for street lights and was piped into houses for heating, lighting, and cooking. Factories used it for steam boilers, and farmers operated their machinery on wood gas and coal gas. After the discovery of large petroleum reserves in Pennsylvania in 1859, the entire world changed to oil—a cheaper and more convenient fuel. Thousands of gas works all over the world were eventually dismantled.

Wood gas generators are not technological marvels that can totally eliminate our current dependence on oil, reduce the impacts of an energy crunch, or produce long-term economic relief from high fossil fuel prices, but they are a proven emergency solution when such fuels become unobtainable in case of war, civil upheaval, or natural disaster. In fact, many people can recall a widespread use of wood gas generators during World War II, when petroleum products were not available for the civilian populations in many countries. Naturally, the people most affected by oil and petroleum scarcity made the greatest advancements in wood gas generator technology.

In occupied Denmark during World War II, 95% of all mobile farm machinery, tractors, trucks, stationary engines, fishing and ferry boats were powered by wood gas generators. Even in neutral Sweden, 40% of all motor traffic operated on gas derived from wood or charcoal (Reed and Jantzen 1979). All over Europe, Asia, and Australia, millions of gas generators were in operation between 1940 and 1946. Because of the wood gasifier's somewhat low efficiency, the inconvenience of operation, and the potential health risks from toxic fumes, most of such units were abandoned when oil again became available in 1945. Except for the technology of producing alternate fuels, such as methane or alcohol, the only solution for operating existing internal combustion engines, when oil and petroleum products are not available, has been these simple, inexpensive gasifier units.

1.3.1 The World War II, Imbert Gasifier

The basic operation of two gasifiers is described in this and the following section. Their operating advantages and disadvantages will also be discussed. This information is included for the technically interested reader only; it is intended to give the reader more insight into the subtleties of the operating principles of the wood gas generator described in this manual. Those readers who are anxious to begin construction of their own wood gas generator may skip the material below and proceed directly to Sect. 2 without any loss of continuity.

The constricted hearth, downdraft gasifier shown in Fig. 1-2 is sometimes called the "Imbert" gasifier after its inventor, Jacques Imbert; although, it has been commercially manufactured under various names. Such units were mass produced during World War II by many European automotive companies, including General Motors, Ford, and Mercedes-Benz. These units cost about \$1500 (1985 evaluation) each. However, after World War II began in 1939, it took six to eight months before factory-made gasifiers were generally available. Thousands of Europeans were saved from certain starvation by home-built, simple gasifier units made from washing machine tubs, old water heaters, and metal gas or oxygen cylinders. Surprisingly, the operation of these units was nearly as efficient as the factory-made units; however, the homemade units lasted for only about 20,000 miles with many repairs, while the factory-made units operated, with few repairs, up to 100,000 miles.

In Fig. 1-2, the upper cylindrical portion of the gasifier unit is simply a storage bin or hopper for wood chips or other biomass fuel. During operation, this chamber is filled every few hours as needed. The spring-loaded, airtight cover must be opened to refill the fuel hopper; it must remain closed and sealed during gasifier operation. The spring permits the cover to function as a safety valve because it will pop open in case of any excessive internal gas pressure.

About one-third of the way up from the bottom of the gasifier unit, there is a set of radially directed air nozzles; these allow air to be injected into the wood as it moves downward to be gasified. In a gas generator for vehicle use, the downstroke of the engine's pistons creates the suction force which moves the air into and through the gasifier unit; during startup of the gasifier, a blower is used to create the proper airflow. The gas is introduced into the engine and consumed a few seconds after it is made. This gasification method is called "producer gas generation," because no storage system is used; only that amount of gas demanded by the engine is produced. When the engine is shut off, the production of gas stops.

During normal operation, the incoming air burns and pyrolyzes some of the wood, most of the tars and oils, and some of the charcoal that fills the constricted area below the nozzles. Most of the fuel mass is converted to gas within this combustion zone. The Imbert gasifier is, in many ways, self-adjusting. If there is insufficient charcoal at the air nozzles, more wood is burned and pyrolyzed to make more charcoal. If too much charcoal forms, then the charcoal level rises above the nozzles, and the incoming air burns the charcoal. Thus, the combustion zone is maintained very close to the nozzles.

Below this combustion zone, the resulting hot combustion gases—carbon dioxide (CO_2) and water vapor (H_2O)—pass into the hot charcoal where they are chemically reduced to combustible fuel gases: carbon monoxide (CO) and hydrogen (H_2). The hearth constriction causes all gases to pass through the reaction zone, thus giving maximum mixing and minimum heat loss. The highest temperatures are reached in this region.

Fine char and ash dust can eventually clog the charcoal bed and will reduce the gas flow unless the dust is removed. The charcoal is supported by a movable grate which can be

shaken at intervals. Ash buildup below the grate can be removed during cleaning operations. Usually, wood contains less than 1% ash (by weight). However, as the charcoal is consumed, it eventually collapses to form a powdery charcoal/ash mixture which may represent 2 to 10% (by weight) of the total fuel mass.

The cooling unit required for the Imbert gasifier consists of a water-filled precipitating tank and an automotive radiator-type gas cooler. The precipitating tank removes all unacceptable tars and most of the fine ash from the gas flow, while the radiator further cools the gas. A second filter unit, containing a fine-mesh filtration material, is used to remove the last traces of any ash or dust that may have survived passage through the cooling unit. Once out of the filter unit, the wood gas is mixed with air in the vehicle's carburetor and is then introduced directly into the engine's intake manifold.

The World War II, Imbert gasifier requires wood with a low moisture content (less than 20% by weight) and a uniform, blocky fuel in order to allow easy gravity feed through the constricted hearth. Twigs, sticks, and bark shreds cannot be used. The constriction at the hearth and the protruding air nozzles present obstructions to the passage of the fuel and may create bridging and channeling followed by poor quality gas output, as unpyrolyzed fuel falls into the reaction zone. The vehicle units of the World War II era had ample vibration to jar the carefully sized wood blocks through the gasifier. In fact, an entire industry emerged for preparing wood for use in vehicles at that time (Reed and Jantzen 1979). However, the constricted hearth design seriously limits the range of wood fuel shapes that can be successfully gasified without expensive cubing or pelletizing pretreatment. It is this limitation that makes the Imbert gasifier less flexible for emergency use.

In summary, the World War II Imbert gasifier design has stood the test of time and has successfully been mass produced. It is relatively inexpensive, uses simple construction materials, is easy to fabricate, and can be operated by motorists with a minimum amount of training.

1.3.2 The Stratified, Downdraft Gasifier

Until the early 1980s, wood gasifiers all over the world (including the World War II designs) operated on the principle that both the fuel hopper and the combustion unit be airtight; the hopper was sealed with a top or lid that had to be opened every time wood was added. Smoke and gas vented into the atmosphere while new wood was being loaded; the operator had to be careful not to breathe the unpleasant smoke and toxic fumes.

Over the last few years, a new gasifier design has been developed through cooperative efforts among researchers at the Solar Energy Research Institute in Colorado, the University of California in Davis, the Open University in London, the Buck Rogers Company in Kansas, and the Biomass Energy Foundation, Inc., in Florida (Reed and Das 1988). This simplified design employs a balanced, negative-pressure concept in which the old type of sealed fuel hopper is no longer necessary. A closure is only used to preserve the fuel when the engine is stopped. This new technology has several popular names, including "stratified, downdraft gasification" and "open top gasification." Two years of laboratory and field testing have indicated that such simple, inexpensive gasifiers can be built from existing hardware and will perform very well as emergency units.

A schematic diagram of the stratified, downdraft gasifier is shown in Fig. 1-3. During operation of this gasifier, air passes uniformly downward through four zones, hence the name "stratified:"

1. The uppermost zone contains unreacted fuel through which air and oxygen enter. This region serves the same function as the fuel hopper in the Imbert design.
2. In the second zone, the wood fuel reacts with oxygen during pyrolysis. Most of the volatile components of the fuel are burned in this zone and provide heat for continued pyrolysis reactions. At the bottom of this zone, all of the available oxygen from the air has completely reacted. The open top design ensures uniform access of air to the pyrolysis region.
3. The third zone is made up of charcoal from the second zone. Hot combustion gases from the pyrolysis region react with the charcoal to convert the carbon dioxide and water vapor into carbon monoxide and hydrogen.
4. The inert char and ash, which constitute the fourth zone, are normally too cool to cause further reactions; however, since the fourth zone is available to absorb heat or oxygen as conditions change, it serves both as a buffer and as a charcoal storage region. Below this zone is the grate. The presence of char and ash serves to protect the grate from excessive temperatures.

The stratified, downdraft design has a number of advantages over the World War II, Imbert gasifier. The open top permits fuel to be fed more easily and allows easy access. The cylindrical shape is easy to fabricate and permits continuous flow of fuel. No special fuel shape or pretreatment is necessary; any blocky fuel can be used.

The foremost question about the operation of the stratified, downdraft gasifier concerns char and ash removal. As the charcoal reacts with the combustion gases, it eventually reaches a very low density and breaks up into a dust containing all of the ash as well as a percentage of the original carbon. This dust may be partially carried away by the gas; however, it might eventually begin to plug the gasifier, and so it must be removed by shaking or agitation. Both the Imbert gasifiers and the stratified concept have a provision for shaking the grate; when they are used to power vehicles, they are automatically shaken by the vehicle's motion.

An important issue in the design of the stratified, downdraft gasifier is the prevention of fuel bridging and channeling. High-grade biomass fuels such as wood blocks or chips will flow down through the gasifier under the influence of gravity, and downdraft air flow. However, other fuels (such as shredded wood, sawdust, and bark) can form a bridge that will prevent continuous flow and cause very high temperatures. Obviously, it is desirable to use these widely available biomass residues. Bridging can be prevented by stirring, shaking, or by agitating the grate or by having it agitated by the vehicle's movement. For prolonged idling, a hand-operated shaker has been included in the design.

A prototype design of the stratified, downdraft gasifier design has been developed. The detailed but simple design is described and illustrated in Sect. 2; however, it has not been widely tested at this time. The reader is urged to use his ingenuity and initiative in constructing his own wood gas generator. As long as the principle of airtightness in the combustion regions, in the connecting piping, and in the filter units is followed, the form, shape, and method of assembly is not important.

ORNL - DWG 87 - 14553

Fig 1-3. Schematic view of the stratified, downdraft gasifier.

2. BUILDING YOUR OWN WOOD GAS GENERATOR

The following fabrication instructions, parts lists, and illustrations describe the prototype gasifier unit shown schematically in Fig. 1-3. These instructions are simple and easy to follow. The dimensions in the following plans are given in inches rather than in millimeters to make construction easier for those who might be unfamiliar with the metric system and to allow the builder to take advantage of available, alternate construction materials. It will be obvious to the experienced engineer, mechanic, or builder that most of the dimensions (for example, plate thicknesses and cleanout diameters) are not critical to the acceptable performance of the finished gasifier unit.

The prototype gasifier unit described in the following text was actually constructed and field tested on a gasoline-engine farm tractor (a 35-hp, John Deere 1010 Special); see Fig. 2-1. The unit operated very well, and on par with the European, World War II designs, but it has not had the test of time nor the millions of operating hours like the older Imbert design. This new stratified design was developed for the construction of simple, inexpensive emergency wood gas generator units. The prototype design below should be considered to be the absolute minimum in regard to materials, piping and filter arrangement, and carburetor system connections.

The gasifier unit, as described below, is designed to maintain proper cooling, even at moderate vehicle speeds. If this unit is to be used on stationary engines or on slow-moving vehicles, a gas cooler and a secondary filter must be placed in the piping system between the generator unit and the carburetor. The ideal temperature for the wood gas at the inlet to the carburetor manifold would be 70°F, with acceptable peaks of 140 to 160°F. For every 10 degrees above 70°F, an estimated 1% horsepower is lost. Cooler gas has higher density and, therefore, contains more combustible components per unit volume.

The millions of wood gasifiers built during World War II proved that shape, form, and construction material had little or no effect on the performance of the unit. Judicious substitution or the use of scavenged parts is, therefore, quite acceptable. What is important is that:

1. the fire tube dimensions (inside diameter and length) must be correctly selected to match the rated horsepower of particular engine which is to be fueled,
2. airtightness of the gas generator unit and all connecting piping must be maintained at all times, and
3. unnecessary friction should be eliminated in all of the air and gas passages by avoiding sharp bends in the piping and by using piping sizes which are not too small.

2.1. BUILDING THE GAS GENERATOR UNIT AND THE FUEL HOPPER

Figure 2-2 shows an exploded view of the gas generator unit and the fuel hopper; the list of materials is given in Table 2-1 (all figures and tables mentioned in Sect. 2 are presented at the end of Sect. 2). Only the dimensions of the fire tube (Item 1A) must be reasonably close; all other dimensions and materials can be substituted as long as complete airtightness is maintained. In the following instructions, all item numbers refer both to Fig. 2-2 and to Table 2-1.

The prototype unit described in this report was constructed for use with a 35-hp gasoline engine; the unit has a fire tube diameter of 6 in. (as determined from Table 2-2). A gas generator unit containing a fire tube up to 9-in. diameter (i.e., a gasifier unit for fueling engines up to about 65 hp) can be constructed from the following instructions. If your engine requires a fire tube diameter of 10 in. or more, use a 55-gal drum for the gas unit and another 55-gal drum for the fuel hopper.

The following fabrication procedure is very general and can be applied to the construction of gas generator units of any size; however, the specific dimensions which are given in the parts list and in the instructions below are for this particular prototype unit. All accompanying photographs were taken during the actual assembly of the prototype unit.

The fabrication procedure is as follows:

1. Using the displacement or horsepower rating of the engine to be fueled by the gasifier unit, determine the dimensions (inside diameter and length) of the fire tube (Item 1A) from Table 2-2. Fabricate a cylindrical tube or cut a length of correctly sized pipe to match the dimensions from Table 2-2. (For the prototype gasifier unit illustrated in this report, a 6-in.-diam firetube was used; its length was 19 in.)
2. The circular top plate (Item 2A) should be cut to a diameter equal to the outside diameter of the gasifier housing drum (Item 3A) at its top. A circular hole should then be cut in the center of the top plate; the diameter of this hole must be equal to the outside diameter of the fire tube. The fire tube (Item 1A) should then be welded at a right angle to the top plate (Item 2A) as shown in Fig. 2-3.
3. The grate (Item 4A) should be made from a stainless steel mixing bowl or colander. Approximately 125 holes with diameters of 1/2 in. should be drilled in the bottom and up the sides of the mixing bowl; see Fig. 2-4. A U-bolt (Item 5A) should be welded horizontally to the side of the grate, 2 in. from its bottom. This U-bolt will be interlocked with the shaker mechanism (Item 12A) in a later step.
4. The support chains (Item 6A) are to be attached to the grate in three evenly spaced holes drilled under the lip of the mixing bowl or colander; see Fig. 2-5. These chains are to be connected to the top plate (Item 2A) with eyebolts (Item 7A), as shown in Fig. 2-6. Each eyebolt should have two nuts, one on each side of the top plate, so that the eyebolts can be adjusted to the proper length. When assembled, the bottom of the firetube should be 1.25 in. above the bottom of the mixing bowl.
5. A hole equal to the outside diameter of the ash cleanout port (Item 8A) should be cut into the side of the gasifier housing drum (Item 3A); the bottom edge of this hole

should be about 1/2 in. from the bottom of the drum. Because of the thin wall thickness of oil drums and garbage cans, welding is not recommended; brazing such parts to the drums or cans will ensure both strength and airtightness (see Fig. 2-7).

6. Two holes, equal to the outside diameters of the ignition ports (Item 10A), are to be cut with their centers at a distance from the top of the housing drum (Item 3A) equal to the firetube length less 7 in. (19 in. less 7 in. equals 12 in. for this prototype unit); the holes should be placed opposite each other as shown in Fig. 2-2. The ignition ports should be attached to the wall of the housing drum by brazing.
7. When the ash cleanout port (Item 8A) and the ignition ports (Item 10A) have been attached to the wall of the gasifier housing drum (Item 3A), they should then be closed with pipe caps, Items 9A and 11A respectively. The threads of the pipe caps should be first coated with high temperature silicone (Item 27A) to ensure airtightness. An optional steel crossbar welded to the pipe cap will reduce the effort required to open these caps later.
8. The shaker assembly (Item 12A) is shown in Fig. 2-8. The 1/2-in. pipe (Item 1AA) should be brazed into the side of the housing drum (Item 3A), 1.5 inches from the bottom of the drum; the length of this pipe which protrudes into the drum must be chosen so that the upright bar (Item 2AA) is in line with the U-bolt (Item 5A) on the grate. Likewise, the length of the upright bar must be selected so as to connect into the U-bolt.
9. Weld the upright bar (Item 2AA) to the head of the bolt (Item 3AA). The threaded end of the bolt should be ground down or flattened on one side, as shown in Fig. 2-9, to positively interlock with a slot to be drilled and filed in the handle (Item 4AA). The handle can be formed or bent into any desired or convenient shape.
10. A hole should be drilled in the pipe cap (Item 7AA) so that there is a close fit between this hole and the bolt (Item 3AA). The close fit will help to ensure airtightness.
11. Before assembling the shaker, as shown in Fig. 2-8, coat the bolt (Item 3AA) with a small amount of grease. Before inserting the bolt, fill the pipe (Item 1AA) with high temperature silicone (Item 27A) to ensure airtightness. Tighten the nuts (Item 6AA) so that the position of the handle (Item 4AA) is maintained by friction, yet is capable of being turned and agitated during cleanout or stationary operation.
12. Fabricate the supports (Item 13A) for the gasifier unit housing drum (Item 3A) out of rectangular, iron bar stock. The shape and height of the support flanges must be determined by the frame of the vehicle to which the gasifier is to be mounted. The supports can either be bolted to the bottom and side with the 1/4-in. bolts (Item 14A) or can be brazed directly to the drum; see Fig. 2-10. Remember to seal all bolt holes for airtightness.
13. Completely cover the bottom of the housing drum (Item 3A) with 1/2 in. of hydraulic cement (Item 28A). The cement should also be applied to the inside of the drum for

about 5 in. up the inside walls near the bottom. All edges should be rounded for easy ash removal.

14. The fuel hopper (Item 15A) is to be made from a second container with its bottom up as shown in Fig. 2-11. Remove the bottom, leaving a 1/4-in. lip around the circumference.
15. A garden hose (Item 17A) should be cut to a length equal to the circumference of the fuel hopper (Item 15A) and should then be slit along its entire length. It should be placed over the edge of the fuel hopper from which the bottom was removed. This will prevent injury to the operator when adding wood fuel to the unit. To insure close fit of the garbage can lid (Item 16A), a piece of weather stripping (Item 18A) should be attached under the lid where it makes contact with the fuel hopper.
16. Cut four support bars (Item 19A) to lengths 2.5 in. longer than the height of the fuel hopper (Item 15A). Drill a 3/8-in. hole in each end of all four support bars; these holes should be centered 3/4 in. from the ends. Bend 2 in. of each end of these support bars over at a right angle; then, mount them evenly spaced around the fuel hopper (Item 15A) with 1/4-in. bolts (Item 20A). One of the bends on each support bar should be as close to the lower edge of the fuel hopper as possible.
17. Cut four metal triangular standoffs (Item 21A) and braze, weld, or rivet them flat against the edge of the garbage can lid (Item 16A) as shown in Fig. 2-12; they must be aligned with the four support bars (Item 19A) attached to the fuel hopper. During operation, the garbage can lid must have a minimum 3/4-in. opening for air passage; the standoffs should provide this clearance when they are engaged into the holes in the top edges of the support bars (Item 19A); see Fig. 2-13.
18. Two eye hooks (Item 22A) should be attached to opposite sides of the garbage can lid (Item 16A). Two screen door springs (Item 23A) should be attached to the garbage can handles and used under tension to keep the top lid (Item 16A) either open or closed.
19. Cut the oil drum lock ring (Item 24A) to the exact circumference of the top plate (Item 2A) so that it will fit snugly around the gasifier unit housing drum (Item 3A).
20. Cut four 2 by 2 by 1/4-in. tabs (Item 25A); then, braze these tabs to the lock ring (Item 24A), evenly spaced and in alignment with the support bars (Item 19A) on the fuel hopper. Drill a 3/8-in. hole in each tab to align with the holes in the fuel hopper support bars (Item 19A). The lock ring is shown in Fig. 2-14.
21. The connecting pipe (Item 29A) between the gasifier unit and the filter unit should be attached to the gasifier housing drum (Item 3A) at a point 6 in. below the top of the drum. This pipe must be a minimum of 2-in. in diameter and should be at least 6 ft long for cooling purposes. At least one of the ends of this pipe must be removable for cleaning and maintenance. On this prototype unit, an airtight electrical conduit connector was used; this connection is visible in Fig. 2-1. Many similar plumbing devices

are available and can be used if they are suitable for operation at 400° F and above. The pipe can also be welded or brazed directly to the housing drum.

22. When assembling the gasifier unit, the upright bar (Item 2AA) on the shaker assembly must be placed inside the U-bolt (Item 5A) on the grate.
23. The lock ring will then clamp the gasifier unit housing drum (Item 3A) and the top plate (Item 2A) together. The fuel hopper support bars (Item 19A) must be attached to the tabs (Item 25A) on the lock ring with bolts (Item 26A). High temperature silicone (Item 27A) should be applied to all edges to make an airtight connection. The lock ring connections are shown in the lower portion of Fig. 2-13.

2.2 BUILDING THE PRIMARY FILTER UNIT

Figures 2-15 and 2-16 show exploded views of the primary filter unit; the list of materials is given in Table 2-3 (all figures and tables mentioned in Sect. 2 are presented at the end of Sect. 2). In the following instructions, all item numbers refer to either Fig. 2-15 or 2-16 and to Table 2-3.

The prototype primary filter unit was made from a 5-gal paint can. That size seems to be sufficient for gasifiers with fire tubes up to 10 in. in diameter. If a fire tube diameter of more than 10 in. is required, then a 20-gal garbage can or a 30-gal oil drum should be used. The filter unit could be fabricated in any shape or form as long as airtightness and unobstructed flow of gas are provided. If a 5-gal container is used, it must be clean and free of any chemical residue. The top edge must be straight and without any indentations. If an alternate container can be found or fabricated, a larger diameter will permit longer operation between cleanings.

The piping (Item 29A in Figs. 2-2 and 2-15) which connects the gas generator unit to the primary filter should be considered to be a necessary part of the cooling system and should never have an inside diameter less than 2 in. A flexible automotive exhaust pipe was used on the prototype filter unit described below; it was shaped into a semicircular arc so that increased length would achieve a greater cooling effect.

The fabrication procedure for the filter unit follows:

1. A hole equal to the outside diameter of the drain tube (Item 13B in Fig. 2-15) should be cut into the side of the filter container (Item 1B); the bottom edge of this hole should be about 1/2 in. from the inside bottom of the container.
2. The drain tube (Item 13B) should be inserted into the previously cut hole in the filter container and should be positioned so that its nonthreaded end is near the center of the container and is about 1/2 in. off the bottom. Once this position has been ensured, braze (do not weld) the drain pipe into the side of the filter container. Close the threaded, exterior end of the drain pipe with the pipe cap (Item 14B).
3. Coat the bottom of the filter container (Item 1B) with a 1/2-in. layer of hydraulic cement (Item 28A), taking care not to plug or obstruct the end of the drain tube (Item 13B) with cement (i.e., fill the drain tube with a paper, styrofoam, or other easily removable, but rigid material). The cement should also be applied for about 1.5 in. up

the inside walls of the container near its bottom. Round the edges slightly; the cement is to provide a pathway for any liquid condensate to drain out through the drain tube. The cement must be allowed to harden before proceeding with the fabrication steps below. Remove the filler material from the drain tube when the cement has hardened.

4. A circular bottom plate (Item 2B) should be cut to a diameter 1/2 in. smaller than the inside diameter of the filter container (Item 1B). This will allow for heat expansion and easy removal for cleaning. This bottom plate should be drilled with as many 3/4-in. holes as are practical for the size of the plate. Three evenly spaced 3/8-in. holes should also be drilled around the edge of the bottom plate for the spacer bolts (Item 3B).
5. Fig. 2-16 shows the detail of using three bolts (Item 3B) as spacers for the bottom plate (Item 2B). The length of the bolts should be adjusted to provide a clearance of about 2-in. between the layer of cement in the bottom of the container (Item 1B) and the bottom plate (Item 2B).
6. A rectangular divider plate (Item 4B) should be cut to a width 1/4 in. less than the inside diameter of the filter container (Item 1B) and to a height 2.5 in. less than the inside height of the container. This divider plate should then be welded at a right angle to the centerline of the bottom plate (Item 2B) as shown in Fig. 2-17.
7. Cut a piece of high-temperature hydraulic hose (Item 5B) to a length equal to the circumference of the filter container. It should be slit along its entire length and then placed over the top edge of the filter container (Item 1B) to ensure airtightness.
8. A circular lid (Item 6B) should be cut equal to the outside diameter of the filter container (Item 1B). Three holes should be cut into this lid for the exhaust pipe (Item 29A) from the gasifier unit, the blower (Item 7B), and the filter exhaust pipe (Item 10B) to the engine manifold. Note the arrangement of these holes: the pipe (Item 29A) from the gasifier unit must enter the lid on one side of the divider plate (Item 4B); the blower (Item 7B) and the filter exhaust pipe (Item 10B) to the engine manifold must be located on the other side of the divider plate. This arrangement can be seen in Fig. 2-18.
9. The connecting pipe (Item 29A) between the gasifier unit and the filter unit should be attached to the lid (Item 6B) of the filter container. At least one of the ends of the connecting pipe (Item 29A) must be removable for cleaning and maintenance. On this prototype unit, an airtight electrical conduit connector was used. Many similar plumbing devices are available and can be used if they are suitable for operation at 400 °F and above. The pipe can also be welded or brazed directly to the lid.
10. Attach the blower (Item 7B) to the filter container lid (Item 6B). On the prototype gasifier illustrated in this report, a heater blower from a Volkswagen automobile was used. Connections for a vertical extension tube (Item 8B) will have to be fabricated as shown in Fig. 2-19. A closing cap (Item 9B) is required for the blower exhaust tube. A plumbing cap of steel or plastic with a close fit can be used or fabricated to fit. The vertical extension and the closing cap are visible in Fig. 2-1.

11. The gas outlet (Item 10B) to the carbureting unit on the engine should be 1.25 in. minimum diameter. In fabricating this connection, all abrupt bends should be avoided to ensure free flow of gas. Using plumbing elbows is one solution. The gas outlet (Item 10B) can either be welded or brazed to the lid (Item 6B) of the filter container or an airtight, electrical conduit connector can be used.
12. Latching devices (Item 11B) should be welded or brazed to the lid (see Fig. 2-20) and to the sides (see Fig. 2-21) of the filter container. An air-tight connection between the lid and the filter container must be maintained.
13. Cut two lengths of high-temperature hydraulic hose (Item 12B) equal to the height of the divider plate (Item 4B); cut a third length of hose equal to the width of the divider plate. Slit each hose along its entire length. Place the first two hoses on each side of the divider plate, and place the third hose along the top edge of the divider plate as shown in Fig. 2-17.
14. Insert the divider plate (Item 4B) into the filter container (Item 1B), making sure that the hoses (Item 12B) create an airtight seal along all sides. By changing the length of the spacer bolts (Item 3B), adjust the height of the divider plate so that it is exactly flush with the top of the filter container. Make sure that the lid (Item 5B) will seat flatly and tightly against the top edge of the divider plate.
15. Fill the filter container (Item 1B) on both sides of the divider plate with wood chips, the same kind as would be used for fuel in the gasifier unit. After carefully packing and leveling these wood chips, place the lid (Item 6B) on the filter container, and close the latches tightly.

2.3. BUILDING THE CARBURETING UNIT WITH THE AIR AND THROTTLE CONTROLS

Figures 2-22 and 2-23 show exploded views of the carbureting unit; the list of materials is given in Table 2-4 (all figures and tables mentioned in Sect. 2 are presented at the end of Sect. 2). In the following instructions, all item numbers refer both to Figs. 2-22 and 2-23 and to Table 2-4. The following is a simple and easy way to assemble a carburetor to achieve both air mixture and throttle control. It can be mounted to either updraft or downdraft manifolds by simply turning the unit over. Most of the fabrication procedure below is devoted to the assembly of two butterfly valves: one for the throttle valve and one for the air mixture valve. The remainder of the carburetor unit can be assembled from ordinary, threaded plumbing parts.

The inside diameter of the piping used in the carburetor unit must be related to the size of the engine and should never be smaller than the intake opening on the engine manifold. If in doubt on the inside diameter for the pipe and/or hose sizes, always go with a larger diameter. This will reduce friction losses and will give longer operating hours between cleanings.

When the wood gas leaves the filter unit it should normally be below 180°F. About 2 ft from the filter container, an automotive water hose can be connected to the pipe on the carbureting unit. This rubber hose will keep engine vibration from creating air leaks in the

filter unit or in the connecting piping. The hose must be a fairly new item; such hoses have a steel spring inside to keep them from collapsing when negative pressure is applied. The spring will soon rust if it has first been subjected to water and then to the hot wood gas enriched with hydrogen.

The fabrication procedure for the assembly of two butterfly valves follows:

1. The manifold adapter (Item 1C in Fig. 2-22) must be fitted with bolts and/or holes for mounting onto the engine's existing intake manifold. Because gasoline engines are produced with so many different types of intake manifolds, ingenuity and common sense must be used to modify the manifold adapter (Item 1C) for each different engine to be operated on wood gas. A gasket (Item 7C) should be cut to match the shape of the engine intake fitting.
2. The butterfly valve (Item 3C) is shown in Figs. 2-24 and 2-25; two such valves are required. A 3/8-in. hole should be drilled through the diameter of each valve body (Item 1CC) at the midpoint of its length.
3. The valve plate (Item 2CC) must be oval in shape with the dimensions given in Table 2-4. An oval valve plate must be used so that, in the closed position, the valve will be about 10° off center. This will ensure that the valve will come to a complete stop in the closed position.
4. The edges of the valve plate (Item 2CC), around the longer diameter of the oval, should be beveled to provide a positive, airtight closure. Two evenly spaced, 1/4-in. holes should be drilled along the shorter diameter of the oval plate.
5. The valve support rod (Item 3CC) should be filed or ground flat on one side as shown in Fig. 2-24; the flat area must begin 1/4 in. from one end and must continue for a distance equal to the inside diameter of the valve body (Item 1CC).
6. Two 3/16-in. holes should be drilled into the flat area of the valve support rod (Item 3CC); these holes must align with the holes in the valve plate (Item 2CC). They must also be tapped (with threads) to accept the valve plate screws (Item 4CC).
7. The butterfly valve (Item 3C) should be assembled by first placing the valve support rod (Item 3CC) through the hole in the valve body (Item 1CC). The valve plate (Item 2CC) should be dropped into one end of the valve body and then inserted into the flat area of the valve support rod. The two screws (Item 4CC) should be used to attach the valve plate to the support rod. Check to see that the assembled valve plate rotates freely and seats completely in the closed position.
8. A nut (Item 6CC) should be welded flat against one side of the throttle arm (Item 5CC) near its end. A 1/8-in. hole should be drilled into the side of the nut and must be threaded to accept the set screw (Item 7CC). At least one hole should be drilled into the throttle arm for attachment of the engine throttle control or air control linkages.

9. Place the nut (Item 6CC) on the throttle arm over the end of the valve support rod (Item 3CC) and use the set screw (Item 7CC) to secure the assembly. The throttle arm can be placed in any convenient orientation. Assembled butterfly valves are shown in Fig. 2-26.
10. The remaining parts of the carburetor assembly should be screwed together as shown in Fig. 2-27. Pipe thread compound should be used to make airtight connections. The assembled carburetor unit should be attached to the engine's intake manifold as shown in Fig. 2-28
11. This prototype gasifier was designed to operate if gasoline were unavailable; but, if dual operation on wood and gasoline is desired, the elbow (Item 2C) could be replaced with a tee, allowing a gasoline carburetor to also be mounted.
12. The arm on the butterfly valve (Item 3C) which is closest to the elbow (Item 2C) is to be connected to the foot- (or, on tractors, hand-) operated accelerator. The other butterfly valve is to be used as the air mixture control valve and can be operated with a manual choke cable. If the engine has an automatic choking device, then a hand-operated choke cable should be installed. Both butterfly valves and their connecting control linkages must operate smoothly with the ability to adjust the valve yet keep it stationary in the selected position during operation. The linkages must close the valves airtight when the engine is off.
13. The air inlet (Item 6C) should be connected by an extension hose or pipe, either iron or plastic, to the existing engine's air filter in order to prevent road dust or agricultural residue from entering the engine.
14. The wood gas inlet (Item 5C) is to be connected to the outlet piping (Item 10B as shown in Fig. 2-15) from the wood gas filter unit. Part of this connection should be a high-temperature rubber or neoprene hose to absorb engine vibration.

Fig. 2-28. Carburetion unit attached to engine's existing intake manifold. Wood gas enters from the side of the tee; air enters from the right-hand end. The butterfly valve at the right (partially obscured) is connected to the air control (choke) cable; the left valve is connected to the throttle linkage.

Table 2-1. List of materials for the gasifier unit and the wood fuel hopper

Item	Quantity	Description
1A	1	Metal pipe, tube, or other, open-ended metal cylinder; diameter and length from Table 2-2; minimum wall thickness of 1/4 in.
2A	1	Circular metal plate with thickness of 1/8 in.; diameter equal to outside diameter of Item 1A.
3A	1	30-gal metal oil drum or metal container with approximate dimensions of 18 in. (diameter) by 29 in. (height); container must have a bottom.
4A	1	10-quart stainless steel mixing bowl, colander, or other stainless steel bowl with approximately 14-in. diameter and 6-in. depth.
5A	1	2-in. metal U-bolt.
6A	1	3/16-in. metal chain with 1-in. links; 7 ft total length.
7A	3	1/4-in. eyebolts, 3 in. length with two nuts for each eyebolt.
8A	1	4-in. metal pipe nipple.
9A	1	Metal pipe cap for Item 8A.
10A	2	3-in. metal pipe nipple.
11A	2	Metal pipe cap for Item 10A.
12A		Shaker assembly; see Fig. 2-8.
1AA	1	Metal 1/2-in. pipe; 6 in. length.
2AA	1	Iron bar stock; square or round, 1/2 in.; 6 in. length.
3AA	1	1/2-in. bolt; 8 in. long.
4AA	1	Iron bar stock; rectangular, 1/4 by 1 in.; 10 in. length.
5AA	1	1/2-in. flat washer.
6AA	2	1/2-in. nuts.
7AA	1	Metal pipe cap or bushing for Item 1AA.

Table 2-1. (continued)

Item	Quantity	Description
13A	1	Iron bar stock; rectangular, 1/4 by 2 in.; 10 ft length.
14A	25	1/4-in. bolts; 3/4 in. length; with nuts.
15A	1	20-gal metal garbage can or metal container with approximate dimensions of 18 in. (top diameter) by 24 in. (height); bottom is not required.
16A	1	Lid for 20-gal garbage can.
17A	1	Garden hose; 1/2 to 5/8 in. diameter; length equal to circumference of Item 15A.
18A	1	Foam weather stripping with adhesive backing; 1/4 by 1 in.; length equal to circumference of Item 15A.
19A	1	Iron bar stock; rectangular, 1/4 by 2 in.; 10 ft length.
20A	12	1/4-in. bolts; 3/4 in. length; with nuts.
21A	4	Metal triangles; 2 by 2.5 in., 1/8 to 1/4 in. thick.
22A	2	Metal eye hook.
23A	2	Screen door spring, 14 in. length.
24A	1	Lock ring for 30-gal (or larger) oil drum.
25A	4	Metal squares; 2 by 2 in., 1/4 in. thick.
26A	4	3/8-in. bolts; 3 in. length.
27A	1	Tube of high temperature silicone or liquid high temperature gasket material.
28A	1	60-lb. sack of hydraulic or other waterproof cement [such as SEC-PLUG (tm), which is manufactured by the Atlas Chemical Company, Miami, FL].
29A	1	2-in. pipe, electrical conduit, flexible automobile exhaust pipe, or other metal tubing; 6-ft minimum length. Pipe must be able to withstand temperatures of 400°F.

Table 2-2. Fire tube dimensions

Inside diameter (inches)	Minimum length (inches)	Engine power (horsepower)	Typical engine displacement (cubic inches)
2 ^a	16	5	10
4 ^a	16	15	30
6	16	30	60
7	18	40	80
8	20	50	100
9	22	65	130
10	24	80	160
11	26	100	200
12	28	120	240
13	30	140	280
14	32	160	320

^aA fire tube with an inside diameter of less than 6 ¹/₂ in. would create bridging problems with wood chips and blocks. If the engine is rated at or below 15 horsepower, use a 6-in. minimum fire tube diameter and create a throat restriction in the bottom of the tube corresponding to the diameter entered in the above table.

NOTES:

For engines with displacement rated in liters, the conversion factor is 1 liter = 61.02 cubic inches.

The horsepower listed above is the SAE net brake horsepower as measured at the rear of the transmission with standard accessories operating. Since the figures vary when a given engine is installed and used for different purposes, such figures are representative rather than exact. The above horsepower ratings are given at the engine's highest operating speed.

Table 2-3. List of materials for the primary filter unit

Item	Quantity	Description
1B	1	5-gal metal can or other metal container with minimum dimensions of 11.5-in. diameter and 13 in. tall.
2B	1	Circular metal plate; diameter equal to 1/2 in. smaller than inside diameter of Item 1B; thickness of 1/8 in.
3B	3	3/8-in. bolts; 3 in. length with two nuts for each bolt.
4B	1	Rectangular metal plate; width equal to 1/4 in. smaller than inside diameter of Item 1B; height equal to 2.5 in. smaller than internal height of Item 1B; 1/8 in. thick.
5B	1	High-temperature hose, 3/8 to 5/8 in. diameter; length equal to circumference of Item 1B.
6B	1	Circular metal plate; diameter equal to outside diameter of Item 1B; thickness of 1/8 in.
7B	1	12-volt blower (automotive heater type); case and fan must be all metal.
8B	1	Metal extension pipe for blower outlet, including elbows and connections for vertical orientation; 1 ft. minimum length.
9B	1	Cap for Item 8B; plastic is acceptable.
10B	1	1.25-in. metal pipe, electrical conduit, automotive exhaust pipe, or other metal tubing; 2 ft minimum length.
11B	3	Metal latch for securely connecting Items 1B and 6B together. Such devices as suitcase or luggage catches, bail-type latches, window sash catches (with strike), or wing-nut latches are acceptable.
12B	1	High-temperature hose, 3/8 to 5/8 in. diameter; length equal to three times the height of Item 4B.
13B	1	Metal 1/2-in. pipe, threaded on one end; 8 in. length.
14B	1	Metal pipe cap for Item 13B.

Table 2-4. List of materials for the carbureting unit

Item	Quantity	Description
1C	1	1.25-in. closet flange.
2C	1	1.25-in. male-to-female 45° pipe elbow.
3C		Butterfly valve; see Fig. 2-23.
1CC	2	1.25-in. pipe nipple or threaded length of pipe, 3-in. length.
2CC	2	Oval metal plate; 1/16 in. thick; short dimension equal to inside diameter of Item 1CC; long dimension equal to 1.02 times the short dimension.
3CC	2	3/8-in. diameter rod; 2.5 in. length.
4CC	4	3/16-in. screws; 3/16 in. length.
5CC	2	Flat bar stock; rectangular, 1/2 by 3 in.; 1/8 in. thick.
6CC	1	7/16-in. nut.
7CC	1	1/8-in. set screw.
4C	1	1.25-in. tee with all female threads.
5C	1	1.25-in. pipe nipple or threaded length of pipe, 3 in. length.
6C	1	1.25-in. pipe or hose.
7C	1	Gasket material; sized to cover Item 1C.
8C	1	Tube of pipe compound or Teflon tape for sealing threaded assemblies.

3. OPERATING AND MAINTAINING YOUR WOOD GAS GENERATOR

3.1 USING WOOD AS A FUEL

Because wood was used extensively as generator fuel during World War II, and since it is plentiful in most parts of the populated United States, it merits particular attention for use as an emergency source of energy. When used in gas generators, about 20 lb of wood have the energy equivalence of one gallon of gasoline.

Wood consists of carbon, oxygen, hydrogen, and a small amount of nitrogen. As a gas generator fuel, wood has several advantages. The ash content is quite low, only 0.5 to 2% (by weight), depending on the species and upon the presence of bark. Wood is free of sulphur, a contaminant that easily forms sulfuric acid which can cause corrosion damage to both the engine and the gas generator. Wood is easily ignited—a definite virtue for the operation of any gas generator unit.

The main disadvantages for wood as a fuel are its bulkiness and its moisture content. As it is a relatively light material, one cubic yard of wood produces only 500 to 600 lb of gas generator fuel. Moisture content is notoriously high in wood fuels, and it must be brought below 20% (by weight) before it can be used in a gas generator unit. By weight, the moisture in green wood runs from 25 to 60%, in air-dried wood from 12 to 15%, and in kiln-dried wood about 8%. Moisture content can be measured quite easily by carefully weighing a specimen of the wood, placing it in an oven at 220°F for thirty minutes, reweighing the specimen, and reheating it until its weight decreases to a constant value. The original moisture content is equivalent to the weight lost.

The prototype unit in this manual (with an 6-in.-diam firetube) operated well on both wood chips (minimum size: 3/4 by 3/4 by 1/4 in.) and blocks (up to 2-in. cubes); see Fig. 3-1 (all figures and tables mentioned in Sect. 3 are presented at the end of Sect. 3). Larger sizes could be used, if the firetube diameter is increased to prevent bridging of the individual pieces of wood; of course, a throat restriction would then have to be added to the bottom of the firetube so as to satisfy the dimensions in Table 2-2 in Sect. 2.

3.2 SPECIAL CONSIDERATIONS AND ENGINE MODIFICATIONS

To start the fire in the gasifier, the blower must be used to create a suction airflow through the wood in the hopper and downward in the firetube. If an especially high horsepower engine is to be fueled by the gasifier unit, then it might be necessary to install two such blowers and run them simultaneously during start-up.

When the wood gas leaves the gasifier unit, all the oxygen pulled down with the air through the firetube has been chemically converted and is contained in carbon monoxide (CO) and water (H₂O). The wood gas is unable to burn without being mixed with the proper amount of additional oxygen. If an air leak develops below the grate area, the hot gas will burn while consuming the available oxygen and will create heat; this will almost certainly destroy the gasifier unit if it is not detected soon. If an air leak develops in the filter unit or in the connecting piping, the gas will become saturated with improper amounts of oxygen

and will become too dilute to power the engine. Therefore, airtightness from the gasifier unit to the engine is absolutely essential.

Ideally, as the wood gas enters the engine manifold it should be mixed with air in a ratio of 1:1 or 1.1:1 (air to gas) by volume. The carburetion system described in this report will provide this mixture with a minimum of friction losses in the piping. The throttle control valve and the air control valve must be operable from the driver's seat of the vehicle.

The engine's spark plug gaps should be adjusted to between 0.012 and 0.015 in.; the ignition timing should be adjusted to "early."

3.3 INITIAL START-UP PROCEDURE

Initially, you will need to add charcoal to the grate below the firetube. Subsequent operation will already have the grate full of charcoal which has been left over from the previous operating period.

Fill the firetube with charcoal* to a level 4 in. above the grate. Fill the hopper with air-dried wood; then, proceed with the routine start-up directions below.

3.4 ROUTINE START-UP PROCEDURE

1. Agitate the grate shaker handle for at least twenty seconds to shake down the charcoal from the previous operating period.
2. Open the ash cleanout port and remove the ashes from the generator housing drum. Lubricate the threads of the cleanout port with high-temperature silicone, and close the cover of the cleanout port so that it is airtight.
3. Fill the hopper with wood fuel, and tamp the fuel down lightly. Either leave the lid completely off the fuel hopper, or adjust the opening around the lid to a 3/4-in. (or larger) clearance.
4. Close the carburetor's air control valve and remove the cover from the blower exhaust on top of the filter unit. Start the blower, and let it run for thirty seconds to avoid explosion of residual gas in the system. Then, with the blower still operating, proceed with the next step.
5. Open the ignition port, and ignite a 12- by 12-in. piece of newspaper; with a long stick or wire, push the burning sheet of newspaper into the grate; see Fig. 3-2. Close the ignition port. If no smoke appears at the blower's exhaust port, repeat the start-up

*Charcoal produced for outdoor barbecue grills is not well suited for gas generator use. To produce a better grade of charcoal, place a rag soaked in alcohol on the grate, or place 3 to 5 pages of newspaper on the grate, then fill the fire tube to a height of 10 to 12 in. with well-dried wood. Have all the valves closed and let the fire tube act as a chimney until the wood is converted to charcoal.

sequence from Step (c). If repeated attempts fail, new charcoal should be added to the unit as described in Sect. 3.3, above, and the start-up ignition sequence should be repeated.

6. After a few minutes of smoky exhaust, test the gas at the blower exhaust by safely and carefully attempting to ignite it; see Fig. 3-3. When the gas burns consistently well, stop the blower and replace the cover on the blower exhaust.
7. Open the carburetor's air control valve, adjust the engine's accelerator, and start the engine in a normal manner. Let the engine warm up slowly (two to five minutes). If the engine fails to start or dies repeatedly, restart the blower and repeat the ignition sequence from Step (4).

3.5 DRIVING AND NORMAL OPERATION

Shift gears so as to keep the engine speed (rpm) high at all times. Remember that it is the vacuum created by the pistons that provides the force which moves the gas from the gasifier unit into the engine.

Refill the hopper with wood (as shown in Fig. 3-4) before it is completely empty, but avoid refilling just before the end of engine operation. Periodically shake down the ashes from the grate. If your system is equipped with a gas cooler, drain water from the cooler from time to time.

Under operation in dry weather, the gasifier can be operated without the lid on the fuel hopper. However, when the gasifier unit is shut down the hopper must be covered to prevent air from continuing to burn the wood in the hopper. Under wet-weather operation, the cover must be placed on the fuel hopper, and then lifted up and rotated about 2 in. until the triangular pieces line up with the holes in the support bars. The tension of the screen door springs will then hold the lid closed. See Fig. 3-5 for clarification.

3.6 SHUTTING-DOWN THE GASIFIER UNIT

When shutting down the gasifier unit, turn off the ignition switch and open the carburetor's air control valve for ten seconds to relieve any pressure from within the system. Then, completely close the air control valve, and place the cover tightly on the fuel hopper. When restarting after a short stopover, let the engine warm up briefly. After longer stops (up to one hour), tamp down the wood lightly and try to use the blower for restarting without relighting the wood fuel. After very long stops (over two hours) the charcoal must be ignited again.

3.7 ROUTINE MAINTENANCE

Periodically check all nuts on the gasifier unit, the fuel hopper, the filter unit, and the carburetor for snugness; check all penetrations and fittings for airtightness. In addition, perform the following maintenance activities as scheduled:

3.7.1 Daily Maintenance

Open the ash cleanout port of the gasifier housing drum and remove the ashes after shaking the grate for at least thirty seconds. Replace the cover of the port after coating the threads with high-temperature silicone to ensure airtightness. Open the drain tube at the bottom of the filter container and allow any liquid condensate to drain out; remember to close the drain tube when finished.

3.7.2 Weekly Maintenance (or every 15 hours of operation)

Clean out the gasifier housing drum, the fuel hopper, and the filter. Rinse out the piping and connections to and from the filter. Replace the wood chips inside the filter. (The used wood chips from the filter can be dumped into the fuel hopper and burned to produce wood gas.) Use high-temperature silicone on all pipe connections and on the filter lid to ensure airtightness.

3.7.3 Biweekly Maintenance (or every 30 hours of operation)

Make sure that all pipe connections are secure and airtight. Check and tighten all mounting connections to the vehicle chassis. Check for rust on the outside of the gas generator housing drum, especially on the lower region. Coat with high-temperature protective paint as necessary.

3.8 OPERATING PROBLEMS AND TROUBLE-SHOOTING

A discussion of problems and their related causes and cures is contained in the troubleshooting guide of Table 3-1. Many operational problems can be traced to failure to maintain the airtightness of all piping connections and fittings; the piping should be routinely checked to prevent such problems.

3.9 HAZARDS ASSOCIATED WITH GASIFIER OPERATION

Unfortunately, gas generator operation involves certain problems, such as toxic hazards and fire hazards. These hazards should not be treated lightly; their inclusion here, at the end of this report, does not mean that these hazards are unimportant. The reader should not underestimate the dangerous nature of these hazards.

3.9.1 Toxic Hazards

Many deaths in Europe during World War II were attributed to poisoning from wood gas generators. The danger of "generator gas poisoning" was one of the reasons that such gasifiers were readily abandoned at the end of World War II. It is important to emphasize that "generator gas poisoning" is carbon monoxide (CO) poisoning. Acute "generator gas

poisoning" is identical with the symptoms that may develop if a heating stove damper is closed too early, or if a gasoline vehicle is allowed to idle in a poorly ventilated garage. Table 3-2 shows how poisoning symptoms develop according to the concentration of carbon monoxide in breathable air. It is important to note that rather brief exposures to very small concentrations of carbon monoxide result in undesirable physiological effects.

In case of carbon monoxide poisoning, first aid should consist of the following procedures:

1. Move the victim quickly out into the open air or to a room with fresh air and good ventilation. All physical exertion on the part of the victim must be avoided.
2. If the victim is unconscious, every second is valuable. Loosen any tight clothing around the neck. If breathing has stopped, remove foreign objects from the mouth (false teeth, chewing gum, etc.) and immediately give artificial respiration.
3. Keep the victim warm.
4. Always call a physician.
5. In case of mild carbon monoxide poisoning without unconsciousness, the victim should be given oxygen if possible.

3.9.2 Technical Aspects of "Generator Gas Poisoning"

Generator gas poisoning is often caused by technical defects in the functioning of the gas generator unit. When the engine is running, independent of the starting blower, the entire system is under negative pressure created by the engine's pistons; the risk of poisoning through leakage is therefore minimal. However, when the engine is shut off, formation of wood gas continues, causing an increase of pressure inside the generator unit. This pressure increase lasts for approximately 20 minutes after the engine is shut off. For this reason, it is not advisable to stay in the vehicle during this period. Also, the gas generator unit should be allowed to cool for at least 20 minutes before the vehicle is placed in an enclosed garage connected with living quarters. It should be emphasized that the gas formed during the shut-down period has a carbon monoxide content of 23 to 27% and is thus very toxic.

3.9.3 Fire Hazard

The outside of a gas generator housing drum may reach the same temperature as a catalytic converter on today's automobiles. Care should be taken when operating in areas where dry grass or combustible material can come into contact with the housing drum of the gas generator unit. If a gas generator unit is mounted on a personal car, bus, van or truck, a minimum 6-in. clearance must be maintained around the unit. Disposal of ashes must only be attempted after the unit has cooled down (to below 150°F). Such residue must be placed away from any combustible material and preferably be hosed down with water for absolute safety.

Fig. 3-1. Virtually all varieties of wood chips can be used for fuel. (Minimum size for this 6-in. firetube unit: 3/4 by 3/4 by 1/4 in.; maximum size: 2-in. cubes.)

Fig. 3-2. Ignite a single piece of newspaper to start the gasifier unit. Push the flaming newspaper through the ignition port and directly into the grate. (At the right of the photo, note the battery which is operating the blower atop the filter unit.)

Fig. 3-3. Igniting the exhaust gas will demonstrate that the gasifier unit is working properly.

Fig. 3-4. Refill the fuel hopper before it becomes two-thirds empty.

ORNL-Photo 5314-86

Fig. 3-5. The lid must be used to cover the fuel hopper in wet weather or when shutting the unit down.

Table 3-1. Trouble-shooting your wood gas generator

Trouble	Cause	Remedy
Start up takes too long.	1. Dirty system or clogged pipes.	Clean the gasifier unit and all connecting piping.
	2. Blower is too weak.	Check the blower and test the battery's charge.
	3. Wet or poor quality charcoal.	Check charcoal and replace or refill to proper level.
	4. Wood fuel bridges in the fire tube.	Lightly tamp down the wood fuel in the hopper and fire tube or replace the fuel with smaller-sized chips.
Engine will not start.	1. Insufficient gas.	Use the blower longer during start up.
	2. Wet wood fuel.	Vent steam and smoke through the fire tube and fuel hopper for several minutes.
	3. Incorrect fuel-air mixture.	Regulate the carburetor's air control valve for proper mixing.
Engine starts, but soon dies.	1. Not enough gas has been produced.	Use low RPM while starting engine and do not rev engine for several minutes.
	2. Air channels through fire tube.	Tamp down wood fuel lightly in hopper. <u>Do not</u> crush charcoal above the grate.
Engine loses power under load.	1. Restricted gas flow in piping.	Reduce air mixture valve setting. Check for partial blockage of unit or piping.
	2. Leaks in system.	Check all covers and pipes for air tightness.

Table 3-2. Effects of breathing carbon monoxide

Carbon monoxide content of inhaled air (%)	Physiological effects
0.020	Possible mild frontal headache after two to three hours.
0.040	Frontal headache and nausea after one to two hours; occipital (rear of head) headache after 2.5 to 3.5 hours.
0.080	Headache, dizziness, and nausea in 45 min; collapse and possible unconsciousness in two hours.
0.160	Headache, dizziness, and nausea in 20 min; collapse, unconsciousness and possible death in two hours.
0.320	Headache and dizziness in 5 to 10 min; unconsciousness and danger of death in 30 min.
0.640	Headache and dizziness in 1 to 2 min; unconsciousness and danger of death in 10 to 15 min.
1.280	Immediate physiological effect; unconsciousness and danger of death in 1 to 3 min.

Biofuels

Table of Contents:

[Overview: Biofuels.](#)

Growing it on the farm.

[Biodiesel: Make Your Own Biodiesel](#)

"Anybody can make biodiesel. It's easy, you can make it in your kitchen -- and it's BETTER than the petro-diesel fuel the big oil companies sell you. Your diesel motor will run better and last longer on your home-made fuel, and it's much cleaner -- better for the environment and better for health. If you make it from used oil it's not only cheap but you'll be recycling a troublesome waste product. Best of all is the GREAT feeling of freedom, independence and empowerment it will give you. Here's how to do it -- everything you need to know. " (Quoted from: Journey to Forever)

[SEALED Make Your Own Biodiesel](#)

After Nuclear Holocaust](#)

Making it on the Farm

RAPESEED, LINSEED, FLAXSEED, SUNFLOWERSEED, SESAMESEED, PEANUT, GROUNDNUTS, MUSTARDSEED, POPPY, COTTON SEED etc. are but a few of the seeds that have been suggested for making biofuel. There are also techniques that have used grasses, corn, and all sorts of other vegetable and biomass. Some techniques require stills which we cover elsewhere but perhaps you will find some simpler techniques and guidance in the material presented here.

Stills

Table of Contents:

[Overview: Stills.](#)

The problems of stills.

[SEALED How Distillation Works](#)

This is a SEALED 8 page .pdf file explains the basic concepts. This site that won't be opened until after The Great Catastrophe.

[SEALED Building a home still](#)

This is a SEALED 78 page .pdf file with lots of pictures. This site that won't be opened until after The Great Catastrophe.

[LINK: Running on Alcohol](#)

This is the present open source for the mirrored copy that we have below.

[SEALED Running on Alcohol](#)

This sealed site has three pages that can be linked from the open site above. This first one describes a small home still that the owner actually uses to provide fuel for a number of automobiles.

[SEALED A Large Farm System](#)

This second sealed site describes a somewhat larger system that was built to produce fuel on a commercial basis.

[SEALED Still Safety](#)

This third sealed site discusses safety aspects regarding stills.

[SEALED Making It On The Farm](#)

This is another SEALED 182 page manual in .pdf that we purchased. This site won't be opened until after The Great Catastrophe.

[LINK: The Manual For the Home and Farm Production of Alcohol](#)

This is the present open source for the mirrored copy that we have below.

[SEALED The Manual For the Home and Farm Production of Alcohol](#)

This is a site SEALED mirror of the above source. This site won't be opened until after The Great Catastrophe. However, below is an overview of the chapters so that you can see its thoroughness AND also at this time you can go to the open site above.

Chapter 1 AN OVERVIEW

- Alcohol Fuel
- Uses of Alcohol Fuel
- Other Alternative Fuels

Chapter 2 BASIC FUEL THEORY

- Chemical Composition
- Combustion Properties
- Volatility
- Octane Ratings
- Water Injection
- Exhaust Composition
- Engine Performance - Straight Alcohol
- Engine Performance - Alcohol Blends

Chapter 3 UTILIZATION OF ALCOHOL FUELS

- Methods of Utilization
- Alcohol Blends
- Pure Alcohol
- Diesel Engines
- Engine Modification
- Alcohol Injection

Chapter 4 ETHANOL PRODUCTION - GENERAL DISCUSSION

- Raw Materials
- Manufacturing Steps
- Process Design

Chapter 5 PROCESSING STEPS COMMON TO ALL MATERIALS

- Dilution
- Ph Control
- Backslopping

Cleanliness

Hydrometers

Chapter 6 PROCESSING STEPS SPECIFIC TO SACCHARINE MATERIALS

General Description

Extraction

Chapter 7 PROCESSING STEPS SPECIFIC TO STARCHY MATERIALS

Preparation of Starchy Materials

Milling

Cooking

Conversion

Malting

Premalting

Preparation of Malt

Enzyme Conversion

Acid Hydrolysis

Mash Cooling

Chapter 8 PROCESSING STEPS SPECIFIC TO CELLULOSE MATERIALS

Cellulose Conversion

The Problem of Stills

I am personally a teetotaler and totally opposed to the use of alcohol as a recreational drink. Still alcohol

does have its medicinal purposes and can also be used as an antiseptic and as a aesthetic. In fact in may be about the only aesthetic available until the production of ether can be established.

Here we are principally talking about the use of stills for making fuel. With all the surplus rotting potatoes in the area we would have liked to make a still and produce fuel for our diesel generators. But, presently, there is a \$100,000 annual fine (license) for doing so. We will simply have to wait for a more propitious time.

The building and operation of a still takes some skill but it is not what we would call a high-tech operation. After all, the skill is most often identified with hillbilly moonshine makers. The designs here will at least demonstrate the principles involved. It may be largely a matter of scale to get up to larger volumes needed for fuel.

Solar Energy

Table of Contents:

[Overview: Solar Energy.](#)

What works and what doesn't.

[Cooking: An overall survey of solar cookers.](#)

This is an online overall survey of solar cookers that ties into the next two explanations.

[SEALED: Overall survey of Solar Cookers.](#)

The SEALED version of the of the above site. This file will not be opened until after the nuclear war.

[Cooking 2: An overall survey of BOX solar cookers.](#)

Because there are so many different designs of solar cookers the information referenced here has been narrowed to what seemed most applicable to the anticipated immediate needs of nuclear survivors.

[SEALED: An overall survey of BOX solar cookers.](#)

The SEALED version of the of the above site. This file will not be opened until after the nuclear war.

[Cooking 3: A very simple design.](#)

This is a detailed explanation about one exceptionally simple design. With more time and resources one will probably wish to consider one of the other designs in the links above. This design, however, has the additional advantage in that it is very portable.

[SEALED: A very simple design.](#)

The SEALED version of the of the above site. This file will not be opened until after the nuclear war.

[Hotwater 1: Make it with the sun even in cold climates.](#)

This SEALED 9 page .pdf file is about a closed anti-freeze system. This file will not be opened until after the nuclear war.

[Hotwater 2: Build Your Own Solar Water Heater.](#)

This SEALED 118 page .pdf file is much more detailed. This file will not be opened until after the nuclear war.

[Hotwater 3: Solar Hotwater Heating - A DIY Guide.](#)

This SEALED 31 page .pdf file is another system. It is always good to get a variety of ideas and explanations. This file will not be opened until after the nuclear war.

Solar Overview

After a nuclear war, solar power for making electricity is probably not going to be an option unless one happens to find some salvagable solar panels. I obtained books on the subject of making "hobbyist" solar panels and they are so terribly inefficient that it is just not a practical way to go at all. Solar panels operate only during daytime, on days that are not cloudy, and in locations near enough to the equator that you don't get low sun angles and long nights. Consequently commercial solar panels presently have a payout of about a hundred years which means, given interest rates, the value of money, the life expectancy of the panels themselves, and human life expectancy - they just are not a practical way to go in most situations. They have application for some small power requirements in very remote locations but that is about it in many parts of the world. In outerspace with 24 hour sunlight they may be the cat's meow - but nothing that we need to concern ourselves about in a nuclear recovery situation.

Still, sunlight is a great power source for stills, solar cookers and as a means of heating water. Those are the applications that are treated here.

Simple Technology

Table of Contents:

Some of the information regarding Simplified Technology is presently in locked files because it is copyrighted information. The concept behind putting it on this site in that manner is to gather the information now and to archive it in a form that may possibly be disseminated later. Some of the information here could as well as have gone under farming or pioneering skills. There is so much information about using bicycles, that while they might have gone under simple machines, they have gotten a category of their own. The same applies to windmills and waterwheels. Some of the decisions as where to put information have been arbitrary but there is just too much to put it all under one category, so the reader needs to look under all the categories when studying the subject.

[Basic Machines: The Basic Principles of Machinery](#)

This 168 page .pdf book is open and available for downloading NOW. It covers levers, block and tackle, plane and wedge, and on up through hydraulic devices, and internal combustion engines, and more.

[Simple Machines: Descriptions of Simple Machines](#)

This 81 page .pdf book from MIT explains how to build dozens of primitive machines, drills, lathes, pumps, and all sorts of other useful devices. Currently a locked file because of copyright.

[Farm Devices: Patterns for Simple Farm Devices](#)

This 150 page .pdf book shows how farmers built their own devices in the 1700s and 1800s (and for perhaps centuries earlier). Practical ideas that are still used today.

[Scythes: A tool of the centuries](#)

This 63 page .pdf copyrighted and presently sealed book covers one of the most basic and essential tools of the centuries. Along with ax, hoe, hammer and shovel, it has been essential to the establishment of civilization. Largely displaced by modern harvesting methods it is a technology that may need to be at least temporarily "recovered".

[Blacksmithing: An essential technology](#)

This 132 page .pdf copyrighted and presently sealed book covers an essential technology that may have to be recovered. About a hundred years ago every village would have one or more blacksmiths, but then the

skill largely disappeared except as retained by farriers (horse shoeing is another subject) and some ornamental artists.

PREFACE

Basic Machines is written as a reference for the enlisted men in the Navy whose duties require knowledge of the fundamentals of machinery.

Beginning with the simplest of machines—the lever—the book proceeds with the discussion of block and tackle, wheel and axle, inclined plane, screw and gears. It explains the concepts of work and power, and differentiates between the terms "force" and "pressure." The fundamentals of hydrostatic and hydraulic mechanisms are discussed in detail. The final chapters include several examples of the combination of simple mechanisms to make complex machines.

As one of several basic Navy Training Courses, this book was prepared by the Education and Training Support Service, Washington, D.C., for the Chief of Naval Personnel.

CHAPTER 1

LEVERS

YOUR HELPERS

Ships have evolved through the ages from crude rafts to the huge complex cruisers and carriers of today's Navy. It was a long step from oars to sails, and another long step from sails to steam. With today's modern nuclear-powered ships another long step has been taken. Each step in the progress of shipbuilding has involved the use of more and more machines, until today's Navy men are specialists in operating and maintaining machinery. The Boatswain operates the winches to hoist cargo and the anchor; the men in the engine room operate pumps, valves, generators, and other machines to produce and control the ship's power; men in the weapons department operate shell hoist, and rammers; elevate and train the guns and missile launchers; the cooks operate mixers and can openers; men in the CB rates drive trucks, operate cranes, graders, and bulldozers. In fact it is safe to say every rate in the Navy uses machinery some time during the day's work.

Each machine used aboard ship has made the physical work load of the crew lighter. You don't walk the capstan to raise the anchor, or heave on a line to sling cargo aboard. Machines have taken over these jobs, and have simplified and made countless others easier. Machines are your friends. They have taken much of the backache and drudgery out of a sailor's life. Reading this book should help you recognize and understand the operations of many of the machines you see about you.

WHAT IS A MACHINE?

As you look about you, you probably see half a dozen machines that you don't recognize as such. Ordinarily you think of a machine as a complex device—a gasoline engine or a typewriter. They are machines, but so is a

hammer, a screwdriver, a ship's wheel. A machine is any device that helps you to do work. It may help by changing the amount of the force or the speed of action. For example, a claw hammer is a machine—you can use it to apply a large force for pulling out a nail. A relatively small pull on the handle produces a much greater force at the claws.

We use machines to TRANSFORM energy. For example, a generator transforms mechanical energy into electrical energy. We use machines to TRANSFER energy from one place to another. For example, the connecting rods, crankshaft, drive shaft, and rear axle transfer energy from the automobile engine to the rear wheels.

Another use of machines is to MULTIPLY FORCE. We use a system of pulleys (a chain hoist for example) to lift a heavy load. The pulley system enables us to raise the load by exerting a force which is smaller than the weight of the load. We must exert this force over a greater distance than the height through which the load is raised; thus, the load moves more slowly than the chain on which we pull. A machine enables us to gain force, but only at the expense of speed.

Machines may also be used to MULTIPLY SPEED. The best example of this is the bicycle, by which we gain speed by exerting a greater force.

Machines are also used to CHANGE THE DIRECTION OF A FORCE. For example, the signalman's halyard enables one end of the line to exert an upward force on a signal flag as a downward force is exerted on the other end.

There are only six simple machines—the LEVER, the BLOCK, the WHEEL and AXLE, the INCLINED PLANE, the SCREW, and the GEAR. However, physicists recognize that there are only two basic principles in machines; namely, the lever and the inclined plane. The wheel and

axle, the block and tackle, and gears may be considered levers. The wedge and the screw use the principle of the inclined plane.

When you are familiar with the principles of these simple machines, you can readily understand the operation of complex machines. Complex machines are merely combinations of two or more simple machines.

THE LEVER

The simplest machine, and perhaps the one with which you are most familiar, is the LEVER. A seasaw is a familiar example of a lever in which one weight balances the other.

There are three basic parts which you will find in all levers; namely, the FULCRUM (F), a force or EFFORT (E), and a RESISTANCE (R). Look at the lever in figure 1-1. You see the pivotal point F (fulcrum); the EFFORT (E) which you apply at a distance A from the fulcrum; and a resistance (R) which acts at a distance a from the fulcrum. Distances A and a are the lever arms.

CLASSES OF LEVERS

The three classes of levers are shown in figure 1-2. The location of the fulcrum (the fixed or pivot point) with relation to the resistance (or weight) and the effort determines the lever class.

First-Class Levers

In the first-class lever (fig. 1-2A), the fulcrum is located between the effort and the resistance. As mentioned earlier, the seasaw is a good example of the first-class lever.

Figure 1-1.—A simple lever.

131.1

The amount of weight and the distance from the fulcrum can be varied to suit the need. Another good example is the oars in a rowboat. Notice that the sailor in figure 1-3 applies his effort on the handles of the oars. The oarlock acts as the fulcrum, and the water acts as the resistance to be overcome. In this case, as in figure 1-1, the force is applied on one side of the fulcrum and the resistance to be overcome is applied to the opposite side, hence this is a first-class lever. Crowbars, shears, and pliers are common examples of this class of lever.

Second-Class Levers

The second-class lever (fig. 1-2B) has the fulcrum at one end; the effort is applied at the other end. The resistance is somewhere between these points. The wheelbarrow in figure 1-4 is a good example of a second-class lever. If you apply 50 pounds of effort to the handles of a wheelbarrow 4 feet from the fulcrum (wheel), you can lift 200 pounds of weight 1 foot from the fulcrum. If the load were placed farther back away from the wheel, would it be easier or harder to lift?

Both first- and second-class levers are commonly used to help in overcoming big resistances with a relatively small effort.

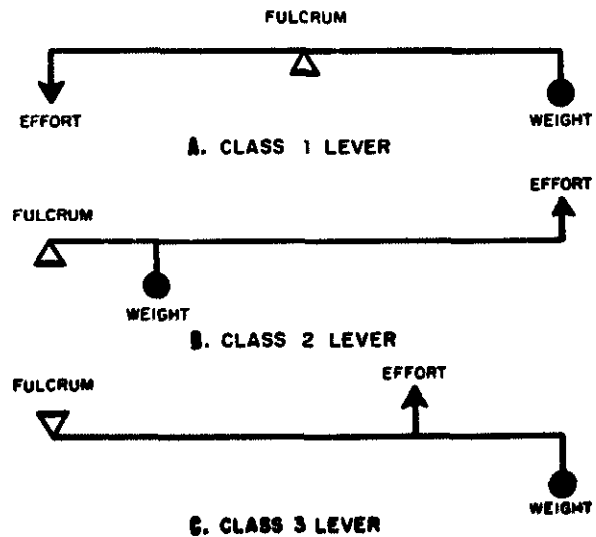

Figure 1-2.—Three classes of levers.

5.30

Figure 1-3.—Oars are levers.

131.2

Third-Class Levers

There are occasions when you will want to speed up the movement of the resistance even though you have to use a large amount of effort. Levers that help you accomplish this are third-class levers. As shown in figure 1-2C, the fulcrum is at one end of the lever and the weight or resistance to be overcome is at the

other end, with the effort applied at some point between the fulcrum and the resistance. You can always spot third-class levers because you will find the effort applied between the fulcrum and the resistance. Look at figure 1-5. It is easy to see that while point E is moving the short distance e , the resistance R has been moved a greater distance. The speed of R must have been greater than that of E, since R covered a greater distance in the same length of time.

Figure 1-4.—This makes it easier.

131.3

Figure 1-5.—A third-class lever.

131.4

Figure 1-6.—Your arm is a lever.

131.5

which ties onto your forearm about an inch below the elbow, applies the effort; and your hand is the resistance, located some 18 inches from the fulcrum. In the split second it takes your biceps muscle to contract an inch, your hand has moved through an 18-inch arc. You know from experience that it takes a big pull at E to overcome a relatively small resistance at R. Just to remind yourself of this principle, try closing a door by pushing on it about three or four inches from the hinges (fulcrum). The moral is, you don't use third-class levers to do heavy jobs, you use them to gain speed.

One convenient thing about machines is that you can determine in advance the forces required for their operation, as well as the forces they will exert. Consider for a moment the first-class lever. Suppose you have an iron bar, like the one shown in figure 1-7. This bar is 9 feet long, and you want to use it to raise a 300-pound crate off the deck while you slide a dolly under the crate. But you can exert only 100 pounds to lift the crate. So you place the fulcrum—a wooden block—beneath one end of the bar, and force that end of the bar under the crate. Then you push down on the other end of the bar. After a few adjustments of the position of the fulcrum, you will find that your 100-pound force will just fit the crate when the fulcrum is 2 feet from center of the crate.

Figure 1-7.—Easy does it.

110.4

This leaves a 6-foot length of bar from the fulcrum to the point where you push down. The 6-foot portion is three times as long as the distance from the fulcrum to the center of the crate. But you lifted a load three times as great as the force you applied— $3 \times 100 = 300$ pounds. Here is an indication of a direct relationship between lengths of lever arms and forces acting on those arms.

You can state this relationship in general terms by saying—the length of the effort arm is the same number of times greater than the length of the resistance arm as the resistance to be overcome is greater than the effort you must apply. Writing these words as a mathematical equation, it looks like this—

$$\frac{L}{l} = \frac{R}{E}$$

in which,

- L = length of effort arm.
- l = length of resistance arm.
- R = resistance weight or force.
- E = effort force.

Remember that all distances must be in the same units—such as feet, and all forces must be in the same units—such as pounds.

Now take another problem and see how it works out. Suppose you want to pry up the lid of a paint can (fig. 1-8) with a 6-inch file scraper, and you know that the average force holding the lid is 50 pounds. If the distance from the edge of the paint can to the edge of

Figure 1-8.—A first-class job.

131.6

the cover is one inch, what force will you have to apply on the end of the file scraper?

According to the formula:

$$\frac{L}{l} = \frac{R}{E}$$

Here $L = 5$ inches; $l = 1$ inch; $R = 50$ pounds, and E is unknown.

Substitute the numbers in their proper places, Then,

$$\frac{5}{1} = \frac{50}{E}$$

and

$$E = \frac{50 \times 1}{5} = 10 \text{ pounds}$$

You will need to apply a force of only 10 pounds.

The same general formula applies for second-class levers. But you must be careful to measure the proper lengths of the effort arm and the resistance arm. Looking back at the wheelbarrow problem, assume that the length of the handles from the axle of the wheel—which is the fulcrum—to the grip is 4 feet. How long is the effort arm? You're right, it's 4 feet. If the center of the load of sand is 1 foot from

the axle, then the length of the resistance arm is 1 foot.

By substituting in the formula,

$$\frac{L}{l} = \frac{R}{E}$$

$$\frac{4}{1} = \frac{200}{E}$$

and

$$E = 50 \text{ lb.}$$

Now for the third-class lever. With one hand, you lift a projectile weighing approximately 10 pounds. If your biceps muscle attaches to your forearm 1 inch below your elbow, and the distance from the elbow to the palm of your hand is 18 inches, what pull must your muscle exert in order to hold the projectile and flex your arm at the elbow?

By substituting in the formula,

$$\frac{L}{l} = \frac{R}{E}, \text{ it becomes } \frac{1}{18} = \frac{10}{E}$$

and

$$E = 18 \times 10 = 180 \text{ lb.}$$

Your muscle must exert a 180-pound pull to hold up a 10-pound shell. Our muscles are poorly arranged for lifting or pulling—and that's why some work seems pretty tough. But remember, third-class levers are used primarily to speed up the motion of the resistance.

Curved Lever Arms

Up to this point you have been looking at levers with straight arms. In every case, the direction in which the resistance acts is parallel to the direction in which the effort is exerted. However, all levers are not straight. You'll need to learn to recognize all types of levers, and to understand their operation.

Look at figure 1-9. You may wonder how to measure the length of the effort arm, which is represented by the curved pump handle. You do not measure around the curve—you still use a straight-line distance. To determine the length of the effort arm, draw a straight line AB through the point where the effort is applied and in the direction that it is applied. From point E on this line, draw a second line EF that passes through the fulcrum and is perpendicular to line AB. The length of the line EF is the actual length L of the effort arm.

131.7

Figure 1-9.—A curved lever arm.

To find the length of the resistance arm, use the same method. Draw a line MN in the direction that the resistance is operating, and through the point where the resistance is attached to the other end of the handle. From point R on this line, draw a line RF perpendicular to MN so that it passes through the fulcrum. The length of RF is the length l of the resistance arm.

Regardless of the curvature of the handle, this method can be used to find the lengths L and l. Then curved levers are solved just like straight levers.

MECHANICAL ADVANTAGE

There is another thing about first-class and second-class levers that you have probably noticed by now. Since they can be used to magnify the applied force, they provide positive mechanical advantages. The third-class lever provides what's called a fractional mechanical advantage, which is really a mechanical disadvantage—you use more force than the force of the load you lift.

In the wheelbarrow problem, you saw that a 50-pound pull actually overcame the 200-pound weight of the sand. The sailor's effort was magnified four times, so you may say that the mechanical advantage of the wheelbarrow is

4. Expressing the same idea in mathematical terms,

$$\text{MECHANICAL ADVANTAGE} = \frac{\text{RESISTANCE}}{\text{EFFORT}}$$

or

$$M. A. = \frac{R}{E}$$

Thus, in the case of the wheelbarrow,

$$M.A. = \frac{200}{50} = 4$$

This rule applies to all machines.

Mechanical advantage of levers may also be found by dividing the length of the effort arm A by the length of the resistance arm a. Stated as a formula, this reads:

$$\text{MECHANICAL ADVANTAGE} = \frac{\text{EFFORT ARM}}{\text{RESISTANCE ARM}}$$

$$M. A. = \frac{A}{a}$$

How does this apply to third-class levers? Your muscle pulls with a force of 1,800 pounds in order to lift a 100-pound projectile. So you

have a mechanical advantage of $\frac{100}{1,800}$ or $\frac{1}{18}$, which is fractional—less than 1.

SUMMARY

Now for a brief summary of levers.

Levers are machines because they help you to do your work. They help by changing the size, direction, or speed of the force you apply.

There are three classes of levers. They differ primarily in the relative points where effort is applied, where the resistance is overcome, and where the fulcrum is located.

First-class levers have the effort and the resistance on opposite sides of the fulcrum, and effort and resistance move in opposite directions.

Second-class levers have the effort and the resistance on the same side of the fulcrum, but the effort is farther from the fulcrum than is the resistance. Both effort and resistance move in the same direction.

Third-class levers have the effort applied on the same side of the fulcrum as the resistance, but the effort is applied between the resistance and the fulcrum. Both move in the same direction.

First- and second-class levers can be used to magnify the amount of the effort exerted, and to decrease the speed of effort. First-class and third-class levers can be used to magnify the distance and the speed of the effort exerted, and to decrease its magnitude.

The same general formula applies to all three types of levers:

$$\frac{L}{l} = \frac{R}{E}$$

MECHANICAL ADVANTAGE (M.A.) is an expression of the ratio of the applied force and the resistance. It may be written:

$$M. A. = \frac{R}{E}$$

APPLICATIONS AFLOAT AND ASHORE

Doors aboard a ship are locked shut by lugs called dogs. Figure 1-10 shows you how these dogs are used to secure the door. If the handle is four times as long as the lug, that 50-pound heave of yours is multiplied to 200 pounds against the slanting face of the wedge. Incidentally, take a look at that wedge—it's an inclined plane, and it multiplies the 200-pound

Figure 1-10.—It's a dog.

3.100

force by about four. Result—your 50-pound heave actually ends up as an 800-pound force on each wedge to keep the hatch closed! The hatch dog is one use of a first-class lever, in combination with an inclined plane.

The breech of a big gun is closed with a breech plug. Figure 1-11 shows you that this plug has some interrupted screw threads on it which fit into similar interrupted threads in the breech. Turning the plug part way around locks it into the breech. The plug is locked and unlocked by the operating lever. Notice that the connecting rod is secured to the operating lever a few inches from the fulcrum. You'll see that this is an application of a second-class lever!

You know that the plug is in there good and tight. But, with a mechanical advantage of ten, your 100-pound pull on the handle will twist the plug loose with a force of a half-ton.

If you've spent any time opening crates at a base, you've already used a wrecking bar. The blue-jacket in figure 1-12 is busily engaged in tearing that crate open. The wrecking bar is a first-class lever. Notice that it has curved lever arms. Can you figure the mechanical advantage of this one? Your answer should be M. A. = 5.

The crane in figure 1-13 is used for handling relatively light loads around a warehouse or a dock. You can see that the crane is rigged as a third-class lever. The effort is applied between the fulcrum and the load. This gives a mechanical advantage of less than one. If it's going to support that 1/2 ton load, you know that the pull on the lifting cable will have to be considerably greater than 1000 pounds. How much greater? Use the formula, and figure it out—

$$\frac{L}{l} = \frac{R}{E}$$

Got the answer? Right—E=1,333 lb. Now, because the cable is pulling at an angle of about 22° at E, you can use some trigonometry to find that the pull on the cable will be about 3,560 pounds to lift the 1/2-ton weight! However, since the loads are generally light, and speed is important, it is a practical and useful machine.

Anchors are usually housed in the hawsepole and secured by a chain stopper. The chain

Figure 1-11.—An 8-inchers breech.

80.213:.214

Figure 1-12.—Using a wrecking bar. 131.8

stopper consists of a short length of chain containing a turnbuckle and a pelican hook. When you secure one end of the stopper to a pad eye in the deck and lock the pelican hook over the anchor chain, the winch is relieved of the strain.

Figure 1-14A gives you the details of the pelican hook.

Figure 1-14B shows the chain stopper as a whole. Notice that the load is applied close

Figure 1-13.—An electric crane. 131.9

3.223

Figure 1-14.—A. A pelican hook;
B. A chain stopper.

to the fulcrum. The resistance arm a is very short. The bale shackle, which holds the hook secure, exerts its force at a considerable distance A from the fulcrum. If the chain rests against the hook one inch from the fulcrum, and the bale shackle is holding the hook closed $12 + 1 = 13$ inches from the fulcrum, what's the mechanical advantage? It's 13. A strain of only 1,000 pounds on the base shackle can hold the hook closed when a $6 \frac{1}{2}$ -ton anchor is dangling over the ship's side. You'll recognize

the pelican hook as a second-class lever with curved arms.

Figure 1-15 shows you a couple of guys who are using their heads to spare their muscles. Rather than exert themselves by bearing down on that drill, they pick up a board from a nearby crate and use it as a second-class lever.

If the drill is placed half way along the board, they will get a mechanical advantage of two. How would you increase the mechanical advantage if you were using this rig? Right. You move the drill in closer to the fulcrum. In the Navy, a knowledge of levers and how to apply them pays off.

131.10

Figure 1-15.—An improvised drill press.

CHAPTER 2

BLOCK AND TACKLE

Blocks—pulleys to a landlubber—are simple machines that have many uses aboard ship, as well as on shore. Remember how your mouth hung open as you watched movers taking a piano out of a fourth story window? The fat guy on the end of the tackle eased the piano safely to the sidewalk with a mysterious arrangement of blocks and ropes. Or perhaps you've been in the country and watched the farmer use a block-and-tackle to put hay in a barn. Since old Dobbin or the tractor did the hauling, there was no need for a fancy arrangement of ropes and blocks. Incidentally, you'll often hear the rope or tackle called the fall. Block-and-tackle, or block-and-fall.

In the Navy you'll rig a block-and-tackle to make some of your work easier. Learn the names of the parts of a block. Figure 2-1 will give you a good start on this. Look at the single block and see some of the ways you can use it. If you lash a single block to a fixed object—an overhead, a yardarm, or a bulkhead—you give yourself the advantage of being able to pull from a convenient direction. For example, in figure 2-2 you haul up a flag hoist, but you really pull down. You can do this by having a single sheaved block made fast to the yardarm. This makes it possible for you to stand in a convenient place near the flag bag and do the job. Otherwise you would have to go aloft, dragging the flag hoist behind you.

MECHANICAL ADVANTAGE

With a single fixed sheave, the force of your down-pull on the fall must be equal to the weight of the object being hoisted. You can't use this rig to lift a heavy load or resistance with a small effort—you can change only the direction of your pull.

A single fixed block is really a first-class lever with equal arms. The arms EF and FR in figure 2-3 are equal; hence the mechanical advantage is one. When you pull down at A with a force of one pound, you raise a load of one pound at B. A single fixed block does not magnify force nor speed.

You can, however, use a single block-and-fall to magnify the force you exert. Notice, in figure 2-4 that the block is not fixed, and that the fall is doubled as it supports the 200-pound cask. When rigged this way, a single block-and-fall is called a runner. Each half of the fall carries one half of the total load, or 100 pounds. Thus, by the use of the runner, the bluejacket is lifting a 200-pound cask with a 100-pound pull. The

Figure 2-1.—Look it over.

29.184

Figure 2-2.—A flag hoist.

69.122

mechanical advantage is two. Check this by the formula:

$$M. A. = \frac{R}{E} = \frac{200}{100}, \text{ or } 2$$

The single movable block in this setup is really a second-class lever. See figure 2-5. Your effort *E* acts upward upon the arm *EF*, which is the diameter of the sheave. The resistance *R* acts downward on the arm *FR*, which is the radius of the sheave. Since the diameter is twice the radius, the mechanical advantage is two.

But, when the effort at *E* moves up two feet, the load at *R* is raised only one foot. That's one thing to remember about blocks and falls—if you are actually getting a mechanical advantage from the system, the length of rope that passes through your hands is greater than the distance

Figure 2-3.—No advantage.

29.187

that the load is raised. However, if you can lift a big load with a small effort, you don't care how much rope you have to pull.

The bluejacket in figure 2-4 is in an awkward position to pull. If he had another single block handy, he could use it to change the direction of the pull, as in figure 2-6. This second arrangement is known as a gun tackle purchase. Because the second block is fixed, it merely changes the direction of pull—and the mechanical advantage of the whole system remains two.

You can arrange blocks in a number of ways, depending on the job to be done and the mechanical advantage you want to get. For example, a luff tackle consists of a double block and a single block, rigged as in figure 2-7. Notice that the weight is suspended by the three parts of rope which extend from the movable single block. Each part of the rope carries its share of the load. If the crate weighs 600 pounds, then each of the three parts of the rope supports its share—200 pounds. If there's a pull of 200 pounds downward on rope *B*, you will have to pull downward

Figure 2-4.—A runner.

29.187

with a force of 200 pounds on A to counterbalance the pull on B. Neglecting the friction in the block, a pull of 200 pounds is all that is necessary to raise the crate. The mechanical advantage is:

$$M. A. = \frac{R}{E} = \frac{600}{200} = 3$$

Here's a good tip. If you count the number of the parts of rope going to and from the movable block, you can figure the mechanical advantage at a glance. This simple rule will help you to quickly approximate the mechanical advantage of most tackles you see in the Navy.

Many combinations of single, double, and triple sheave blocks are possible. Two of these combinations are shown in figure 2-8.

If you can secure the dead end of the fall to the movable block, the advantage is increased by one. Notice that this is done in figure 2-7. That is a good point to remember. Don't forget, either, that the strength of your fall-rope—is a limiting factor in any tackle. Be sure your fall will carry the load. There is no point in rigging a six-fold purchase which carries a 5-ton load with two triple blocks on a 3-inch manila rope attached to

a winch. The winch could take it, but the rope couldn't.

Now for a review of the points you have learned about blocks, and then to some practical applications aboard ship—

With a single fixed block the only advantage is the change of direction of the pull. The mechanical advantage is still one.

A single movable block gives a mechanical advantage of two.

Many combinations of single, double, and triple blocks can be rigged to give greater advantages.

Figure 2-5.—It's 2 to 1.

29.187

29.187

Figure 2-6.—A gun tackle.

A general rule of thumb is that the number of the parts of the fall going to and from the movable block tells you the approximate mechanical advantage of that tackle.

If you fix the dead end of the fall to the movable block you increase the mechanical advantage by one.

APPLICATIONS AFLOAT AND ASHORE

Blocks and tackle are used for a great number of lifting and moving jobs afloat and ashore. The five or six basic combinations are used over and over again in many situations. Cargo is loaded aboard, depth charges are placed in their racks, life boats are lowered over the side by the use of this machine. Heavy machinery, guns, and gun mounts are swung into position with the aid of blocks and tackle. In a thousand situations, bluejackets find this machine useful and efficient.

Yard and stay tackles are used on shipboard when you want to pick up a load from the hold and

swing it onto the deck, or to shift any load a short distance. Figure 2-9 shows you how the load is first picked up by the yard tackle. The stay tackle is left slack. After the load is raised to the height necessary to clear obstructions, you take up on the stay tackle, and ease off on the yard fall. A glance at the rig tells you that the mechanical advantage of each of these tackles is only two. You may think that it isn't worth the trouble to rig a yard and stay tackle with that small advantage just to move a 400-pound crate along the deck. However, a few minutes spent in rigging may save many unpleasant hours with a sprained back.

If you want a high mechanical advantage, a luff upon luff is a good rig for you. You can raise heavy loads with this setup. Figure 2-10 shows you how it is rigged. If you apply the rule by which you count the parts of the fall going to and from the movable blocks, you find that block A gives a mechanical advantage of 3 to 1. Block B has four parts of fall running to and from it, a

29.187

Figure 2-7.—A luff tackle.

29.187

Figure 2-8.—Some other tackles.

mechanical advantage of 4 to 1. The mechanical advantage of those obtained from A is multiplied four times in B. The overall mechanical advantage of a luff upon luff is the product of the two mechanical advantages—or 12.

Don't make the mistake of adding mechanical advantages. Always multiply them.

You can easily figure out the M.A. for the apparatus shown in figure 2-10. Suppose the load weighs 1,200 pounds. Since it is supported by the parts 1, 2, and 3 of the fall running to and from block A, each part must be supporting one third of the load, or 400 pounds. If part 3 has a pull of 400 pounds on it, part 4 which is made fast to block B, also has a 400-pound pull on it. There are four parts of the second fall going to and from block B, and each of these takes an

29.187

Figure 2-9.—A yard and stay tackle.

equal part of the 400-pound pull. Therefore, the hauling part requires a pull of only $1/4 \times 400$, or 100 pounds. So, here you have a 100-pound pull raising a 1,200-pound load. That's a mechanical advantage of 12.

In shops ashore and aboard ship you are almost certain to run into a chain hoist, or differential pulley. Ordinarily, these hoists are suspended from overhead trolleys, and are used to lift heavy objects and move them from one part of the shop to another.

29.187

Figure 2-10.—Luff upon luff.

To help you to understand the operation of a chain hoist, look at the one in figure 2-11. Assume that you grasp the chain at E and pull until the large wheel A has turned around once. Then the distance through which your effort has moved is equal to the circumference of that wheel, or $2\pi R$. How much will the lower wheel C and its load be raised? Since wheel C is a single movable block, its center will be raised only one-half the distance that the chain E was pulled, or a distance πR . However, the smaller wheel B, which is rigidly fixed to A, makes one revolution at the same time as A does so B will feed some chain down to C. The length of the chain fed down will be equal to the circumference of B, or $2\pi r$. Again, since C is single movable block, the downward movement of its center will be equal to only one-half the length of the chain fed to it, or πr .

Of course, C does not first move up a distance πR and then move down a distance πr . Actually, its steady movement upward is equal

to the difference between the two, or $(\pi R - \pi r)$. Don't worry about the size of the movable pulley, C. It doesn't enter into these calculations. Usually its diameter is between that of A and that of B.

The mechanical advantage equals the distance through which the effort E is moved, divided by the distance that the load is moved. This is called the velocity ratio, or theoretical mechanical advantage. It is theoretical because the frictional resistance to the movement of mechanical parts is left out. In practical uses, all moving parts have frictional resistance.

The equation for theoretical mechanical advantage may be written—

Theoretical mechanical advantage =

$$\frac{\text{Distance effort moves}}{\text{Distance resistance moves}}$$

and in this case,

$$\text{T. M. A.} = \frac{2\pi R}{\pi R - \pi r} = \frac{2R}{R - r}$$

If A is a large wheel, and B is a little smaller, the value of $2R$ becomes large, and $(R-r)$ becomes small. Then you have a large number for $\frac{2R}{(R-r)}$ which is the theoretical mechanical advantage.

You can lift heavy loads with chain hoists. To give you an idea of the mechanical advantage of a chain hoist, suppose the large wheel has a radius R of 6 inches and the smaller wheel a radius r of $5\frac{3}{4}$ inches. What theoretical mechanical advantage would you get? Use the formula—

$$\text{T. M. A.} = \frac{2R}{R-r}$$

Then substitute the numbers in their proper places, and solve—

$$\text{T. M. A.} = \frac{2 \times 6}{6 - 5\frac{3}{4}} = \frac{12}{\frac{1}{4}} = 48$$

Since the friction in this type of machine is considerable, the actual mechanical advantage is not as high as the theoretical mechanical advantage would lead you to believe. For example, that theoretical mechanical advantage of 48 tells you that with a one-pound pull you should be able to lift a 48-pound load. However, actually your one-pound pull might only lift a 20-pound load. The rest of your effort would be used in overcoming the friction.

Figure 2-11.—A chain hoist.

29.187

CHAPTER 3

THE WHEEL AND AXLE

Have you ever tried to open a door when the knob was missing? If you have, you know that trying to twist that small four-sided shaft with your fingers is tough work. That gives you some appreciation of the advantage you get by using a knob. The door knob is an example of a simple machine called a wheel and axle.

The steering wheel on an automobile, the handle of an ice cream freezer, a brace and bit—these are familiar examples of this type of simple machine. As you know from your experience with these devices, the wheel and axle is commonly used to multiply the force you exert. If a screwdriver won't do a job because you can't turn it, you stick a screwdriver bit in the chuck of a brace and the screw probably goes in with little difficulty.

There's one thing you'll want to get straight right at the beginning. The wheel-and-axle machine consists of a wheel or crank rigidly attached to the axle, which turns with the wheel. Thus, the front wheel of an automobile is not a wheel-and-axle machine because the axle does not turn with the wheel.

MECHANICAL ADVANTAGE

How does the wheel-and-axle arrangement help to magnify the force you exert? Suppose you use a screwdriver bit in a brace to drive a stubborn screw. Look at figure 3-1A. Your effort is applied on the handle which moves in a circular path, the radius of which is 5 inches. If you apply a 10-pound force on the handle, how big a force will be exerted against the resistance at the screw? Assume the radius of the screwdriver blade is 1/4 inch. You are really using the brace as a second-class lever—see figure 3-1B. The size of the resistance

which can be overcome can be found from the formula—

$$\frac{L}{l} = \frac{R}{E}$$

In which—

L = radius of the circle through which the handle turns,

l = one-half the width of the edge of the screwdriver blade,

R = force of the resistance offered by the screw,

E = force of effort applied on the handle.

Substituting in the formula; and solving:

$$\frac{5}{1/4} = \frac{R}{10}$$

$$R = \frac{5 \times 10}{1/4}$$

$$= 5 \times 10 \times 4$$

$$= 200 \text{ lb.}$$

This means that the screwdriver blade will tend to turn the screw with a force of 200 pounds. The relationship between the radii or the diameters, or the circumferences of the wheel and axle tells you how great a mechanical advantage you can get.

Take another situation. The old oaken bucket, figure 3-2, was raised by a wheel-and-axle arrangement. If the distance from the center of the axle to the handle is 8 inches, and the radius of the drum around which the rope is wound is 2 inches, then you have a theoretical mechanical advantage of 4. That's why they used these rigs.

44.20
Figure 3-1.—It magnifies your effort.

MOMENT OF FORCE

In a number of situations you can use the wheel-and-axle to speed up motion. The rear-wheel sprocket of a bike, along with the rear wheel itself, is an example. When you are pedaling, the sprocket is fixed to the wheel, so the combination is a true wheel-and-axle machine. Assume that the sprocket has a circumference of 8 inches, and the wheel circumference is 80 inches. If you turn the sprocket at a rate of one revolution per second, each sprocket tooth moves at a speed of 8 inches per second. Since the wheel makes one revolution for each revolution made by the sprocket, any point on the tire must move through a distance of 80 inches in one second. So, for every eight-inch movement of a point on the sprocket, you have moved a corresponding point on the wheel through 80 inches.

Since a complete revolution of the sprocket and wheel requires only one second, the speed of a point on the circumference of the wheel is 80 inches per second, or ten times the speed of a tooth on the sprocket.

(NOTE: Both sprocket and wheel make the same number of revolutions per second so the speed of turning for the two is the same.)

131.11
Figure 3-2.—The old oaken bucket.

Here is an idea which you will find useful in understanding the wheel and axle, as well as other machines. You probably have noticed that the force you apply to a lever tends to turn or rotate it about the fulcrum? You also know that a heave on a fall tends to rotate the sheave of the block and that turning the steering wheel of a car tends to rotate the steering column. Whenever you use a lever, or a wheel and axle, your effort on the lever arm or the rim of the wheel tends to cause a rotation about the fulcrum or the axle in one direction or another. If the rotation occurs in the same direction as the hands of a clock, that direction is called clockwise. If the rotation occurs in the opposite direction from that of the hands of a clock, the direction of rotation is called counterclockwise. A glance at figure 3-3 will make clear the meaning of these terms.

You have already seen that the result of a force acting on the handle of the carpenter's brace depends not only on the amount of that force but also on the distance from the handle to the center of rotation. From here on you'll know this result as a moment of force, or a torque (pronounced tork). Moment of force and torque have the same meaning.

Look at the effect of counterclockwise movement of the capstan bar in figure 3-4. Here the amount of the effort is designated E_1 and the distance from the point where this force is

CLOCKWISE
ROTATION

COUNTERCLOCKWISE
ROTATION

131.12

Figure 3-3.—Directions of rotation.

applied to the center of the axle is L_1 . Then $E_1 \times L_1$ is the moment of force. You'll notice that this term includes both the amount of the effort and the distance from the point of application of effort to the center of the axle. Ordinarily, the distance is measured in feet and the applied force is measured in pounds.

Therefore, moments of force are generally measured in foot-pounds—abbreviated ft-lb. A moment of force is frequently called a moment.

By using a longer capstan bar, the bluejacket in figure 3-4 can increase the effectiveness of his push without making a bigger effort. But if he applied his effort closer to the head of the capstan and used the same force, the moment of force would be less.

BALANCING MOMENTS

You know that the bluejacket in figure 3-4 would land flat on his face if the anchor hawser snapped. But just as long as nothing breaks, he must continue to push on the capstan bar. He is working against a clockwise moment of force, which is equal in magnitude but opposite in direction to his counterclockwise moment of force. The resisting moment, like the effort moment, depends on two factors. In the case of the resisting moment, these factors are the force R_2 with which the anchor pulls on the hawser, and the distance L_2 from the center of

Figure 3-4.—Using a capstan.

131.13

the capstan to its rim. The existence of this resisting force would be evident if the blue-jacket let go of the capstan bar. The weight of the anchor pulling on the capstan would cause the whole works to spin rapidly in a clockwise direction—and good-bye anchor! The principle involved here is that whenever the counterclockwise and the clockwise moments of force are in balance, the machine either moves at a steady speed or remains at rest.

This idea of the balance of moments of force can be summed up by the expression—

**CLOCKWISE MOMENTS =
COUNTERCLOCKWISE MOMENTS**

And, since a moment of force is the product of the amount of the force times the distance the force acts from the center of rotation, this expression of equality may be written—

$$E_1 \times L_1 = E_2 \times L_2$$

In which—

- E_1 = force of effort,
- L_1 = distance from fulcrum or axle to point where force is applied,
- E_2 = force of resistance,
- L_2 = distance from fulcrum or center of axle to the point where resistance is applied.

EXAMPLE 1

Put this formula to work on a capstan problem. A single capstan bar is gripped 5 feet from the center of a capstan head with a radius of one foot. A 1/2-ton anchor is to be lifted. How big a push does the sailor have to exert?

First, write down the formula—

$$E_1 \times L_1 = E_2 \times L_2$$

Here $L_1 = 5$; $E_2 = 1,000$ pounds; and $L_2 = 1$. Substitute these values in the formula, and it becomes:

$$E_1 \times 5 = 1,000 \times 1$$

and—

$$E_1 = \frac{1,000}{5} = 200 \text{ pounds}$$

EXAMPLE 2

Consider now the sad case of Slim and Sam, as illustrated in figure 3-5. Slim has suggested that they carry the 300-pound crate slung on a

131.14

Figure 3-5.—A practical application.

handy 10-foot pole. He was smart enough to slide the load up 3 feet from Sam's shoulder.

Here's how they made out. Use Slim's shoulder as a fulcrum F_1 . Look at the clockwise moment caused by the 300-pound load. That load is five feet away from Slim's shoulder. If R_1 is the load, and L_1 the distance from Slim's shoulder to the load, the clockwise moment M_A is—

$$M_A = R_1 \times L_1 = 300 \times 5 = 1,500 \text{ ft.-lb.}$$

With Slim's shoulder still acting as the fulcrum, the resistance of Sam's effort causes a counterclockwise moment M_B acting against the load moment. This counterclockwise moment is equal to Sam's effort E_2 times the distance L_3 from his shoulder to the fulcrum F_1 at Slim's shoulder. Since $L_2 = 8$ ft., the formula is—

$$M_B = E_2 \times L_3 = E_2 \times 8 = 8E_2$$

But there is no rotation, so the clockwise moment and the counterclockwise moment are equal. $M_A = M_B$. Hence—

$$1,500 = 8E_2$$

$$E_2 = \frac{1,500}{8} = 187.5 \text{ pounds.}$$

So poor Sam is carrying 187.5 pounds of the 300-pound load.

the capstan to its rim. The existence of this resisting force would be evident if the blue-jacket let go of the capstan bar. The weight of the anchor pulling on the capstan would cause the whole works to spin rapidly in a clockwise direction—and good-bye anchor! The principle involved here is that whenever the counterclockwise and the clockwise moments of force are in balance, the machine either moves at a steady speed or remains at rest.

This idea of the balance of moments of force can be summed up by the expression—

**CLOCKWISE MOMENTS =
COUNTERCLOCKWISE MOMENTS**

And, since a moment of force is the product of the amount of the force times the distance the force acts from the center of rotation, this expression of equality may be written—

$$E_1 \times L_1 = E_2 \times L_2$$

In which—

- E_1 = force of effort,
- L_1 = distance from fulcrum or axle to point where force is applied,
- E_2 = force of resistance,
- L_2 = distance from fulcrum or center of axle to the point where resistance is applied.

EXAMPLE 1

Put this formula to work on a capstan problem. A single capstan bar is gripped 5 feet from the center of a capstan head with a radius of one foot. A 1/2-ton anchor is to be lifted. How big a push does the sailor have to exert?

First, write down the formula—

$$E_1 \times L_1 = E_2 \times L_2$$

Here $L_1 = 5$; $E_2 = 1,000$ pounds; and $L_2 = 1$. Substitute these values in the formula, and it becomes:

$$E_1 \times 5 = 1,000 \times 1$$

and—

$$E_1 = \frac{1,000}{5} = 200 \text{ pounds}$$

EXAMPLE 2

Consider now the sad case of Slim and Sam, as illustrated in figure 3-5. Slim has suggested that they carry the 300-pound crate slung on a

131.14

Figure 3-5.—A practical application.

handy 10-foot pole. He was smart enough to slide the load up 3 feet from Sam's shoulder.

Here's how they made out. Use Slim's shoulder as a fulcrum F_1 . Look at the clockwise moment caused by the 300-pound load. That load is five feet away from Slim's shoulder. If R_1 is the load, and L_1 the distance from Slim's shoulder to the load, the clockwise moment M_A is—

$$M_A = R_1 \times L_1 = 300 \times 5 = 1,500 \text{ ft.-lb.}$$

With Slim's shoulder still acting as the fulcrum, the resistance of Sam's effort causes a counterclockwise moment M_B acting against the load moment. This counterclockwise moment is equal to Sam's effort E_2 times the distance L_3 from his shoulder to the fulcrum F_1 at Slim's shoulder. Since $L_2 = 8$ ft., the formula is—

$$M_B = E_2 \times L_3 = E_2 \times 8 = 8E_2$$

But there is no rotation, so the clockwise moment and the counterclockwise moment are equal. $M_A = M_B$. Hence—

$$1,500 = 8E_2$$

$$E_2 = \frac{1,500}{8} = 187.5 \text{ pounds.}$$

So poor Sam is carrying 187.5 pounds of the 300-pound load.

When an object is at rest or is moving steadily, the clockwise moments are just equal and opposite to the counterclockwise moments.

Moments of the force, depend upon two factors—the amount of the force, and the distance from the fulcrum or axis to the point where the force is applied.

When two equal forces are applied at equal distances on opposite sides of a fulcrum, and move in opposite directions so that they both tend to cause rotation about the fulcrum, you have a couple.

APPLICATIONS AFLOAT AND ASHORE

A trip to the engine room makes you realize how important the wheel and axle is on the modern ship. Everywhere you look you see wheels of all sizes and shapes. Most of them are used to open and close valves quickly. One common type of valve is shown in figure 3-7. Turning the wheel causes the threaded stem to rise and open the valve. Since the valve must close water-tight, air-tight, or steam-tight, all the parts must fit snugly. To move the stem on most valves without the aid of the wheel would be impossible. The wheel gives you the necessary mechanical advantage.

You've handled enough wrenches to know that the longer the handle, the tighter you can turn a nut. Actually, a wrench is a wheel-and-axle machine. You can consider the handle as one spoke of a wheel, and the place where you

take hold of the handle as a point on the rim. The nut which is held in the jaws of the wrench can be compared to the axle.

You know that you can turn a nut too tight—and strip the threads or cause internal parts to seize. This is especially true when you are taking up on bearings. In order to make the proper adjustment, you use a torque wrench. There are several types. Figure 3-8 shows you one that is very simple. When you pull on the handle, its shaft bends. The rod on which the pointer is fixed does not bend—so the pointer indicates on the scale the torque, or moment of force, that you are exerting. The scale is generally stated in pounds, although it is really measuring foot-pounds of torque. If the nut is to be tightened by a moment of 90 ft-lb, you pull until the pointer is opposite the number 90 on the scale. The servicing or repair manual on an engine or piece of machinery generally tells you what the torque—or moment of force—should be on each set of nuts or bolts.

The gun pointer uses a couple to elevate and depress the gun barrel. He cranks away at a hand-wheel that has two handles. The right-hand handle is on the opposite side of the axle from the left-hand handle—180° apart. Look at figure 3-9. When he pulls on one handle and pushes on the other, he's producing a couple. But if he lets go the left handle to scratch himself, and cranks only with his right hand, he no longer has a couple—just a simple first-class lever! And he'd have to push twice as hard with one hand.

Figure 3-7.—Valves.

131.16

Figure 3-8.—A simple torque wrench.

5.9

A system of gears—a gear train—transmits the motion to the barrel. A look at figure 3-10 will help you to figure the forces involved. The radius of the wheel is 6 inches— $1/2$ foot—and each handle is being turned with a force of, say, 20 pounds. The moment on the top which tends to rotate the wheel in a clockwise direction is equal to 20 times $1/2 = 10$ ft-lb. The bottom

handle also rotates the wheel in the same direction with an equal moment. Thus the total twist or torque on the wheel is $10 + 10 = 20$ ft-lb. To get the same moment with one hand, applying a 20-pound force, the radius of the wheel would have to be twice as great—12 inches, or one foot. The couple is a convenient arrangement of the wheel-and-axle machine.

131.17
Figure 3-9.—A pointer's handwheel.

131.18
Figure 3-10.—Developing a torque.

CHAPTER 4

THE INCLINED PLANE AND THE WEDGE

THE BARREL ROLL

You have probably watched a driver load barrels on a truck. The truck is backed up to the curb. The driver places a long double plank or ramp from the sidewalk to the tail gate, and then rolls the barrel up the ramp. A 32-gallon barrel may weigh close to 300 pounds when full, and it would be quite a job to lift one up into the truck. Actually, the driver is using a simple machine called the inclined plane. You have seen the inclined plane used in many situations. Cattle ramps, a mountain highway, and the gangplank are familiar examples.

The inclined plane permits you to overcome a large resistance by applying a relatively small force through a longer distance than the load is raised. Look at figure 4-1. Here you see the driver easing the 300-pound barrel up to the bed of the truck, three feet above the sidewalk. He is using a plank nine feet long. If he didn't use the ramp at all, he'd have to apply a 300-pound force straight up through the three-foot distance. With the ramp, however, he can apply his effort over the entire nine feet of the plank as the barrel is slowly rolled up to a height of three feet. It looks, then, as if he could use a force only three-ninths of 300, or 100 pounds, to do the job. And that is actually the situation.

Here's the formula. Remember it from chapter 1?

$$\frac{L}{l} = \frac{R}{E}$$

In which—L = length of the ramp, measured along the slope,

l = height of the ramp,

R = weight of object to be raised, or lowered,

E = force required to raise or lower object

Now apply the formula to this problem—

In this case, L = 9 ft.; l = 3 ft.; and R = 300 lb. By substituting these values in the formula, you get—

$$\frac{9}{3} = \frac{300}{E}$$

$$9E = 900$$

$$E = 100 \text{ pounds}$$

Since the ramp is three times as long as its height, the mechanical advantage is three. You find the theoretical mechanical advantage by dividing the total distance through which your effort is exerted by the vertical distance through which the load is raised or lowered.

THE WEDGE

The wedge is a special application of the inclined plane. You have probably used wedges. Abe Lincoln used a wedge to help him split logs into rails for fences. The blades of knives, axes, hatchets, and chisels act as wedges when they are forced into a piece of wood. The wedge is two inclined planes, set base-to-base. By driving the wedge full-length into the material to be cut or split, the material is forced apart a distance equal to the width of the broad end of the wedge. See figure 4-2.

Long, slim wedges give high mechanical advantage. For example, the wedge of figure 4-2 has a mechanical advantage of six. Their greatest value, however, lies in the fact that you can use them in situations where other simple machines won't work. Imagine the trouble you'd have trying to pull a log apart with a system of pulleys.

Figure 4-1.—An inclined plane.

110.4

SUMMARY

Before you look at some of the Navy applications of the inclined plane and the wedge, here's a summary of what to remember from this chapter—

The inclined plane is a simple machine that lets you raise or lower heavy objects by applying a small force over a relatively long distance.

The theoretical mechanical advantage of the inclined plane is found by dividing the length of the ramp by the perpendicular height that the load will be raised or lowered. The actual mechanical advantage is equal to the weight of the resistance or load, divided by the force that must be used to move the load up the ramp.

The wedge is two inclined planes set base-to-base. It finds its greatest use in cutting or splitting materials.

APPLICATIONS AFLOAT AND ASHORE

One of the most common uses of the inclined plane in the Navy is the gangplank. Going aboard the ship by gangplank, illustrated in figure 4-3 is certainly easier than climbing up a sea ladder. And you appreciate the M.A. of the gangplank even more when you have to carry your sea bag or a case of prunes aboard.

Remember that hatch dog in figure 1-10. The dog that's used to secure a door not only takes advantage of the lever principle, but—if you look sharply—you can see that the dog seats itself on a steel wedge which is welded to the door. As the dog slides upward along this wedge, it forces the door tightly shut. This is an inclined plane, with its length about eight times its thickness. That means you get a theoretical mechanical advantage of eight. You figured, in

Figure 4-2.—A wedge.

131.19

Figure 4-3.—The gangplank is an inclined plane.

131.20

chapter 1, that you got a mechanical advantage of four from the lever action of the dog—so the overall mechanical advantage is 8 times 4 or 32, neglecting friction. Not bad for such a simple gadget, is it? Push down with 50 pounds heave on the handle and you squeeze the door shut with a force of 1600 pounds, on that dog. You'll find the damage-control parties using wedges by the dozen to shore up bulkheads and decks. A few

sledge-hammer blows on a wedge will quickly and firmly tighten up the shoring.

Chipping scale or paint off steel is a tough job. However, the job is made a lot easier with a compressed air chisel. The wedge-shaped cutting edge of the chisel gets in under the scale or the paint, and exerts great pressure to lift the scale or paintlayer. The chisel bit is another application of the inclined plane.

CHAPTER 5

THE SCREW

A MODIFIED INCLINED PLANE

The screw is a simple machine that has many uses. The vise on a workbench makes use of the great mechanical advantage of the screw. So do the screw clamps used to hold a piece of furniture together while it is being glued. And so do many automobile jacks and even the food grinder in the kitchen at home.

A screw is a modification of the inclined plane. Cut a sheet of paper in the shape of a right triangle—an inclined plane. Wind it around a pencil, as in figure 5-1. Then you can see that the screw is actually an inclined plane wrapped around a cylinder. As the pencil is turned, the paper is wound up so that its hypotenuse forms a spiral thread similar to the thread on the screw shown at the right. The pitch of the screw, and of the paper, is the distance between identical points on the same threads, and measured along the length of the screw.

THE JACK

In order to understand how the screw works, look at figure 5-2. Here you see a jack screw of the type that is used to raise a house or a piece of heavy machinery. The jack has a lever handle with a length r . If you pull the lever handle around one turn, its outer end has described a circle. The circumference of this circle is equal to 2π . (You remember that π equals 3.14, or $\frac{22}{7}$). That is the distance, or the lever arm, through which your effort is applied.

At the same time, the screw has made one revolution, and in doing so has been raised a height equal to its pitch p . You might say that one full thread has come up out of the base. At any rate, the load has been raised a distance p .

Remember that the theoretical mechanical advantage is equal to the distance through which

the effort or pull is applied, divided by the distance the resistance or load is moved. Assuming a 2-foot—24"—length for the lever arm, and a 1/4-inch pitch for the thread, you can find the theoretical mechanical advantage by the formula—

$$M. A. = \frac{2\pi r}{p}$$

in which

r = length of handle = 24 inches
 p = pitch, or distance between corresponding points on successive threads = 1/4-inch.

Substituting,

$$T. M. A. = \frac{2 \times 3.14 \times 24}{1/4} = \frac{150.72}{1/4} = 602.88$$

A 50-pound pull on the handle would result in a theoretical lift of 50×602 or about 30,000 pounds. Fifteen tons for fifty pounds.

But jacks have considerable friction loss. The threads are cut so that the force used to overcome friction is greater than the force used to do useful work. If the threads were not cut this way, if no friction were present, the weight of the load would cause the jack to spin right back down to the bottom as soon as you released the handle.

THE MICROMETER

In using the jack, you exerted your effort through a distance of $2\pi r$, or 150 inches, in order to raise the screw 1/4 inch. It takes a lot of circular motion to get a small amount of straight-line motion from the head of the jack. You will use this point to advantage in the micrometer, which is a useful device for making accurate small measurements, measurements of a few thousandths of an inch.

In figure 5-3, you see a cutaway view of a micrometer. The thimble turns freely on the

Figure 5-1.—A screw is an inclined plane in spiral form.

110.4

sleeve, which is rigidly attached to the micrometer frame. The spindle is attached to the thimble, and is fitted with screw threads which move the spindle and thimble to right or left in the sleeve when you rotate the thimble. These screw threads are cut 40 threads to the inch. Hence one turn of the thimble moves the spindle and thimble 1/40 inch. This represents one of the smallest divisions on the micrometer. Four of these small divisions make 4/40 of an inch, or 1/10 inch. Thus the distance from 0 to 1 or 1 to 2 on the sleeve represents 1/10 or 0.1 inch.

To allow even finer measurements, the thimble is divided into 25 equal parts laid out by graduation marks around its rim, as shown in figure 45. If you turn the thimble through 25 of these equal parts, you have made one complete revolution of the screw, which represents a lengthwise movement of 1/40 of an inch. Now, if you turn the thimble one of these units on its scale, you have moved the spindle a distance of 1/25 of 1/40 inch, or 1/1000 of an inch—0.001 inch.

81.25

Figure 5-2.—A jack screw.

The micrometer in figure 5-4 reads 0.503 inch, which is the true diameter of the half-inch drill-bit shank being measured. This tells you that the diameter of this particular bit is 0.003 inch greater than its nominal diameter of 1/2 inch—0.500".

Because you can make such accurate measurements with this instrument, it is indispensable in every machine shop.

SUMMARY

Look over the basic ideas you have learned from this chapter, and then see how the Navy uses this simple machine—the screw.

4.20

Figure 5-3.—A micrometer.

Figure 5-4.—Taking turns.

4.20

The screw is a modification of the inclined plane—modified to give you a high mechanical advantage.

The theoretical mechanical advantage of the screw can be found by the formula

$$M.A. = \frac{2\pi}{p}$$

As in all machines, the actual mechanical advantage equals the resistance divided by the effort.

In many applications of the screw, you make use of the large amount of friction that is commonly present in this simple machine.

By the use of the screw, large amounts of circular motion are reduced to very small amounts of straight-line motion.

APPLICATIONS AFLOAT AND ASHORE

It's a tough job to pull a rope or cable up tight enough to get all the slack out of it. But you can do it. Use a turnbuckle. The turnbuckle is an application of the screw. See figure 5-5. If

Figure 5-5.—A turnbuckle.

131.21

you turn it in one direction, it takes up the slack in a cable. Turning it the other way slacks off on the cable. You'll notice that one bolt of the turnbuckle has left-hand threads, and the other bolt has right-hand threads. Thus, when you turn the turnbuckle to tighten up the line, both bolts tighten up. If both bolts were right-hand thread—standard thread—one would tighten while the other one loosened an equal amount. Result—no change in cable-slack. Most turnbuckles have the screw threads cut to provide a large amount of frictional resistance to keep the turnbuckle from unwinding under load. In some cases, the turnbuckle has a lock nut on each of the screws to prevent slipping. You'll find turnbuckles used in a hundred different ways afloat and ashore.

Ever wrestled with a length of wire rope? Obstinate and unwieldy, wasn't it? Riggers have dreamed up tools to help subdue wire rope. One of these tools—the rigger's vise—is shown in figure 5-6. This rigger's vise uses the great mechanical advantage of the screw to hold the wire rope while the crew splices a thimble—a reinforced loop—onto the end of the cable. Rotating the handle causes the jaw on that screw to move in or out along its grooves. This machine is a modification of the vise on a work bench. Notice the right-hand and left-hand screws on the left-hand clamp.

Figure 5-7 shows you another use of the screw. Suppose you want to stop a winch with its load suspended in mid-air. To do this, you need a brake. The brake on most anchor or cargo winches consists of a metal band that

Figure 5-6.—A rigger's vise.

131.22

Figure 5-7.—A friction brake.

131.23

encircles the brake drum. The two ends of the band are fastened to nuts connected by a screw attached to a handwheel. As you turn the handwheel, the screw pulls the lower end of the band A up toward its upper end B. The huge M.A. of the screw puts the squeeze on the drum, and all rotation of the drum is stopped.

One type of steering gear used on many small ships—and as a spare steering system on some larger ships—is the screw gear. Figure 5-8

shows you that the wheel turns a long threaded shaft. Half the threads—those nearer the wheel end of this shaft—are right-hand threads. The other half of the threads—those farther from the wheel—are left-hand threads. The nut A has a right-hand thread, and nut B has a left-hand thread. Notice that the cross head which turns the rudder is connected to the nuts by two steering arms. If you stand in front of the wheel and turn it in a clockwise direction—to your right—arm A moves forward and arm B moves backward. This turns the rudder counterclockwise, so that the ship swings in the direction you turn the wheel. There is a great mechanical advantage to this steering mechanism.

Figure 5-9 shows you another practical use of the screw. The quadrant davit makes it possible for two men to put a large life boat over the side with little effort. The operating handle is attached to a threaded screw which passes through a traveling nut. If the operating handle is cranked in a counterclockwise direction (as you face outboard), the nut travels outward along the screw. The traveling nut is fastened to the davit arm by a swivel. The davit arm and the boat swing outboard as a result of the outward movement of the screw. The thread on that screw is the self-locking type—if you let go of the handle the nut remains locked in position.

131.24

Figure 5-8.—The screw gives a tremendous mechanical advantage.

80.101

Figure 5-9.—The quadrant davit.

CHAPTER 6

GEARS

Did you ever take a clock apart to see what made it tick? Of course you came out with some parts left over when you got it back together again. And they probably included a few gear wheels. Gears are used in many machines. Frequently the gears are hidden from view in a protective case filled with grease or oil, and you may not see them.

An egg beater gives you a simple demonstration of the three things that gears do. They can change the direction of motion; increase or decrease the speed of the applied motion; and magnify or reduce the force which you apply. Gears also give you a positive drive. There can be, and usually is, creep or slip in a belt drive. But gear teeth are always in mesh, and there can be no creep and slip.

Follow the directional changes in figure 6-1. The crank handle is turned in the direction indicated by the arrow—clockwise, when viewed from the right. The 32 teeth on the large vertical wheel A mesh with the 8 teeth on the right-hand horizontal wheel B, which rotates as indicated by the arrow. Notice that as B turns in a clockwise direction, its teeth mesh with those of wheel C and cause wheel C to revolve in the opposite direction. The rotation of the crank handle has been transmitted by gears to the beater blades, which also rotate.

Now figure out how the gears change the speed of motion. There are 32 teeth on gear A and 8 teeth on gear B. But the gears mesh, so that one complete revolution of A results in four complete revolutions of gear B. And since gears B and C have the same number of teeth, one revolution of B results in one revolution of C. Thus the blades revolve four times as fast as the crank handle.

In chapter 1 you learned that third-class levers increase speed at the expense of force. The same thing happens with this egg beater. The magnitude of the force is changed. The force required to turn the handle is greater than

the force applied to the frosting by the blades. Therefore a mechanical advantage of less than one results.

TYPES OF GEARS

When two shafts are not lying in the same straight line, but are parallel, motion can be transmitted from one to the other by means of spur gears. This setup is shown in figure 6-2.

Spur gears are wheels with mating teeth cut in their surfaces so that one can turn the other without slippage. When the mating teeth are cut so that they are parallel to the axis of rotation, as shown in figure 6-2, the gears are called straight spur gears.

When two gears of unequal size are meshed together, the smaller of the two is usually called a pinion. By unequal size, we mean an unequal number of teeth causing one gear to be of a larger diameter than the other. The teeth, themselves, must be of the same size in order to mesh properly.

The most commonly used type are the straight spur gears, but quite often you'll run across another type of spur gear called the helical spur gear.

In helical gears the teeth are cut slantwise across the working face of the gear. One end of the tooth, therefore, lies ahead of the other. In other words, each tooth has a leading end and a trailing end. A look at these gears in figure 6-3A will show you how they're constructed.

In the straight spur gears the whole width of the teeth comes in contact at the same time. But with helical (spiral) gears contact between two teeth starts first at the leading ends and moves progressively across the gear faces until the trailing ends are in contact. This kind of meshing action keeps the gears in constant contact with one another. Therefore, less lost

131.25
Figure 6-1.—A simple gear arrangement.

motion and smoother, quieter action is possible. One disadvantage of this helical spur gear is the tendency of each gear to thrust or push axially on its shaft. It is necessary to put a special thrust bearing at the end of the shaft to counteract this thrust.

Thrust bearings are not needed if herringbone gears like those shown in figure 6-4 are used. Since the teeth on each half of the gear are cut in opposite directions, each half of the gear develops a thrust which counterbalances that of the other half. You'll find herringbone gears used mostly on heavy machinery.

Figure 6-3 also shows you three other gear arrangements in common use.

The internal gear in figure 6-3E has teeth on the inside of a ring, pointing inward toward the axis of rotation. An internal gear is always meshed with an external gear, or pinion, whose

5.22.1
Figure 6-2.—Spur gears coupling two parallel shafts.

center is offset from the center of the internal gear. Either the internal or pinion gear can be the driver gear, and the gear ratio is calculated the same as for other gears—by counting teeth.

Often only a portion of a gear is needed where the motion of the pinion is limited. In this case the sector gear (fig. 6-3C) is used to save space and material. The rack and pinion in figure 6-3D are both spur gears. The rack may be considered as a piece cut from a gear with an extremely large radius. The rack-and-pinion arrangement is useful in changing rotary motion into linear motion.

THE BEVEL GEAR.—So far most of the gears you've learned about transmit motion between parallel shafts. But when shafts are not parallel (at an angle), another type of gear is used—the bevel gear. This type of gear can connect shafts lying at any given angle because they can be beveled to suit the angle.

Figure 6-5A shows a special case of the bevel gear—the miter gear. A pair of miter gears is used to connect shafts having a 90° angle, which means the gear faces are beveled at a 45° angle.

You can see in figure 6-5B how bevel gears are designed to join shafts at any angle. Gears cut at any angle other than 45° are called just plain bevel gears.

Figure 6-3.—Gear types.

5.23:24

The gears shown in figure 6-5 are called straight bevel gears, because the whole width of each tooth comes in contact with the mating tooth at the same time. However, you'll also run across spiral bevel gears with teeth cut so as to have advanced and trailing ends. Figure 6-6 shows you what spiral bevel gears look like. They have the same advantages as

other spiral (helical) gears—less lost motion and smoother, quieter operation.

THE WORM AND WORM WHEEL.—Worm and worm-wheel combinations, like those in figure 6-7, have many uses and advantages. But it's better to understand their operating theory before learning of their uses and advantages.

Figure 6-7A shows the action of a single-thread worm. For each revolution of the worm,

Figure 6-4.—Herringbone gear.

5.22.3

A. MITER GEAR

B. BEVEL GEAR

Figure 6-5.—Bevel gears.

5.22.4

Figure 6-6.—Spiral bevel gears.

5.22.6

the worm wheel turns one tooth. Thus if the worm wheel has 25 teeth the gear ratio is 25:1.

Figure 6-7B shows a double-thread worm. For each revolution of the worm in this case, the worm wheel turns two teeth. That makes the gear ratio 25:2 if the worm wheel has 25 teeth.

Likewise, a triple-threaded worm would turn the worm wheel three teeth per revolution of the worm.

A worm gear is really a combination of a screw and a spur gear. Tremendous mechanical advantages can be obtained with this arrangement. Worm drives can also be designed so that only the worm is the driver—the

spur cannot drive the worm. On a hoist, for example, you can raise or lower the load by pulling on the chain which turns the worm. But if you let go of the chain, the load cannot drive the spur gear and let the load drop to the deck. This is a non-reversing worm drive.

CHANGING DIRECTION WITH GEARS

No doubt you know that the crankshaft in an automobile engine can turn in only one direction. If you want the car to go backwards, the effect of the engine's rotation must be reversed. This is done by a reversing gear in the transmission, not by reversing the direction in which the crankshaft turns.

A study of figure 6-8 will show you how gears are used to change the direction of motion. This is a schematic diagram of the sight mounts on a Navy gun. If you crank the range-adjusting handle A in a clockwise direction the gear B directly above it is made to rotate in a counter-clockwise direction. This motion causes the two pinions C and D on the shaft to turn in the same direction as gear B against the teeth cut in the bottom of the table. The table is tipped in the direction indicated by the arrow.

As you turn the deflection-adjusting handle E in a clockwise direction the gear F directly above it turns in the opposite direction. Since the two bevel gears G and H are fixed on the

Figure 6-7.—Worm gears.

5.22.9

131.26

Figure 6-8.—Gears change direction of applied motion.

shaft with F, they also turn. These bevel gears, meshing with the horizontal bevel gears I and J, cause I and J to swing the front ends of the telescopes to the right. Thus with a simple system of gears, it is possible to keep the two telescopes pointed at a moving target. In this and many other practical applications, gears serve one purpose—to change the direction of motion.

CHANGING SPEED

As you've already seen in the egg-beater, gears can be used to change the speed of motion. Another example of this use of gears is found in your clock or watch. The mainspring slowly unwinds and causes the hour hand to make one revolution in 12 hours. Through a series—or train—of gears, the minute hand makes one revolution each hour, while the second hand goes around once per minute.

Figure 6-9 will help you to understand how speed changes are made possible. Wheel A has 10 teeth which mesh with the 40 teeth on wheel B. Wheel A will have to rotate four times to cause B to make one revolution. Wheel C is rigidly fixed on the same shaft with B. Thus C makes the same number of revolutions as B. However, C has 20 teeth, and meshes with wheel D which has only 10 teeth. Hence, wheel D turns twice as fast as wheel C.

Now, if you turn A at a speed of four revolutions per second, B will be rotated at one revolution per second. Wheel C also moves at one revolution per second, and causes D to turn at two revolutions per second. You get out two revolutions per second after having put in four revolutions per second. Thus the overall speed reduction is 2/4—or 1/2—which means that you got half the speed out of the last driven wheel that you put into the first driver wheel.

You can solve any gear speed-reduction problem with this formula—

$$S_2 = S_1 \times \frac{T_1}{T_2}$$

where

S_1 = speed of first shaft in train

S_2 = speed of last shaft in train

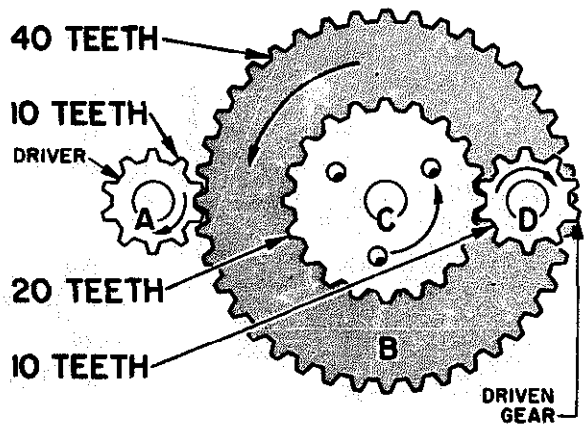

T_1 = product of teeth on all drivers

T_2 = product of teeth on all driven gears

Now use the formula on the gear train of figure 6-8.

$$S_2 = S_1 \times \frac{T_1}{T_2} = 4 \times \frac{10 \times 20}{40 \times 10} =$$

$$\frac{800}{400} = 2 \text{ revs. per sec.}$$

131.27

Figure 6-9.—Gears can change speed of applied motion.

Almost any increase or decrease in speed can be obtained by choosing the correct gears for the job. For example, the turbines on a ship have to turn at high speeds—say 5800 rpm—if they are going to be efficient. But the propellers, or screws, must turn rather slowly—say 195 rpm—to push the ship ahead with maximum efficiency. So, a set of reduction gears is placed between the turbines and the propeller shaft.

When two external gears mesh, they rotate in opposite directions. Often you'll want to avoid this. Put a third gear, called an idler, between the driver and the driven gear. But don't let this extra gear confuse you on speeds. Just neglect the idler entirely. It doesn't change the gear ratio at all, and the formula still applies. The idler merely makes the driver and its driven gear turn in the same direction. Figure 6-10 will show you how this works.

MAGNIFYING FORCE WITH GEARS

Gear trains are used to increase the mechanical advantage. In fact, wherever there is a speed reduction, the effect of the effort you apply is multiplied. Look at the cable winch in figure 6-11. The crank arm is 30 inches long, and the drum on which the cable is wound has a 15-inch radius. The small pinion gear has 10

teeth, which mesh with the 60 teeth on the internal spur gear. You will find it easier to figure the mechanical advantage of this machine if you think of it as two machines.

First, figure out what the gear and pinion do for you. The theoretical mechanical advantage of any arrangement of two meshed gears can be found by the following formula—

$$M. A. (\text{theoretical}) = \frac{T_o}{T_a}$$

In which, T_o = number of teeth on driven gear;

T_a = number of teeth on driver gear.

In this case, $T_o = 60$ and $T_a = 10$. Then,

$$M. A. (\text{theoretical}) = \frac{T_o}{T_a} = \frac{60}{10} = 6$$

Now, for the other part of the machine, which is a simple wheel-and-axle arrangement consisting of the crank arm and the drum. The theoretical mechanical advantage of this can be found by dividing the distance the effort moves— $2\pi R$ —in making one complete revolution, by the distance the cable is drawn up in one revolution of the drum— $2\pi r$.

$$M. A. (\text{theoretical}) = \frac{2\pi R}{2\pi r} = \frac{R}{r} = \frac{30}{15} = 2$$

Figure 6-10.—An idler gear.

12.55

131.28

Figure 6-11.—This magnifies your effort.

You know that the total, or overall, theoretical mechanical advantage of a compound machine is equal to the product of the mechanical advantages of the several simple machines that make it up. In this case you considered the winch as being two machines—one having an M. A. of 6, and the other an M. A. of 2. Therefore, the over-all theoretical mechanical advantage of the winch is 6×2 , or 12. Since friction is always present, the actual mechanical advantage may be only 7 or 8. Even so, by applying a force of 100 pounds on the handle, you could lift a load of 700 or 800 pounds.

You use gears to produce circular motion. But you often want to change rotary motion into up-and-down or linear motion. You can use cams to do this. For example—

The cam shaft in figure 6-12 is turned by the gear. A cam is keyed to the shaft and turns with it. The cam has an irregular shape which is designed to move the valve stem up and down, giving the valve a straight-line motion as the cam shaft rotates.

When the cam shaft rotates, the high point—lobe—of the cam raises the valve to its open position. As the shaft continues to rotate, the high point of the cam is passed and the valve is lowered to closed position.

A set of cams, two to a cylinder, driven by timing gears from the crankshaft operate the exhaust and intake valves on the gasoline automobile engine as shown in figure 6-13. Cams are widely used in machine tools and other devices to make rotating gears and shafts do up-and-down work.

SUMMARY

These are the important points you should keep in mind about gears—

Gears can do a job for you by changing the direction, speed, or size of the force which you apply.

When two external gears mesh, they always turn in opposite directions. You can make them turn in the same direction by placing an idler gear between the two.

The product of the number of teeth on each of the driver gears, divided by the product of the number of teeth on each of the driven gears, gives you the speed ratio of any gear train.

The theoretical mechanical advantage of any gear train is the product of the number of teeth on the driven gear wheels, divided by the product of the number of teeth on the driver gears.

The overall theoretical mechanical advantage of a compound machine is equal to the product of the theoretical mechanical advantages of all the simple machines which make it up.

Cams are used to change rotary motion into linear motion.

One of the gear systems you'll get to see frequently aboard ship is that on the anchor winch. Figure 6-14 shows you one type in which you can readily see how the wheels go 'round. The driving gear A is turned by the winch engine or motor. This gear has 22 teeth, which mesh with the 88 teeth on the large wheel B. Thus, you know that the large wheel makes one revolution for every four revolutions of the driving gear A. You get a 4-to-1 theoretical mechanical advantage out of that pair. Secured to the same shaft with B is the small spur gear C, covered up here. The gear C has 30 teeth which mesh with the 90 teeth on the large gear D, also covered up. The advantage from C to D is

Figure 6-12.—Cam-driven valve.

131.29

Figure 6-13.—Automobile valve gear.

131.30

3 to 1. The sprocket wheel to the far left, on the same shaft with D, is called a wildcat. The anchor chain is drawn up over this. Every second link is caught and held by the protruding teeth of the wildcat. The overall mechanical advantage of the winch is 4×3 , or 12 to 1.

Figure 6-15 shows you an application of the rack and pinion as a steering mechanism. Turning the ship's wheel turns the small pinion A. This pinion causes the internal spur gear to turn. Notice that there is a large mechanical advantage in the arrangement.

Now you see that center pinion P turns. It meshes with the two vertical racks. When the wheel is turned full to the right, one rack moves downward and the other moves upward to the positions of the racks. Attached to the bottom

of the racks are two hydraulic pistons which control the steering of the ship. You'll get some information on this hydraulic system in a later chapter.

CHAPTER 7

WORK

MEASUREMENT

You know that machines help you to do work. But just what is work? Work doesn't mean simply applying a force. If that were so, you would have to consider that Big-Boy, busily applying his 220-pound force on the sea bag in figure 7-1 is doing work. But no work is being done!

Work, in the mechanical sense of the term, is done when a resistance is overcome by a force acting through a measureable distance. Now, if Big-Boy were to lift his 90-pound bag off the deck and put it on his bunk, he would be doing work. He would be overcoming a resistance by applying a force through a distance.

Notice that two factors are involved—force and movement through a distance. The force is normally measured in pounds, and the distance in feet. Work, therefore, is commonly measured in units called foot-pounds. You do one foot-pound of work when you lift a one-pound weight through a height of one foot. But—you also do one foot-pound of work when you apply one pound of force on any object through a distance of one foot. Writing this as a formula, it becomes—

$$\text{WORK} = \text{FORCE} \times \text{DISTANCE}$$

(foot-pounds) = (pounds) × (feet)

Thus, if the sailor lifts a 90-pound bag through a vertical distance of 5 feet, he will do—

$$\text{WORK} = 90 \times 5 = 450 \text{ ft-lb.}$$

There are two points concerning work that you should get straight right at the beginning.

First, in calculating the work done you measure the actual resistance being overcome. This is not necessarily the weight of the object being

moved. To make this clear, look at the job the bluejacket in figure 7-2 is doing. He is pulling a 900-pound load of supplies 200 feet along the dock. Does this mean that he is doing 900 times 200, or 180,000 foot-pounds of work? Of course not. He isn't working against the pull of gravity—or the total weight—of the load. He's pulling only against the rolling friction of the truck, and that may be as little as 90 pounds. That is the resistance which is being overcome. Always be sure that you know what resistance is being overcome by the effort, as well as the distance through which it is moved. The resistance in one case may be the weight of the object; in another it may be the frictional resistance of the object as it is dragged or rolled along the deck.

The second point to hold in mind is that you have to move the resistance to do any work on it. Look at Willie in figure 7-3. The poor guy has been holding that suitcase for the past 15 minutes waiting for the bus. His arm is getting tired; but according to the definition of work, he isn't doing any—because he isn't moving the suitcase. He is merely exerting a force against the pull of gravity on the bag.

You already know about the mechanical advantage of a lever. Now consider it in terms of getting work done easily. Look at figure 7-4. The load weighs 300 pounds, and you want to lift it up onto a platform a foot above the deck. How much work must you do on it? Since 300 pounds must be raised one foot, 300 times 1, or 300 foot-pounds of work must be done. You can't make this weight any smaller by the use of any machine. However, if you use the eight-foot plank as shown, you can do that amount of work, by applying a smaller force through a longer distance. Notice that you have a mechanical advantage of 3, so that a 100-pound push down on the end of the plank will raise the 300-pound crate. Through how long a distance will you have to exert that 100-pound push? Neglecting

131.33

Figure 7-1.—No work is being done.

friction—and in this case you can safely do so—the work done on the machine is equal to the work done by the machine. Say it this way—

Work put in = work put out.

And since Work = force x distance, you can substitute "force times distance" on each side of the work equation. Thus—

$$F_1 \text{ times } S_1 = F_2 \text{ times } S_2$$

in which,

F_1 = effort applied, in pounds

S_1 = distance through which effort moves, in feet

F_2 = resistance overcome, in pounds

S_2 = distance resistance is moved, in feet

Now substitute the known values, and you obtain—

$$100 \text{ times } S_1 = 300 \text{ times } 1$$

$$S_1 = 3 \text{ feet}$$

131.34

Figure 7-2.—Working against friction.

131.35

Figure 7-3.—No motion no work.

The advantage of using the lever is not that it makes any less work for you, but that it allows you to do the job with the force at your command. You'd probably have some difficulty lifting 300 pounds directly upward without a machine to help you!

A block and tackle also makes work easier. But like any other machine, it can't decrease the total amount of work to be done. With a rig like the one shown in figure 7-5, the bluejacket has a mechanical advantage of 5, neglecting friction. Notice that five parts of the rope go to and from the movable block. To raise the 600-pound load 20 feet, he needs to exert a pull of only 1/5 of 600—or 120 pounds. But—he is going to have to pull more than 20 feet of rope through his hands in order to do this. Use the formula again to figure why this is so—

Work input = work output

$$F_1 \times S_1 = F_2 \times S_2$$

And by substituting the known values—

$$120 \times S = 600 \times 20$$

$$S_1 = 100 \text{ feet.}$$

This means that he has to pull 100 feet of rope through his hands in order to raise the load 20 feet. Again, the advantage lies in the fact that a relatively small force operating through a large distance can move a big load through a small distance.

The sailor busy with the big piece of machinery in figure 7-6 has his work cut out for him. He is trying to seat the machine square on its foundations. The rear end must be shoved over one-half foot against a frictional resistance of 1,500 pounds. The amount of work to be done is $1,500 \times 1/2$, or 750 foot-pounds. He will have to do at least this much work on the jack he is using. If the jack has a 2 1/2-foot handle— $R = 2 1/2 \text{ ft}$ —and the pitch of the jack screw is 1/4 inch, he can do the job with little effort. Neglecting friction, you can figure it out this way—

Work input = work output

$$F_1 \times S_1 = F_2 \times S_2$$

In which

F_1 = force in pounds applied on the handle;
 S_1 = distance, in feet, that the end of the handle travels in one revolution;

F_2 = resistance to be overcome;
 S_2 = distance in feet that head of jack is advanced by one revolution of the screw.
 Or, the pitch of the screw.

And, by substitution,

$$F_1 \times 2R = 1500 \times 1/48,$$

since $1/4'' = 1/48$ of a foot

$$F_1 \times 2 \times 2 1/2 = 1500 \times 1/48$$

$$F_1 = 2 \text{ pounds}$$

The jack makes it theoretically possible for the sailor to exert a 1,500-pound push with a 2-pound effort, but look at the distance through which he must apply that effort. One complete turn of the handle represents a distance of 15.7 feet. That 15.7-foot rotation advances the piece of machinery only 1/4th of an inch—or 1/48th of a foot. Force is gained at the expense of distance.

131.37

Figure 7-5.—A block and tackle makes work easier.

lump of sugar on a table and give each an equal push, the marble will move farther. This is because rolling friction is always less than sliding friction. You take advantage of this fact whenever you use ball bearings or roller bearings. See figure 7-7.

Remember that rolling friction is always less than sliding friction. The Navy takes advantage of that fact. Look at figure 7-8. This roller chock not only cuts down the wear and tear on lines and cables which are run through it, but—by reducing friction—also reduces the load the winch has to work against.

The roller bitt in figure 7-9 is another example of how you can cut down the wear and tear on lines or cable and also reduce your frictional loss.

When it is necessary to have one surface move over another, you can decrease the friction by the use of lubricants, such as oil, grease, or soap. You will use lubricants on flat surfaces, gun slides for example, as well as on ball and

131.38

Figure 7-6.—A big push.

roller bearings, to further reduce the frictional resistance and to cut down the wear.

Don't forget that in a lot of situations friction is mighty helpful, however. Many a blue-jacket has found out about this the hard way—on a wet, slippery deck. On some of our ships you'll find that a rough-grained deck covering is used. Here you have friction working for you. It helps you to keep your footing.

EFFICIENCY

Up to this point you have been neglecting the effect of friction on machines. This makes it easier to explain machine operation, but you know from practical experience that friction is involved every time two surfaces move against one another. And the work used in overcoming the frictional resistance does not appear in the work output. Since this is so, it's obvious that you have to put more work into a machine than you get out of it. In other words, no machine is 100 percent efficient.

Take the jack in figure 7-6, for example. The chances are good that a 2-pound force exerted on the handle wouldn't do the job at all. More likely a pull of at least 10 pounds would be required. This indicates that only 2 out of the 10 pounds, or 20 percent of the effort is usefully employed to do the job. The remaining 8 pounds of effort were consumed in overcoming the friction in the jack. Thus, the jack has an efficiency of only 20 percent. Most jacks are inefficient, but even with this inefficiency, it is possible to deliver a huge push with a small amount of effort.

Actually, $50 \div 0.60 = 83.3$ pounds. You can check this yourself in the following manner—

$$\begin{aligned} \text{Efficiency} &= \frac{\text{Output}}{\text{Input}} \\ &= \frac{F_2 \times S_2}{F_1 \times S_1} \end{aligned}$$

One revolution of the drum would raise the 600-pound load a distance S_2 of $2\pi r$ or 7.85 feet. To make the drum revolve once, the pinion gear must be rotated six times by the handle; and the handle must be turned through a distance S_1 of $6 \times 2\pi R$, or 94.2 feet. Then, by substitution—

$$0.60 = \frac{600 \times 7.85}{F_1 \times 94.2}$$

$$F_1 = \frac{600 \times 7.85}{94.2 \times 0.60} = 83.3 \text{ pounds.}$$

12.50

Figure 7-7.—These reduce friction.

A simple way to calculate the efficiency of a machine is to divide the output by the input—convert to percentage

$$\text{Efficiency} = \frac{\text{Output}}{\text{Input}}$$

Now go back to the block-and-tackle problem illustrated in figure 7-5. It's likely that instead of being able to lift the load with a 120-pound pull, the bluejacket would perhaps have to use a 160-pound pull through the 100 feet. You can calculate the efficiency of the rig by the following method—

$$\text{Efficiency} = \frac{\text{output}}{\text{input}} = \frac{F_2 \times S_2}{F_1 \times S_1}$$

and, by substitution,

$$= \frac{600 \times 20}{160 \times 100} = 0.75 \text{ or } 75 \text{ percent.}$$

Theoretically, with the mechanical advantage of twelve developed by the cable winch back in figure 6-11 you should be able to lift a 600-pound load with a 50-pound push on the handle. If the machine has an efficiency of 60 percent, how big a push would you actually have to apply?

131.39

Figure 7-8.—It saves wear and tear.

Because this machine is only 60-percent efficient, you have to put 94.2×83.3 , or 7,847 foot-pounds of work into it in order to get 4,710 foot-pounds of work out of it. The difference— $7,847 - 4,710$ 3,137 foot-pounds—is used to overcome friction within the machine.

SUMMARY

Here are some of the important points you should remember about friction, work, and efficiency—

You do work when you apply a force against a resistance and move the resistance. Since force—measured in pounds—and distance—measured in feet—are involved, work is measured in foot-pounds. One foot-pound of work is the result of a one-pound force, acting against a resistance through a distance of one foot.

Machines help you to do work by making it possible to move a large resistance through a small distance by the application of a small force through a large distance.

Since friction is present in all machines, more work must be done on the machine than the machine actually does on the load.

The efficiency of any machine can be found by dividing the output by the input.

The resistance that one surface offers to movement over a second surface is called friction.

Friction between two surfaces depends upon the nature of the materials and the magnitude of the forces pushing them together.

131.40
Figure 7-9.—Roller bitt saves line.

CHAPTER 8

POWER

It's all very well to talk about how much work a man can do, but the payoff is how long it takes him to do it. Look at "Lightning" in figure 8-1. He has lugged 3 tons of bricks up to the second deck of the new barracks. However, it has taken him three 10-hour days—1800 minutes—to do the job. In raising the 6000 pounds 15 feet he did 90,000 foot-pounds of work. Remember—force x distance = work. Since it took him 1800 minutes, he has been working at the rate of $90,000 \div 1800$, or 50 foot-pounds of work per minute.

That's power—the rate of doing work. Thus, power always includes the time element. Doubtless you could do the same amount of work in one 10-hour day, or 600 minutes—which would mean that you would work at the rate of $90,000 \div 600 = 150$ foot-pounds per minute. You then would have a power value three times as great as that of "Lightning."

By formula—

$$\text{Power} = \frac{\text{Work, in ft-lb}}{\text{Time, in minutes}}$$

HORSEPOWER

You measure force in pounds; distance in feet; work in foot-pounds. What is the common unit used for measuring power? The horsepower. If you want to tell someone how powerful an engine is, you could say that it is so many times more powerful than a man, or an ox, or a horse. But what man, and whose ox or horse? James Watt, the fellow who invented the steam engine, compared his early models with the horse. By experiment, he found that an average horse could lift a 330-pound load straight up through a distance of 100 feet in one minute. Figure 8-2 shows you the type of rig he used to find this out. By agreement among scientists, that figure of 33,000 foot-pounds of work done in one minute has been

accepted as the standard unit of power, and it is called a horsepower—hp.

Since there are 60 seconds in a minute, one horsepower is also equal to $\frac{33,000}{60} = 550$ foot-pounds per second. By formula—

$$\text{Horsepower} = \frac{\text{Power (in ft-lb per min)}}{33,000}$$

CALCULATING POWER

It isn't difficult to figure how much power is needed to do a certain job in a given length of time, nor to predict what size engine or motor is

Figure 8-1.—Get a horse.

131.41

Figure 8-2.—One horsepower.

131.42

needed to do it. Suppose an anchor winch must raise a 6,600-pound anchor through 120 feet in 2 minutes. What must be the theoretical horsepower rating of the motor on the winch?

The first thing to do is to find the rate at which the work must be done. You see the formula—

$$\text{Power} = \frac{\text{work}}{\text{time}} = \frac{\text{force} \times \text{distance}}{\text{time}}$$

Substitute the known values in the formula, and you get—

$$\text{Power} = \frac{6,600 \times 120}{2} = 396,000 \text{ ft-lb/min}$$

So far, you know that the winch must work at a rate of 396,000 ft-lb/min. To change this rate to horsepower, you divide by the rate at

which the average horse can work—33,000 ft-lb/min.

$$\begin{aligned} \text{Horsepower} &= \frac{\text{Power (ft-lb/min)}}{33,000} = \\ &= \frac{396,000}{33,000} = 12 \text{ hp.} \end{aligned}$$

Theoretically, the winch would have to be able to work at a rate of 12 horsepower in order to get the anchor raised in 2 minutes. Of course, you've left out all friction in this problem, so the winch motor would actually have to be larger than 12 hp.

Planes are raised from the hangar deck to the flight deck of a carrier on an elevator. Some place along the line, an engineer had to figure out how powerful the motor had to be in order

to raise the elevator. It's not too tough when you know how. Allow a weight of 10 tons for the elevator, and 5 tons for the plane. Suppose that you want to raise the elevator and plane 25 feet in 10 seconds. And that the overall efficiency of the elevator mechanism is 70 percent. With that information you can figure what the delivery horsepower of the motor must be. Set up the formulas—

$$\text{Power} = \frac{\text{force} \times \text{distance}}{\text{time}}$$

$$\text{hp} = \frac{\text{power}}{33,000}$$

Substitute the known values in their proper places, and you have—

$$\text{power} = \frac{30,000 \times 25 \text{ ft}}{10/60 \text{ minute}} = 4,500,000 \text{ ft lb/min.}$$

$$\text{hp} = \frac{4,500,000}{33,000} = 136.4 \text{ hp.}$$

So, 136.4 horsepower would be needed if the engine had 100 percent overall efficiency. You want to use 70 percent efficiency, so you use the formula—

$$\text{Efficiency} = \frac{\text{Output}}{\text{Input}}$$

$$\text{Input} = \frac{136.4}{0.70} = 194.8 \text{ hp.}$$

This is the rate at which the engine must be able to work. To be on the safe side, you'd probably select a 200-horsepower auxiliary to do the job.

FIGURING THE HORSEPOWER RATING OF A MOTOR

You have probably seen the horsepower rating plates on electric motors. A number of methods may be used to determine this rating. One way that the rating of a motor or a steam or gas engine can be found is by the use of the prony brake. Figure 8-3 shows you the Prony brake setup. A pulley wheel is fixed to the shaft of the motor, and a leather belt is held firmly against the pulley. Attached to the two ends of the belt are spring scales. When the motor is standing still, each scale reads the same—say 15 pounds.

Figure 8-3.—A prony brake. 131.43

When the pulley turns in a clockwise direction, the friction between the belt and the pulley makes the belt try to move with the pulley. Therefore, pull on scale A will be greater, and the pull on scale B will be less than 15 pounds.

Suppose that scale A reads 25 pounds, and scale B reads 5 pounds. That tells you that the drag, or the force against which the motor is working, is 25-5=20 pounds. In this case the normal speed of the motor is 1800 rpm (revolutions per minute) and the diameter of the pulley is one foot.

The number of revolutions can be found by holding the revolution counter C against the end of the shaft for one minute. This counter will record the number of turns the shaft makes per minute. The distance D which any point on the pulley travels in one minute is equal to the circumference of the pulley times the number of revolutions—3.14x1x1800=5652 ft.

You know that the motor is exerting a force of 20 pounds through that distance. The work done

in one minute is equal to the force times the distance, or work = $F \times D = 20 \times 5,652 = 113,040$ ft -lb/min. Change this to horsepower—

$$\frac{113,040}{33,000} = 3.43 \text{ hp.}$$

Here are a few ratings for motors or engines with which you are familiar—an electric mixer

has a 1/16-hp motor; a washing machine a 1/4-hp motor.

SUMMARY

There are two important points for you to remember about Power—

Power is the rate at which work is done.

The unit in which power is measured is the horsepower, which is equivalent to working at a rate of 33,000 ft-lb per min, or 550 ft-lb per sec.

CHAPTER 9

FORCE AND PRESSURE

By this time you should have a pretty good idea of what a force is. A force is a push or a pull exerted on—or by—an object. You apply a force on a machine, and the machine in turn transmits a force to the load. Men and machines, however, are not the only things that can exert forces. If you've been out in a sailboat you know that the wind can exert a force. Further, you don't have to get knocked on your ear more than a couple of times by the waves to get the idea that water, too, can exert a force. As a matter of fact, from reveille to taps you are almost constantly either exerting forces or resisting them. That's the reason you are pooped when you hit the sack.

MEASURING FORCES

You've had a lot of experience in measuring forces. You can estimate or "guess" the weight of a package you're going to mail by "hefting" it. Or you can put it on a scale to find its weight accurately. Weight is a common term that tells you how much force or pull gravity is exerting on the object.

You can readily measure force with a spring scale. An Englishman named Hooke discovered that if you hang a 1-pound weight on a spring, the spring stretches a certain distance. A 2-pound weight will extend the spring just twice as far, and 3 pounds will lengthen it three times as far as the 1-pound weight did. Right there is the makings of the spring scale. All you need to do is attach a pointer to the spring, put a face on the scale, and mark on the face the positions of the pointer for various loads in pounds or ounces.

This type of scale can be used to measure the pull of gravity—the weight—of an object, or the force of a pull exerted against friction, as shown in figure 9-1. Unfortunately, springs get tired, just as you do. When they get old, they don't always snap back to the original position. Hence an old spring or an overloaded spring will give inaccurate readings.

HONEST WEIGHT—NO SPRINGS

Because springs do get tired, other types of force-measuring devices are made. You've seen the sign, "Honest Weight—No Springs", on the butchershop scales. Scales of this type are shown in figure 9-2. They are applications of first-class levers. The one shown in figure 9-2A is the simplest type. Since the distance from the fulcrum to the center of each platform is equal, the scale is balanced when equal weights are placed on the platforms. With your knowledge of levers, you will be able to figure out how the steel yard shown in figure 9-2B operates.

PRESSURE

Have you ever tried to walk on crusted snow that would breakthrough when you put your weight on it? But you could walk on the same snow if you put on snowshoes. Further, you know that snowshoes do not reduce your weight—they merely distribute it over a larger area. In doing this, they reduce the pressure per square inch. Figure out how that works. If you weigh 160 pounds, that weight, or force, is more or less evenly distributed by the soles of your shoes. The area of the soles of an average man's shoes is roughly 60 square inches. Each one of those square inches has to carry $160 \div 60 = 2.6$ pounds of your weight. Since 2.6 pounds per square inch is too much for the snow crust, you break through.

When you put on the snowshoes, you distribute your weight over an area of approximately 900 sq in.—depending, of course, on the size of the snowshoes. Now the force on each one of those square inches is equal to only $160 \div 900 = 0.18$ pound. The pressure on the snow has been decreased, and the snow can easily support you.

Pressure is force per unit area—and is measured, in pounds per square inch—"psi." With snowshoes on, you exert a pressure of 0.18

Figure 9-1.—You can measure force with a scale.

131.44

psi. To calculate pressure, divide the force by the area over which the force is applied. The formula is—

$$\text{Pressure, in psi} = \frac{\text{Force, in lb}}{\text{Area, in sq in}}$$

Or

$$P = \frac{F}{A}$$

To get this idea, follow this problem. A tank for holding fresh water aboard a ship is 10 feet long, 6 feet wide, and 4 feet deep. It holds, therefore, 10x6x4, or 240 cubic feet of water. Each cubic foot of water weighs about 62.5 pounds. The total force tending to push the bottom out of the tank is equal to the weight of the water—240x62.5, or 15,000 lb. What is the pressure on the bottom? Since the weight is evenly distributed on the bottom, you apply the formula $P = \frac{F}{A}$ and substitute the proper values for F and A. In this case, F=15,000 lb, and the area of the bottom in

square inches is 10x6x144, since 144 sq in.=1 sq ft.

$$P = \frac{15,000}{10 \times 6 \times 144} = 1.74 \text{ psi}$$

Now work out the idea in reverse. You live at the bottom of the great sea of air which surrounds the earth. Because the air has weight—gravity pulls on the air, too—the air exerts a force on every object which it surrounds. Near sea level that force on an area of 1 square inch is roughly 15 pounds. Thus, the air-pressure at sea level is about 15 psi. The pressure gets less and less as you go up to higher altitudes.

With your finger, mark out an area of one square foot on your chest. What is the total force which tends to push in your chest? Again use the formula $P = \frac{F}{A}$. Now substitute 15 psi for P, and for A use 144 sq. in. Then $F = 144 \times 15$, or 2160 lb. The force on your chest is 2160 lb per square foot—more than a ton pushing against an area of

Figure 9-2.—Balances.

18.30

1 sq ft. If there were no air inside your chest to push outward with the same pressure, you'd be squashed flatter than a bride's biscuit.

MEASURING PRESSURE

Fluids—which include both liquids and gases—exert pressure. A fluid at rest exerts

equal pressure in all directions. Figure 9-3 shows that. Whether the hole is in the top, the bottom, or in one of the sides of a submarine, the water pushes in through the hole.

In many jobs aboard ship, it is necessary to know the pressure exerted by gas or a liquid. For example, it is important at all times to know

Figure 9-3.—Fluids exert pressure in all directions.

131.45

the steam pressure inside of a boiler. One device to measure pressure is the Bourdon gage, shown in figure 9-4. Its working principle is the same as that of those snakelike paper tubes which you get at a New Year's party. They straighten out when you blow into them.

In the Bourdon gage there is a thin-walled metal tube, somewhat flattened, and bent into the form of a C. Attached to its free end is a lever system which magnifies any motion of the free end of the tube. The fixed end of the gage ends in a fitting which is threaded into the boiler system so that the pressure in the boiler will be transmitted to the tube. Like the paper "snake," the metal tube tends to straighten out when the pressure inside it is increased. As the tube straightens, the pointer is made to move around the dial. The pressure, in psi, may be read directly on the dial.

Air pressure and pressures of steam and other gases, and fluid pressures in hydraulic systems, are generally measured in pounds per square inch. For convenience, however, the pressure exerted by water is commonly measured in pounds per square foot. You'll find more about this in chapter 10.

The Bourdon gage is a highly accurate but rather delicate instrument, and can be very easily damaged. In addition, it develops trouble where pressure fluctuates rapidly. To overcome this, another type of gage, the Schrader, was developed. The Schrader gage (fig. 9-5) is not as accurate as the Bourdon, but is sturdily constructed and quite suitable for ordinary hydraulic pressure measurements. It is especially recommended for fluctuating loads. In the Schrader gage a piston is directly actuated by the liquid pressure to be measured, and moves up a cylinder against the resistance of a spring, carrying a bar or indicator with it over a calibrated scale. In this manner, all levers, gears, cams, and bearings are eliminated, and a sturdy instrument can be constructed.

Where accurate measurements of comparatively slight pressures are desired, a diaphragm type gage may be used.

Diaphragm gages give sensitive and reliable indications of small pressure differences. Diaphragm gages are often used to measure the air pressure in the space between inner and outer boiler casings. In this type of gage, a diaphragm is connected to a pointer through a metal spring and a simple linkage system (fig. 9-6). One side

Figure 9-4.—The Bourdon gage.

38.211

Figure 9-5.—The Schrader gage.

131.46

of the diaphragm is exposed to the pressure being measured, while the other side is exposed to the pressure of the atmosphere.

Any increase in the pressure line will move the diaphragm upwards against the action of the spring. The linkage system operates and the pointer rotates to a higher reading. When the pressure being measured decreases, the spring moves the diaphragm downward, rotating the pointer to a lower reading. Thus the position of the pointer is a balance between the pressure tending to push the diaphragm upward and the

spring action tending to push it down. When the gage reads "0" the pressure in the line is equal to the outside air pressure.

THE BAROMETER

To the average man, the chief importance of weather is as an introduction to general conversation. But at sea and in the air, advance knowledge of what the weather will do is a matter of great concern to all hands. Operations are

38.212X

Figure 9-6.—Diaphragm pressure gage.

planned or cancelled on the basis of weather predictions. Accurate weather forecasts are made only after a great deal of information has been collected by many observers located over a wide area.

One of the instruments used in gathering weather data is the barometer. Remember, the air is pressing on you all the time. So-called normal atmospheric pressure is 14.7 psi. But as the weather changes, the air pressure may be greater or less than normal. If the air pressure is low in the area where you are, you know that air from one or more of the surrounding high-pressure areas is going to move in toward you. Moving air—or wind—is one of the most important factors in weather changes. In general, if you're in a low-pressure area you may expect wind, rain, and storms. A high-pressure area generally enjoys clear weather. The barometer can tell you the air pressure in your locality, and give you a rough idea of what kind of weather may be expected.

The aneroid barometer shown in figure 9-7 is an instrument which measures air pressure. It contains a thin-walled metal box from which

69.87

Figure 9-7.—An aneroid barometer.

most of the air has been pumped. A pointer is mechanically connected to the box by a lever system. If the pressure of the atmosphere increases, it tends to squeeze in the sides of the box. This squeeze causes the pointer to move towards the high-pressure end of the scale. If the pressure decreases, the sides of the box expand outward. This causes the pointer to move toward the low-pressure end of the dial.

Notice that the numbers on the dial run from 27 to 31. To understand why these particular numbers are used, you have to understand the operation of the mercurial barometer. You see one of these in figure 9-8. It consists of a glass tube partly filled with mercury. The upper end is closed. There is a vacuum above the mercury in the tube, and the lower end of the tube is submerged in a pool of mercury in an open cup. The atmosphere presses down on the mercury in the cup, and tends to push the mercury up in the tube. The greater the air pressure, the higher the column of mercury rises. At sea level, the

69.86
Figure 9-8.—A mercurial barometer.

normal pressure is 14.7 psi, and the height of the mercury in the tube is 30 inches. As the air pressure increases or decreases from day to day, the height of the mercury rises or falls. A mercury barometer aboard ship is usually mounted in gimbals to keep it in a vertical position despite the rolling and pitching of the ship.

Pressures indicated on dials of most gages are relative. That is, they are either greater or less than normal. But remember—the dial of an aneroid barometer always indicates absolute pressures, not relative. When the pressure exerted by any gas is less than 14.7 psi, you have what's called a partial vacuum. The condensers on steam turbines, for instance, are operated at pressure well below 14.7 psi. Steam under very high pressure is run into the turbine and causes the rotor to turn. After it has passed through the turbine it still exerts a back pressure against the blades. You can see that this is bad. Soon the back pressure would be nearly as

large as that of the incoming steam, and the turbine would not turn at all. To reduce the back pressure as much as possible, the exhaust steam is run through pipes which are surrounded by cold sea water. This causes the steam in the pipes to condense into water, and the pressure drops well below atmospheric pressure.

It is important for the engineer to know the pressure in the condensers at all times. To measure this reduced pressure, or partial vacuum, he uses a gage called a manometer. Figure 9-9 shows you how this simple device is made. A U-shaped tube has one end connected to the low-pressure condenser and the other end is open to the air. The tube is partly filled with colored water. The normal air pressure on the open end exerts a bigger push on the colored water than the push of the low-pressure steam, and the colored water is forced part way up into the left arm of the tube. From the scale between the two arms of the U, the difference in the height of the two columns of water can be read. This tells the engineer the degree of vacuum—or how much below atmospheric pressure the pressure is in the condenser.

61.4
Figure 9-9.—A manometer.

SUMMARY

Here are seven points that you should remember--

A force is a push or a pull exerted on—or by—an object.

Force is generally measured in pounds.

Pressure is the force per unit area which is exerted on, or by, an object. It is commonly measured in pounds per square inch—psi.

Pressure is calculated by the formula $P = \frac{F}{A}$.

Spring scales and lever balances are familiar instruments you use for measuring forces. Bourdon gages, barometers, and manometers are instruments for the measurement of pressure.

The normal pressure of the air is 14.7 psi at sea level.

Pressure is generally relative. It is sometimes greater—sometimes less—than normal air pressure. When pressure is less than the normal air pressure, you call it vacuum.

CHAPTER 10

HYDROSTATIC AND HYDRAULIC MACHINES

HYDROSTATIC MACHINES

LIQUIDS AT REST

You know that liquids exert pressure. In order that your ship may remain afloat, the water must push upward on the hull. But the water is also exerting pressure on the sides. If you are billeted on a submarine, you are more conscious of water pressure—when you're submerged the sub is being squeezed from all sides. If your duties include deep-sea diving, you'll go over the side pumped up like a tire so that you can withstand the terrific force of the water below. The pressure exerted by the sea water, or by any liquid at rest, is called hydrostatic pressure. In handling torpedoes, mines, depth charges, and some types of aerial bombs, you'll be dealing with devices which are operated by hydrostatic pressure.

In chapter 9, you found out that all fluids exert pressure in all directions. That's simple enough. But how great is the pressure? Try a little experiment. Place a pile of blocks in front of you on the table. Stick the tip of your finger under the first block from the top. Not much pressure on your finger, is there? Stick it in between the third and fourth blocks. The pressure on your finger has increased. Now slide your finger under the bottom block in the pile. There you find the pressure is greatest. The pressure increases as you go lower in the pile. You might say that pressure increases with depth. The same is true in liquids. The deeper you go, the greater the pressure becomes. But, depth isn't the whole story.

Suppose the blocks in the preceding paragraph were made of lead. The pressure at any level in the pile would be considerably greater. Or, suppose they were blocks of balsa wood—the

pressure at each level wouldn't be so great. Pressure, then, depends not only on the depth, but also on the weight of the material. Since you are dealing with pressure—force per unit of area—you will also be dealing with weight per unit of volume—or density.

When you talk about the density of a substance you are talking about its weight per cubic foot—or per cubic inch. For example, the density of water is 62.5 lb. per cu. ft. This gives you a more exact way of comparing the weights of two materials. To say that lead is heavier than water isn't a complete statement. A 22-caliber bullet doesn't weigh as much as a pail of water. It is true, however, that a cubic foot of lead is lots heavier than a cubic foot of water. Lead has a greater density than water. The density of lead is 710 lb. per cu. ft., as compared with 62.5 lb. per cu. ft. for water.

Pressure depends on two factors—depth and density—so it is easy to write a formula that will help you find the pressure at any depth in any liquid. Here it is—

$$P = H \times D$$

in which

P = pressure, in lb. per sq. in., or lb. per sq. ft

H = depth of the point, measured in feet or inches.

and

D = density in lb. per cu. in. or in lb. per cu. ft.

Note: If inches are used, they must be used throughout; if feet are used, they must be used throughout.

What is the pressure on one square foot of the surface of a submarine if the submarine is 200 feet below the surface? Use the formula—

$$P = H \times D$$

and

$$P = 200 \times 62.5 = 12,500 \text{ lb. per sq. ft.}$$

Every square foot of the sub's surface which is at that depth has a force of over 6 tons pushing in on it. If the height of the hull is 20 feet, and the area in question is midway between the sub's top and bottom, you can see that the pressure on the hull will be at least $(200 - 10) \times 62.5 = 11,875$ lb. per sq. ft., and the greatest pressure will be $(200 + 10) \times 62.5 = 13,125$ lb. per sq. ft. Obviously, the hull has to be made very strong to withstand such pressures.

Using Pressure to Fire the Depth Charge

Although hiding below the surface exposes the sub to great fluid pressure, it also provides the sub with a great advantage. A submarine is hard to kill because it is hard to hit. A depth charge must explode within 30 to 50 feet of a submarine to really score. And that means the depth charge must not go off until it has had time to sink to approximately the same level as the sub. You use a firing mechanism which is set off by the pressure at the estimated depth of the submarine.

Figure 10-1 shows a depth charge and its interior components. A depth charge is a sheet-metal container filled with a high explosive and a firing device. A tube passes through its center from end to end. Fitted in one end of this tube is the booster, which is a load of granular TNT to set off the main charge. The safety fork is knocked off on launching, and the inlet valve cover is removed from an inlet through which the water enters.

When the depth charge gets about 12 to 15 feet below the surface, the water pressure is sufficient to extend a bellows in the booster extender. The bellows trips a release mechanism, and a spring pushes the booster up against the centering flange. Notice that the detonator fits into a pocket in the booster. Unless the detonator is in this pocket, it cannot set off the booster charge.

Nothing further happens until the detonator is fired. As you can see, the detonator is held in the end of the pistol, with the firing pin aimed

4.198

Figure 10-1.—A depth charge.

at the detonator base. The pistol also contains a bellows into which the water rushes as the charge goes down. As the pressure increases, the bellows begins to expand against the depth spring. You can adjust this spring so that the bellows will have to exert a predetermined force in order to compress it. Figure 10-2 shows you the depth-setting dials of one type of depth charge. Since the pressure on the bellows depends directly on the depth, you can arrange to have the charge go off at any depth you select on the dial. When the pressure in the bellows becomes sufficiently great it releases the firing spring, which drives the firing pin into the detonator. The booster, already moved into position, is fired, and this in turn sets off the entire load of TNT.

4.204
Figure 10-2.—You select the depth on these dials.

These two bellows—operated by hydrostatic pressure—serve two purposes. First they permit the depth charge to be fired at the proper depth; second, they make the charge safe to handle and carry. If the safety fork and the valve inlet cover should accidentally be knocked off on deck, nothing would happen. Even if the detonator went off while the charge was being handled, the main charge would not let go unless the booster were in the extended position.

To keep a torpedo on course toward its target is quite a job. Maintaining the proper compass course by the use of a gyroscope is only part of the problem. The torpedo must travel at the proper depth so that it will neither pass under the target ship nor hop out of the water on the way. Here again hydrostatic pressure is used to advantage.

As figure 10-3 indicates, the tin fish contains an air-filled chamber which is sealed with a thin, flexible metal plate, or diaphragm. This diaphragm can bend upward or downward against the spring. The tension on this spring is determined by setting the depth-adjusting knob.

Suppose the torpedo starts to dive below the selected depth. The water, which enters the torpedo and surrounds the chamber, exerts an increased pressure on the diaphragm and causes it

4.122
Figure 10-3.—Inside a torpedo.

to bend down. If you follow the lever system, you can see that the pendulum will be pushed forward. Notice that a valve rod connects the pendulum to the piston of the depth engine. As the piston moves to the left, low-pressure air from the torpedo's air supply enters the depth engine to the right of the piston and pushes it to the left. A depth engine must be used because the diaphragm is not strong enough to move the rudders.

The depth-engine's piston is connected to the horizontal rudders as shown. When the piston moves to the left, the rudder is turned upward, and the torpedo begins to rise to the proper depth. If the nose goes up, the pendulum tends to swing backward and keep the rudder from elevating the torpedo too rapidly. As long as the torpedo runs at the selected depth, the pressure on the chamber remains constant, and the rudders do not change from their horizontal position.

Pressure and the Deep-Sea Diver

Navy divers have a practical, first-hand knowledge of hydrostatic pressure. Think what happens to a diver who goes down 100 feet to work on a salvage job. The pressure on him at that depth is 6,250 lbs. per sq. ft.! Something must be done about that, or he'd be squashed flatter than a pancake.

To counterbalance this external pressure, the diver is enclosed in a rubber suit into which air under pressure is pumped by a shipboard

compressor. Fortunately, the air not only inflates the suit, but gets inside of the diver's body as well. It enters his lungs, and even gets into his blood stream which carries it to every part of his body. In that way his internal pressure can be kept just equal to the hydrostatic pressure.

As he goes deeper, the air pressure is increased to meet that of the water. In coming up, the pressure on the air is gradually reduced. If he is brought up too rapidly, he gets the "bends." The air which was dissolved in his blood begins to come out of solution, and form as bubbles in his veins. Any sudden release in the pressure on a fluid results in freeing some of the gases which are dissolved in the fluid.

You have seen this happen when you suddenly relieve the pressure on a bottle of pop by removing the cap. The careful matching of hydrostatic pressure on the diver by means of air pressure in his suit is essential if diving is to be done at all.

A Sea-Going Speedometer

Here's another device that shows you how your Navy applies its knowledge of hydrostatic pressure. Did you ever wonder how the skipper knows the speed the ship is making through the water? There are several instruments used to give this information—the patent log, the engine revolution counter, and the pitometer log. The "PIT. LOG" is operated, in part, by hydrostatic pressure. It really indicates the difference between hydrostatic pressure and the pressure of the water flowing past the ship—but you can use this difference to indicate ship's speed.

Figure 10-4 shows you a schematic drawing of a pitometer log. A double-wall tube sticks out forward of the ship's hull into water which is not disturbed by the ship's motion. In the tip of the tube is an opening A. When the ship is moving there are two forces or pressures acting on this opening—the hydrostatic pressure due to the depth of water above the opening, and a pressure caused by the push of the ship through the water. The total pressure from these two forces is transmitted through the central or white tube to the left-hand arm of a manometer.

In the side of the tube is a second opening B which does not face in the direction the ship is moving. Opening B passed through the outer wall of the double-wall tube, but not through the inner wall. The only pressure affecting this opening

131.47
Figure 10-4.—A Pitometer log.

B is the hydrostatic pressure. This pressure is transmitted through the outer tube (shaded in the drawing) to the right-hand arm of the manometer.

When the ship is dead in the water, the pressure through both openings A and B is the same, and the mercury in each arm of the manometer stands at the same level. However, as soon as the ship begins to move, additional pressure is developed at opening A, and the mercury is pushed down in the left-hand arm and up into the right-hand arm of the tube. The faster the ship goes, the greater this additional pressure becomes, and the greater the difference will be between the levels of the mercury in the two arms of the manometer. The speed of the ship can be read directly from the calibrated scale on the manometer.

Incidentally—since air is also a fluid—the airspeed of an aircraft can be found by a similar device. You have probably seen the thin tube sticking out from the leading edge of a wing, or from the nose of the plane. Flyers call this tube a pitot tube. Its fundamental principle is the same as that of the pitometer log.

SUMMARY

The Navy uses many devices whose operation is dependent on the hydrostatic principle. Here are three points to remember about the operation of these devices.

Pressure in a liquid is exerted equally in all directions.

You use the term hydrostatic pressure when you are talking about the pressure at any depth in a liquid that is not flowing. Pressure depends upon both depth and density.

The formula for finding pressure is—

$$P = H \times D$$

HYDRAULIC MACHINES

LIQUIDS IN MOTION

Perhaps your earliest contact with a hydraulic machine was when you got your first haircut. Tony put a board across the arms of the chair, sat you on it, and began to pump the chair up to a convenient level. As you grew older, you probably discovered that the filling station attendant could put a car on the greasing rack, and—by some mysterious arrangement—jack it head-high. No doubt the attendant told you that oil under pressure below the piston was doing the job.

Come to think about it, you've probably known something about hydraulics for a long time. Automobiles and airplanes use hydraulic brakes. As a bluejacket, you'll have to operate many hydraulic machines, so you'll want to understand the basic principles on which they work.

Simple machines such as the lever, the inclined plane, the pulley, the wedge, and the wheel and axle, were used by primitive man. But it was considerably later before someone discovered that liquids and gases could be used to exert forces at a distance. Then, a vast number of new machines appeared. A machine which transmits forces by means of a liquid is a hydraulic machine. A variation of the hydraulic machine is the type that operates by the use of a compressed gas. This type is called the pneumatic machine. This chapter deals only with basic hydraulic machines.

Pascal's Law

A Frenchman named Pascal discovered that a pressure applied to any part of a confined fluid is transmitted to every other part with no loss. The pressure acts with equal force on all equal areas of the confining walls, and perpendicular to the walls.

But remember this—when you are talking about the hydraulic principle as applied to a

hydraulic machine, you are talking about the way a liquid acts in a closed system of pipes and cylinders. The action of a liquid under such conditions is somewhat different from its behavior in open containers, or in lakes, rivers, or oceans. You should also keep in mind that most liquids cannot be compressed—squeezed into a smaller space. Liquids don't "give" the way air does when pressure is applied, nor do liquids expand when pressure is removed.

Punch a hole in a tube of shaving cream. If you push down at any point on the tube the cream comes out of the hole. Your force has been transmitted from one place to another by the shaving cream—which is fluid—a thick liquid. Figure 10-5 shows what would happen if you punched four holes in the tube. If you press on the tube at one point, the cream comes out of all four holes. This tells you that a force applied on a liquid is transmitted equally in every direction to all parts of the container. Right there you have illustrated a basic principle of hydraulic machines.

This principle is used in the operation of four-wheel hydraulic automobile brakes. Figure 10-6 is a simplified drawing of this brake system. You push down on the brake pedal and force the piston in the master cylinder against the fluid in that cylinder. This push sets up a pressure on the fluid just as your finger did on the shaving cream in the tube. The pressure on the fluid in the master cylinder is transmitted through the lines to the brake cylinders in each wheel. This fluid under pressure pushes against the pistons in each of the brake cylinders and forces the brake shoes out against the drums.

Figure 10-5.—Pressure is transmitted in all directions.

131.48

Figure 10-6.—Hydraulic brakes.

81.280

Mechanical Advantage Through Hydraulics

The next thing to understand about hydraulic machines is the relationship between the force you apply and the result you get. Figure 10-7 will help you on this. The U-shaped tube has a

Figure 10-7.—The liquid transmits the force.

131.49

cross-sectional area of one sq. inch. In each arm there's a piston which fits snugly, but which can move up and down. If you place a one-pound weight on one piston, the other will be pushed out the top of its arm immediately. Place a one-pound weight on each piston, however, and they remain in their original positions, as shown in figure 10-8.

Thus you see that a pressure of one pound per sq. in. applied down on the right-hand piston exerts a pressure of one pound per sq. in. upward against the left-hand piston. In other words, not only is the force transmitted by the liquid around the curve, but the force is the same on each unit area of the container. It makes no difference how long the connecting tube is, or how many turns it makes. It is important, however, that the entire system be full of liquid. Hydraulic systems will fail to operate properly if air is present in the lines or cylinders.

Now look at figure 10-9. The piston on the right has an area of one sq. in., but the piston on the left has an area of 10 sq. in. If you push down on the smaller piston with a force of one pound, the liquid will transmit this pressure to every square inch of surface in the system. Since the left-hand piston has an area of 10 sq. in., and each square inch has a force of one pound transmitted to it, the total effect is to push on the larger piston with a total force of 10 pounds. Set a 10-pound weight on the larger piston and it will be supported by the one-pound force of the smaller piston.

There you have a one-pound push resulting in a 10-pound force. That's a mechanical advantage of ten. This is why hydraulic machines

Figure 10-8.—Pressure is the same on all parts of an enclosed liquid.

5.181

166

4.7

Figure 10-9.—A mechanical advantage of 10.

are important. Here's a formula which will help you to figure the forces that act in a hydraulic machine—

$$\frac{F_1}{F_2} = \frac{A_1}{A_2}$$

- In which F_1 = force, in pounds, applied to the small piston,
- F_2 = force, in pounds, applied to the large piston,
- A_1 = area of small piston, in square inches,
- A_2 = area of large piston, in square inches.

Try out the formula on the hydraulic press in figure 10-10. The large piston has an area of 90 sq. in. and the smaller one an area of two sq. in. The handle exerts a total force of 15 pounds on the small piston. With what total force will the large piston be raised?

Write down the formula—

$$\frac{F_1}{F_2} = \frac{A_1}{A_2}$$

Substitute the known values—

$$\frac{15}{F_2} = \frac{2}{90}$$

and—

$$F_2 = \frac{90 \times 15}{2} = 675 \text{ pounds.}$$

Where's The Catch?

You know from your experience with levers that you can't get something for nothing. Applying this knowledge to the simple system in figure 10-9, you know that you can't get a 10-pound force from a one-pound effort without sacrificing distance. The one-pound effort will have to be applied through a much greater distance than the 10-pound force will move. If you raise the 10-pound weight through a distance of one foot, through what distance will the one-pound effort have to be applied? Remember—if you neglect friction, the work done on any machine equals the work done by that machine. Use the work formula, and you can find how far the smaller piston will have to move.

Work input = Work output

$$F_1 \times D_1 = F_2 \times D_2$$

By substituting— $1 \times D_1 = 10 \times 1$

and— $D_1 = 10 \text{ feet}$

There's the catch. The smaller piston will have to move through a distance of 10 feet in order to raise the 10-pound load one foot. It looks then as though the smaller cylinder would have to be at least 10 feet long—and that wouldn't be practical. Actually, it isn't necessary—if you put a valve in the system.

The hydraulic press in figure 10-10 contains a valve for just this purpose. As the small piston moves down, it forces the fluid past the check valve A into the large cylinder. As soon as you start to move the small piston upward, the pressure to the right of the check valve A is removed, and the pressure of the fluid below the large piston helps the checkvalve spring force that valve shut. The liquid which has passed through the valve opening on the down stroke of the small piston is trapped in the large cylinder.

The small piston rises on the up-stroke until its bottom passes the opening to the fluid reservoir. More fluid is sucked past a check valve B and into the small cylinder. The next down-stroke forces this new charge of fluid out of the small cylinder past the check valve into the large cylinder. This process is repeated stroke by stroke until enough fluid has been forced into the large cylinder to raise the large piston the required distance of one foot. The force has been applied through a distance of 10 feet on the pump handle,

Figure 10-10.—Hydraulic press.

131.50

but it was done by making a series of relatively short strokes—the sum of all the strokes being equal to 10 feet.

Maybe you're beginning to wonder how the large piston gets back down after you've baled the cotton. The fluid can't run back past the check valve B—that's obvious. You lower the piston by letting the oil flow back to the reservoir through a return line. Notice that a simple gate valve is inserted in this line. When the gate valve is opened, the fluid flows back into the reservoir. Of course, this valve is kept shut while the pump is in operation.

Hydraulics Aid the Helmsman

You've probably seen the helmsman swing a ship weighing thousands of tons about as easily as you turn your car. No, he's not a superman. He does it with machines.

Many of these machines are hydraulic. There are several types of hydraulic and electro-hydraulic steering mechanisms, but the simplified diagram in figure 10-11 will help you to understand the general principles of their operation. As the hand steering wheel is turned in a counterclockwise direction, its motion turns the pinion gear *g*. This causes the left-hand rack *r*₁ to move downward, and the right-hand rack *r*₂ to move upward. Notice that each rack is attached to a piston *P*₁ or *P*₂. The downward motion of rack *r*₁ moves piston *p*₁ downward in its cylinder and pushes the oil out of that cylinder through the line. At the same time, piston *p*₂ moves upward and pulls oil from the right-hand line into the right-hand cylinder.

If you follow these two lines, you see that they enter a hydraulic cylinder *S*—one line entering above and one below the single piston in that cylinder. In the direction of the oil flow in the diagram, this piston and the attached plunger are pushed down toward the hydraulic pump *h*. So far, in this operation, you have used hand power to develop enough oil pressure to move the control plunger attached to the hydraulic pump. At this point an electric motor takes over and drives the pump *h*.

Oil is pumped under pressure to the two big steering rams *R*₁ and *R*₂. You can see that the pistons in these rams are connected directly to the rudder crosshead which controls the position of the rudder. With the pump operating in the direction shown, the ship's rudder is thrown to the left, and the bow will swing to port. This operation demonstrates how a small force applied on the steering wheel sets in motion a series of operations which result in a force of thousands of pounds.

Getting Planes on Deck

The swift, smooth power required to get airplanes from the hanger deck to the flight deck of a carrier is supplied by a hydraulic lift. Figure 10-12 explains how this lifting is done. A variable-speed gear pump is driven by an electric motor. Oil enters the pump from the reservoir and is forced through the lines to four hydraulic rams, the pistons of which raise the elevator platform. The oil under pressure exerts its force on each square inch of surface area of the four pistons. Since the pistons are large, a

Figure 10-11.—Steering is easy with this machine.

131.51

large total lifting force results. The elevator can be lowered by reversing the pump, or by opening valve 1 and closing valve 2. The weight of the elevator will then force the oil out of the cylinders and back into the reservoir.

Submarines Use Hydraulics

Here's another application of hydraulics which you will find interesting. Inside a submarine, between the outer skin and the pressure hull, are several tanks of various design and purpose. These are used to control the total weight of the ship, allowing it to submerge or surface, and to control the trim, or balance fore and aft, of the submarine. The main ballast tanks have the primary function of either destroying or restoring positive buoyancy in the submarine. By allowing air to escape through hydraulically operated vents at the top of the tanks, sea water is able to enter through the flood ports at the bottom—replacing the air that had been holding it out. To regain positive buoyancy, the tanks are "blown" free of sea water with compressed air. Sufficient air is then left trapped in the tanks to prevent the sea water from reentering.

Other tanks, such as the variable ballast tanks and special ballast tanks like the negative tank, safety tank, and bow buoyancy tank, are used either to control trim, or stability, or for emergency weight compensating purposes. The variable ballast tanks have no direct connection to the sea. Therefore, water must be pumped into or out of them. The negative tank and the safety tank, however, can be opened to the sea through large flood valves. These valves, as well as the vent valves for the main ballast tanks and those for the safety and negative tanks, are all hydraulically operated. The vents and flood valves are outside of the pressure hull, so some means of remote control is necessary if they are to be opened and closed from within the submarine. For this purpose, hydraulic pumps, lines, and rams are used. Oil pumped through tubing running through the pressure hull actuates the valve's operating mechanisms by exerting pressure on and moving a piston in a hydraulic cylinder. It is easier and simpler to operate the valves by a hydraulic system from a control room than it would be to do so by a mechanical system of gears, shafts, and levers. The hydraulic lines can be readily led around corners and obstructions, and a minimum of moving parts is required.

Figure 10-12.—This gets them there in a hurry.

131.52

Figure 10-13 is a schematic sketch of the safety tank—one of the special ballast tanks in a submarine. The main vent and the flood valves of this tank are operated hydraulically from remote control; although, in an emergency, they may be operated manually.

Hydraulics are also used in many other ways aboard the submarine. The periscope is raised and lowered, the submarine is steered, and the bow and stern planes are controlled by means of hydraulic systems. The windlass and capstan system, used in mooring the submarine, is hydraulically operated, and many more applications of hydraulics can be found aboard the submarine.

The Accumulator

In some hydraulic systems, oil is kept under pressure in a container called an accumulator. Figure 11-14 shows you this large cylinder, into the top of which oil is pumped. A free piston

divides the cylinder into two parts. Compressed air is forced in below the piston at a pressure of, say, 600 psi. Oil is then forced in on top of the piston. As the pressure above it increases, the piston is forced down, and squeezes the air into a smaller space. Air is elastic—it can be compressed under pressure—but it will expand as soon as the pressure is reduced. When oil pressure is reduced, relatively large quantities of oil under working pressure are instantly available to operate hydraulic rams or motors any place on the sub.

SUMMARY

The working principle of all hydraulic mechanisms is simple enough. Whenever you find an application that seems a bit hard to understand, keep these points in mind—

Hydraulics is the term applied to the behavior of enclosed liquids. Machines which are operated by liquids under pressure are called hydraulic machines.

Figure 10-13.—Submarine special ballast tank (safety tank).

131.53

Liquids are incompressible. They cannot be squeezed into spaces smaller than they originally occupied.

A force applied on any area of a confined liquid is transmitted equally to every part of the liquid.

In hydraulic cylinders, the relation between the force exerted by the larger piston to the force applied on the smaller piston is the same as the relation between the area

of the larger piston and the area of the smaller piston.

Some of the advantages of hydraulic machines are—

Tubing is used to transmit forces, and tubing can readily transmit forces around corners.

Little space is required for tubing.

Few moving parts are required.

Efficiency is high, generally 80-95%.

Figure 10-14.—This keeps pressure on tap.

131.54

CHAPTER 11

MACHINE ELEMENTS AND BASIC MECHANISMS

MACHINE ELEMENTS

Any machine, however simple, utilizes one or more basic machine elements or mechanisms in its makeup. In this chapter we will take a look at some of the more familiar elements and mechanisms used in naval machinery and equipment.

BEARINGS

In chapter 7 we saw that wherever two objects rub against each other, friction is produced. If the surfaces are very smooth, there will be little friction; if either or both are rough, there will be more friction. **FRICTION** is the resistance to any force that tends to produce motion of one surface over another. When you are trying to start a loaded hand truck rolling, you have to give it a hard tug (to overcome the resistance of static friction) to get it started. Starting to slide the same load across the deck would require a harder push than starting it on rollers. That is because rolling friction is always less than sliding friction. To take advantage of this fact, rollers or bearings are used in machines to reduce friction. Lubricants on bearing surfaces reduce the friction even further.

A bearing is a support and guide which carries a moving part (or parts) of a machine and maintains the proper relationship between the moving part or parts and the stationary part. It usually permits only one form of motion, as rotation, and prevents any other. There are two basic types of bearings: sliding type (plain bearings), also called friction or guide bearings, and anti-frictional type (roller and ball bearings).

Sliding Type (Plain) Bearings

In bearings of this type a film of lubricant separates the moving part from the stationary

part. There are three types of sliding motion bearings in common use: Reciprocal motion bearings, journal bearings, and thrust bearings.

1. **RECIPROCAL MOTION BEARINGS** provide a bearing surface on which an object slides back and forth. They are found on steam reciprocating pumps, where connecting rods slide on bearing surfaces near their connections to the pistons. Similar bearings are used on the connecting rods of large internal-combustion engines, and in many mechanisms operated by cams.

2. **JOURNAL BEARINGS** are used to guide and support revolving shafts. The shaft revolves in a housing fitted with a liner. The inside of the liner, on which the shaft bears, is made of babbitt metal or similar soft alloy (antifriction metal) to reduce friction. The soft metal is backed by a bronze or a copper layer, and that has a steel back for strength. Sometimes the bearing is made in two halves, and is clamped or screwed around the shaft (fig. 11-1). It is also called a laminated sleeve bearing.

Under favorable conditions the friction in journal bearings is remarkably small. However, when the rubbing speed of a journal bearing is very low or extremely high, the friction loss may become excessive when compared with the performance of a rolling surface bearing. A good example is the railroad car, now being fitted with roller bearings to eliminate the "hot box" troubles of journal bearings.

Heavy-duty bearings have oil circulated around and through them and some have an additional cooling system that circulates water around the bearing. Although revolving the steel shaft against babbitt metal produces less friction (and therefore less heat and wear) than steel against steel, it is still a problem to keep the parts cool. You know what causes a "burned out bearing" on your car, and how to prevent it. The same care and lubrication are necessary on all Navy equipment, only more so, because

5.20

Figure 11-1.—Babbitt-lined bearing in which steel shaft revolves.

there is a lot of equipment, and many lives depend on its continued operation.

3. **THRUST BEARINGS** are used on rotating shafts, such as those supporting bevel gears, worm gears, propellers, and fans. They are installed to resist axial thrust or force and to limit

axial movement. They are used chiefly on heavy machinery, such as Kingsbury thrust bearings used in heavy marine propelling machinery (figs. 11-2 and 11-3). The base of the housing holds an oil bath, and the rotation of the shaft continually distributes the oil. The bearing consists of a thrust collar on the propeller shaft and two or more stationary thrust shoes on either side of the collar. Thrust is transmitted from the collar through the shoes to the gear housing and the ship's structure to which the gear housing is bolted.

Antifrictional Or Roller and Ball Bearings

You have had first-hand acquaintance with ball bearings since you were a child. They are what made your roller skates or bicycle wheels spin freely. If any of the little steel balls came out and were lost, your roller skates screeched and groaned. The balls or rollers are of hard, highly polished steel. The typical bearing consists of two hardened steel rings (called RACES), the hardened steel balls or rollers, and a SEPARATOR. The motion occurs between the race surfaces and the rolling elements. There

Figure 11-2.—Kingsbury pivoted-shoe thrust bearing.

38.85:.86X

38.86.1

Figure 11-3.—Diagrammatic arrangement of a Kingsburg thrust bearing, showing oil film.

are seven basic types of antifrictional bearings (fig. 11-4).

1. Ball bearings
2. Cylindrical roller bearings
3. Tapered roller bearings
4. Self-aligning roller bearings with spherical outer raceway
5. Self-aligning roller bearings with spherical inner raceway
6. Ball thrust bearings
7. Needle roller bearings

Roller bearing assemblies are usually easy to disassemble for inspection, cleaning, and replacement of parts. Ball bearings, however, are assembled by the manufacturer and installed, or replaced, as a unit. Sometimes maintenance publications refer to roller and ball bearings as being either thrust or radial bearings. The difference between the two depends on the angle of intersection between the direction of the load and the plane of rotation of the bearing. Figure 11-5A shows a radial ball bearing assembly. The load here is pressing outward along the radius of the shaft. Now suppose a strong thrust were to be exerted on the right end of the shaft, tending to move it to the left. You can see that the radial bearing is not designed to support this axial thrust. Even putting a shoulder between the load and the inner race wouldn't do. It would just

pop the bearings out of their races. The answer is to arrange the races differently, as in figure 11-5B. Here is a thrust bearing. With a shoulder under the lower race, and another between the load and the upper race, it will handle any axial load up to its design limit. Sometimes bearings are designed to support both thrust and radial loads. This is the explanation of the term **RADIAL THRUST** bearings. The tapered roller bearing in figure 11-6 is an example.

Antifriction bearings require smaller housings than other bearings of the same load capacity, and can operate at higher speeds.

SPRINGS

Springs are elastic bodies (generally metal) which can be twisted, pulled, or stretched by some force, and which have the ability to return to their original shape when the force is released. All springs used in naval machinery are made of metal—usually steel, though some are of phosphor bronze, brass, or other alloys. A part that is subject to constant spring thrust or pressure is said to be **SPRING LOADED**. (Some components that appear to be spring loaded are actually under hydraulic or pneumatic pressure, or are moved by weights.)

Functions of Springs

Springs are used for many purposes, and one spring may serve more than one purpose. Listed below are some of the more common of these functional purposes. As you read them, try to think of at least one familiar application of each.

1. To store energy for part of a functioning cycle.
2. To force a component to bear against, to maintain contact with, to engage, to disengage, or to remain clear of, some other component.
3. To counterbalance a weight or thrust (gravitational, hydraulic, etc.). Such springs are usually called equilibrator springs.
4. To maintain electrical continuity.
5. To return a component to its original position after displacement.
6. To reduce shock or impact by gradually checking the motion of a moving weight.
7. To permit some freedom of movement between aligned components without disengaging them. These are sometimes called take-up springs.

Figure 11-4.—The seven basic types of antifrictional bearings.

5.21

Types of Springs

As you read different books you will find that authors do not agree on classification of types of springs. The names are not as important as the types of work they can do and the loads they can bear. We may say there are three basic types: (1) flat; (2) spiral; (3) helical or coil.

1. FLAT springs include various forms of elliptic or leaf springs (fig. 11-7A (1&2)), made up of flat or slightly curved bars, plates, or leaves, and special flat springs (fig. 11-7A (3)). A special flat spring is made from a flat strip or bar, into whatever shape or design is calculated to be best suited for its position and purpose.

5.21
Figure 11-5.—Ball bearings. A. Radial type;
B. Thrust type.

2. **SPIRAL** springs are sometimes called clock or power springs (11-7B), and sometimes coil springs. A well known example is a watch or clock spring, which is wound (tightened) and then gradually releases the power as it unwinds.

Although there is good authority for calling this spring by other names, to avoid confusion we shall consistently call it **SPIRAL**.

3. **HELICAL** springs, often called spiral, but not in this text (fig. 11-7D), are probably the most common type of spring. They may be used in compression (fig. 11-7D (L)), extension or tension (fig. 11-7D (2)), or torsion (fig. 11-7D (3)). A spring used in compression tends to shorten in action, while a tension spring

84.120
Figure 11-6.—Radial-thrust roller bearing.

lengthens in action. Torsion springs are made to transmit a twist instead of a direct pull, and operate by coiling or uncoiling action.

In addition to straight helical springs, cone, double cone, keg, and volute springs are also classed as helical. These are usually used in compression. A cone spring (fig. 11-7D (4)), often called a valve spring because it is frequently used in valves, is shaped by winding the wire on a tapered mandrel instead of a straight one. A double cone spring (not illustrated) is composed of two cones joined at the small ends, and a keg spring (not illustrated) is two cone springs joined at their large ends.

VOLUTE springs (fig. 11-7D (5)) are conical springs made from a flat bar which is so wound that each coil partially overlaps the adjacent one. The width (and thickness) of the material gives it great strength or resistance.

A conical spring can be pressed flat so it requires little space, and it is not likely to buckle sidewise.

4. **TORSION BARS** (fig. 11-7C) are straight bars that are acted on by torsion (twisting force). The bar may be circular or rectangular in cross

Figure 11-7.—Types of springs.

84.131

section, or less commonly in other shapes. It may also be a tube.

5. A special type of spring is a **RING SPRING** or **DISC spring** (not illustrated). It is made of a number of metal rings or discs that overlap each other.

BASIC MECHANISMS

THE GEAR DIFFERENTIAL

A gear differential is a mechanism that is capable of adding and subtracting mechanically. To be more precise, it adds the total revolutions

of two shafts—or subtracts the total revolutions of one shaft from the total revolutions of another shaft—and delivers the answer by positioning a third shaft. The gear differential will add or subtract any number of revolutions, or very small fractions of revolutions, continuously and accurately. It will produce a continuous series of answers as the inputs change.

Figure 11-8 is a cutaway drawing of a bevel gear differential showing all its parts and how they are related to each other. Grouped around the center of the mechanism are four bevel gears, meshed together. The two bevel gears on either side are called "end gears." The two bevel gears above and below are called "spider gears." The long shaft running through the end gears and the three spur gears is called the "spider shaft." The short shaft running through the spider gears, together with the spider gears themselves, is called the "spider."

Each of the spider gears and the end gears are bearing mounted on their shafts and are free to rotate. The spider shaft is rigidly connected with the spider cross shaft at the center block where they intersect. The ends of the spider shaft are secured in flanges or hangers, but they are bearing mounted and the shaft is free to rotate on its axis. It follows then that to rotate the spider shaft, the spider, consisting of the spider cross shaft and the spider gears, must tumble, or spin, on the axis of the spider shaft, inasmuch as the two shafts are rigidly connected.

The three spur gears shown in figure 11-8 are used to connect the two end gears and the spider shaft to other mechanisms. They may be of any convenient size. Each of the two input spur gears is attached to an end gear. An input gear and an end gear together are called a "side" of a differential. The third spur gear is the output gear, as designated in figure 11-8. This is the

Figure 11-8.—Bevel gear differential.

only gear that is pinned to the spider shaft. All of the other gears, both bevel and spur, in the differential are bearing mounted.

Figure 11-9 is an exploded view of a gear differential showing each of its individual parts, and figure 11-10 is a schematic sketch showing the relationship of the principle parts.

How it Works

For the present we will assume that the two sides are the inputs and the gear on the spider shaft is the output. Later it will be shown that any of these three gears can be either an input or an output. Now let's look at figure 11-11. In this hookup the two end gears are positioned by the input shafts, which represent the quantities to be added or subtracted. The spider gears do the actual adding and subtracting. They follow the rotation of the two end gears, turning the spider shaft a number of revolutions proportional to the sum, or difference, of the revolutions of the end gears.

Suppose the left side of the differential is rotated while the other remains stationary, as in block 2 of figure 11-11. The moving end gear will drive the spider gears, making them roll on the stationary right end gear. This motion will turn the spider in the same direction as the input and, through the spider shaft and output gear, the output shaft. The output shaft will turn a number of revolutions proportional to the input.

110.8

Figure 11-10. --The differential. End gears and spider arrangement.

131.55

Figure 11-9. --Exploded view of differential gear system.

If the right side is now rotated and the left side held stationary, as in block 3 of figure 11-11, the same thing will happen. If both input sides of the differential are turned in the same direction at the same time, the spider will be turned by both at once, as in block 4 of figure 11-11. The output will be proportional to the sum of the two inputs. Actually, the spider makes only half as many revolutions as the sum of the revolutions of the end gears, because the spider gears are free to roll between the end gears. To understand this better, let's look at figure 11-12. Here a cylindrical drinking glass is rolled along a table top by pushing a ruler across its upper side. The glass will roll only half as far as the ruler travels. The spider gears in the differential roll against the end gears in exactly the same way. Of course, the answer can be corrected by

110.9 Figure 11-11.—How a differential works.

131.56 Figure 11-12.—The spider makes only half as many revolutions.

using a 2:1 gear ratio between the gear on the spider shaft and the gear for the output shaft. Very often, for design purposes, this gear ratio will be found to be different.

When the two sides of the differential move in opposite directions, the output of the spider shaft is proportional to the difference of the revolutions of the two inputs. This is because the spider gears are free to turn, and are driven in opposite directions by the two inputs. If the two inputs are equal and opposite, the spider gears will turn, but there will be no movement of the spider shaft. If the two inputs turn in opposite directions for an unequal number of revolutions, the spider gears roll on the end gear that makes the lesser number of revolutions, rotating the spider in the direction of the input making the greater number of revolutions. The motion of the spider shaft will be equal to half the difference between the revolutions of the two inputs. A change in the gear ratio to the output shaft can then give us any proportional answer we wish.

We have thus far been describing a hookup wherein the two sides are inputs and the spider shaft the output. As long as it is recognized that the spider follows the end gears for half the sum, or difference, of their revolutions, however, it is not necessary to always use this type hookup. The spider shaft may be used as one input and either of the sides used as the other. The other side will then become the output. This fact permits three different hookups for any given differential, as is illustrated in figure 11-13. Whichever proves the most convenient mechanically may be used.

In chapter 14 of this book, the differential as used in the automobile will be described. This differential is similar in principle, but, as you

Figure 11-13.—Any of these three hookups can be used.

110.9

will see, is somewhat different in its mechanical makeup. In chapter 15 you will be given information on differentials as they are used in computers.

LINKAGES

A linkage may consist of either one or a combination of the following basic parts:

1. Rod, shaft, or plunger
2. Lever
3. Rocker arm
4. Bell crank

These parts combined are used to transmit limited rotary or linear motion. To change the direction of a motion, cams are used with the linkage.

Lever type linkages (fig. 11-14) are used in equipment which has to be opened and closed; for instance, valves in electric-hydraulic systems, gates, clutches, clutch-solenoid interlocks, etc. Rocker arms are merely a variation, or special use, of levers.

Bell cranks are used primarily to transmit motion from a link traveling in one direction to another link which is to be moved in a different direction. The bell crank is mounted on a fixed pivot, and the two links are connected at two points in different directions from the pivot. By properly locating the connection points, the output links can be made to move in any desired direction.

All linkages require occasional adjustments or repair, particularly when they become worn. To make the proper adjustments, a person must be familiar with the basic parts which constitute

a linkage. Adjustments are normally made by lengthening or shortening the rods and shafts by means of a clevis or turnbuckle.

COUPLINGS

In a broad sense, the term "coupling" applies to any device that holds two parts together. Line shafts which are made up of several shafts of different lengths may be held together by any of several types of shaft couplings. When shafts are very closely aligned, the sleeve coupling, as in figure 11-15, may be used. It consists of a metal tube slit at each end. The slitted ends enable the clamps to fasten the sleeve securely to the shaft ends. With the clamps tightened, the shafts are held firmly together and turn as one shaft. The sleeve coupling also serves as a convenient device for making adjustments between units. The weight at the opposite end of the clamp from the screw is merely to offset the weight of the screw and clamp arms. By distributing the weight more evenly, shaft vibration is reduced.

The Oldham coupling, named for its inventor, may be used to transmit rotary motion between shafts which are parallel but not necessarily always in perfect alignment.

An Oldham coupling (fig. 11-16), consists of a pair of disks, one flat and the other hollow. These disks are pinned to the ends of the shafts. A third (center) disk, with a pair of lugs projecting from each face of the disk, fits into the slots between the two end disks and thus enables one shaft to drive the other shaft. A coil spring, housed within the center and the hollow end disk,

131.57

Figure 11-14.—Linkages.

forces the center disk against the flat disk. When the coupling is assembled on the shaft ends, a flat lock spring is slipped into the space around the coil spring. The ends of the flat spring are formed so that when the flat spring is pushed into the proper place, the ends of the spring are pushed out and locked around the lugs. A lock wire is passed between the holes drilled through the projecting lugs to guard the assembly. The coil spring compensates for any change in shaft length. (Shaft length may vary due to changes in temperature.)

12.51

Figure 11-15.—Sleeve coupling.

The disks, or rings, connecting the shafts allow a small amount of radial play, and this allows a small amount of misalignment of the shafts as they rotate. Oldham type couplings can be easily connected and disconnected.

A universal joint is the answer when two shafts not in the same plane must be coupled. Universal joints may have various forms. They are used in nearly all types and classes of machinery. An elementary universal joint, sometimes called a Hooke joint (fig. 11-17), consists of two U-shaped yokes fastened to the ends of the shafts to be connected. Within these yokes is a cross-shaped part which holds the yokes together and allows each yoke to bend, or pivot, one with respect to the other. With this arrangement, one shaft can drive the other even though the angle between the two is as great as 25° from alignment. Figure 11-18 shows a ring and trunnion type of universal joint. This is merely a slight modification of the old Hooke joint. This type is commonly used in automobile drive shaft systems. Two, and sometimes three, are utilized. You will read more about these in chapter 14 of this book. Another type of universal joint is used where a smoother torque transmission is desired and less structural strength is required. This is the Bendix-Weiss universal joint (fig. 11-19). In this type of joint, four large balls transmit the rotary force, with a smaller ball as a spacer. With the Hooke type of universal joint, a whipping motion occurs as the shafts rotate—the amount of whip depending on the degree of shaft misalignment. The Bendix-Weiss joint does not have this disadvantage; it

Figure 11-16.—Oldham coupling.

12.52

transmits rotary motion with a constant angular velocity. This type of joint is both more expensive to manufacture and of less strength than the Hooke types, however.

The following four types of couplings are also used extensively in naval equipment:

1. The fixed (sliding lug) coupling is non-adjustable; however, it does allow for a small amount of misalignment in shafting (fig. 11-20).
2. The flexible coupling (fig. 11-21), connects two shafts by means of a metal disk. Two coupling hubs, each splined to its respective shaft, are bolted to the metal disk. The flexible coupling provides a small amount of flexibility to allow for a slight axial misalignment of the shafts.
3. The adjustable (vernier) coupling provides a means of finely adjusting the relationship of two interconnected rotating shafts, (fig. 11-22). By loosening a clamping bolt and turning an adjusting worm, one shaft may be rotated while the other remains stationary. When the proper relationship is attained, the clamping bolt is retightened, locking the shafts together again.

4. The adjustable flexible (vernier) coupling (fig. 11-23) is simply a combination of the flexible disk coupling and the adjustable (vernier) coupling.

CAM AND CAM FOLLOWERS

A cam is a specially shaped surface, projection, or groove whose movement with respect to a part in contact with it (cam follower) drives the cam follower in another movement in response. A cam may be a projection on a revolving shaft (or on a wheel) for the purpose of changing the direction of motion from rotary to up-and-down, or vice versa. It may be a sliding piece or a groove to impart an eccentric motion. Some cams do not move at all, but cause a change of motion in the contacting part. Cams are not ordinarily used to transmit power in the sense that gear trains are. They are generally used to modify mechanical movement, the power for which is furnished through other means. They may control other mechanical units, or lock together or synchronize two or more engaging units.

5.34

Figure 11-19.—Bendix-Weiss universal joint.

5.34

84.133.3

Figure 11-20.—Fixed coupling.

Types and Uses

Cams are of many shapes and sizes and are widely used in machines and machine tools (fig. 11-24). Cams may be classified as:

1. Radial or plate cams
2. Cylindrical or barrel cams
3. Pivoted beams

A similar grouping of types of cams is: Drum or barrel cams; edge cams; face cams.

The drum or barrel cam has a path for the roll or follower cut around the outside, and imparts a to-and-fro motion to a slide or lever in a plane parallel to the axis of the cam. Sometimes these cams are built up on a plain drum with cam plates attached.

Plate cams are used in 5''/38 and 3''/50 guns to open the breechblock during counter-recoil.

Edge or peripheral cams, also called disc cams, operate a mechanism in one direction only, gravity or a spring being relied upon to hold the cam roll in contact with the edge of the cam. The shape of the cam may be made to suit the action required, such as heart shape.

Face cams have a groove or roll path cut in the face and operate a lever or other mechanism positively in both directions, as the roll is always guided by the sides of the slot. Such a groove can be seen on top of the bolt of the Browning machine gun, caliber .30, or in fire control cams. The shape of the groove may give its name to the cam, as for example, constant lead cam, square cam, run-out cam.

The toe and wiper cam shown in figure 11-24 (d) is an example of a pivoted beam.

CLUTCHES

TYPES

A clutch is a form of coupling which is designed to connect or disconnect a driving and a driven member for stopping or starting the driven part. There are two general classes of clutches—positive clutches and friction clutches.

Positive Clutches. Positive clutches have teeth which interlock. The simplest is the jaw or claw type (fig. 11-25A), which is usable only at low speeds. The spiral claw or ratchet type (fig. 11-25B) cannot be reversed. An example of a clutch is seen in bicycles—it engages the rear sprocket with the rear wheel when the pedals are pushed forward, and lets the rear wheel revolve freely when the pedals are stopped.

Friction Clutches. The object of a friction clutch is to connect a rotating member to one that is stationary, to bring it up to speed, and to transmit power with a minimum of slippage. Figure 11-25C shows a cone clutch commonly used in motor trucks. They may be single-cone or double-cone. Figure 11-25D shows a disc clutch, also used in autos. A disc clutch may also have a number of plates (multiple-disc clutch). In a series of discs, each driven disc is located between two driving discs. You may have had experience with a multiple-disc clutch on your car. The Hele-Shaw clutch is a combined conical-disc clutch (fig. 11-25E). The groove permits circulation of oil, and cooling. Single-disc clutches are frequently dry clutches (no lubrication); multiple-disc clutches may be dry or wet (lubricated or run in oil).

84.133.2

Figure 11-21.—Flexible coupling.

131.58

Figure 11-22.—Adjustable (vernier) coupling.

Figure 11-23.—Adjustable flexible (vernier) coupling.

11.133.4

Magnetic clutches are a recent development in which the friction surfaces are brought together by magnetic force when the electricity is turned on (fig. 11-25F). The induction clutch transmits power without contact between driving and driven members.

Expanding clutches or rim clutches are named according to the way the pressure is applied to the rim—block, split-ring, band, or roller. In one type of expanding clutch a powerful effect is gained by the expanding action of right-and left-hand screws as a sliding sleeve is moved along a shaft, and expands the band

against the rim. The centrifugal clutch is a special application of a block clutch.

Coil clutches are used where heavy parts are to be moved, as in a rolling mill. Great friction is caused by the grip of the coil when it is thrust onto a cone on the driving shaft, yet the clutch is very sensitive to control.

Pneumatic and hydraulic clutches are used on Diesel engines and transportation equipment. Hydraulic couplings (fig. 11-25G), which serve also as clutches, are used in the hydraulic A-end of electric-hydraulic gun drives.

CHAPTER 12

COMPLEX MACHINES

We've been studying only the more simple machines so far. Now that we've learned about them, let's take a look at some complex machines. One of the first things you should learn is to recognize the simple machines which make up a complex machine; for a complex machine is only a combination of simple machines. In the examples given in this chapter, look first for the simple machines. If you've been studying well, you should be able to predict what will happen when a force is applied at a given point in a simple machine. Make a step-by-step analysis, and you'll discover that complex machines are not as complicated or mysterious as they first appear to be.

PORTHOLE CLOSER-BLANKET PULLER-UPPER

Take a good look at figure 12-1 and read the directions for operation. This machine was invented by a guy named Oscar. Sea water entering open port is caught in helmet (1) hung on rubber band. Rubber stretches and helmet is pushed down against shaft of Australian spear (2). Head of spear tips over box of bird seed (3) which falls in cage (4) where parrot (5) bends over to pick it up. Board strapped on parrot's back pulls on string (6) which releases arrow (7) and slams the port shut. Breeze from closing port turns page on calendar (8) to new day.

In the meantime, water falling over water-wheel (9) turns gears (10) which wind string (11) on drum (12). This pulls blanket up over Oscar. Arm (13) pulls on cord (14) and raises board under alarm clock (15) sliding same into bucket of water.

In case of mechanical breakdown at any point in the system, helmet is tipped by off-center peg (16) emptying water into funnel (17). Pipe (18) directs water onto Elmer, who is sleeping below. The theory is that Elmer will get up and do something about that open port--or about Oscar.

You'll probably agree that this nightmare is a complex machine. But, if you look carefully, you can see that Oscar has put together several simple machines to make this complicated device. He has used a couple of levers, several blocks, a gear train, and you can even find an inclined plane under the alarm clock.

While this gadget is nonsensical, it does call attention to the important fact that a complex machine is nothing more than a combination of two or more simple machines, conveniently arranged to do the job at hand. It makes no difference how big or complicated the machine is, you can figure out how it works if you understand the operation of the simple machines from which it is made. Just as you did with Oscar's Goldberg, always start at the point where the energy is applied and follow the movement systematically, step-by-step, to the business end.

FUEL-OIL-HATCH COVER

Here's a complex mechanism that is easy to figure out. The hatch cover in figure 12-2 weighs a couple of hundred pounds; and the device which raises it is a complex machine. It is complex because it consists of two simple machines--a jackscrew and a first-class lever.

First locate the point where you apply a force to the machine. That wrench handle seems a likely spot. Remember that you can consider this handle as if it were the spoke of a wheel. Suppose you turn this handle in a counter-clockwise direction. That will cause the nut n to move upward along the threaded bolt. One complete turn of the handle will cause the nut to move upward a distance equal to the pitch of the thread on the bolt. The collar c follows the nut up and permits the lever arm l to rise. The other part of the lever arm L will move downward. Since l is much shorter than L, the downward movement of the cover will be much greater

131.59
Figure 12-1.—A complex machine.

than the upward movement of the collar. It's a "speed-up" arrangement.

The hatch cover is closed by turning the handle counterclockwise, and is opened by turning the handle clockwise. This combination of two simple machines is better mechanically than one machine.

Here's how to go about figuring out how a complex machine works. Locate the point where the energy is applied and look over the part of the machine next in line. You say to yourself, "Oh, yeah, this is really a jackscrew"—or a wheel and axle, or whatever the machine happens to be. "If I turn it clockwise, then the piece right here will move so. That's going to cause this arm to move to the right. And since the arm is part of a first-class lever, the other end will move over to here to the left." In every case, you follow through in a similar manner from one part to another—carefully determining the direction and magnitude of the motion.

Perhaps you will want to know the size of the force that is exerted at some point in the machine, or perhaps the mechanical advantage up to a point. Remember that the mechanical advantage of a complex machine is equal to the

product of the mechanical advantage of each simple machine from which it is made.

Assume some numerical values for the hatch cover in figure 12-2 and see how you can calculate the mechanical advantage. For example, allow 18 inches for the length of the wrench from the end of the handle to the center of the bolt. Let the pitch of the thread be 1/4 inch. The collar is attached to arm 15 inches from the fulcrum, and the center of the cover lies 18 inches from the fulcrum along arm L.

The theoretical mechanical advantage of the jackscrew can be found by using the formula—

$$\begin{aligned} \text{M. A.} &= \frac{2\pi r}{p} \\ &= \frac{2 \times 3.14 \times 18}{1/4} = \frac{113}{1/4} = 452 \end{aligned}$$

Since jackscrews rarely have an efficiency of better than 30 percent, you'd be wise to multiply this theoretical mechanical advantage by 0.30, which gives an actual mechanical advantage of $452 \times 0.30 = 136$ for this part of the machine.

Now figure what the lever action does for you. The theoretical mechanical advantage of a lever system can be found by dividing the length of the resistance arm by the length of the effort arm.

$$\text{M. A.} = \frac{1}{L} = \frac{5}{18} = 0.278$$

Notice that the lever gives you a mechanical advantage of less than one. Whenever the M.A. is less than one, you know that either the speed or the distance of motion has been magnified at the expense of force. In this case, you can afford to sacrifice force for distance.

The overall mechanical advantage of the machine is equal to the product of the two mechanical advantages, or $136 \times 0.278 = 37.8$. This is the standard method for figuring the M. A. of complex machines.

A WATERTIGHT DOOR

Figure 12-3 shows you a watertight door—a complex machine that is a combination of a wheel-and-axle and a system of levers. That big center handle A is the point of input, which is the place to start. If you pull the handle to the right, point a on drive link 1 moves to the right. That's going to make point b on the same link move to the left. Now look at drag link 2.

Figure 12-2.—A not-too-complex machine.

131.60

It will be moved to the left. Point a on drag line 2 moves in the direction indicated by the arrow. That action moves the outer—or right-hand—end of the bellcrank 3 upward, and the dog is extended to the locking position. At the same time drag link 4 moves downward—because it is pivoted to the left-hand end of bell-crank 3. If you follow the movement of link 4 you will see that as its end a moves down, it raises the end b of bellcrank 5 into the locking position.

Now come back to the end b of lever arm 2. Its motion is indicated by the arrow. End b moves lever 6 outward and into the locking position, and at the same time causes arm 7 to move

downward. This motion causes lever 8 to be swung in a clockwise direction until it too locks. You can see that lever arm 9 follows the movement of 8 and thus causes the dog at the top of the door to swing into the locked position.

Probably, at first glance, this mechanism looked highly complicated. But it isn't so tough to figure out, after all.

THE TYPEWRITER

The standard typewriter (fig. 12-4) is a good example of basic, or simple, machines combined

Figure 12-3.—It works too. 131.61

to make up a complex machine. In the following text and illustrations, see how many basic machines you can identify.

CONSTRUCTION AND OPERATION

The keyboard of a typewriter contains all the keys, bars, levers, etc., which are used when operating the machine.

Each type key operates a type bar with a type head having two characters (top and bottom). When a key is depressed, the type head is carried up by a system of levers into the type guide where it strikes a ribbon in front of paper on the platen (roller) and prints one of the characters (soldered on the type head).

The bar at the lower front position of the keyboard is for spacing the escapement mechanism. There is a SHIFT key on each side of the

keyboard for shifting the type bars and segments up and down, as necessary, in order to use characters in the upper and lower positions on the type heads. Other keys are for backspacing, setting and clearing the tabulator mechanism, margin releasing, and so forth. There is also a ribbon selector lever, and another lever for changing direction of the ribbon.

A typewriter carriage is positioned on or between rails, and rides upon some type of roller or ball bearings. This carriage includes the platen and all parts of the typewriter which ride with it. The energy which drives the carriage while the machine is being operated comes from a mainspring enclosed in a metal drum. A ratchet wheel and pawl hold the mainspring in the position desired for a certain amount of tension. A draw band connects the end of the mainspring to the right end of the carriage.

The carriage rack, through the escapement mechanism (explained later), controls the space-by-space movement of the carriage. The teeth of the rack mesh with the escapement wheel pinion. The rack and pinion are conventional spur gear and rack assemblies. The pinion, when turned by movement of the carriage rack, turns the escapement wheel. The movement of the escapement wheel is limited by the escapement rocker, which moves forward and backward each time a key or the space bar is depressed and released, moving the carriage one space. Thus the escapement rocker allows the carriage to move only one type space each time a key or the space bar is struck. Movement of the carriage for each type space is controlled by the escapement wheel held by the LOOSE dog of the escapement rocker. The escapement wheel may rotate during regular typing only by the disengagement of the loose dog from the escapement wheel. When the escapement wheel shaft turns, it also feeds the ribbon through the ribbon guide.

The platen holds and controls the paper in the typewriter carriage and serves as a backstop for the typeface when it strikes the paper. At the left end of the platen there is a ratchet, which is held in position by a detent (shown later), until it is moved by the carriage return lever on the left of the carriage. The function of this ratchet is to establish evenly spaced typed lines on the paper.

In the middle of the left platen knob in figure 12-4 a variable line spacer is indicated. This variable line spacer is actually a clutch between the ratchet and the platen; it holds the platen ratchet in a fixed, locked relation to the platen. By pushing the variable line spacer in with the

91

Figure 12-4.—External parts of a standard typewriter.

61.38X

left hand, the operator releases the clutch and can then turn the FREE platen to any desired position, forward or backward, with either hand. The line finder mechanism on a typewriter releases the ratchet detent and enables the operator to return the platen to an established writing line without using the variable mechanism.

ESCAPEMENT MECHANISM

The escapement mechanism (fig. 12-5) is the "heart" of a typewriter. It controls movement of the carriage during typing, allowing it to move a prescribed distance for each actuation of the escapement dogs (illustrated). The escapement is actuated once every time a type key is depressed and released, or once with each actuation of the space bar.

An escapement consists primarily of a wheel (with teeth on its perimeter) which works in conjunction with two holding dogs in a pivoted rocker mechanism. Study the illustration. As the dogs are moved back and forth, the wheel teeth contact the dogs alternately, resulting in the rotation of the wheel in EQUAL movements or steps.

The escapement rocker rocks forward and backward with respect to the front of the typewriter. This rocker contains the loose dog (catch) and the rigid (stationary) dog. As the escapement rocker pivots on a pivot pin and a pivot screw, it disengages the loose dog from an escapement wheel tooth and permits the escapement wheel to rotate. As the loose dog moves

off an escapement wheel tooth, the stationary dog moves between the teeth of the escapement wheel, limiting the rotation of the escapement wheel to the distance from one tooth to another.

When a typewriter is not in use, one tooth of the escapement wheel rests against the LOOSE DOG. Note the position of the loose dog in figure 12-5 (rear view). Tension of the carriage main-spring creates a force on the escapement wheel and overcomes the tension of the loose dog spring and forces the loose dog against a stop. When a key is depressed, or the space bar is depressed, the upper portion of the escapement dog body is rocked to the rear, moving the loose dog out of the path of the wheel tooth. At the same time, the rigid dog is moved into the path of the wheel tooth and the tooth stops against the rigid dog. When the loose dog is disengaged from an escapement wheel tooth, the loose dog spring pulls the loose dog to a position halfway between the next tooth and the one from which it was disengaged.

When the escapement mechanism returns to its normal position, the loose dog engages an escapement wheel tooth and is forced back against the loose dog stop by the pull of the main-spring on the carriage. The escapement is then completely restored and ready for the next cycle.

The sequence of mechanical action which takes place during typing is as follows:

1. When a key is struck (depressed) with sufficient force to type, the ribbon rises to cover the type.

Figure 12-5.—Escapement mechanism.

61.39X

2. The type prints on the paper and the ribbon is advanced 1/2 space by the ribbon feed mechanism.
3. The escapement rocks, allowing the escapement wheel to advance 1/2 space; and the escapement wheel pinion and carriage feed rack allow the carriage to move 1/2 space.
4. The escapement returns to its original position, allowing the carriage to move 1/2 space and the ribbon to advance 1/2 space.

TYPE BAR MECHANISM

The type bar mechanism carries the type bar up to the platen when a key is depressed. The manner in which this mechanism works is illustrated in figure 12-6. When a type key is depressed, it pivots and depresses a spring beneath (key lever tension spring). At the same time, it pulls the bell crank forward and causes it to pivot on the fulcrum wire which passes through its base. A wire link between the bell crank and the type bar then pulls the base of the type bar forward, causing it to pivot on the fulcrum wire and move the type bar into the type guide (fig. 12-6). When the type bar goes into the type guide, the bar pushes the universal bar back, causing the hunter rod to trip the escapement dogs and allow the carriage to move one space. The segment stop ring (fig. 12-6), called the WHIP, prevents the type bar from springing, thus ensuring clear printing on the paper. When the key is released, the key lever tension spring (plus the weight of the type bar) forces the key lever up, returning the type bar action mechanism to its REST position.

While the type bar action mechanism is operating, the key lever and the ribbon universal bar also actuate the ribbon lift mechanism.

RIBBON DRIVE MECHANISM

The function of the ribbon drive mechanism is to move the ribbon from one spool to another in definite increments each time a key or the space bar is depressed, and to raise the ribbon to the line of type. Refer to figure 12-7 as you study how the ribbon drive mechanism works.

When the typewriter carriage moves one space to the left, the escapement wheel (fig. 12-7) rotates the distance of one tooth. A small gear on the escapement wheel shaft meshes with a small gear on the ribbon feed shaft, causing

a sprocket and chain on the other end of the shaft to rotate. The chain which passes over this sprocket drives another sprocket wheel on the right end of the ribbon drive shaft (fig. 12-7). Two idler pulleys guide the drive chain and maintain proper tension on it.

When the drive chain turns the large sprocket wheel on the ribbon drive shaft, a small gear on the drive shaft meshes with a ribbon spool shaft gear (right or left) and drives the ribbon spool shaft. When the ribbon spool shaft revolves, it turns a ribbon spool on top and winds the ribbon in small increments onto it. If the ribbon drive shaft is shifted to the right, automatically or manually, the right drive shaft gear meshes with the right ribbon spool shaft gear and revolves the ribbon spool shaft. When the ribbon drive shaft is shifted to the left, the gear on its left end drives the left ribbon spool shaft and winds the ribbon to the left.

Ribbon Drive Shaft Detent

You can change the direction of a typewriter ribbon by shifting a reverse lever (fig. 12-7) to the right or left. A slot in the lever limits the amount of space the lever may be moved, and a small spring retains it in the position to which it is moved. The rear arm of the reverse lever fits in a notch in the collar on the left end of the ribbon drive shaft, and moves the shaft to the right or left when the ribbon reverse lever is moved.

Ribbon Reverse Mechanism

The function of the ribbon reverse mechanism is to reverse the ribbon automatically from a full ribbon spool to the empty ribbon spool. The action of this mechanism ensures utilization of the ink in the full length of the ribbon and the same degree of brightness of color in every line of type. The ribbon reverse mechanism is illustrated in figure 12-7.

Note the ribbon spool, ribbon reverse trigger, ribbon reverse plunger, and the reversing cam on the ribbon drive shaft.

The end of the ribbon is attached to the ribbon spool by a catch. As long as there is one complete turn of ribbon on the ribbon spool, the ribbon reverse trigger is held in the IN position and the trigger holds up the plunger inside the ribbon spool shaft, so that the lower end of the plunger does not come into contact with the

BASIC MACHINES

Figure 12-6.—Type bar action mechanism.

61.40X

reversing cam on the ribbon drive shaft as it rotates.

When a ribbon spool starts its last revolution before becoming completely empty, the ribbon reverse trigger which has been holding the ribbon reverse plunger up, moves OUT from the ribbon

spool and releases its hold on the top of the ribbon reverse plunger. As the ribbon reverse plunger drops down, it moves into the path of a reversing cam on the ribbon drive shaft, causing the drive shaft to move laterally, thereby disengaging the drive shaft gear from the ribbon spool

Figure 12-7.—Ribbon feed mechanism.

61.41X

shaft gear at one end and engaging the drive shaft gear and opposite spool shaft gear at the other end.

As the ribbon starts to wind onto the empty ribbon spool, it pushes the ribbon reverse trigger in, causing the other end of the trigger to engage the slot in the top of the ribbon reverse plunger and raise it above the reversing cam on the ribbon drive shaft.

Ribbon Lift Mechanism

The ribbon lift mechanism lifts the ribbon to a position in which it may be struck by the type when its presence is required, and to let it down when not required (to allow reading of a line that is being typed). Study illustration 12-8 as you follow the description of the operation of this mechanism.

When a type key is depressed, the key lever contacts a prong, immediately beneath, which is connected to the ribbon universal bar (U-bar), causing the U-bar to pivot its top forward. As the U-bar top pivots forward it raises the ribbon guide actuating lever link between the U-bar and the ribbon guide actuating lever. The ribbon guide actuating lever is connected to the ribbon guide (carrier) and raises it when the key is depressed, bringing the ribbon up in position to be struck by the type head. A spring provides tension to restore the ribbon guide actuating lever.

Note that the ribbon guide actuating lever has a horizontal slot in the middle, and the horizontal slot has an indentation in its upper surface. Then note the ribbon guide actuating lever link shift lever connected to the left end of the ribbon-shift shaft. On the right end of the ribbon shift shaft is the ribbon shift detent to which the ribbon bichrome shift lever is connected.

When the ribbon bichrome shift lever is in the BLACK position, the ribbon guide actuating lever link shift lever moves to position the ribbon guide actuating lever link at the front end (black position) of the horizontal slot in the ribbon guide actuating lever. Now, when a key is depressed, the ribbon guide actuating lever moves the ribbon guide in position for the type head to strike the upper (black) portion of the ribbon. If the ribbon bichrome shift lever is moved to the WHITE position (stencil), the ribbon guide actuating lever link shift lever moves the ribbon guide actuating lever link to the center of the horizontal slot in the ribbon guide actuating lever. When type keys are depressed, the ribbon

guide actuating lever link moves up and down in the vertical slot of the ribbon guide actuating lever without moving it, enabling the typist to print characters directly on the stencil because there is no ribbon in front of the type heads. If the ribbon bichrome shift lever is moved to the RED position, the ribbon guide actuating lever link shift lever moves the ribbon guide actuating lever link to the rear end of the slot in the ribbon guide actuating lever. If typing is done with the ribbon guide actuating lever link in this position, the ribbon guide actuating lever carries the ribbon guide high enough for the type heads to strike the lower (red) portion of the ribbon.

Having three positions for setting the ribbon lift mechanism permits efficient use of a standard two-color typewriter ribbon and allows the typist to cut a stencil by merely moving the ribbon bichrome shift lever to the WHITE position.

BACKSPACE MECHANISM

The function of the backspace mechanism is to enable a typist to move the carriage one or more spaces to the right whenever necessary. This mechanism is shown in figure 12-9. When the backspace key lever is depressed, the backspace key lever link causes the bell crank to pivot and transfer the PULL to a horizontal plane. The backspace slide is then moved to the left at the two guide slots shown in the illustration. This action causes a backspacing pawl to engage a tooth on the escapement wheel pinion and turn the pinion clockwise until the pinion pawl on the escapement wheel moves over one tooth on the pinion. Since the carriage rack is engaged with the escapement wheel pinion, the carriage is also moved back one space to the RIGHT.

TABULATOR MECHANISM

The tabulator mechanism of a typewriter enables the typist to move the carriage a definite, predetermined distance by depressing the tabulator bar (fig. 12-10). Refer to this illustration frequently as you study the manner in which the tabulator mechanism works.

If the tabulator stops are set as shown at left-center in figure 12-10 and the tabulator bar is depressed, the tabulator bar frame raises the key set tabulator (KST) stop blade and an arm on the KST stop blade contacts and raises

Figure 12-8.—Ribbon lift mechanism.

61.42X

the tabulator lever actuating plate in front of the KST frame, causing the shaft to rotate. A short arm (shaft arm) attached to the end of this shaft moves down and depresses the tabulator lever, which pivots, and a roller on front of the tabulator lever lifts the carriage feed

rack out of mesh with the escapement wheel pinion, allowing the carriage to move to the left.

By the time the carriage feed rack is raised out of mesh with the pinion, the KST stop blade has moved up into the path of a set tabulator stop, as shown in figure 12-10 (left-center).

Figure 12-9.—Back spacer mechanism.

61.43X

The stop prevents the carriage from moving beyond this point.

The escapement wheel locking pawl, in conjunction with the escapement dogs, prevents the escapement wheel from moving out of position while the feed rack is disengaged. When the tabulator lever actuating plate in front of the KST frame is raised, a yielding device on the left end of the shaft moves against the spring drum brake arm and presses the brakeshoes against the side of the spring drum with enough force to regulate the speed of the carriage.

Tabulator Stop Setting Mechanism

The tabulator stop mechanism stops the carriage at the desired position. When the SET key is depressed with the carriage in any desired position, the key lever raises the stop setting link (lower link), shown in figure 12-11, moving the stop setting link (upper link) down against the stop immediately beneath it, and moves the stop to its lower or SET position. The stop remains in this position until it is cleared.

Tabulator Stop Clearing Mechanism

The tabulator stop clearing mechanism enables you to clear a set tabulator stop by

depressing the TAB-CLEAR key. To clear individual stops, tabulate to the stop which is to be cleared and depress the tab-clear key. The key lever then raises the clearing plunger, which contacts the bottom of the stop and raises it to the cleared or UP position.

To clear all stops which are set, move the carriage to the extreme left. Then depress the TAB-CLEAR key and hold it down while you move the carriage to the extreme right. The bottoms of the tabulator stops contact the beveled portion of the clearing plunger, which raises them to the top of the plunger.

SHIFT MECHANISM

The function of the shift mechanism (fig. 12-12) is to raise and lower the segment and type bars so that the typist may be able to type the upper and lower case characters on the type heads on a common line. When you depress a SHIFT key, the shift mechanism moves the segment and type bars to the DOWN position. By depressing a shift key LOCK next to the shift key, you can retain the segment and type bars in the down position as long as desired. The shift key lock lever is a simple, spring-loaded catch. When the lock is released, the segment returns to the rest position.

Figure 12-10.—Tabulator mechanism.

61.44X

BASIC MACHINES

Figure 12-11.—Tabulator stop setting mechanism.

61.45X

61.46X

Figure 12-12.—Shift mechanism.

Depressing the shift key rotates the shift lock release shaft through a connecting link and an arm secured to the shaft. The shift lock release shaft, through the shift operating link, turns the segment lock release link shaft (illustrated). The

lower toggle arm is secured to the segment lock release link shaft and the upper toggle arm at the toggle arm pivot (fig. 12-12). The upper toggle arm is connected to an adjustment eccentric (shift toggle stud). As the lower toggle arm

BASIC MACHINES

pivots forward, the lock is released and the action of the lower and upper toggle arms pulls the segment bracket (carrying the segment and type bars) down until the upper stop rests against the lower stop.

When a shift key lever, right or left, is released, a spring raises the shift key lever. This reverse action helps to restore the entire mechanism, but the power required to raise the segment bracket is supplied by two springs, one right and one left, which are connected between the segment bracket and the ribbon spool shaft brackets.

When the segment bracket is in the extreme upper position and the key shift lever is up, the lower toggle arm moves slightly over center toward the rear of the machine, locking the segment bracket in the upper position, thus preventing it from bouncing and causing irregular printing on the line.

BELL RINGER MECHANISM

The bell ringer mechanism rings a bell to indicate that the carriage is approaching the tabular stop set for the right margin. Refer to figure 12-13 as you study this mechanism.

As the typewriter carriage moves to the left, the bell trip pawl on the right margin stop moves the bell hammer lever and the hammer away from the bell. When the bell trip pawl moves past the cam portion of the bell hammer lever, the bell

hammer lever is released, allowing the hammer to strike the bell under spring tension.

LINE LOCK MECHANISM

The margin stops arrest the movement of the carriage to the right or left. The line lock, actuated by the margin stop, locks the universal bar to prevent type keys from overtyping on the last letter when the carriage is stopped. The line lock lever also locks the escapement in position to prevent operation of the space bar while the line is locked, and to prevent overspacing when the margin release key is depressed.

When the carriage moves to the left, the margin stop contacts the margin release rod arm (center). See figure 12-14. As the margin release rod moves to the left, the margin release rod arm (right) on its right extremity contacts the line lock actuating lever and moves it to the left. The line lock actuating lever then pivots at the pivot point (fig. 12-14) and pulls the line lock lever comb link connected to the link lock lever to the right, causing the line lock lever to position itself behind the bunter plate and around the bunter rod.

If a key is depressed when the line lock mechanism is in this position, the type bar is prevented from making an impression on the paper by the universal bar bunter plate being stopped by the link lock lever adjusting screw. Because the

Figure 12-13.—Bell ringer mechanism.

61.47X

Figure 12-14.—Line lock mechanism.

61.48X

U-bar cannot move the bunter rod rearwards, this action also prevents the escapement from tripping. If the space bar is depressed with the line lock mechanism in this position, the line lock lever prevents actuation of the escapement by its contact with the bunter rod.

With the link lock mechanism in the position just explained, no more typing can be done on this line until the MARGIN-RELEASE key is depressed, causing the margin release rod to rotate and move the margin release rod arm fastened to it down below the margin stop. Study the illustration. The margin release rod then moves to the right and allows the line lock lever actuating lever to move to the right under spring tension, freeing the line lock lever from the bunter rod and the U-bar bunter plate.

LINE SPACE MECHANISM

A typewriter line space mechanism ensures the same amount of space between lines of type when the adjuster is set for a definite distance.

The manner in which this mechanism works is illustrated in figure 12-15.

There are three positions to which the line space adjuster of a typewriter may be set. The action of the line space pawl on the platen ratchet for all three positions is shown in figure 12-15. Study it carefully. The ratchet wheel in the illustration has 30 teeth (6 lines per inch).

When the line space lever is moved to the RIGHT, the line space pawl contacts a tooth on the platen ratchet and moves it rearwards the amount of space set (position 1, 2, or 3). After the ratchet is moved back to one of the three positions, a detent roller (fig. 12-15) which is engaged with the platen ratchet holds it in place.

PINION STOP SLIDE MECHANISM

The purpose of the pinion stop slide mechanism is to prevent overbanking at the left margin when the carriage is returned with excessive force or speed, and also to prevent underbanking when it is returned with little force. The pinion

Figure 12-15.—Line space mechanism.

61.49X

stop slide (fig. 12-16) maintains the pinion in a fixed position as the carriage is banked. Any yielding of the carriage as a result of excessive force or speed when it banks is compensated for by the spring-loaded carriage feed rack.

As the carriage moves through the last space just before banking, the left margin stop contacts the pinion stop slide actuating slide and moves it to the right until it contacts and stops against the margin release rod arm. By means of the pinion stop slide intermediate lever, the pinion stop slide is moved to the left and the edge of the lip moves into the teeth of the escapement wheel pinion and prevents the pinion from turning. If

the carriage yields enough to equal one space, the yielding device and yield spring on the carriage feed rack (fig. 12-10) yields and allows the rack to remain at a correctly fixed relation with the pinion while the carriage continues until its momentum is expended.

SUMMARY

The operation of complex machines will be much easier for you to understand if you will keep in mind the following points:

A complex machine is nothing more than a combination of two or more simple machines.

Figure 12-16.—Pinion stop slide mechanism.

61.50X

You can figure out how a complex machine works if you understand the operation of the simple machines from which it is made. Look first for the point where energy is applied, and follow the action through step-by-step—carefully determining the DIRECTION and MAGNITUDE of movement at each step.

The mechanical advantage of a complex machine is equal to the PRODUCT of the mechanical advantage of each simple machine from which it is made.

When a machine gives a mechanical advantage of MORE THAN ONE, it multiplies the FORCE of the applied energy. When it gives a mechanical advantage of LESS THAN ONE, it multiplies both the DISTANCE and the SPEED of the applied movement.

More examples of complex machines will be given in the following chapters of this book. None of them should be too difficult for you to understand if you analyze each of them carefully by the methods described in the foregoing.

CHAPTER 13

INTERNAL COMBUSTION ENGINE

The automobile is a familiar object to all of us; and the engine that makes it go is one of the most fascinating and talked about of all the complex machines we use today. In this chapter we will explain briefly some of the operational principles of this machine, and then break it down to its more basic mechanisms. In its makeup you will find many of the devices and basic mechanisms that you have studied earlier in this book. Look for these and the simple machines that make up the engine as you study its operation and construction.

COMBUSTION ENGINE

An engine is defined simply as a machine that converts heat energy to mechanical energy. To fulfill this purpose, the engine may take one of several forms.

Combustion is the act of burning. Internal means inside or enclosed. Thus an internal combustion engine is one in which the fuel burns inside; that is, burning takes place within the same cylinder that produces energy to turn the crankshaft. In external combustion engines, such as steam engines, the combustion takes place outside the engine. Figure 13-1 shows, in simplified form, an external and an internal combustion engine.

The external combustion engine requires a boiler to which heat is applied. This combustion causes water to boil to produce steam. The steam passes into the engine cylinder under pressure and forces the piston to move downward. With the internal combustion engine, the combustion takes place inside the cylinder and is directly responsible for forcing the piston to move downward.

The transformation of heat energy to mechanical energy by the engine is based on a fundamental law of physics which states that gas will expand upon application of heat. The law

also states that when a gas is compressed the temperature of the gas will increase. If the gas is confined with no outlet for expansion, then the pressure of the gas will be increased when heat is applied (as it is in an automotive cylinder). In an engine, this pressure acts against the head of a piston, causing it to move downward.

As you know, the piston moves up and down in the cylinder. The up-and-down motion is known as reciprocating motion. This reciprocating motion (straight line motion) must be changed to rotary motion (turning motion) in order to turn the wheels of a vehicle. A crank and a connecting rod change this reciprocating motion to rotary motion.

All internal combustion engines, whether gasoline or diesel, are basically the same. We can best demonstrate this by saying they all rely on three things—air, fuel, and ignition.

Fuel contains potential energy for operating the engine; air contains the oxygen necessary for combustion; and ignition starts combustion. All are fundamental, and the engine will not operate without any one of them. Any discussion of engines must be based on these three factors and the steps and mechanisms involved in delivering them to the combustion chamber at the proper time.

DEVELOPMENT OF POWER

The power of an internal combustion engine comes from the burning of a mixture of fuel and air in a small, enclosed space. When this mixture burns it expands greatly, and the push or pressure created is used to move the piston, thereby cranking the engine. This movement is eventually sent back to the wheels to drive the vehicle.

Since similar action occurs in all cylinders of an engine, let's use one cylinder in our development of power. The one-cylinder engine

81.41

Figure 13-1.—Simple external and internal combustion engine.

consists of four basic parts as shown in figure 13-2.

First we must have a cylinder which is closed at one end; this cylinder is similar to a tall metal can.

Inside the cylinder is the piston, a movable metal plug, which fits snugly into the cylinder,

but can still slide up and down easily. This up-and-down movement, produced by the burning of fuel in the cylinder, results in the production of power from the engine.

You have already learned that the up-and-down movement is called reciprocating motion. This motion must be changed to rotary motion

65.95

Figure 13-2.—Cylinder, piston, connecting rod, and crankshaft for a one-cylinder engine.

so the wheels or tracks of vehicles can be made to rotate. This change is accomplished by a crank on the crankshaft and a connecting rod which connects between the piston and the crank.

The crankshaft is a shaft with an offset portion, the crank, which describes a circle as the shaft rotates. The top end of the connecting rod is connected to the piston and must therefore go up and down. The lower end of the connecting rod is attached to the crankshaft. The lower end of the connecting rod also moves up and down but, because it is attached to the crankshaft, it must also move in a circle with the crank.

When the piston of the engine slides downward because of the pressure of the expanding gases in the cylinder, the upper end of the connecting rod moves downward with the piston, in a straight line. The lower end of the connecting rod moves down and in a circular motion at the same time. This moves the crank and in turn the crank rotates the shaft; this rotation is the desired result. So remember, the crankshaft and connecting rod combination is a mechanism for the purpose of changing straightline, up-and-down motion to circular, or rotary motion.

BASIC ENGINE STROKES

Each movement of the piston from top to bottom or from bottom to top is called a stroke. The piston takes two strokes (an upstroke and a downstroke) as the crankshaft makes one complete revolution. When the piston is at the top of a stroke, it is said to be at top dead center (TDC). When the piston is at the bottom of a stroke, it is said to be at bottom dead center (BDC). These positions are called rock positions and will be discussed further in this chapter under "Timing." See figure 13-3 and figure 13-7.

The basic engine you have studied so far has had no provisions for getting the fuel-air mixture into the cylinder or burned gases out of the cylinder. There are two openings in the enclosed end of a cylinder. One of the openings, or ports, permits the mixture of air and fuel to enter and the other port permits the burned gases to escape from the cylinder. The two ports have valves assembled in them. These valves, actuated by the camshaft, close off either one or the other of the ports, or both of them, during various stages of engine operation. One of the valves, called the intake valve, opens to admit a mixture of fuel and air into the cylinder.

The other valve, called the exhaust valve, opens to allow the escape of burned gases after the fuel-and-air mixture has burned. Later on you will learn more about how these valves and their mechanisms operate.

The following paragraphs give a simplified explanation of the action that takes place within the engine cylinder. This action may be divided into four parts: the intake stroke, the compression stroke, the power stroke, and the exhaust stroke. Since these strokes are easy to identify in the operation of a four-cycle engine, that engine is used in the description. This type of engine is also called a four-stroke-Otto-cycle engine, because it was Dr. N.A. Otto who, in 1876, first applied the principle of this engine.

INTAKE STROKE

The first stroke in the sequence is called the intake stroke (fig. 13-4). During this stroke, the piston is moving downward and the intake valve is open. This downward movement of the piston produces a partial vacuum in the cylinder, and air and fuel rush into the cylinder past the open intake valve. This is somewhat the same effect as when you drink through a straw. A partial vacuum is produced in the mouth and the liquid moves up through the straw to fill the vacuum.

COMPRESSION STROKE

When the piston reaches bottom dead center at the end of the intake stroke and is therefore at the bottom of the cylinder, the intake valve closes. This seals the upper end of the cylinder. As the crankshaft continues to rotate, it pushes up, through the connecting rod, on the piston. The piston is therefore pushed upward and compresses the combustible mixture in the cylinder; this is called the compression stroke (fig. 13-4). In gasoline engines, the mixture is compressed to about one-eighth of its original volume. (In a diesel engine the mixture may be compressed to as little as one-sixteenth of its original volume.) This compression of the air-fuel mixture increases the pressure within the cylinder. Compressing the mixture in this way makes it still more combustible; not only does the pressure in the cylinder go up, but the temperature of the mixture also increases.

81.42
 Figure 13-3.—Relationship of piston, connecting rod, and crank on crankshaft as crankshaft turns one revolution.

POWER STROKE

As the piston reaches top dead center at the end of the compression stroke and therefore has moved to the top of the cylinder, the compressed fuel-air mixture is ignited. The ignition system causes an electric spark to occur suddenly in the cylinder, and the spark sets fire to the fuel-air mixture. In burning, the mixture gets very hot and tries to expand in all directions. The pressure rises to about 600 or 700 pounds per square inch. Since the piston is the only thing that can move, the force produced by the expanding gases forces the piston down. This force, or thrust, is carried through the connecting rod to the crankpin on the crankshaft. The crankshaft is given a powerful twist. This is called the power stroke (fig. 13-4). This turning effort, rapidly repeated in the engine and carried through gears and shafts, will turn

the wheels of a vehicle and cause it to move along the highway.

EXHAUST STROKE

After the fuel-air mixture has burned, it must be cleared from the cylinder. This is done by opening the exhaust valve just as the power stroke is finished and the piston starts back up on the exhaust stroke (fig. 13-4). The piston forces the burned gases out of the cylinder past the open exhaust valve. The four strokes (intake, compression, power, and exhaust) are continuously repeated as the engine runs.

ENGINE CYCLES

Now, with the basic knowledge you have of the parts and the four strokes of the engine, let

BASIC MACHINES

Figure 13-4.—Four-stroke cycle in a gasoline engine.

54.19

us see what happens during the actual running of the engine. To produce sustained power, an engine must accomplish a definite series of operations over and over again. All you have to do is follow one series of events—intake, compression, power, and exhaust—until they repeat themselves. This one series of events is called a cycle.

Most engines of today are called four-cycle engines. What is meant is four-stroke-cycle, but our habit of abbreviating has eliminated the middle word. Just the same, when you see four-cycle it means there are four strokes of the piston, two up and two down, to each cycle. Then it starts over again on another cycle of the same four strokes.

TWO-CYCLE ENGINE

In the two-cycle engine, the entire cycle of events (intake, compression, power, and exhaust) takes place in two piston strokes.

A two-cycle engine is shown in figure 13-5. Every other stroke in this engine is a power stroke. Each time the piston moves down it is on the power stroke. Intake, compression, power, and exhaust still take place, but they are completed in just two strokes. In figure 13-5 the intake and exhaust ports are cut into the cylinder wall instead of being placed at the top of the combustion chamber as in the four-cycle engine. As the piston moves down on its power stroke, it first uncovers the exhaust port to let

Figure 13-5.—Events in a two-cycle, internal combustion engine.

54.20

burned gases escape and then uncovers the intake port to allow a new fuel-air mixture to enter the combustion chamber. Then, on the upward stroke, the piston covers both ports and, at the same time, compresses the new mixture in preparation for ignition and another power stroke.

In the engine shown in figure 13-5 the piston is shaped so that the incoming fuel-air mixture is directed upward, thereby sweeping out ahead of it the burned exhaust gases. Also, there is an inlet into the crankcase through which the fuel-air mixture passes before it enters the cylinder. This inlet is opened as the piston moves upward, but it is sealed off as the piston moves downward on the power stroke. The downward moving piston slightly compresses the mixture in the crankcase, thus giving the mixture enough pressure to pass rapidly through the intake port as the piston clears this port. This improves the sweeping-out, or scavenging, effect of the mixture as it enters and clears the burned gases from the cylinder through the exhaust port.

FOUR-CYCLE vs TWO-CYCLE ENGINES

You have probably noted that the two-cycle engine produces a power stroke every crankshaft revolution; the four-cycle engine requires two crankshaft revolutions for each power stroke. It might appear then that the two-cycle could produce twice as much power as the four-cycle of the same size, operating at the same speed. However, this is not true. With the two-cycle engine some of the power is used to drive the blower that forces the air-fuel charge into the cylinder under pressure. Also, the burned gases are not completely cleared from the cylinder. Additionally, because of the much shorter period the intake port is open (as compared to the period the intake valve in a four-stroke-cycle is open), a relatively smaller amount of fuel-air mixture is admitted. Hence, with less fuel-air mixture, less power per power stroke is produced as compared to the power produced in a four-stroke cycle engine of like size operating at the same speed and with other conditions being the same. To increase the amount of fuel-air mixture, auxiliary devices are used with the two-stroke engine to ensure delivery of greater amounts of fuel-air mixture into the cylinder.

MULTIPLE-CYLINDER ENGINES

The discussion so far in this chapter has concerned a single-cylinder engine. A single cylinder provides only one power impulse every two crankshaft revolutions in a four-cycle engine and is delivering power only one-fourth of the time. To provide for a more continuous flow of power, modern engines use four, six, eight, or more cylinders. The same series of cycles take place in each cylinder.

In a four-stroke cycle six-cylinder engine, for example, the cranks on the crankshaft are set 120 degrees apart, the cranks for cylinders 1 and 6, 2 and 5, and 3 and 4 being in line with each other (fig. 13-6). The cylinders fire or deliver the power strokes in the following order: 1-5-3-6-2-4. Thus the power strokes follow each other so closely that there is a fairly continuous and even delivery of power to the crankshaft.

TIMING

In a gasoline engine, the valves must open and close at the proper times with regard to piston position and stroke. In addition, the ignition system must produce the sparks at the proper time so that the power strokes can start. Both valve and ignition system action must be properly timed if good engine performance is to be obtained.

Valve timing refers to the exact times in the engine cycle at which the valves trap the mixture and then allow the burned gases to escape. The valves must open and close so that they are constantly in step with the piston movement of the cylinder which they control. The position of the valves is determined by the camshaft; the position of the piston is determined by the crankshaft. Correct valve timing is obtained by providing the proper relationship between the camshaft and the crankshaft.

When the piston is at TDC the crankshaft can move 15° to 20° without causing the piston to move up and down any noticeable distance. This is one of the two rock positions (fig. 13-7). When the piston moves up on the exhaust stroke, considerable momentum is given to the exhaust gases as they pass out through the exhaust valve port, but if the exhaust valve closes at TDC, a small amount of the gases will be trapped and will dilute the incoming fuel-air mixture when the intake valves open. Since the piston has

Figure 13-6.—Crankshaft for a six-cylinder engine.

81.42

little downward movement while in the rock position, the exhaust valve can remain open during this period and thereby permit a more complete scavenging of the exhaust gases.

Ignition timing refers to the timing of the spark at the spark plug gap with relation to the piston position during the compression and power strokes. The ignition system is timed so that the spark occurs before the piston reaches TDC on the compression stroke. This gives the mixture enough time to ignite and start burning. If this time were not provided, that is, if the spark occurred at or after TDC, then the pressure increase would not keep pace with the piston movement.

At higher speeds, there is still less time for the fuel-air mixture to ignite and burn. In order to compensate for this, and thereby avoid power loss, the ignition system includes an advance mechanism that functions on speed.

CLASSIFICATION OF ENGINES

Engines for automotive and construction equipment may be classified in a number of ways: type of fuel used; type of cooling employed; or valve and cylinder arrangement. They all operate on the internal combustion principle, and the application of basic principles of construction to particular needs or systems

Figure 13-7.—Rock position.

81.45

BASIC MACHINES

of manufacture has caused certain designs to be recognized as conventional.

The most common method of classification is by the type of fuel used; that is, whether the engine burns gasoline or diesel fuel.

GASOLINE ENGINES VS DIESEL ENGINES

Mechanically and in overall appearance, gasoline and diesel engines resemble one another. However, in the diesel engine, many parts are somewhat heavier and stronger, so that they can withstand the higher temperatures and pressures the engine generates. The engines differ also in the fuel used, in the method of introducing it into the cylinders, and in how the air-fuel mixture is ignited. In the gasoline engine, air and fuel first are mixed together in the carburetor. After this mixture is compressed in the cylinders, it is ignited by an electrical spark from the spark plugs. The source of the energy producing the electrical spark may be a storage battery or a high-tension magneto.

The diesel engine has no carburetor. Air alone enters its cylinders, where it is compressed and reaches high temperature due to compression. The heat of compression ignites the fuel injected into the cylinder and causes the fuel-air mixture to burn. The diesel engine needs no spark plugs; the very contact of the diesel fuel with the hot air in the cylinders causes ignition. In the gasoline engine the heat from compression is not enough to ignite the air-fuel mixture, therefore spark plugs are necessary.

ARRANGEMENT OF CYLINDERS

Engines are classified also according to the arrangement of the cylinders: inline, with all cylinders cast in a straight line above the crankshaft, as in most trucks; and V-type with two banks of cylinders mounted in a "V" shape above the crankshaft, as in many passenger vehicles. Another not-so-common arrangement is the horizontally opposed engine whose cylinders are mounted in two side rows, each opposite a central crankshaft. Buses often are equipped with this type of engine.

The cylinders are numbered. The cylinder nearest the front of an in-line engine is No. 1. The others are numbered 2, 3, 4, etc., from

front to rear. In V-type engines the numbering sequence varies with the manufacturer.

The firing order (which is different from the numbering order) of the cylinders is usually stamped on the cylinder block or on the manufacturer's nameplate.

VALVE ARRANGEMENT

The majority of internal combustion engines also are classified according to the position and arrangement of the intake and exhaust valves—that is, whether the valves are in the cylinder block or in the cylinder head. Various arrangements have been used, but the most common are L-head, I-head, and F-head (fig. 13-8). The letter designation is used because the shape of the combustion chamber resembles the form of the letter identifying it.

L-Head

In the L-head engines both valves are placed in the block on the same side of the cylinder. The valve-operating mechanism is located directly below the valves, and one camshaft actuates both the intake and exhaust valves.

I-Head

Engines using the I-head construction are commonly called valve-in-head or over-head valve engines, because the valves are mounted in a cylinder head above the cylinder. This arrangement requires a tappet, a push rod, and a rocker arm above the cylinder to reverse the direction of valve movement, but only one camshaft is required for both valves. Some overhead valve engines make use of an overhead camshaft. This arrangement eliminates the long linkage between the camshaft and valve.

F-Head

In the F-head engine, the intake valves normally are located in the head, while the exhaust valves are located in the engine block. This arrangement combines, in effect, the L-head and the I-head valve arrangements. The valves in the head are actuated from the camshaft through tappets, push rods, and rocker arms (I-head arrangement), while the valves in the block are actuated directly from the camshaft by tappets (L-head arrangement).

Figure 13-8.—L-, I-, and F-valve arrangement.

81.46

ENGINE CONSTRUCTION

Basic engine construction varies little, regardless of size and design of the engine. The intended use of an engine must be considered before the design and size can be determined. The temperature at which an engine will operate has a great deal to do with determining what metals must be used in its construction.

To simplify the service parts problem in the field, and also to simplify servicing procedures, the present trend in engine construction and design is toward what is called engine families. There must, of necessity, be many different kinds of engines because there are many kinds of jobs to be done. However, the service and service parts problem can be simplified by designing engines so that they are closely related in cylinder size, valve arrangement, etc. As an example, the GM series 71 engines can be obtained in 2, 3, 4, and 6 cylinders; but they are so designed that the same pistons, connecting rods, bearings, valve operating mechanisms and valves can be used in all 4 engines.

Engine construction, in this chapter, will be broken down into two categories: stationary parts and moving parts.

STATIONARY PARTS

The stationary parts of an engine include the cylinder block, cylinders, cylinder head or heads, crankcase, and the exhaust and intake manifolds. These parts furnish the framework of the engine. All movable parts are attached to or fitted into this framework.

Engine Cylinder Block

The engine cylinder block is the basic frame of a liquid-cooled engine, whether it be in-line, horizontally-opposed, or V-type. The cylinder block and crankcase are often cast in one piece which is the heaviest single piece of metal in the engine. (See fig. 13-9). In small engines, where weight is an important consideration, the crankcase may be cast separately. In most large diesel engines, such as those used in power plants, the crankcase is cast separately and is attached to a heavy stationary engine base.

In practically all automotive and construction equipment, however, the cylinder block and crankcase are cast in one piece. In this course we are concerned primarily with liquid-cooled engines, of this type.

Figure 13-9.—Cylinder block and components.

The cylinders of a liquid-cooled engine are surrounded by jackets through which the cooling liquid circulates. These jackets are cast integrally with the cylinder block. Communicating passages permit the coolant to circulate around the cylinders and through the head.

The air-cooled engine cylinder differs from that of a liquid-cooled engine in that the cylinders are made individually, rather than cast in block. The cylinders of air-cooled engines have closely spaced fins surrounding the barrel; these fins provide a greatly increased surface area from which heat can be dissipated. This is in contrast to the liquid-cooled engine, which has a water jacket around its cylinders.

Cylinder Block Construction

The cylinder block is cast from gray iron or iron alloyed with other metals such as nickel, chromium, or molybdenum. Some light weight engine blocks are made from aluminum.

Cylinders are machined by grinding, and/or boring, to give them the desired true inner surface. During normal engine operation, cylinder walls will wear out-of-round, or they may become cracked and scored if not properly lubricated or cooled. Liners (sleeves) made of metal alloys resistant to wear, are used in many gasoline engines and practically all diesel engines to lessen wear. After they have been worn beyond the maximum oversize, the liners can be replaced individually permitting the use of standard pistons and rings. Thus you can avoid replacing the entire cylinder block.

The liners are inserted into a hole in the block with either a PRESS FIT or a SLIP FIT. Liners are further designated as WET TYPE or DRY TYPE. The wet type line comes in direct contact with the coolant and is sealed at the top by the use of a metallic sealing ring and at the bottom by a rubber sealing ring; the dry type liner does not contact the coolant.

Engine blocks for L-head engines contain the passageways for the valves and valve ports. The lower part of the block (crankcase) supports the crankshaft (with main bearings and bearing caps) and also provides a place for fastening the oil pan.

The camshaft is supported in the cylinder block by bushings that fit into machined holes in the block. On L-head in-line engines, the intake and exhaust manifolds are attached to the side of the cylinder block. On L-head V-8 engines, the intake manifold is located between the two banks

of cylinders. In this engine, there are two exhaust manifolds, one on the outside of each bank.

Cylinder Head

The cylinder head provides the combustion chambers for the engine cylinders. It is built to conform to the arrangement of the valves: L-head, I-head, or other.

In the water-cooled engine the cylinder head (fig. 13-10) is bolted to the top of the cylinder block to close the upper end of the cylinders. It contains passages, matching those of the cylinder block, which allow the cooling water to circulate in the head. The head also helps retain compression in the cylinders. In the gasoline engine there are tapped holes in the cylinder head which lead into the combustion chamber. The spark plugs are inserted into these tapped holes.

In the diesel engine the cylinder head may be cast in a single unit, or may be cast for a single cylinder or two or more cylinders. Separated head sections (usually covering 1, 2, or 3 cylinders in large engines) are easy to handle and can be readily removed.

The L-head type of cylinder head shown in figure 13-10 is a comparatively simple casting. It contains water jackets for cooling, and openings for spark plugs. Pockets into which the valves operate are also provided. Each pocket serves as a part of the combustion chamber. The fuel-air mixture is compressed in the pocket as the piston reaches the end of the compression stroke. Note that the pockets have a rather complex curved surface. This shape has been carefully designed so that the fuel-air mixture, in being compressed, will be subjected to violent turbulence. This turbulence assures uniform mixing of the fuel and air, thus improving the combustion process.

The I-head (overhead-valve) type of cylinder head contains not only water jackets for cooling spark-plug openings, and valve and combustion-chamber pockets, but it also contains and supports the valves and valve-operating mechanisms. In this type of cylinder head, the water jackets must be large enough to cool not only the top of the combustion chamber but also the valve seats, valves, and valve-operating mechanisms.

Crankcase

The crankcase is that part of the engine block below the cylinders. It supports and encloses the

Figure 13-10.—Cylinder head for L-head engine.

81.50

crankshaft and provides a reservoir for the lubricating oil. Oftentimes there are places provided on the crankcase for the mounting of the oil pump, oil filter, starting motor, and the generator. The lower part of the crankcase is the OIL PAN, which is bolted at the bottom. The oil pan is made of pressed or cast steel and holds from 4 to 9 quarts of oil, depending on the engine design.

The crankcase also has mounting brackets which support the entire engine on the vehicle frame. These brackets are either an integral part of the crankcase or are bolted to it in such a way that they support the engine at 3 or 4 points. These points of contact usually are cushioned with rubber, which insulates the frame and body of the vehicle from engine vibration and therefore prevents damage to the engine supports and the transmission.

Exhaust Manifold

The exhaust manifold is essentially a tube that carries waste products of combustion from the cylinders. On L-head engines the exhaust manifold is bolted to the side of the engine block; on overhead-valve engines it is bolted to the side of the engine cylinder head. Exhaust manifolds may be single iron castings or may be cast in sections. They have a smooth interior surface with no abrupt changes in size. (See fig. 13-11.)

Intake Manifold

The intake manifold on a gasoline engine carries the fuel-air mixture from the carburetor and distributes it as evenly as possible to the cylinders. On a diesel engine the manifold carries only air to the cylinders. The intake

Figure 13-11.—Intake and exhaust manifolds.

65.93

manifold is attached to the block on L-head engines and to the side of the cylinder head on overhead-valve engines. (See fig. 13-11.)

In gasoline engines, smooth and efficient engine performance depends largely on whether or not the fuel-air mixtures that enter each cylinder are uniform in strength, quality, and degree of vaporization. The inside walls of the manifold must be smooth to offer little obstruction to the flow of the fuel-air mixture. The manifold is designed to prevent collecting of fuel at the bends in the manifold.

The intake manifold should be as short and straight as possible to reduce the chances of condensation between the carburetor and cylinders. To assist in vaporization of fuel, some intake manifolds are constructed so that part of their surfaces can be heated by hot exhaust gases.

Gaskets

The principal stationary parts of an engine have just been explained. The gaskets (fig. 13-12)

that serve as seals between these parts in assembly, require as much attention during assembly as any other part. It is impractical to machine all surfaces so that they fit together to form a perfect seal. The gaskets make a joint that is air, water, or oil tight; therefore, when properly installed, they prevent loss of compression, coolant, or lubricant.

MOVING PARTS OF AN ENGINE

The moving parts of an engine serve an important function in turning heat energy into mechanical energy. They further convert reciprocal motion into rotary motion. The principal moving parts are the piston assembly, connecting rods, crankshaft assembly (includes flywheel and vibration dampener), camshaft, valves, and gear train.

The burning of the fuel-air mixture within the cylinder exerts a pressure on the piston, thus pushing it down in the cylinder. The action of

81.52
Figure 13-12.—Engine overhaul gasket kit.

the connecting rod and crankshaft converts this downward motion to a rotary motion.

Piston Assembly

Engine pistons serve several purposes: they transmit the force of combustion to the crankshaft through the connecting rod; they act as a guide for the upper end of the connecting rod; and they also serve as a carrier for the piston rings used to seal the compression in the cylinder. (See fig. 13-13.)

The piston must come to a complete stop at the end of each stroke before reversing its course in the cylinder. To withstand this rugged treatment and wear, it must be made of tough material, yet be light in weight. To overcome inertia and momentum at high speeds, it must be carefully balanced and weighed. All the pistons used in any one engine must be of similar weight to avoid excessive vibration. Ribs are used on

the underside of the piston to reinforce the head; the ribs also assist in conducting heat from the head of the piston to the piston rings and out through the cylinder walls.

The structural components of the piston are the HEAD, SKIRT, RING GROOVES, and LANDS (fig. 13-14). However, all pistons do not look like the typical one here illustrated. Some have differently shaped heads. Diesel engine pistons usually have more ring grooves and rings than the pistons of gasoline engines. Some of these rings may be installed below as well as above the WRIST or PISTON PIN (fig. 13-15).

Fitting pistons properly is important. Because metal expands when heated, and because space must be provided for lubricants between the pistons and the cylinder walls, the pistons are fitted to the engine with a specified clearance. This clearance depends upon the size or diameter of the piston and the material from which it is made. Cast iron does not expand as fast or as much as aluminum. Aluminum pistons require more clearance to prevent binding or seizing

75.70
Figure 13-13.—Piston and connecting rod (exploded view).

81.53

Figure 13-14.—The parts of a piston.

81.54

Figure 13-15.—Piston assembly of General Motors series 71 engine.

BASIC MACHINES

when the engine gets hot. The skirt or bottom part of the piston runs much cooler than the top; therefore, it does not require as much clearance as the head.

The piston is kept in alignment by the skirt, which is usually CAM GROUND (elliptical in cross section) (fig. 13-16). This elliptical shape permits the piston to fit the cylinder, regardless of whether the piston is cold or at operating temperature. The narrowest diameter of the piston is at the piston pin bosses, where the metal is thickest. At the widest diameter of the piston, the piston skirt is thinnest. The piston is fitted to close limits at its widest diameter so that piston noise (slap) is prevented during engine warm-up. As the piston is expanded by the heat generated during operation, it becomes round because the expansion is proportional to the temperature of the metal. The walls of the skirt are cut away as much as possible to reduce weight and to prevent excessive expansion during

engine operation. Many aluminum pistons are made with SPLIT SKIRTS so that when the pistons expand the skirt diameter will not increase. The two types of piston skirts found in most engines are the FULL TRUNK and the SLIPPER. The full-trunk-type skirt, which is more widely used, has a full cylindrical shape with bearing surfaces parallel to those of the cylinder, giving more strength and better control of the oil film. The SLIPPER-TYPE (CUTAWAY) skirt has considerable relief on the sides of the skirt, leaving less area for possible contact with the cylinder walls and thereby reducing friction.

PISTON PINS.—The piston is attached to the connecting rod by means of the piston pin (wrist pin). The pin passes through the piston pin bosses and through the upper end of the connecting rod, which rides within the piston on the middle of the pin. Piston pins are made of alloy steel with a precision finish and are case

Figure 13-16.—Cam-ground piston.

81.55

hardened and sometimes chromium plated to increase their wearing qualities. Their tubular construction gives them a maximum of strength with a minimum of weight. They are lubricated by splash from the crankcase or by pressure through passages bored in the connecting rods.

There are three methods commonly used for fastening a piston pin to the piston and the connecting rod. (See fig. 13-17.) An anchored, or "fixed," pin is attached to the piston by a screw running through one of the bosses; the connecting rod oscillates on the pin. A "semifloating" pin is anchored to the connecting rod and turns in the piston pin bosses. A "full-floating" pin is free to rotate in the connecting rod and in the bosses, but is prevented from working out against the sides of the cylinder by plugs or snapping locks.

PISTON RINGS.—Piston rings are used on pistons to maintain gastight seals between the pistons and cylinders, to assist in cooling the piston, and to control cylinder-wall lubrication. About one-third of the heat absorbed by the piston passes through the rings to the cylinder wall. Piston rings are often quite complicated in design, are heat treated in various ways and are plated with other metals. There are two distinct classifications of piston rings: compression rings and oil control rings. (See fig. 13-18.)

The principal function of a compression ring is to prevent gases from leaking by the piston during the compression and power strokes. All piston rings are split to permit assembly to the piston and to allow for expansion. When the ring

is in place, the ends of the split joint do not form a perfect seal; therefore, it is necessary to use more than one ring and to stagger the joints around the piston. If cylinders are worn, expanders (fig. 13-15 and 13-18) are sometimes used to ensure a perfect seal.

The bottom ring, usually located just above the piston pin, is an oil regulating ring. This ring scrapes the excess oil from the cylinder walls and returns some of it, through slots, to the piston ring grooves. The ring groove under an oil ring is provided with openings through which the oil flows back into the crankcase. In some engines, additional oil rings are used in the piston skirt below the piston pin.

Connecting Rods

Connecting rods must be light and yet strong enough to transmit the thrust of the pistons to the crankshaft. Connecting rods are drop forged from a steel alloy capable of withstanding heavy loads without bending or twisting. Holes at the upper and lower ends are machined to permit accurate fitting of bearings. These holes must be parallel.

The upper end of the connecting rod is connected to the piston by the piston pin. If the piston pin is locked in the piston pin bosses, or if it floats in both piston and connecting rod, the upper hole of the connecting rod will have a solid bearing (bushing) of bronze or similar material. As the lower end of the connecting rod revolves with the crankshaft, the upper end is forced to

Figure 13-17.—Piston pin types.

75.51

Figure 13-18.—Piston rings.

turn back and forth on the piston pin. Although this movement is slight, the bushing is necessary because the temperatures and the pressures are high. If the piston pin is semifloating, a bushing is not needed.

The lower hole in the connecting rod is split to permit it to be clamped around the crankshaft. The bottom part, or cap, is made of the same material as the rod and is attached by two or more bolts. The surface that bears on the crankshaft is generally a bearing material in the form of a separate split shell, although, in a few cases, it may be spun or die-cast in the inside of the rod and cap during manufacture. The two parts of the separate bearing are positioned in the rod and cap by dowel pins, projections, or short brass screws. Split bearings may be of the precision or semiprecision type.

The PRECISION type bearing is accurately finished to fit the crankpin and does not require further fitting during installation. It is positioned by projections on the shell which match reliefs in the rod and cap. The projections prevent the bearings from moving sideways and from rotary motion in the rod and cap.

The SEMIPRECISION type bearing is usually fastened to or die-cast with the rod and cap. Prior to installation, it is machined and fitted to the proper inside diameter with the cap and rod bolted together.

Crankshaft

As the pistons collectively might be regarded as the heart of the engine, so the CRANKSHAFT may be considered its backbone (fig. 13-19). It ties together the reactions of the pistons and the connecting rods, transforming their reciprocating motion into a rotary motion. And it transmits engine power through the flywheel, clutch, transmission, and differential to drive your vehicle.

The crankshaft is forged or cast from an alloy of steel and nickel, is machined smooth to provide bearing surfaces for the connecting rods and the main bearings, and is CASE-HARDENED, or coated in a furnace with copper alloyed with carbon. These bearing surfaces are called JOURNALS. The crankshaft counterweights impede the centrifugal force of the connecting rod assembly attached to the THROWS or points of bearing support. These

75.81

Figure 13-19.—Crankshaft of a 4-cylinder engine.

throws must be placed so that they counter-balance each other.

Crank throw arrangements for 4-, 6-, and 8-cylinder engines are shown in figure 13-20. Four-cylinder engine crankshafts have either 3 or 5 main support bearings and 4 throws in one plane. In figure 13-20 you see that the throws for No. 1 and No. 4 cylinders (4-cylinder engine) are 180° from those for No. 2 and No. 3 cylinders. On 6-cylinder engine crankshafts each of the 3 pairs of throws is arranged 120° from the other 2. Such crankshafts may be supported by as many as 7 main bearings, that is one at each end of the shaft and one between each pair of crankshaft throws. The crankshafts of 8-cylinder V-type engines are similar to those for the 4-cylinder in-line type or may have each of the 4 throws fixed at 90° from each other (as in fig. 13-20) for better balance and smoother operation.

V-type engines usually have two connecting rods fastened side by side on one crankshaft

throw. With this arrangement, one bank of the engine cylinders is set slightly ahead of the other to allow the two rods to clear each other.

Vibration Damper

The power impulses of an engine tend to set up torsional vibration in the crankshaft. If this torsional vibration were not controlled, the crankshaft might actually break at certain speeds; a vibration damper mounted on the front of the crankshaft is used to control this vibration (fig. 13-21).

Most types of vibration dampers resemble a miniature clutch. A friction facing is mounted between the hub face and a small damper flywheel. The damper flywheel is mounted on the hub face with bolts that go through rubber cones in the flywheel. These cones permit limited circumferential movement between the crankshaft and damper flywheel. This minimizes the

Figure 13-20.—Crankshaft and throw arrangements commonly used.

75.81

81.62

Figure 13-21.—Sectional view of a typical vibration damper.

effects of the torsional vibration in the crankshaft. Several other types of vibration dampers are used. However, they all operate in essentially the same way.

Engine Flywheel

The flywheel is mounted at the rear of the crankshaft near the rear main bearing. This is usually the longest and heaviest main bearing in the engine, as it must support the weight of the flywheel.

The flywheel (fig. 13-22) stores up energy of rotation during power impulses of the engine. It releases this energy between power impulses, thus assuring less fluctuation in engine speed and smoother engine operation. The size of the flywheel will vary with the number of cylinders and the general construction of the engine. With a large number of cylinders and the consequent

81.63

Figure 13-22.—Flywheel.

overlapping of power impulses, there is less need for a flywheel; consequently, the flywheel can be relatively small. The flywheel rim carries a ring gear, either integral with the flywheel or shrunk on, that meshes with the starter driving gear for cranking the engine. The rear face of the flywheel is usually machined and ground, and acts as one of the pressure surfaces for the clutch, becoming a part of the clutch assembly.

Valves And Valve Mechanisms

There are two valves for each cylinder in most engines, one intake and one exhaust valve. Since each of these valves operates at different times, it is necessary that separate operating mechanisms be provided for each valve. Valves are normally held closed by heavy springs and by compression in the combustion chamber. The purpose of the valve-actuating mechanism is to overcome the spring pressure and open the valves at the proper time. The valve-actuating mechanism includes the engine camshaft, camshaft followers (tappets), pushrods, and rocker arms.

CAMSHAFT.—The camshaft (fig. 13-23) is inclosed in the engine block. It has eccentric lobes (cams) ground on it for each valve in the

A - CAMSHAFT
B - CAMSHAFT BEARING
C - BEARING JOURNAL

81.61

Figure 13-23.—Camshaft and bushings.

engine. As the camshaft rotates, the cam lobe moves up under the valve tappet, exerting an upward thrust through the tappet against the valve stem or a pushrod. This thrust overcomes the valve spring pressure as well as the gas pressure in the cylinder, causing the valve to open. When the lobe moves from under the tappet, the valve spring pressure reseats the valve.

On L-, F-, or I-head engines, the camshaft is usually located to one side and above the crankshaft, while in V-type engines it is usually located directly above the crankshaft. On the overhead camshaft engine, such as the Murphy diesel, the camshaft is located above the cylinder head.

The camshaft of a 4-stroke cycle engine turns at one-half engine speed. It is driven off the crankshaft through timing gears or a timing chain. In the 2-stroke cycle engine the camshaft must turn at the same speed as the crankshaft in order that each valve may open and close once in each revolution of the engine.

In most cases the camshaft will do more than operate the valve mechanism. It may have extra cams or gears that operate fuel pumps, fuel injectors, the ignition distributor, or the lubrication pump.

Camshafts are supported in the engine block by journals in bearings. Camshaft bearing journals are the largest machined surfaces on the shaft. The bearings are usually made of bronze and are bushings rather than split bearings. The bushings are lubricated by oil circulating through drilled passages from the crankcase. The stresses on the camshaft are

small, therefore the bushings are not adjustable and require little attention. The camshaft bushings are generally replaced only when the engine requires a complete overhaul.

FOLLOWERS.—Camshaft followers (figs. 13-24 and 13-25) are the parts of the valve-actuating mechanism that contact the camshaft. You will probably hear them called valve tappets or valve lifters. In the L-head engine the followers directly contact the end of the valve stem and have an adjusting device in them. In the overhead valve engine the followers contact the pushrod that operates the rocker arm. The end of the rocker arm opposite the pushrod contacts the valve stem. The valve adjusting device, in this case, is in the rocker arm.

Many engines have self-adjusting valve lifters of the hydraulic type that operate at zero clearance at all times. The operation of one type of hydraulic valve tappet mechanism is shown in figure 13-26. Oil under pressure is forced into the tappet when the valve is closed, and this pressure extends the plunger in the tappet so that all valve clearance, or lash, is eliminated. When the cam lobe moves around under the tappet and starts to raise it, there will not be any tappet noise. As the lobe starts to

81.64

Figure 13-24.—L-head valve operating mechanism.

Figure 13-25.—Valve operating mechanism for an overhead valve engine.

81.65

raise the tappet, the oil is forced upward in the lower chamber of the tappet. This action closes the ball check valve so oil cannot escape. Then the tappet acts as though it were a simple, 1-piece tappet and the valve is opened. When the lobe moves out from under the tappet and the valve closes, the pressure in the lower chamber of the tappet is relieved. Any slight loss of oil from the lower chamber is then replaced by the oil pressure from the engine lubricating system. This causes the plunger to move up snugly

against the push rod so that any clearance is eliminated.

Timing Gears (Gear Trains)

Timing gears keep the crankshaft and camshaft turning in proper relation to one another so that the valves open and close at the proper time. In some engines, sprockets and chains are used.

81.66

Figure 13-26.—Operation of a hydraulic valve lifter.

The gears or sprockets, as the case may be, of the camshaft and crankshaft are keyed in position so that they cannot slip. Since they are keyed to their respective shafts, they can be replaced if they become worn or noisy.

With directly driven timing gears (fig. 13-27), one gear usually has a mark on two adjacent teeth and the other a mark on only one tooth. To time the valves properly, it is necessary only to mesh the gears so that the two marked teeth of one gear straddle the single marked tooth of the other.

in air-cooled engines a blower is generally used to force cool air around the engine cylinders.

In addition, an exhaust system is provided to carry away the burned gases exhausted from the engine cylinders. These systems will not be discussed in this course, however. For further information on them refer to NavPers 10644D, Construction Mechanic 3 & 2.

AUXILIARY ASSEMBLIES

We have discussed the main parts of the engine proper; but there are other parts, both moving and stationary, that are essential to engine operation. They are not built into the engine itself, but, in most cases, are attached to the engine block or cylinder head.

The fuel system includes a fuel pump and carburetor mounted on the engine. In diesel engines the fuel injection mechanism replaces the carburetor. An electrical system is provided to supply power for starting the engine and also for ignition during operation. An efficient cooling system is necessary for operating an internal combustion engine. In water-cooled engines a water pump and fan are used, while

81.69

Figure 13-27.—Timing gears and their markings.

CHAPTER 14

POWER TRAINS

In chapter 13 we saw how a combination of simple machines and basic mechanisms were utilized in constructing the internal combustion engine. In this chapter we will go on from there to learn how the power developed by the engine is transmitted to perform the work required of it. To illustrate this, we will use the power train system as used by the automobile, and most trucks, as a familiar example. In this application, once again you are to look for the simple machines that make up each of the machines or mechanisms which are interconnected to make up the power train.

In a vehicle, the mechanism that transmits the power of the engine to the wheels and/or tracks and accessory equipment is called the power train. In a simple situation, a set of gears or a chain and sprocket could perform this task, but automotive and construction vehicles are not usually designed for such simple operating conditions. They are designed to have great pulling power, to move at high speeds, to travel in reverse as well as forward, and to operate on rough terrain as well as smooth roads. To meet these widely varying demands, a number of units have been added to the vehicles.

Automobiles and light trucks driven by the two rear wheels have a power train consisting of clutch, transmission, propeller shaft, differential, and driving axles (fig. 14-1).

In 4- and 6-wheel drive trucks, you will find transfer cases with additional drive shafts and live axles. Tractors, shovels, cranes, and other heavy-duty vehicles that move on tracks also have similar power trains. In addition to assemblies that drive sprockets to move the tracks, these vehicles also have auxiliary transmissions or power takeoff units which may be used to operate accessory attachments. The propeller shafts and clutch assemblies of these power trains are very much like those used to drive the wheels.

THE CLUTCH

The clutch is placed in the power train of motorized equipment for two purposes:

First, it provides a means of disconnecting the power of the engine from the driving wheels and accessory equipment. When the clutch is disengaged, the engine can run without driving the vehicle or operating the accessories.

Second, when the vehicle is started, the clutch allows the engine to take up the load of driving the vehicle or accessories gradually and without shock.

Clutches are located in the power train between the source of power and the operating unit. Usually, they are placed between the engine and the transmission assembly, as shown in figure 14-1.

Clutches generally transmit power from the clutch driving member to the driven member by friction. In the plate clutch, figure 14-2 the driving member or plate, which is secured to the engine flywheel, is gradually brought in contact with the driven member (disc). The contact is made and held by strong spring pressure controlled by the driver with the clutch pedal. With only a light spring pressure, there is little friction between the two members and the clutch is permitted to slip. As the spring pressure increases, friction also increases, and less slippage occurs. When the driver removes his foot from the clutch pedal and full spring pressure is applied, the speed of the driving plate and driven disc is the same, and all slipping stops. There is then a direct connection between the driving and driven shafts.

In most clutches, there is a direct mechanical linkage between the clutch pedal and the clutch release yoke lever. On many late model vehicles, and on some of the larger units which require great pressure to release the spring, a hydraulic clutch release system is used. A master cylinder (fig. 14-3), similar to the brake

81.174

Figure 14-1.—Type of power transmission.

master cylinder, is attached to the clutch pedal. A cylinder, similar to a single-acting brake wheel cylinder, is connected to the master cylinder by flexible pressure hose or metal tubing (fig. 14-3). The slave cylinder is connected to the clutch release yoke lever. Movement of the clutch pedal actuates the clutch master cylinder. This movement is transferred

by hydraulic pressure to the slave cylinder, which in turn actuates the clutch release yoke lever.

TYPES OF CLUTCHES

There are various types of clutches. The type most used in passenger cars and light

81.175

Figure 14-2.—Exploded and cross-section view of a plate clutch.

81.177

Figure 14-3.—Master cylinder, slave cylinder and connections for standard hydraulic clutch.

trucks is the previously-mentioned plate clutch. The plate clutch is a simple clutch with three plates, one of which is clamped between the other two. Exploded and cross-sectional views of a plate clutch are shown in figure 14-2.

Single Disk Clutch

The driving members of the single disk clutch consist of the flywheel and the driving

(pressure) plate. The driven member consists of a single disk, splined to the clutch shaft and faced on both sides with friction material. When the clutch is fully engaged, the driven disc is firmly clamped between the flywheel and the driving plate by pressure of the clutch springs, forming a direct, nonslipping connection between the driving and driven members of the clutch. In this position, the drivendisc rotates the clutch shaft to which it is splined. The clutch shaft is

connected to the driving wheels through the transmission, propeller shaft, final drive, differential, and live axles.

The double disk clutch (fig. 14-4) is substantially the same as the single plate disk clutch except that another driven disk and intermediate driving plate is added.

Multiple Disk Clutch

A multiple disk clutch is one having more than three plates or disks. Some have as many as 11 driving plates and 10 driven disks. Because the multiple disk type has a greater frictional area than a plate clutch, it is best suited as a steering clutch on crawler type tractors. The multiple disk clutch is sometimes used on heavy trucks. In operation, it is very much like the plate clutch and has the same release mechanism. The facings, however, are usually attached to the driving plates rather than to the driven disks. This reduces the weight of the driven disks and keeps them from spinning after the clutch is released.

You may run into other types of friction clutches such as the lubricated plate clutch and the cone clutch. These types are seldom used on automotive equipment. However, fluid drive is largely replacing the friction clutches in automobiles and light trucks, and even in some tractors.

For information on fluid drives (automatic transmissions), refer to Construction Mechanic 3 & 2, NavPers 10644-D, chapter 11.

TRANSMISSION

The transmission is part of the power train. It consists of a metal case filled with gears (fig. 14-5), and is usually located in the rear of the engine between the clutch housing and the propeller shaft, as shown in figure 14-1. The transmission transfers engine power from the clutch shaft to the propeller shaft, and allows the driver or operator to control the power and speed of the vehicle. The transmission shown in figure 14-5 and 14-6 is a sliding gear transmission. Many late model trucks

Figure 14-4.--Double disk clutch--exploded view.

81.179

Figure 14-5.—Four-speed truck transmission.

81.181

have either constant mesh or synchromesh transmissions (explained later). However, the principles of operation and gear ratios are the same.

A review of chapter 6 of this book will help you to understand the transmissions and power transfer mechanisms described in this chapter.

FOUR-SPEED TRUCK TRANSMISSION

The gear shift lever positions shown in the small inset in figure 14-6 are typical of most four-speed truck transmissions. The gear shifting lever, shown at A, B, C, D, and E in the illustration, moves the position of the two shifting forks which slide on separate shafts secured in the transmission case cover. Follow the separate diagrams to learn what takes place in shifting from one speed to another. For example, as you

move the top of the gear shift lever toward the forward left position, the lower arm of the lever moves in the opposite direction to shift the gears. The fulcrum of this lever is in the transmission cover.

In shifting transmission gears it is necessary to use the clutch to disengage the engine. Improper use of the clutch will cause the gears to clash, and may damage them by breaking the gear teeth. A broken tooth or piece of metal can wedge itself between two moving gears and ruin the entire transmission assembly.

When you shift from neutral to first or low speed (A of fig. 14-6), the smallest countershaft gear engages with the largest sliding gear. Low gear moves the truck at its lowest speed and maximum power. The arrow indicates the flow of power from the clutch shaft to the propeller shaft.

Figure 14-6.—Power flow through a 4-speed transmission.

81.182

The second speed position is obtained by moving the gear shift lever straight back from the low speed position. You will, of course, use the clutch when shifting. In B of figure 14-6 you will see that the next to the smallest countershaft gear is in mesh with the second largest sliding gear. The largest sliding gear (shift gear) has been disengaged. The flow of power has been changed as shown by the arrow. The power transmitted to the wheels in second gear (speed) is less, but the truck will move at a greater speed than it will in low gear if the engine speed is kept the same.

In shifting from the second speed to the third speed position, you move the gear shift lever through the neutral position. This is done in all selective gear transmissions. From the neutral position the driver can select the speed position required to get the power he needs. In C of figure 14-6 you will notice that the gear shift lever is in contact with the other shifting fork, and that the forward slide gear

has been meshed with the second countershaft gear. The power flow through the transmission has again been changed, as indicated by the arrow, and the truck will move at an intermediate speed between second and high.

You shift into fourth or high speed position by moving the top of the shift lever back and to the right from the neutral position. In the high speed position, the forward shift or sliding gear is engaged with the constant speed gear as shown in D of figure 14-6. The clutch shaft and the transmission shaft are now locked together and the power flow is in a straight line. In high, the truck propeller shaft revolves at the same speed as the engine crankshaft, or at a 1 to 1 ratio.

You shift to reverse by moving the top of the gear shift lever to the far right and then to the rear. Most trucks have a trigger arrangement at the gear shift ball to unlock the lever so that it can be moved from neutral to the far right. The lock prevents unintentional

shifts into reverse. Never attempt to shift into reverse until the forward motion of the vehicle has been completely stopped.

In F of figure 14-6, you can see how the idler gear fits into the transmission gear train. In E of figure 14-6, you can see what happens when you shift into reverse. An additional shifting fork is contacted by the shift lever in the far right position. When the shift to reverse is completed, this fork moves the idling gear into mesh with the small countershaft gear and the large sliding gear at the same time. The small arrows in the inset show how the engine power flows through the transmission to move the propeller shaft and the wheels in a reverse direction.

The different combination of gears in the transmission case makes it possible to change the vehicle speed while the engine speed remains the same. It is all a matter of gear ratios. That is, having large gears drive small gears, and small gears drive large gears. If a gear with 100 teeth drives a gear with 25 teeth, the small gear will travel four times as fast as the large one. You have stepped up the speed. Now, let the small gear drive the large gear, and the large gear will make one revolution for every four of the small gear. You have reduced speed, and the ratio of gear reduction is 4 to 1.

In the truck transmission just described, the gear reduction in low gear is 7 to 1 from the engine to the propeller shaft. In high gear the ratio is 1 to 1, and the propeller shaft turns at the same speed as the engine. This holds true for most transmissions. The second and third speed positions provide intermediate gear reductions between low and high. The gear ratio in second speed is 3.48 to 1, and in third is 1.71 to 1. The gear reduction or gear ratio in reverse is about the same as it is in low gear, and the propeller shaft makes one revolution for every seven revolutions of the engine.

All transmissions do not have four speeds forward, and the gear reductions at the various speeds are not necessarily the same. Passenger cars, for example, usually have only three forward speeds and one reverse speed. Their gear ratios are about 3 to 1 in both low and reverse gear combinations. You must remember, the gear reduction in the transmission is only between the engine and the propeller shaft. Another reduction gear ratio is provided in the rear axle assembly. If you have a common rear axle ratio of about 4 to 1, the gear reduction from the engine of a passenger car to the

rear wheels in low gear would be approximately 12 to 1. In high gear the ratio would be 4 to 1 as there would be no reduction of speed in the transmission.

CONSTANT MESH TRANSMISSION

To eliminate the noise developed in the old-type spur-tooth gears used in the sliding gear transmission, the automotive manufacturers developed the constant-mesh transmission which contains helical gears.

In this type of transmission certain countershaft gears are constantly in mesh with the main shaft gears. The main shaft meshing gears are arranged so that they cannot move endwise. They are supported by roller bearings so that they can rotate independently of the main shaft (figs. 14-7 and 14-8).

In operation, when the shift lever is moved to third, the third and fourth shifter fork moves the clutch gear (A, fig. 14-8) toward the third speed gear (D, fig. 14-8). This engages the external teeth of the clutch gear with the internal teeth of the third speed gear. Since the third speed gear is rotating with the rotating countershaft gear, the clutch gear must also rotate. The clutch gear is splined to the main shaft, and therefore the main shaft rotates with the clutch gear. This principle is carried out when the shift lever moves from one speed to the next.

Constant-mesh gears are seldom used for all speeds. Common practice is to use such gears for the higher gears, with sliding gears for first and reverse speeds, or for reverse only. When the shift is made to first or reverse, the first and reverse sliding gear is moved to the left on the main shaft. The inner teeth of the sliding gear mesh with the main shaft first gear.

SYNCHROMESH TRANSMISSION

The synchromesh transmission is a type of constant-mesh transmission that permits gears to be selected without clashing, by synchronizing the speeds of mating parts before they engage. It employs a combination metal-to-metal friction cone clutch and a dog or gear positive clutch to engage the main drive gear and second-speed main shaft gear with the transmission main shaft. The friction cone clutch engages first, bringing the driving and driven members to the same speed, after which the dog clutch engages easily without clashing. This process is accomplished

Figure 14-7.—Constant-mesh transmission assembly—sectional view.

81.183

Figure 14-8.—Disassembled main shaft assembly.

81.184

in one continuous operation when the driver declutches and moves the control lever in the usual manner. The construction of synchromesh transmissions varies somewhat with different manufacturers, but the principle is the same in all.

The construction of a popular synchromesh clutch is shown in figure 14-9. The driving member consists of a sliding gear splined to the transmission main shaft with bronze internal cones on each side. It is surrounded by a sliding sleeve having internal teeth that are meshed with the external teeth of the sliding gear. The sliding sleeve is grooved around the outside to receive the shift fork. Six spring-loaded balls in radially-drilled holes in the gear fit into an internal groove in the sliding sleeve and prevent it from moving endwise relative to the gear until the latter has reached the end of its travel. The driven members are the main drive gear and second-speed main shaft gear, each of which has external cones and external teeth machined on its sides to engage the internal cones of the sliding gear and the internal teeth of the sliding sleeve.

The synchromesh clutch operates as follows: when the transmission control lever is moved by the driver to the third-speed or direct-drive position, the shift fork moves the sliding gear and sliding sleeve forward as a unit until the internal cone on the sliding gear engages the external cone on the main drive gear. This action brings the two gears to the same speed and stops endwise travel of the sliding gear. The sliding sleeve then slides over the balls and silently engages the external teeth on the main drive gear, locking the main drive gear and transmission main shaft together as shown in figure 14-9. When the transmission control lever is shifted to the second-speed position, the sliding gear and sleeve move rearward and the same action takes place, locking the transmission main shaft to the second-speed main shaft gear. The synchromesh clutch is not applied to first speed or to reverse. First speed is engaged by an ordinary dog clutch when constant mesh is employed, or by a sliding gear; reverse is always engaged by means of a sliding gear. Figure 14-10 shows a cross section of a synchromesh transmission which uses constant-mesh helical gears for the

Figure 14-9.—Synchronesh clutch—disengaged and engaged.

81.185

three forward speeds and a sliding spur gear for reverse.

Some transmissions are controlled by a steering column control lever (fig. 14-11). The positions for the various speeds are the same as those for the vertical control lever except that the lever is horizontal. The shifter forks are pivoted on belleranks which are turned by a steering column control lever through the linkage shown. The poppets shown in figure 14-10 engage notches at the inner end of each bell crank. Other types of synchronesh transmissions controlled by steering column levers have shifter shafts and forks moved by a linkage similar to those used with a vertical control lever.

AUXILIARY TRANSMISSION

The auxiliary transmission allows a rather small engine to move heavy loads in trucks by increasing the engine-to-axle gear ratios. The auxiliary transmission provides a link in the

power trains of construction vehicles to divert engine power to drive 4 and 6 wheels, and also to operate accessory equipment through transfer cases and power takeoff units. (See fig. 14-12).

Trucks require a greater engine-to-axle gear ratio than passenger cars, particularly when manufacturers put the same engine in both types of equipment. In a truck, the auxiliary transmission doubles the mechanical advantage. It is connected to the rear of the main transmission by a short propeller shaft and universal joint. Its weight is supported on a frame cross-member as shown in figure 14-12. The illustration also shows how the shifting lever would extend into the driver's compartment near the lever operating the main transmission.

In appearance and in operation, auxiliary transmissions are similar to main transmissions, except that some may have two and some three speeds (low, direct and overdrive).

81.186

Figure 14-10.—Synchromesh transmission arranged for steering column control.

TRANSFER CASES

Transfer cases are placed in the power trains of vehicles driven by all wheels. Their purpose is to provide the necessary offsets for additional propeller shaft connections to drive the wheels.

Transfer cases in heavier vehicles have two speed positions and a declutching device for disconnecting the front driving wheels. Two speed transfer cases like the one shown in figure 14-13 serve also as auxiliary transmissions.

Some transfer cases are quite complicated. When they have speed changing gears, declutching devices, and attachments for three or more propeller shafts, they are even larger than the main transmission. A cross section of a common type of two-speed transfer case is shown in figure 14-14. Compare it with the actual installation in figure 14-13.

The declutching mechanism for the front wheels consists of a sliding sleeve spline clutch.

This same type of transfer case is used for a 6-wheel drive vehicle. The additional propeller shaft connects the drive shaft of the transfer case to the rearmost axle assembly. It is connected to the transfer case through the transmission brake drum.

Some transfer cases contain an overrunning sprag unit (or units) on the front output shaft. (A sprag unit is a form of overrunning clutch; power can be transmitted through it in one direction but not in the other.)

On these units the transfer is designed to drive the front axle slightly slower than the rear axle. During normal operation, when both front and rear wheels turn at the same speed, only the rear wheels drive the vehicle. However, if the rear wheels should lose traction and begin to slip, they tend to turn faster than the front wheels. As this happens, the sprag unit automatically engages so that the front wheels also drive the vehicle. The sprag unit simply provides an automatic means of engaging the

81.187
 Figure 14-11.—Steering column transmission control lever and linkage.

front wheels in drive whenever additional tractive effort is required. There are two types of sprag-unit-equipped transfers, a single-sprag-unit transfer and a double-sprag-unit transfer. Essentially, both types work in the same manner.

POWER TAKEOFFS

Power takeoffs are attachments in the power train for power to drive auxiliary accessories. They are attached to the transmission, auxiliary transmission, or transfer case. A common type of power takeoff is the single-gear, single-speed type shown in figure 14-15. This unit is bolted to an opening provided in the side of the transmission case as shown in figure 14-12. The sliding gear of the power takeoff will then mesh with the transmission countershaft gear. The operator can move a shifter shaft control lever to slide the gear in and out of mesh with the counter shaft gear. The spring-loaded ball holds the shifter shaft in position.

On some vehicles you will find power take-off units with gear arrangements that will give

81.188
 Figure 14-12.—Auxiliary transmission power takeoff driving winch.

Figure 14-13.—Transfer case installed in a 4-wheel drive truck.

81.190

two speeds forward and one in reverse. Several forward speeds and a reverse gear arrangement are usually provided in power take-off units which operate winches and hoists. Their operation is about the same as the single speed units.

PROPELLER SHAFT ASSEMBLIES

The propeller shaft assembly consists of a propeller shaft, a slip joint, and one or more universal joints. This assembly provides a flexible connection through which power is transmitted from the transmission to the live axles.

The propeller shaft may be solid or tubular. A solid shaft is somewhat stronger than a hollow or tubular shaft of the same diameter, but a hollow shaft is stronger than a solid shaft of the same weight. Solid shafts are generally used inside of a shaft housing that encloses the entire propeller shaft assembly. These are called torque tube drives.

A slip joint is provided at one end of the propeller shaft to take care of end play. The driving axle, being attached to the springs, is

free to move up and down while the transmission is attached to the frame and cannot move. Any upward or downward movement of the axle, as the springs are flexed, shortens or lengthens the distance between the axle assembly and the transmission. To compensate for this changing distance, the slip joint is provided at one end of the propeller shaft.

The usual type of slip joint consists of a splined stub shaft, welded to the propeller shaft, which fits into a splined sleeve in the universal joint. A cross-sectional view of the slip joint and universal joint is shown in figure 14-16.

A universal joint is a connection between two shafts that permits one to drive the other at an angle. Passenger vehicles and trucks usually have universal joints at both ends of the propeller shaft.

Universal joints are double-hinged with the pins of the hinges set at right angles. They are made in many different designs, but they all work on the same principle. (See chapter 11.)

FINAL DRIVES

A final drive is that part of the power train that transmits the power delivered through the

Figure 14-14.—Cross section of a 2-speed transfer case.

81.191

propeller shaft to the drive wheels or sprockets. Because it is encased in the rear axle housing, the final drive is usually referred to as a part of the rear axle assembly. It consists of two gears called the ring gear and pinion. These may be spur, spiral, or hypoid beveled gears, or wormgears, as illustrated in figure 14-17.

The function of the final drive is to change by 90 degrees the direction of the power transmitted through the propeller shaft to the driving axles. It also provides a fixed reduction between the speed of the propeller shaft and the axle shafts and wheels. In passenger cars this

reduction varies from about 3 to 1 to 5 to 1. In trucks, it can vary from 5 to 1 as much as 11 to 1.

The gear ratio of a final drive having bevel gears is found by dividing the number of teeth on the drive gear by the number of teeth on the pinion. In a worm gear final drive, the gear ratio is found by dividing the number of teeth on the gear by the number of threads on the worm.

Most final drives are of the gear type. Hypoid gears are used in passenger cars and light trucks to give more body clearance. They permit the bevel drive pinion to be placed below the center of the bevel drive gear, thereby

Figure 14-15.--Single speed, single gear, power takeoff.

81.192

lowering the propeller shaft (see fig. 14-17). Worm gears allow a large speed reduction and are used extensively in the larger trucks. Spiral bevel gears are similar to hypoid gears. They are used in both passenger cars and trucks to replace spur gears that are considered too noisy.

DIFFERENTIALS

The construction and principles of operation of the gear differential were described in chapter 11 of this book. We will briefly review some of the high points of that chapter here, and then go on to describe some of the more common types

Figure 14-16.—Slip joint and common type of universal joint.

2.200

Figure 14-17.—Gears used in final drives.

81.195

of gear differentials as applied in automobiles and trucks.

The purpose of the differential is easy to understand when you compare a vehicle to a company of men marching in mass formation. When the company makes a turn, the men in the inside file must take short steps, almost marking time, while men in the outside file must take long steps and walk a greater distance to make the turn. When a motor vehicle turns a corner, the wheels on the outside of the turn must rotate faster and travel a greater distance than the wheels on the inside. This causes no difficulty for front wheels of the usual passenger car because each wheel rotates independently on opposite ends of a dead axle. However, in order to drive the rear wheels at different speeds, the differential is needed. It connects the individual axle shaft for each wheel to the bevel drive gear. Therefore, each shaft can turn at a different speed and still be driven as a single unit. Refer to the illustration in figure 14-18 as you study the following discussion on differential operation.

81.196

Figure 14-18.—Differential with part of case cut away.

The differential described in chapter 11 had two inputs and a single output. The differential as used in the automobile, however, has a single input and two outputs, the input being introduced from the propeller shaft, and the outputs going to the rear axles and wheels. In this discussion, the "spider gears" are referred to as "differential pinions," so don't let this confuse you.

The bevel drive pinion, connected to the propeller shaft, drives the bevel drive gear and the differential case to which it is attached. Therefore, the entire differential case always rotates with the bevel drive gear whenever the propeller shaft is transmitting rotary motion. Within the case, the differential pinions are free to rotate on individual shafts called trunnions. These trunnions are attached to the walls of the differential case, so that whenever the case is turning, the differential pinions must revolve—one about the other—in the same plane as the bevel drive gear.

The differential pinions mesh with the side gears, as did the spider and side gears in the differential described in chapter 11. The axle shafts are splined to the side gears and keyed to the wheels. Power is transmitted to the axle shafts through the differential pinions and the side gears. When resistance is equal on each rear wheel, the differential pinions, side gears, and axle shafts all rotate as one unit with the bevel drive gear. In this case, there is no relative motion between the pinions and the side gears in the differential case. That is, the pinions do not turn on the trunnions, and their teeth will not move over the teeth of the side gears.

When the vehicle turns a corner, one wheel must turn faster than the other. The side gear driving the outside wheel will run faster than the side gear connected to the axle shaft of the inside wheel. To compensate for this difference in speed, and to remain in mesh with the two side gears, the differential pinions must then turn on the trunnions. The average speed of the two side gears, axle shafts, or wheels is always equal to the speed of the bevel drive gear.

To overcome the situation where one spinning wheel might be undesirable, some trucks are provided with a differential lock. This is a simple dog clutch, controlled manually or automatically, which locks one axle shaft to the differential case and bevel drive gear. Although this device forms a rigid connection between the two axle shafts and makes both wheels rotate at

the same speed, it is used very little. Too often the driver forgets to disengage the lock after using it. There are, however, automatic devices for doing almost the same thing. One of these, which is rather extensively used today, is the high-traction differential. It consists of a set of differential pinions and side gears which have fewer teeth and a different tooth form from the conventional gears. Figure 14-19 shows a comparison between these and standard gears. These differential pinions and side gears depend on a variable radius from the center of the differential pinion to the point where it comes in contact with the side gear teeth, which is, in effect, a variable lever arm. As long as there is relative motion between the pinions and side gears, the torque is unevenly divided between the two driving shafts and wheels; whereas, with the usual differential, the torque is evenly divided at all times. With the high-traction differential, the torque becomes greater on one wheel and less on the other as the pinions move around, until both wheels start to rotate at the same speed. When this occurs, the relative motion between the pinion and side gears stops and the

torque on each wheel is again equal. This device assists considerably in starting the vehicle or keeping it rolling in cases where one wheel encounters a slippery spot and loses traction while the other wheel is on a firm spot and has traction. It will not work, however, when one wheel loses traction completely. In this respect it is inferior to the differential lock.

With the no-spin differential (fig. 14-20), one wheel cannot spin because of loss of tractive effort and thereby deprive the other wheel of driving effort. For example, one wheel is on ice and the other wheel is on dry pavement. The wheel on ice is assumed to have no traction. However, the wheel on dry pavement will pull to the limit of its tractional resistance at the pavement. The wheel on ice cannot spin because wheel speed is governed by the speed of the wheel applying tractive effort.

The no-spin differential does not contain pinion gears and side gears as does the conventional differential. Instead, it consists essentially of a spider attached to the differential drive ring gear through four trunnions, plus two driven clutch members with side teeth that are

81.197
 Figure 14-19.—Comparison of high-traction differential gears and standard differential gears.

Figure 14-20.—No spin differential—exploded view.

81.198

indexed by spring pressure with side teeth in the spider. Two side members are splined to the wheel axles and in turn are splined into the driven clutch members.

AXLES

A live axle is one that supports part of the weight of a vehicle and also drives the wheels connected to it. A dead axle is one that carries part of the weight of a vehicle but does not drive the wheels. The wheels rotate on the ends of the dead axle.

Usually, the front axle of a passenger car is a dead axle and the rear axle is a live axle. In 4-wheel drive vehicles, both front and rear axles are live axles, and in 6-wheel drive vehicles, all three axles are live axles. The third axle, part of a bogie drive, is joined to the rearmost axle by a trunnion axle. The trunnion axle is attached rigidly to the frame. Its purpose is to help in distributing the load on the rear of the vehicle to the two live axles which it connects.

There are four types of live axles used in automotive and construction equipment. They are: plain, semifloating, three-quarter floating, and full floating.

The plain live axle, or nonfloating rear axle, is seldom used in equipment today. The

axle shafts in this assembly are called nonfloating because they are supported directly in bearings located in the center and ends of the axle housing. In addition to turning the wheels, these shafts carry the entire load of the vehicle on their outer ends. Plain axles also support the weight of the differential case.

The semifloating axle (fig. 14-21) that is used on most passenger cars and light trucks

Figure 14-21.—Semifloating rear axle.

81.200

has its differential case independently supported. The differential carrier relieves the axle shafts from the weight of the differential assembly and the stresses caused by its operation. For this reason the inner ends of the axle shafts are said to be floated. The wheels are keyed to outer ends of axle shafts and the outer bearings are between the shafts and the housing. The axle shafts therefore must take the stresses caused by turning, skidding, or wobbling of the wheels. The axle shaft in a semifloating live axle can be removed after the wheel has been pulled off.

The axle shafts in a three-quarter floating axle (fig. 14-22) may be removed with the wheels, which are keyed to the tapered outer ends of the shafts. The inner ends of the shafts are carried as in a semifloating axle. The axle housing, instead of the shafts, carries the weight of the vehicle because the wheels are supported by

bearings on the outer ends of the housing. However, axle shafts must take the stresses caused by the turning, skidding, and wobbling of the wheels. Three-quarter floating axles are used in some trucks but in very few passenger cars. The full floating axle is used in most heavy trucks. (See fig. 14-23). These axle shafts may be removed and replaced without removing the wheels or disturbing the differential. Each wheel is carried on the end of the axle tube on two ball bearings or roller bearings and the axle shafts are not rigidly connected to the wheels. The wheels are driven through a clutch arrangement or flange on the ends of the axle shaft which is bolted to the outside of the wheel hub. The bolted connection between axle and wheel does not make this assembly a true full floating axle, but nevertheless, it is called a floating axle. A true full floating axle transmits only turning effort, or torque.

CHAPTER 15

BASIC COMPUTER MECHANISMS

We have already studied several examples of complex machines in the preceding chapters to learn how simple machines and basic mechanisms are utilized in their design. The analog computer, of the kind used in modern fire control systems, is a complex machine in every sense of the word. We will not attempt in this book to break down and analyze a complete computer. We will, however, examine a few of the special devices commonly used in computers. These devices have come to be known as basic computer mechanisms. They are, however, quite complex machines in themselves—as you'll soon agree. Like the engine, the typewriter, and the other machines we've studied, these mechanisms are only combinations of simple machines cleverly designed to do a specific kind of work. As before, the watchword is Look For the Simple Machines.

DIFFERENTIALS

The differentials used in the analog computer are gear differentials similar to those described in chapter 11. They are different from the automobile differential in that instead of receiving a single input and delivering two outputs, they receive two inputs and combine them into a single output. Most of the differentials in a computer are quite small, averaging about 2" x 2 1/2" in size, and are designed for light loads. Some computers may have as many as 150 gear differentials in their makeup.

Figure 15-1 illustrates the symbol used to indicate the differential in schematic drawings. The cross in the center represents the spider. The arrows pointing inward represent inputs, and the arrow pointing outward is the output.

Figure 15-2 shows one of the many applications of the gear differential in a computer. In this case, the differential is being used as an integral part of a followup control. Computing mechanisms are not designed to drive heavy

loads. The outputs from such mechanisms often merely control the action of servomotors. The motors do the actual driving of the loads to be handled. The device which makes it possible for the comparatively weak output from a computing mechanism to control the action of a servomotor is called a followup control. In this device, the differential is used to measure the difference, or "error," in position between the input and the output. The input is geared to one side of the differential. The servo output is used to do two things: (1) to position whatever mechanism is being handled, and (2) to drive the other side of the differential. This second operation is known as the servo "response."

When there is a difference between the input and the output, the spider of the differential turns. As this happens, the spider shaft operates a set of controls which control the action of the servomotor in such a way that the motor drives its side of the differential in a direction opposite to that taken by the input. That is, the servo always drives to reduce the difference, or error, to zero.

LINKAGES FOR ADDING AND SUBTRACTING

Addition of two quantities is performed in the linkage mechanism by means of adding levers as shown in figure 15-3. In the example two quantities, designated X and Y, are to be added. Their values are represented by the movements of the two slide bars. The adding lever is pivoted at its center to another slide bar, and its opposite ends are connected through links to the X and Y slides. To illustrate the problem, scales showing the values of the quantities represented by movements of slides have been drawn in the figure, and index marks are placed on the slides. The units on the center scale are half as large as those on the other two.

12.87
Figure 15-1.—This is the symbol used to indicate the differential in schematic drawings.

If the Y slide is held in place and the X slide is moved, the adding lever pivots about its lower end. The center slide, which is connected to the midpoint of the lever then moves half as far as the X slide. If the X movement is one unit, the center slide also moves one unit since the units on the center scale are half as large as those on the X scale. Similarly, movements of the Y slide with the X slide held in place add one unit on the center scale for each unit movement of

Y. At the left of figure 15-3, the parts are shown in zero position, with the three index marks opposite the zero points of the scales. At the right, the X slide has been moved one unit, and the Y slide has been moved three.

The center slide has traveled one unit in response to the X-travel and three more in response to the Y-travel, and so stands at a reading of four. Similarly, for any position of the X and Y slides, the reading on the center scale represents the quantity X plus Y.

There are several variations of the adding lever used in computing linkage, but their operating principles are the same.

MECHANICAL MULTIPLIERS

There are two basic types of mechanical multipliers—those using rotary gearing and those using linkages.

The rotary gearing type produces a solution through the use of similar triangles. There are four types of rotary multipliers in use—screw, rack, sector, and cam. Since they all operate in fundamentally the same manner, we will discuss the screw type multiplier and then compare the other types to it.

110.9
Figure 15-2.—Simplified sketch of a followup control showing application of a gear differential.

12.88

Figure 15-3.—Adding lever.

The screw multiplier, shown in figure 15-4, has two inputs and one output. The inputs are shaft values which position the input slide and input rack. The output appears at the output rack which positions the output shaft. Thus the output shaft value is always proportional to the product of the two inputs.

One input gearing is connected to two long screws. These screws pass through the threaded sleeve-like ends of the slotted input slide. As the input gears to the screws are rotated, the two screws turn to move the slide to the left or right. At the same time, the other input moves the input rack up or down, moving the slotted pivot arm around the stationary pin.

12.91

Figure 15-4.—Screw type multiplier.

The multiplier pin is mounted in the slots of the input slide, pivot arms, and output rack, connecting all three where the slots cross. As the multiplier pin moves the input slide and pivot arm, it positions the output rack and gear.

Now, consider the multiplier in the zero position shown in figure 15-5. If only the screws are rotated, the input slide moves to the right; but it will not affect the output rack. Similarly, if only the input rack is moved up or down from the zero position, the output rack will be unaffected. This is a reasonable result, for any number multiplied by zero is equal to zero.

From this we can conclude that both inputs must be removed from the zero position for an output. Such a condition is shown in figure 15-6. Notice the triangle superimposed on the device. The value *a* represents the amount of rack input. The value *b* represents the amount of slide input. *K* is a fixed distance, since the multiplier pin cannot move and the input rack travels in a machined guide.

Because the angles are equal, the triangles are similar. Thus the value of *X* can be determined if the other values are known.

$$\text{(Actually, } X = \frac{ba}{K}\text{)}$$

This equation shows that the output (*X*) is always proportional to the product of the two inputs. The constant value (*K*) can be compensated for by the proper choice of input and output gearing for the multiplier. These

12.92

Figure 15-5.—Screw type multiplier—zero position.

Figure 15-6.—Screw type multiplier—multiplying positive values. 12.93

multipliers can also determine the product of negative values.

The rack type multiplier in figure 15-7 performs the same task as the screw type multiplier. The differences are that (1) the screw input has been replaced with an input rack, and (2) the output rack is placed on the same side as the second input rack.

The sector type, although different in construction, also employs triangles for the multiplication of the two inputs. A sector type multiplier is shown in figure 15-8. One input positions the input sector arm and the other input turns a large screw that is mounted on the input sector arm. The bevel gear turns this lead screw through a universal joint. The use of the universal joint permits the input to drive the lead screw as the sector arm changes its angular position. Notice that the lead screw drives the multiplier pin up and down the sector arm. Thus the position of the input sector arm and the position of the multiplier on the lead screw represents the two values to be multiplied.

Figure 15-7.—Rack type multiplier. 12.94

A study of figure 15-9 along with figure 15-8 will reveal how the triangles are established. While the sector type multiplier can handle both positive and negative inputs on the input sector arm, the input to the lead screw must always be a positive quantity.

The cam computing multiplier is a dual operation device. It computes a function of one value on a cam and multiplies that function by a second value. It is a combination of a cam and a rack type multiplier.

Figure 15-8.—Sector type multiplier. 12.95

Figure 15-9.—Multiplying with the sector type multiplier. 12.96

A single cam computing multiplier is shown in figure 15-10. Notice it is like the rack type multiplier except that one of the inputs is positioned by a cam instead of a rack. The cam follower pin is mounted directly on the multiplier input slide. This cam may be cut to compute any desired function of the cam input.

One input drives the input rack through the rack input gear. The other input drives the cam

Figure 15-10.—Single cam computing multiplier. 12.97

directly. The cam positions the input slide according to the function for which the cam was cut. Thus the cam output becomes the slide input. The position of the output rack represents a value which is proportional to the product of the cam output and the rack input, just as in the rack type multiplier.

A two-cam computing multiplier computes the function of both inputs and multiplies these functions together. The output is proportional to the product of the functions of the two inputs.

Linkage multipliers of the type described here are used when one of the factors is a constant, as shown in figure 15-11. In this example we want to transform a movement representing the quantity X into one representing $1.5X$. One end of the multiplying lever is pivoted on the fixed frame of the computer, as indicated by the cross-hatched circle in the figure.

The input and output links are connected to the lever at different points, the connection of the output link being 1.5 times as far from the fixed pivot as the connection of the input link. The two scales shown in figure 15-11 have units of the same size; but because of the difference in lever arms, each one-unit movement of the input link moves the output link a unit and a half. Then, if the input movement represents the quantity X , the output represents $1.5X$.

In many cases the computing problem requires the multiplication of two variable quantities. The multiplying levers shown in figure 15-11 cannot be used for this purpose. Figure 15-12 shows a linkage designed to multiply two variables, X and Y . The levers AB and ED are pivoted on the fixed structure and are connected by links BC and CD , both of which have exactly the same length as AB . The X input is applied by a link connected at B . The Y input is applied by a link connected at C ;

Figure 15-11.—Multiplying lever. 12.98

Figure 15-9.—Multiplying with the sector type multiplier. 12.96

A single cam computing multiplier is shown in figure 15-10. Notice it is like the rack type multiplier except that one of the inputs is positioned by a cam instead of a rack. The cam follower pin is mounted directly on the multiplier input slide. This cam may be cut to compute any desired function of the cam input.

One input drives the input rack through the rack input gear. The other input drives the cam

Figure 15-10.—Single cam computing multiplier. 12.97

directly. The cam positions the input slide according to the function for which the cam was cut. Thus the cam output becomes the slide input. The position of the output rack represents a value which is proportional to the product of the cam output and the rack input, just as in the rack type multiplier.

A two-cam computing multiplier computes the function of both inputs and multiplies these functions together. The output is proportional to the product of the functions of the two inputs.

Linkage multipliers of the type described here are used when one of the factors is a constant, as shown in figure 15-11. In this example we want to transform a movement representing the quantity X into one representing $1.5X$. One end of the multiplying lever is pivoted on the fixed frame of the computer, as indicated by the cross-hatched circle in the figure.

The input and output links are connected to the lever at different points, the connection of the output link being 1.5 times as far from the fixed pivot as the connection of the input link. The two scales shown in figure 15-11 have units of the same size; but because of the difference in lever arms, each one-unit movement of the input link moves the output link a unit and a half. Then, if the input movement represents the quantity X , the output represents $1.5X$.

In many cases the computing problem requires the multiplication of two variable quantities. The multiplying levers shown in figure 15-11 cannot be used for this purpose. Figure 15-12 shows a linkage designed to multiply two variables, X and Y . The levers AB and ED are pivoted on the fixed structure and are connected by links BC and CD , both of which have exactly the same length as AB . The X input is applied by a link connected at B . The Y input is applied by a link connected at C ;

Figure 15-11.—Multiplying lever. 12.98

12.99

Figure 15-12.—Multiplying linkage.

and the output XY is taken off at D . In the position of the links shown in figure 15-12, X equals two units, Y equals two units, and XY equals four.

This type of linkage in the computer can be operated in reverse to serve as a divider instead of a multiplier. Two inputs are applied at the points corresponding to B and D in figure 15-12. The output taken off at C then represents the input at D divided by the input at B .

Component solvers are devices that are used in mechanical computers. The component solver takes a vector of a given magnitude and angular position, and resolves it into its two rectangular components.

There are several types of component solvers. However, this discussion will be limited to the screw type component solver. The device consists of a vector gear, two racks, two output gears, two input gears, and a screw and pin assembly. The speed input gear drives a gear train which causes the screw to turn. As the screw turns, it drives an assembly carrying the pin,

thus changing the length of the vector which is proportional to the input component, such as r (slant range). (See figure 15-13.)

In this type of component solver the pin can travel nearly the full width of the vector gear. From the pin's zero or center position it can be moved in either of two directions, which correspond to positive or negative.

The vector input gear drives the vector gear in the desired angular direction indicating target position. The pin positions the racks as it moves along the slot, thus resolving the vector into its components.

An angle resolver is a linkage mechanism which computes the sine and cosine of an angle. Figure 15-14A shows an angle resolver consisting of gear H with two crank pins M and N , mounted 90° apart and equidistant from the center of the gear. Attached to each crank pin is an output link which transmits the horizontal component of motion of the pin as the gear rotates. The horizontal component of the displacement of pin M is proportional to the sine of the angle through which gear H rotates. The horizontal component of pin N is proportional to the cosine of the angle through which gear H rotates.

Figure 15-14B shows the resolver in its zero position, with the radius OM perpendicular to the horizontal center line and the radius ON in the horizontal center line. Notice that link R (sine output) is at zero horizontal displacement, and that link S (cosine output) is at maximum

12.113

Figure 15-13.—Screw type component solver.

horizontal displacement. If we rotated gear H clockwise through an angle 30° , link R would move to the right and link S to the left along the horizontal center line. The linear displacement of the output links would be proportional to the sine and cosine function of the angle.

The outputs of the resolver of figure 15-14 are only approximate values. This is because the output links are not parallel to the horizontal center line. The output links have a slight angular movement that must be compensated for to eliminate distortion. This is accomplished by additional gearing, and by making the pins M and N eccentric.

Integrators, as used in computers, perform a special type of multiplication. In the disc-type integrator, illustrated in figure 15-15, a constantly changing value, such as time, is multiplied by a variable such as range rate, such as range (the rate that a target range is opening or closing), the output being a continuous value of their product which can be accumulated as shaft rotation.

The instrument consists of a flat circular disc revolved at constant speed by a motor equipped with a clock escapement; a carriage, containing two balls driven by friction with the surface of the disc, and themselves driving an output roller; and suitable shafts and gears for transmission of values to and from the unit. Rotation of the disc rotates the lower ball, which turns the upper ball, and this in turn

rotates the output roller. The balls are supported in a movable carriage so that the point of contact between the lower ball and the disc can be shifted along a diameter from the center of the disc to either edge. Spring tension on the roller provides sufficient pressure to prevent slipping. Two balls are used to reduce the sliding friction that results when only one is used.

The speed of roller rotation depends upon the speed at which the balls rotate. If the carriage is in the center of the disc, no motion is imparted to the roller. As the carriage is moved off center, the balls will begin to rotate, and will reach their maximum speed at the edge of the disc. The speed varies with the distance of the carriage from the center. Values of rotation on one side of center are considered positive, while if the carriage is moved to the opposite side, rotation will be in the opposite direction and will give negative output values.

SUMMARY

Of the many existing complex machines to choose from, you have been given only a few examples to study. The operational principles of some of them may have come to you quite easily—others may have been a bit harder to grasp. In any case, if you'll keep firmly in mind the following points that have been brought out in this book—you'll find all machines much easier to analyze and understand.

A machine is any device that helps you do work. It helps you by changing motion, magnitude, or speed of the effort you apply.

All machines consist of one or more of the six basic, or simple machines. These are the lever, the block and tackle, the wheel and axle, the inclined plane, the screw, and gears.

When machines give a mechanical advantage of more than one, they multiply the force of your effort. When they give a mechanical advantage of less than one, they multiply either the motion, or the speed of the force you apply.

No machine is 100 percent efficient. Some of your effort is always used to overcome friction. You always do more work on the machine than it does on the load.

You can figure out how any complex machine works by breaking it down into the simple machines from which it is made, and following the action through, step by step.

BASIC MACHINES AND HOW THEY WORK

BUREAU OF NAVAL PERSONNEL

Covering thoroughly basic theory, ranging from the lever and inclined plane up through basic computer mechanisms, this extraordinarily clear book leaves nothing to be desired in its presentation. Nothing more than the most elementary mathematics is required to follow it.

Beginning with the simplest of machines—the lever—the course proceeds with the discussion of the block and tackle (pulleys and hoists), the wheel and axle, the inclined plane and the wedge, the screw, and different types of gears (simple, spur, bevel, herringbone, spiral, worm, etc.). A chapter on the concept of work discusses the measurement of work, friction, and efficiency; this is followed by investigations of power, force and pressure, explaining the uses of scales, balances, gauges and barometers. *The fundamentals of hydrostatic and hydraulic machines* (such as the hydraulic braking system and the hydraulic press) are discussed in detail. The remaining chapters cover machine elements (bearings and springs), basic mechanisms (gear differential, couplings, cam and cam followers, clutches), complex machines (water-tight door, typewriter), the internal combustion engine (its components and how it works), power trains (including explanations of various transmission systems—synchronesh, auxiliary, etc.), and basic computer mechanisms (linkages, multipliers, integrators, etc.).

Every concept is clearly defined and the discussions always build easily from elementary theory to particular applications that are familiar to anyone with the slightest interest in mechanics. Important concepts, machine components and techniques are clearly illustrated in more than 200 diagrams and drawings, cross-sections that reveal inner workings—all of these help to clarify even further an already clear and well-organized presentation. Although it was originally designed for use in U.S. Naval Training Schools, this book can be used to great advantage as a basic text in mechanical engineering in standard technical schools, and it will be immensely valuable even to the layman who desires a basic knowledge of machines.

Unabridged republication of Navy Training Course NavPers 10624-A (1965). 204 figures. Preface. Index. viii + 161pp. 6½ x 9¼.

21709-4 Paperbound

A DOVER EDITION DESIGNED FOR YEARS OF USE!

We have made every effort to make this the best book possible. Our paper is opaque, with minimal show-through; it will not discolor or become brittle with age. Pages are sewn in signatures, in the method traditionally used for the best books, and will not drop out, as often happens with paperbacks held together with glue. Books open flat for easy reference. The binding will not crack or split. This is a permanent book.

Handy Farm Devices

and How to

Make Them

HANDY FARM DEVICES AND HOW TO MAKE THEM, a classic from the Golden Age of American Farming, is as useful and pertinent for homesteaders and small-scale farmers today as it was when it was first published more than seventy-five years ago. A wealth of labor- and money-saving projects fills its pages: spill-proof chicken waterers; a portable chicken coop; a lightweight orchard ladder; a small truss bridge; an easy fence-post and stump-puller; gates that don't sag; gates that lift over snowdrifts; a handy wood splitter—even a bicycle-powered washing machine.

HANDY FARM DEVICES AND HOW TO MAKE THEM is a rare and engaging combination of nostalgic Americana and helpful instruction, sure to appeal to everyone inclined toward self-sufficiency and the country life.

1. Farm equipment - Design and construction

Foreword to the 1996 Edition

IN 1972, after a brief and unsuccessful experiment with urban living, I moved to a small hardscrabble homestead in midcoast Maine—as one of many in my generation who migrated to places like Oregon and Montana, determined to live apart from a society that seemed to value us only as producers and consumers of goods. We came to get a living with our hands, to become latter-day Thoreaus, working the soil and communing with nature—with, of course, the Grateful Dead blaring reassuringly in the background.

That few of us had been closer to nature than dozing in the sun on Boston Common or Golden Gate Park troubled us not a whit: We were brilliant, clever, omniscient. We were baby boomers.

Mother Earth News would show us the way. *The Whole Earth Catalog*. *Living on the Earth*. All we needed were the right books and a pair of low-back overalls. How hard could country life be?

Pretty hard, as it turned out. The hands-on experience of our generation's back-to-the-land authors could most charitably be described as recent and shallow—a fact that quickly became evident when our hand-crafted homesteads needed essentials about which our gurus knew only basics, not details: chicken coops, grain storage bins, cistern filters. So our chickens didn't stay cooped, grains didn't stay binned, and cisterns were filtered only through rose-colored granny glasses.

I had a bit more experience in country living than most, having come from farm country. But I soon found that dozing in VocAg class doesn't properly equip one for running a homestead in Maine.

Then I found *The Book*, dust-covered and neglected in a crossroads junk store, and my homestead creations quickly assumed a more professional air: the chickens stayed cooped, the grain stayed binned.

More important, the grain dried fast and stayed rodent-free; the chickens were healthier and produced more eggs with less feed.

Handy Farm Devices and How to Make Them dates from The Golden Age of American Farming, when farmers were truly self-sufficient, making what they needed from what they had. It is recent enough to be technologically pertinent and old enough to be free from the baleful influences of advertising and its artificial demands. It is both helpful instruction and nostalgic Americana.

In its pages you will find detailed instructions for building the things without which a small farm or homestead simply cannot exist, as well as valuable insights into building things in general, including the best treatise I've seen on the most useful but least appreciated tool in the box: the carpenter's square.

The projects range from the merely curious—a bicycle-powered washing machine; or a dog-powered water pump—to the absolutely essential—an improved stone boat; a portable chicken coop; a light-weight orchard ladder; a small truss bridge; an easy fence-post and stump-puller; gates that don't sag; gates that lift over snowdrifts; and—the handiest farm device I've ever found: the accurately described Handy Wood Splitter, which has saved me countless hours trying to balance a lopsided chunk of wood long enough to whack it with an ax.

Farming and homesteading are hard work, and long-term success lies in minimizing both the amount of work needed to produce a desired result and outside expenditures. *Handy Farm Devices and How to Make Them*—as succinct and accurate a book title as was ever writ—will help you do that and more.

James R. Babb

By Way of Introduction

SUCCESS comes to the man who so works that his efforts will bring the most and the best results—not to the man who simply works hard. It is the know-how, things-to-do-with and economy that count. Labor-saving machinery has revolutionized many a trade and industry. It has made farming an industry and a science of possibilities undreamed of and unattainable a hundred years ago. But it is not enough for the modern farm to be equipped with the best tools and machinery that shops and factories turn out, to know how to use them and keep them in repair. There are many handy devices, not made in any factory and not sold in any store, that every intelligent man can make himself, which save money and labor and time. Inventive men are constantly contriving simple but valuable things to meet the needs of their own practical experience. We are all the time hunting after and gathering these ideas. Now we are putting a lot of the best ones into this book. We are trying, by words and pictures, to explain clearly just how to make each device. Everything described is tried and practical. Some are old, many are new, all are good for the purpose intended. They represent the practical, successful experience of farmers and other wide-awake workers all over the United States.

This book is broader than its title. The overflow of good measure includes a valuable chapter on the steel square and its uses. Nowhere else has this subject been handled in a way so easily understood, with confusing mathematics cut out. We especially commend this chapter to our readers. We also present some good house and barn plans, that will be appreciated by those who contemplate building.

In addition to the direct benefit to be derived from doing what the book tells how to do, we have in mind the larger purpose of education toward putting more thought into our work and doing what we have to do the easiest, the cheapest and the quickest way. Out of it all, we trust our readers will make progress toward greater prosperity, greater happiness and greater usefulness.

· WORK · SHOP · · AND · TOOLS ·

THE FARMER'S WORKSHOP

HERE is no doubt that of all the handy farm devices good tools head the list. So, in this book, we are going to start with carpenter tools and the place to keep and use them. Every farmer ought to have a workshop in which he can do odd jobs and make things when the weather prevents out-of-door work, or at times when there is little to do on the farm. Economy and thrift demand that a farmer should have and keep in good condition a few essential carpenter tools. First of all he should have a long, strong, smooth-top bench and, either on racks above the bench or in a tool chest, he should keep in order, and where he can easily find them when wanted, his stock of carpenter tools. Some of the tools that will be found useful are the following:

A rip saw, a crosscut saw, a back saw, and a compass saw; a jack plane, a fore plane, and a smoothing plane; a shave or drawing knife; two or three chisels of different sizes for woodworking and a cold chisel for metal; a gouge or two; a good hatchet; two or three hammers, including a tack hammer and a bell-faced claw hammer; a brace or bit stock with a set of half a dozen or more bits of different sizes; one or more gimlets; a mallet; a nail set, a large screw driver and a small one; a gauge; a spirit level; a miter box; a good carpenter's square—No. 100 is a good standard size;

compasses or dividers; cut nippers, a pair of small pincers and a pair of large ones; a rasp; a large, flat file; at least one medium-sized three-cornered file and a half-round file.

It is poor economy to buy cheap tools. Of course extravagance is to be avoided, but be sure that you get first-class material in every tool you buy. It is a good plan to get a good practical carpenter to assist you in selecting your tools. Keep on hand in the shop a variety of nails, brads and tacks, screws, rivets, bolts, washers and nuts, and such small articles of builders' hardware that are likely to be needed occasionally, including hinges, hasps and staples and some sand-paper. Have a good plumb line, chalk and pencils. Keep in a handy place a jar of a good liquid glue, and some cement. See to it that the shop contains a good stock of well-seasoned lumber, both hard wood and soft.

Attached to the bench should be a bench screw or vise. This need not be an expensive one, but should be of good size and strong. There should also be a pair of carpenter's saw benches, a shaving horse, a small anvil and a grindstone. Every farmer has a grindstone somewhere about the buildings, but it is a great convenience to have a good one in the workshop.

A corner of the shop should be devoted to painting supplies, including several colors of good standard ready-mixed paints and stains, raw linseed oil, boiled linseed oil, turpentine, varnish, putty, points for setting glass, several brushes of different sizes, a good putty knife and panes of glass of different sizes ready for emergency.

A farmer ought to be able to do occasional little jobs of soldering. He needs soldering iron, a bar of solder, resin, a little bottle of soldering fluid,

which can be purchased already prepared, also a small sheet-iron furnace in which to heat the soldering iron.

It would cost quite a tidy sum to buy all these things at once, but they can be gradually accumulated as one is able to purchase them, and then the outfit should be kept complete. Whenever anything in the shop is broken, worn out, or disappears it should be replaced.

Whenever farm implements or anything about the barn or house are broken or out of order, they should be properly fixed. Often a few minutes spent at the right time will make a thing almost as good as new, while, if neglected, it may soon get beyond repair and have to be thrown away. A thrifty farmer always keeps his farm implements well housed and in repair. It is not what we earn, but what we save, that makes us rich. It is quite as important to stop the leaks as it is to figure on big profits directly.

RUNNING THE GRINDSTONE

If the face of the grindstone is hard and glazed pour a little sand on the stone every few minutes until the glaze is worn off and the stone will cut like a new one. This condition is caused by exposing the stone to the weather. It is best to keep the stone in a shed under cover, but if this is not possible, set it under a tree and put a box over it when not in use. It is surprising how easy a little oil on the bearings will make the stone run. A few drops of kerosene will cut the gum if it runs hard and then some oil or axle grease will make it go easy.

It is hard to stand on one foot and work the

treadle with the other. The job can be made easy by bolting two boards to the grindstone frame, and extending it 2 feet, on which place a seat as shown

HANDY GRINDSTONE RIG

in the cut. An uneven stone needs to be cut down and toned up. This can be done by grinding against the end of a piece of pipe, having the stone dry.

Good nature is as contagious as the measles. Put on your best smile when you get up in the morning and observe how everybody will greet you with a sunny face.

A HOMEMADE ANVIL

A homemade anvil can be constructed from a 4-foot piece of railroad rail mounted on a trestle, as shown in the sketch. This affair will stand a lot

of heavy pounding, and comes in handy in many ways. The rail is just about the right shape to make an anvil.

RAIL ANVIL

MAKING A NEW TOOL

A very handy wrench for many kinds of work, such as making gates and contrivances, where small bolts are used, is shown in the cut. From a small monkey wrench remove the wooden handle, and weld the metal part to an old bit-stock, as shown in the cut. This permits of very rapid work in screwing up small bolts. Where there are so many things to do as there are on a farm, it pays to do things in the easiest and quickest way. This is one of the real time-savers.

BIT-STOCK WRENCH

Learn to live, and live to learn,
Ignorance like a fire doth burn,
Little tasks make large return.—Bayard Taylor.

HOW TO MAKE A SHAVING HORSE

One of the most useful devices on a farm is a shaving horse. Make a bench 18 feet high of a good 2-inch plank, *c*, level off the edges so that it will make a comfortable seat. Upon this place a slanting platform, *b*, through which is cut a hole in which the clamp, *a*, works.

The clamp must be made of heavy hard wood that is tough and will not split. The shank, *f*, must

SHAVING HORSE

be an extension of the clamp, *a*. Several holes in the plank will allow the clamp to be raised so as to take in larger pieces of wood. The treadle, *g*, is kept in place by a peg at *h*. To operate this horse the workman places his foot upon the treadle, inserts the wood to be clamped under the edge of *a*, and pushes backward upon the treadle. This clamps the wood and the drawing knife can be used readily and much more rapidly than with a vise.

A CONVENIENT FARM HORSE

On the farm there is continual use for such a horse as is shown in the drawing. Not only when

doing little jobs of carpentering, but also in many other operations, such a support is found necessary. This little horse is an improvement over the ordinary stiff affair, in that it shuts together when not in use, and so can be packed out of the way.

HORSE READY FOR USE

It is made of boards cut in strips, the two horizontal boards at the top being hinged together, as shown herewith. While in use the legs are kept apart by long hooks, as may be plainly seen in the picture.

When tillage begins, other arts follow. The farmers, therefore, are the founders of human civilization.—Daniel Webster.

A WIRE SPLICER

The neatest and strongest splice can be made with this little instrument. It is a strip of iron 1 inch wide and $\frac{1}{8}$ inch thick. One end is cut narrow and is bent into a hook large enough to fit

neatly the largest wire to be spliced. At the sides of this two notches are filed, as shown at the left. At the right the splicer is seen in position on the wire. The splicer should be turned backward, as it appears in the right-hand drawing, to make the splice. A pair of large pincers or a vise should be used to hold the two wires between the coils while turning the splicer. The

WIRE SPLICING

splice as finished appears above. The length of the handle may vary. If the splicer is to be used for net wire, of course the handle cannot be longer than the width of the mesh. Otherwise, 6 or 7 inches is about right for No. 8 wire. If it is to be used only for small wire, the length of the handle should be reduced for the sake of convenience.

SERVICEABLE HOMEMADE LEVEL

A serviceable level is shown in the illustration. Take two 1-inch boards of rather hard wood, well-seasoned, 2 to 3 feet long, bolt or screw them together at right angles. This union must be so strong as never to be moved by ordinary pressure. At the top of the perpendicular piece cut a slit and insert a piece of strong thread. To the bottom of the thread tie a thin circular

LEVEL

weight. Lay the device across two trestles of nearly the same level. Just above the weight mark the place where the string hangs. Reverse the position of the instrument by turning it end for end, and again mark the position of the string. Half way between the two marks place a third. When the string hangs over this mark the lower board will be level. A shield of tin may be placed over the weight. A nail on each side of the string, just above the weight, will keep it from swinging far out of place. It must be allowed to swing freely.

A simple level may be improvised by filling a small flat bottle with water, so that only a bubble of air remains, and attaching it lengthwise and near the middle of a straight stick or narrow board.

TO MAKE A HANDLE STAY ON

To secure the handle of a hammer or ax is often quite a bothersome problem. A special wedge made with a piece of wood as at *a*, in the sketch, held in place by a fence staple, *b*, has been devised to meet the need for a wedge that really holds. The prongs of the staple should be bent slightly outward before it is driven in, so that they will spread in the handle. There is little danger of handles coming loose when they are attached in this manner, and

HOLDS WEDGE

it is little more difficult to set a handle as indicated than in the old-fashioned way.

A TOOL BOX REQUISITE

Among the handiest things to have in the tool box are some small bolts about 2 inches long with thumb nuts. A dozen or so of these will prove their value many times over in the course of a year. In making tables for fairs or suppers or in any sort of knock-down arrangement, or temporary convenience where strength is essential, nothing surpasses a bolt of this description. With a brace and a bit the right size, one may be entirely independent of nails and screws.

A farmer friend of ours was once called upon to make a fence about a child's crib without any marring nails. A slot in the fence post with a thumb bolt just above the crib line gave an alligator jaw result which was very satisfactory. On another occasion a knock-down stage was carried from the storeroom in pieces and put together by two men in 20 minutes. An actual computation of its strength showed that a locomotive might safely run over it.

The man referred to above has 100 feet of tables for hall purposes, depending entirely upon the 2-inch bolt and thumb nut for their fastenings and braces. There is never any trouble about knocking out nails. To one having a brace and bit these handy things will suggest of themselves many satisfactory uses. A supply of iron washers should be kept in hand, and in time a collection of various sizes of wooden washers will accumulate.

SOLDERING

Soldering may be done by anyone having a very simple outfit. All that is required is a copper sol-

dering iron, some solder, a vial of muriatic acid and some resin. A fairly successful job of soldering a tin dish may be done by scraping the surface bright where the hole is, sprinkling on a little finely powdered resin, laying on a bit of solder and holding the dish over a flame, which may be from an alcohol lamp, until the solder melts. It will cover the hole and stick. If the dish is rusty or badly tarnished use muriatic acid in place of resin. Resin works best when tin is bright, but usually solder sticks most successfully when the acid is used.

For soldering large breaks or doing important jobs of soldering the iron must be used. In order to work well the iron has to be kept coated with solder. When it gets blackened it should be filed until bright and then rubbed upon a smooth board while hot in a mixture of melted solder and resin. When the hot iron is taken from the fire wipe it on a damp cloth before trying to use it to lift the melted solder. A soldering iron is best heated in charcoal or the coals of a wood fire. The copper should never get red hot, as that causes the coating of the point to be burned off. The metal to be soldered must always be heated before the solder will unite it.

Solder may be obtained in bars at any tin shop. It can be made by melting together 2 parts of lead and 1 of bar tin. This is the usual proportion for most purposes. Soft solder that will melt quickly and can be easily used for mending tinware can be made of pure lead and tin in equal parts. A hard solder is made by melting together 2 parts of copper to 1 of tin. Brazing solder is made by melting together brass and one-sixth its weight of zinc. When cool it should be granulated by pounding

with a hammer. For soldering steel and iron to brass the following combination of metal is melted together, 3 parts tin, $39\frac{1}{2}$ copper, and $7\frac{1}{2}$ zinc. Before it is applied, all the metals to be jointed together must be heated to the same temperature as the soldering alloy. Gold solder is made of 24 parts gold, 2 parts silver and 1 part copper. A hard silver solder is made of 4 parts silver to 1 of copper. A soft silver solder is made of 2 parts silver to 1 of brass.

Use of the Steel Square

BY J. HAMILTON ELLIOT

A steel square, often called a carpenter's square, can be found in almost any kit of mechanic's tools and a little knowledge of this instrument will aid the user to perform many problems easily and quickly that otherwise might prove difficult. Squares of different kinds and materials have been used by mechanics in all ages. The first were made of wood and were used in the construction of the earliest buildings of which we have historic record. The squares of today are made of steel, finely polished and stamped with many

figures, tables and rules, according to the taste of the manufacturer and the special mechanic for whom they are designed.

We will not attempt to deal with the several special kinds or makes, taking up only a few of the possibilities of the standard 2-foot square. This is 2 feet long on the blade, which is two inches wide, and it is 16 or 18 inches on the tongue or angular leg. The latter is $1\frac{1}{2}$ inches wide. Beginning at the heel or corner of the square, inches and fractions of inches are marked. It is necessary that the marking be in this way, in order to form the different combinations desired in connection with the different problems which have to be solved. A few of these problems are explained in the following pages.

LUMBER RULE

On the side of the blade of the square that is divided into inches and eighths is placed the lumber rule or scale. This is used for computing the number of feet in board measure contained in a given board or piece of lumber. We show a picture of a section cut from the center of the lumber rule. The space running lengthwise of the blade between the parallel lines contains the number of feet board measure for a given width of board. The first space is for boards 8 inches wide, the second for those 9 inches wide, the third for those 10 inches wide and so on. To determine the space which should be used for any given width, look under the 12-inch mark on the outside edge of the blade. These numbers give the width of the board, also the number of feet board measure. If a board is 10 inches wide and 12 feet long, it contains 10 feet board measure.

Now let it be required to find the number of feet board measure in a board 13 inches wide and 11 feet long. Find the space for boards 13 inches wide under the 12-inch mark on the square, follow this space to the left and under the 11-inch mark on the square will be found the answer desired: 11—11. This is read 11 feet and $\frac{1}{12}$, and is the number of feet board measure contained in a board

11	12	13	14
7-4	8-	8-8	9-4
8-5	9-	9-9	10-6
9-2	10-	10-10	11-8
10-1	11-	11-11	12-10
11-11	12-	12-12	13-10
12-10	13-	13-12	14-10
13-9	14-	14-12	15-10
	10	11	12
			13

LUMBER RULE

13 inches wide and 11 feet long. With a little practice, anyone can measure lumber or timber and check up his bills for this kind of material.

Do not confound foot board measure with square feet. Square feet are in surface measure, with no reference to thickness, while a foot board measure is the equivalent of a foot square and 1 inch in thickness. The square feet of a 3-inch plank would contain 3 feet board measure.

After becoming familiar with the use of the lumber rule, as described above, you will discover that the space may be taken to contain the amounts for a given width and the different lengths in feet as represented in the different columns, or the space may be taken as containing the amounts for a

given length and the different widths arranged in columns; therefore, find either length in feet or width in inches under the 12-inch mark and follow this space until under the inch mark representing the other measurement. In this space will be found the feet board measure.

BRACE RULE

THE BRACE RULE

The brace rule is on the tongue of the square, and has a series of figures representing the rise or vertical height, the run or horizontal reach and the true length of a brace. For example, they are written $27/27$ 38^{19} and $45/45$ 63^{64} . These would be read 27 inches run, 27 inches rise and a length of 38 and $19/100$ inches, and 45 inches run, 45 inches rise and a length of 63 and $64/100$ inches.

A glance at the illustration on page 22 will give a good idea of the application of the brace rule as it appears on almost any modern make of square.

FIGURE I

THE OCTAGON SCALE

There is an octagon scale on one side of the tongue of the square, but we will not attempt to explain its use, as there are easier and simpler methods of obtaining the same result.

One method is shown in Figure 1. To obtain the lines on a square stick where the corners should come when converted into an octagon or eight-sided stick: Lay the square on the one side of the square stick at such an angle that the end of the square will come exactly at the edges or corners of the stick, make a dot on the 7-inch mark and at the 17-inch mark. Through these dots gauge or mark a line parallel with the edge of the stick. Continue this operation on all of the four sides. This gives the lines for the corners of an octagon. In making a flag-pole or spar for a boat or to round any large stick this is the operation used by all mechanics doing the work by hand.

THE MITER BOX

Of all homemade devices, one of the most frequently used in the shop is the miter box. After the box is put together it is a simple problem, with the use of a steel square, to make the cuts necessary to intersect two pieces of wood, as shown in Figure 2. First, the box must be straight and true and the sides form a perfect right angle or square with the bottom. Lay the steel square on the top

FIGURE 5A

of the box so that the 12-inch mark on the blade and the 12-inch mark on the tongue will both come

FIGURES 2 AND 3

FIGURES 5 AND 4

exactly on the edge of the box. This gives the miter cut of the intersection of the angle of a perfect square, as shown in Figure 2. Figure 3 shows the manner of placing the square on the box to give the desired angle.

A sprung molding, which is a molding not solid on the back, as shown in Figure 4, must be placed in the box bottom side up as shown in Figure 5, so as to get a solid bearing to hold it. Cuts in the box to miter around an eight-sided figure or an octagon, as shown in 5A, can be obtained by using 7 inches and 17 inches, marking the cut on the 7-inch side, as shown in Figure 5.

TRUING THE SQUARE

After obtaining a steel square, the first and most essential thing is to test or prove it to see that it is accurate, forming the angle of a perfect square.

FIGURE 6

Take a board planed on one side and straighten one edge of it perfectly as described under Making a Straight Edge. Make a mark across this board

with the square, as shown in Figure 6, Position A, then reverse the square to Position B. If the square is true it should exactly fit the mark made. It is necessary to work very accurately, making the mark with the point of a knife and having the edge of the board absolutely straight.

If the square is found to be out or inaccurate, it is not necessary to throw it away; it can be made true by a simple method by any handy mechanic. If you do not possess an anvil, make a substitute by

FIGURE 7

sticking the ax into a chopping block, lay the square on the head of the ax so that the bearing will come from the throat or inside angle to the heel or outside of the square. To close up the angle, strike with a hammer a sharp blow at a point near the heel; to open the angle, strike near the throat at a point indicated in Figure 7. Don't strike too hard. Use a bell-face nail hammer and the dent will not be noticed.

A STRAIGHT EDGE

In connection with the work with the steel square a straight-edged board is necessary to have ready for immediate use. Procure a board 8 or 10 feet long of good, dry pine, free from knots and 6 to 8 inches wide. Plane the edge until it seems

FIGURE 8

straight to the eye, then lay it on the bench or on another board and make a mark along the edge, just straight with a fine lead pencil; reverse it or turn it over and fit it to the other side of the pencil line. This multiplies any inaccuracy or deviation from a straight line. Make a new line each time you plane the edge. Work with as long a plane as you have and set the blade to take a fine shaving. When the edge will fit both sides of the line made from it while in one position, it is straight. Figure 8 will give a clear idea of this operation.

RAFTERS

The common rafter for a pitch roof is easily laid out with the steel square. There are many methods,

but the easiest and most simple is by spacing. Two dimensions, half the width of the building and the height of the roof, are divided into an equal number of parts. The width of half the building is called the run and is usually divided into parts of 12 inches or a foot for convenience. The height is called the rise, and is divided into an equal number of parts. A glance at Figure 9 tells us that the run there shown is 10 inches rise to 12 inches run.

FIGURE 9

When the square is laid on the stick to be cut into a rafter, the 10-inch mark on the tongue and the 12-inch mark on the blade are held so that they come exactly even with the outside edge. The blade then takes a level position and the tongue a vertical position or plumb position. This gives the proper level for the cut at the top of the rafter and

the level cut at the top of the plate. As the square now lies on the stick make a fine mark and move the square along, marking another space. Mark as many of these spaces as the parts into which the rise and run were divided. This gives the length of a rafter from the ridge to a point exactly over the outside of the plate.

Where the rafter overhangs the plate, it is necessary to square down or in to form the notch for the plate. By studying Figure 9 you can readily see the different positions taken by the square, also, how and why the rise and run are divided into an equal number of spaces. By this method the length of the rafter is obtained without use of mathematics.

STAIR STRINGER

The stair stringer is laid out in much the same manner as the common rafter. The total rise of height to go up is divided into parts of about $7\frac{1}{2}$ inches, as near as possible. This makes the easiest step. The run is always divided into one less space than the rise. The reason for this can be easily understood by examining Figure 10. Lay the square on the stick to be used as a stair stringer, taking the numbers into which the rise and run have been divided, mark, and slide the square along until the required number of spaces are marked. A little experience, with allowance made for the surrounding conditions, and any handy mechanic can lay out stringers for an ordinary flight of stairs. To get an easy flight of stairs for the person of average size where plenty of room can be used, experience teaches that $7\frac{1}{2}$ inches rise and 10 inches run or tread makes an easy flight.

From this some stair-building experts have put together the following rule, which works very well for the average stair: When the rise multiplied by the tread equals 75, the run will be an easy one, as $7\frac{1}{2}$ inches rise by $10\frac{1}{2}$ inches tread equals 75; $8\frac{1}{3}$ inches rise by 9 inches tread equals

FIGURE 10

75; 8 inches rise by $9\frac{1}{2}$ inches tread equals 76, which is very near the desired result. When the rise is 9 inches or over, the rule is not good, as the tread must be shortened up much more, and the rise should never be more than 11 inches—that is about the rise in an ordinary ladder leaning against a house.

THE 47TH PROBLEM OF EUCLID

The problem shown in Figure 11 is known as the 47th Problem of Euclid, and is an invention by an ancient Greek geometer who sought many years for a method of finding the length of the hypotenuse of a right angle triangle in mathematics, and when the method was discovered, history tells us there was great rejoicing. Pythagoras is credited with having first proved the rule successfully applied to the problem.

FIGURE 11

The rule is that the square of the base added to the square of the altitude equals the square of the hypotenuse. The base of a right angle triangle is the side on which it rests, marked B in Figure 11. The altitude is the height and is marked A in Figure 11. The hypotenuse is the connecting side of the triangle, marked H in Figure 11. The base, 6, squared or multiplied by itself, equals 36. The altitude, 8, squared, equals 64. By adding these together we have 100, which is the square of the hypotenuse. It remains but to extract the square root of 100, which we know is 10, therefore 10 is the length of the hypotenuse or third side of this right angle triangle. All right angle triangles can be figured in the same manner, but only multiples of the

length of the three sides come even—such as 3, 4, 5 and 12, 16, 20, as shown in Figure 12; and many others, of course.

length of the three sides come even—such as 3, 4, 5 and 12, 16, 20, as shown in Figure 12; and many others, of course.

FIGURE 12

THE RULE OF 6, 8 AND 10

This is a rule so extensively used in the building trades and others that it has finally come to be known by the above name. It is derived from the 47th Problem of Euclid, and is used in the manner shown in Figure 13.

Measure 6 feet on the end sill of a building and 8 feet on the side sill. If it measures 10 feet across the angle the building is square. This is a very useful rule and easily remembered. It is always available in running lines for batter boards for masonry or lines for walks. By starting from a corner stake into which a nail is driven, measure off on the string or line used and insert a stake to mark the place. Drive a nail into this stake and

proceed in like manner on the other side. With a little care and practice, quite a job of surveying can be done by using a few stakes, a ball of string and a tape or 10-foot pole.

FIGURE 13

ANGLES

An angle is the opening between two lines meeting at a point. Angles are usually spoken of as being of a number of degrees. The degrees are measured on the circumference, the center of which is on the point of the angle. There are 360 degrees of the circumference of a circle. The surface of the earth is so divided north and south by the parallels of latitude, which are numbered from the equator each way; also east and west by the meridians of longi-

tude, which are numbered from Greenwich, England. They can be seen on any map.

By the use of a protractor, the number of degrees of any angle can be obtained. Figure 14 shows one-half of a circle or 180 degrees.

FIGURE 14

PLOTTING ANGLES

To strike an angle in a field on a large scale where one line is given or can be obtained, measure off from the point of the angle $57\frac{3}{10}$ feet; lay one

FIGURE 15

end of a 10-foot pole at this point. The other end should be swung around so that it also will be $57\frac{3}{10}$ feet from the starting point. Each foot marks

off 1 degree on the circumference of a circle whose radius is $57\frac{3}{10}$ feet. If more than 10 degrees are required, continue as before, keeping the ends of the 10-foot pole always on the circumference of the circle from the starting point. A clear idea of this operation can be obtained from Figure 15.

Labor is rest from the sorrows that greet us;
 Rest from all petty vexations that meet us,
 Rest from sin-promptings that ever entreat us,
 Rest from world-sirens that hire us to ill.
 Work—and pure slumbers shall wait on thy pillow;
 Work—thou shalt ride over Care's coming billow;
 Lie not down wearied 'neath Woe's weeping willow!
 Work with a stout heart and resolute will!
 —Frances S. Osgood.

IN and AROUND the HOUSE

THE STEP-SAVING DUMB WAITER

ONE may save many steps in every house where the kitchen is situated over the cellar, to say nothing of other considerations, with a small outlay of time, and perhaps, without the expenditure of a single dollar, by means of a dumb waiter, which may be placed in any convenient corner out of the way. A handy size for an ordinary family is 2 feet square with four shelves, counting the top, 1 foot apart. These shelves may be hung from the corners, the center or the middle of the sides, by means of manila sash cord over pulleys placed close to the ceiling of the kitchen and nearly balanced with weights, which should be confined in a little case. They should be guided in ascending and descending by means of grooves in the middle of the sides extending from top to bottom of the inclosed case. In the cellar the case may have a fine

DUMB WAITER

wire screen door and in the kitchen an ordinary cupboard door or one with a glass front, as desired.

The doors should slide upward and be balanced like an ordinary window with sash weights and pulleys. In order to prevent the waiter from descending when being overloaded a pivoted wooden latch, as shown on the right-hand side, should engage with the ends of the shelves, and to prevent any shock from too quick descent some coiled springs should be placed at the bottom of the case. If desired a small cupboard may be built at the top of the case for storing little-used articles.

Some advantages of such a waiter are that food may be placed on the shelves and lowered into the cool cellar and either allowed to stay there or removed to the refrigerator. Thus it will be unnecessary to carry anything to or from the cellar, and this will often mean a saving of several trips up and down. If the cellar is clean and cool there may be no need to use a refrigerator or an ice box.

RACK FOR PRESERVES

A convenient rack for preserves may be made just at the turn of the cellar stairs in a house, so that the housewife need not step off the stairs, when she descends for a can of preserves. Several circular pieces of wood are pierced through the centers and nailed to a kind of wooden shaft that runs through the entire rack. Nail barrel hoops of the thick, wide variety around the edge of the shelves, so that the contents cannot fall off. The barrel hoops are soaked in water for several hours to make them pliable, so they can be fitted around the shelves.

In a socket at the bottom, the middle shaft slips,

the upper end working in a socket in the end of a stout piece of wood nailed to the beam overhead. The sockets may be purchased at the hardware store. The glass cans are arranged on the shelves, and the housewife can stand in one spot and turn the rack around until she finds the jar for which she is looking.

From the covers of large cheese boxes anyone could make a similar rack, using it in attic or kitchen, anywhere where one wants a rack which will hold an extra large number of articles for the amount of space involved.

Ill husbandry braggeth
To go with the best:
Good husbandry baggeth
Up gold in his chest.—Tusser.

TRANSFORMING A WASHSTAND

The kitchen cabinet here shown was made from an antiquated washstand and table, using old lumber, odds and ends of varnish, nails and screws, the finished article costing less than 50 cents. The only tools used were a saw, hammer, plane and square, such as can be found in any farmer's collection.

First, the shelf shown in Figure I was made, it being wide enough to reach each end of the table and deep enough for the washstand to set on it flush. To the right end was screwed a board of the same width, the shelf being so placed that it would be 2 feet above the

FIGURE I

WASHSTAND AS IT WAS

of the shelf, and the two were securely fastened together. This left a narrow open space between the right end of the washstand and the right support of the shelf. A board was then nailed on top from one end to the other, and a back added.

The drawer of the washstand had to be fixed so that it would slide the other way, as it was now upside down. That necessitated a shelf inside the washstand above the drawer. Old lumber was used, and

table. A board of equal width formed the support at the other end.

Then the washstand, from which the top had been removed, was placed upside down on the shelf (*bbb*), one end of the washstand reaching to the extreme left end

THE COMPLETED CABINET

this was smoothed with a plane, then sandpapered and holes and cracks filled with putty. When the putty was dry it was sandpapered again.

A support was then nailed to the back of the recess for a spice cabinet. This left the cabinet about 4 inches from the table. This support also did for two shelves, one in each corner of the recess. The spice cabinet contained eight small drawers and added much to the whole. A door with a glass sash (*e*) was then made for the narrow space to the right of the washstand above the recess. This made a little china closet with two shelves and containing over a dozen brass cup hooks. The space near the top on the left-hand side, between the short legs of the washstand, was left open for the crumb and draining trays. A piece of batten was nailed around the top as a finishing touch.

A leaf, which could be raised when required, added to the table room. The cabinet being placed in a corner left the front and one end free. On this end or side were placed two salt boxes, one for salt, and the other for kitchen cloths. Directly above these and reaching the length of the end was a shelf (*f*) for the clock, etc. Finally, walnut varnish stain, two coats, was applied. In each side of the recess were screwed two large cup hooks. Similar hooks were screwed on the inside of the washstand doors, to hang up biscuit cutter, corkscrew, nutmeg grater, etc.

HOMEMADE DRESSER

Sometimes it is necessary to use homemade makeshifts in the house furnishing, and sometimes it is done through a desire to exercise one's in-

geny in fashioning simple affairs. The accompanying illustration shows a plan for making a simple dresser that when finished will not only be very useful in itself, but will also add a useful bit of furnishing to the room.

DRESSER MADE FROM A BOX

Select a drygoods box of the right size to fit well into the space to be utilized, then fit two shelves to the interior, as suggested. The whole box should be covered on the outside with some pretty cloth, the edges being drawn over and around the front edges of the box, and neatly tacked inside. Make a shelf with a length equal to the width of the box and fasten it to the wall above the box with some pretty nickel brackets, as shown in illustration. Cover the shelf with cloth, also. Now place a looking-glass above the shelf and have a curtain like the covering in front of the opening. This curtain can have little brass rings sewed to the upper edge, which will slide on a small brass rod.

Dost thou love life? Then do not squander time, for that is the stuff life is made of.—Benjamin Franklin.

Earth is here so kind, that just tickle her with a hoe and she laughs with a harvest.—Douglas Jerrold.

Blest is the man whose wish and care
Is just to be happy anywhere.

KITCHEN WINDOW CABINET

Nothing lightens labor so much as cheerfulness, and cheerfulness may often be secured by very simple means. In the accompanying picture is shown one way that works well. Instead of the usual kitchen table a cabinet is built below and at the sides of the kitchen window and the top made large enough to serve as a table. In this way the

wife may have a pleasant view when she looks up from her kitchen work. It is not necessary to go into details concerning the construction of such a cabinet, because no two people would be satisfied

CABINET AT WINDOW

with the same plan. The plan shown is merely suggestive for the thoughtful wife and the handy man to work out to suit their own particular needs.

TO LET IN MORE LIGHT

Many farm kitchens and dining rooms are dark and gloomy. It is not an easy matter to cut new windows in the outside wall, though this can often

be done to great advantage; but where there is an outside door in a dark room, conditions can very easily be improved, and that, too, at small expense. Doors vary greatly in the manner of construction, some having wide panels at the top and some having two narrow ones of varying lengths. But almost every panel door that was ever constructed can be treated in the way which we will describe. The two upper panels can be removed, and their place filled with two lights of glass. If the door is of modern make it will be found that the wooden panel is held in place by a narrow molding all about it, both inside and out. Remove the molding on one side, and take out the panel. Put in the glass and replace the molding, and the work is done. If, however, the door is of older manufacture the molding on either side may be found to be a part of the door frame. In this case, cut the molding away on one side, neatly and evenly, and remove the panel. Then insert the glass, and having made, or bought, a little strip of molding, fasten it neatly in place around the glass with brads.

In the case of some doors the two panels could be removed, and also the upright between them, leaving a large rectangular opening, into which a single sash of four, or nine, lights could be inserted, the joints being made tight about it with putty and white lead. Then tack a narrow bit of molding about the sash, both inside and out, and a door that will give light to the room will be the result. An outside door looks better with glass in the upper half, and the interior will certainly be made more cheerful and healthful because of it.

We know what we are, but know not what we may be.—Hamlet.

A BARREL CRADLE

Anyone who can use a hammer and nails and needle and thread can make this inexpensive, accessible, easily moved, and cool yet sheltering cradle.

Secure a nice white sugar barrel, clean it thoroughly and remove half of both heads. Place the barrel on its side, removing half the staves, and leaving the other half to form the bed of the cradle.

BARREL READY TO TRIM

Next remove the hoop that is second from the bottom, and then two hoops will be left at the top to form the frame for the hood, and one hoop at the bottom to form the foot. (See illustration.) Carefully nail the remaining staves to the hoops, clinching each nail securely.

Now cover the frame thus formed, as shown in the accompanying illustration. Any thin cotton goods that may be laundered can be used. Figured lawn would be very pretty, and if economy is an item, a worn bleaching sheet will do. Place a little mattress or pad and a tiny pillow within, or

the usual cradle furnishings may be used. One yard of mosquito netting stretched over the opening of the cradle will prevent insects from bothering, and the netting itself cannot touch and awaken the baby.

FINISHED CRADLE

TO PROTECT BABY FROM HOT STOVE

Winter months mean extra care for the mother of a baby, but possibly the greatest of the additional cares that winter brings in this regard is that of keeping the curious tot from the hot stove. Build a pen around the stove to protect him from it. The pen is a simple affair. It consists of four little gates, made just large enough to surround the stove, and covered with netting. The wire netting does not interfere with the free passage of heat and is very effective in keeping baby from getting burned. The gates are made of $1\frac{1}{4}$ -inch strips, mortised or neatly fitted. For netting use ordinary poultry wire of 2-foot width. The gates are held in place by hooks and screw eyes. This arrangement is better than hinges, as it makes the

taking down of the affair, for sweeping or cleaning the stove, much easier.

In the summer you may use the gate at the foot of the stairs, across the porch door, and in other places where baby is determined to go, and where he is in danger of falling and getting hurt unless protected in this way. For this pen, the lumber costs 25 cents, the netting 25 cents, and the hook and screw eyes 15 cents, making a total of only 65 cents.

A BOX FOR CLOTHES

In many of the furniture stores one may see pretty cloth-covered boxes that are used in bedrooms as a receptacle for various articles of apparel, the inside, as well as the outside, being covered with pretty figured cloth. The inside of the cover is fitted with pockets for slippers and slumber shoes. These little chests are so light that they may be lifted about with one hand.

To make such a chest, select one of the very light and well-made grocery boxes in which cereals and various brands of breakfast foods are shipped, which may be had at any grocery store. See that the corners and the bottom are nailed securely. The top will be composed of at least two pieces of board, and these can be made into a solid cover by nailing two cleats beneath them. But these will not look very attractive when the covering is being put on, so a more workmanlike plan will be to saw off a couple of inches from each end of the top boards and supply the place of the wood removed by nailing along the ends a 2-inch strip of the same thickness. This gives a cleat at each end, but the cleats in this way form part of the cover itself.

Use long wire nails to secure these end pieces in place.

It will be a simple matter to cover and line the box when the covering material is at hand. Use very small tacks and carry the outside covering up over the top and down over the inside, which will make the use of tacks along the top unnecessary. The lower edge of the cover can be tacked on the bottom of the box, so the tacks will not be seen on the outside at all.

SCOOPS FROM TIN CANS

Scoops for handling sugar and flour are among the most convenient utensils that one can have about the pantry; and in a short time a good supply may be made from materials that are going to waste about almost every home.

Take an ordinary tin can and either melt or cut off the top. With a pair of tinner's shears (a strong pair of household shears may be used), begin at the open end and split the side of the can to within about an inch of the bottom. Opposite this one make a similar slit. Parallel to the bottom of the can, cut from the lower end of one slit to that of the other. Round the corners of the remaining half, and the body of your scoop is finished.

For a handle, about 4 inches off the end of an old broomstick is just the thing. If this is not available, a handle may easily be shaped with a knife from a piece of soft wood. To attach the handle, from the inside drive a small nail through the center of the bottom of the can and into the center of the handle.

Some additional strength is obtained by planning so that the seam of the can will run down the middle of the lip of the scoop, thus stiffening it. A salmon or corn can makes a very convenient sized scoop for the sugar, while tomato cans serve very nicely for flour and meals, and half-gallon paint buckets may be thus utilized for handling light materials.

A HOMEMADE FOLDING TABLE

A handy game or sewing table may be made as follows: Take two planed boards 12 inches wide and 3 feet long. Fasten them together with two

SIMPLE HANDY TABLE

strips 2 inches wide and 24 inches long. Fasten these strips by strong screws in upright position. Now take two similar strips and fasten them by

hinges to the pieces screwed on the boards. Fasten four stout legs to these in the manner shown in the cut. Take two three-cornered boards large enough to hold the legs stiff when dropped into position, and fasten them by hinges, as shown.

The same general plan may be followed in making a much larger and heavier table or a lighter one.

A HOMEMADE BUTTER WORKER

A butter worker is one of the handy devices that should be upon every farm. A good type is shown in the drawing. It is made of close-grained hardwood—maple or birch are recommended—tight-jointed, free from knots and perfectly smooth in size. It slopes enough to drain readily at the narrow end through a short piece of lead pipe inserted

BUTTER WORKER

at the bottom. The working bar has a strong, smooth iron rod or spike at its lower end, which is easily inserted into or removed from the hole in

which it works. The part of the bar that comes in contact with the butter is half-round on one side and two flat sides meet at a right angle. Of course, it must be as smooth as possible.

HOME CHEESEMAKING

Nearly every farm home contains, or may easily be supplied with, the necessary appliances to make cheese, and it is not a difficult task when one is once familiar with the process. For a small batch of about 12 gallons of milk the following method is a good one: Take about 6 gallons of the evening's milk and leave it covered with a cloth in a

CHEESE PRESS

temperature of 65 to 70 degrees until morning and then mix 6 gallons of morning's milk with it in a large tub or boiler. All milk may then be heated together to 80 to 90 degrees. Care must be used not to get it too hot or to expose it to a draft so that it will cool quickly.

Another good method preferred by some is to use 11 gallons of perfectly sweet morning's milk and

to this add 1 gallon of milk that has soured and thickened. The sour milk should be stirred well to get out all the lumps and left for about 15 minutes before the rennet is put in. The easiest way to heat the milk is to place it in a wash boiler right on the stove until it gets up to 86 to 90 degrees and then raise it from the stove by placing it on two bricks. The stove must not be too hot.

Rennet in the form of tablets is most convenient and useful for home cheesemaking. Dissolve one tablet in half a glass of cold water and add to the milk after it has been heated and stir well for two minutes. Some cheesemakers use two or three tablets, as it saves time, but for beginners two are usually enough. If you have liquid rennet extract, use about two tablespoonfuls.

Cutting the Curd

The rennet will curdle the milk and the curd will be ready to cut in 20 to 40 minutes. This can be determined by noting if the curd breaks clean like jelly when raised on a knife blade. The cutting can be done with a wire toaster, a long knife or a heavy wire. Cut lengthwise of the vessel and then crosswise until the curd is in nearly uniform pieces of $\frac{1}{2}$ -inch squares. After cutting, leave the curd on for five minutes, then heat slowly to 100 degrees, stirring all the time. Cook for about 40 minutes at as near 90 degrees as possible, stirring occasionally to prevent the curd from sticking together. Keep the heat up and do not allow the mass to cool.

To determine when the curd is ready, take a handful and squeeze it in the hand firmly and if it feels elastic and does not stick together, it has been cooked long enough. If the milk is good, the curd

should have a pleasant, slightly acid odor. As soon as the curd is cooked, draw off the whey or dip off the curd with a sieve and place in another vessel. After the curd is well drained and before it sticks together, add $\frac{1}{4}$ pound of fine salt and mix well. After salting, let it cool for 15 minutes, stirring occasionally, when it is ready for the hoop.

Pressing and Curing

For a cheese hoop, one can use a tin hoop 7 inches in diameter and 12 inches deep or an old peck measure without a bottom if holes are punched in the sides for drainage. For a press a device shown in the sketch will serve well, the pail at the end of the lever being filled with stones. Before the curd is placed in the hoop, line it with cheesecloth, one piece the size of the bottom and another around the side. Turn the upper edge of the cloth over the edge of the hoop and fasten it tight. When the curd is packed firmly, put a piece of cloth on the upper end and fold it over tight. Make the pressure slight at first, but after an hour rearrange the cloth and make the pressure heavier. The pressing should be finished by the next day. Do not press in too cool a place, but keep the temperature about 50 degrees.

For curing, set the cheese in a damp room or cellar which has an even temperature. Turn it around daily, and if it shows signs of molding, rub occasionally with butter. It should be ready to eat in three or four weeks. Cheese will cure at 40 degrees, but it takes longer than when warmer. Twelve gallons of milk should make about 10 pounds of cheese, according to richness of milk.

After one or two attempts any housekeeper should be able to make good cheese by this method. It is necessary to keep all utensils very clean and the liberal use of boiling water with a little soda will accomplish this purpose.

WASHES WHILE READING

Here is a way of making play of wash day. Perhaps some of our bright boys will try this to help mother. A friend of ours had an old bicycle unfit for use. He made a frame to raise the hind wheel from the floor, wound the rim with twine (tire being off) and reversed the seat. In place of the form he inserted a piece of pipe (a stick would do as well). Then he took some old belting, cut it

PEDAL POWER DEVICE

to $1\frac{3}{4}$ inches wide and about 10 feet long, and with that he runs the washing machine for his wife. He can read the paper while he washes, and he does not lose much time from field work either. An emery wheel can also be run with it by bolting 1-inch strips to the top part of the frame extending over the wheel and mounting a polishing head on same.

Knowledge is power.—Bacon.

TREAD POWER IN THE DAIRY

While the small gasoline engines adapted to running cream separators have been hailed with delight by many dairymen, the old tread power is still a very economical and reliable source of power. With a heavy sheep, dog or the dairy herd bull

SEPARATOR RUN BY RAM POWER

enough power can be produced to run the separator and churn at practically no cost except for the tread.

One difficulty has been to secure a uniform rate of speed, but this is solved if a heavy flywheel is attached to the tread. While the sketch shows a direct drive from tread to separator, a more desirable arrangement is to have the tread located in a room adjoining the separator room, where the milk will not be exposed to the breath of the animal.

A great many men wear themselves out devising schemes to sidestep honest work.

A LAMP FOR COOKING

A lamp may be utilized for cooking purposes in the following way: Make a tripod by taking three strips of wood of equal length, putting in one end a headless nail and making slightly slanting holes in the corners of a 6-inch triangular piece of board in which to fit them. A screw hook in the center of the board, on the under side, completes the device, which has only to be stood over a lighted lamp to be ready for work. A small stew kettle, or tin pail, hung on the hook, within a half inch of the lamp chimney, enables one to have a "pot boiling" in short order. If you have a large lamp, with a round wick, it will give the heat of two or three common ones, and you can cook almost as rapidly as over a stove.

LAMP HEATER

With an ordinary lamp, food can be heated, eggs boiled, or coffee made very quickly, helping wonderfully in the getting of a meal. This is also an easy and convenient way to heat baby's milk, or water, in the night, in case of sickness. Stood on a chair by the table, the device can be used to keep the coffee or chocolate hot during meal time. A round piece of sheet iron, with chains attached to suspend it from the hook, is an additional help, to hold a steeper for tea.

As this tripod can be taken apart readily, when not in use, it will be found a good adjunct to a

camping outfit, even though you carry a camp stove, for there will be times when nothing will be wanted but a hot drink, which can be made over the lamp with less trouble than it would be to make a fire in the stove.

HOT WATER ALL NIGHT

One of the things that must be had quickly when medicine is needed, and still more often for a bottle baby, is hot water at night. The following contrivance has been found to be worth many times the trouble to make it, for it saves annoyance at a time when baby's worrying may mean hours of sitting up.

Place the socket of a wall bracket lamp just high enough above a table so that the top of a hand lamp chimney will be 5 or 6 inches below it. Make an arm of round iron or small piping long enough to extend out over the lamp and to this hang a hook, on which hang a small teakettle or pail. In this enough water for the needs of a night can be kept hot without boiling, and will be ready at an instant's notice. As a night lamp is a necessity in a house where there is a youngster, the cost of this device will be nothing, for the blaze of a small burner will provide sufficient heat. The proper height for the socket on the wall can be determined by measuring the hook and the kettle to be used. The lamp chimney should not be nearer than 2 inches to the bottom of the kettle, or the water will boil and steam away.

HOW TO CUT BREAD EVEN

Here is one of the most useful devices to which the handy man can give his attention. It is very

rarely that a housekeeper can cut even and handsome slices of bread, however much she may desire to have the bread plate look attractive. One slice will be thin, another thick, while another will be thick on one edge and thin on the other. The drawing shows a simple arrangement by which all the slices of bread can be cut of an even thickness without any slant.

Cut a piece of pine board to about 9 x 13 inches. Near one end, on either side, insert firmly two

BREAD CUTTING BOARD

pieces of very stout wire, bent double, as suggested in the cut. These wire supports should be at least 7 inches high, and should have another inch of length firmly inserted in the wood. The wire should be as stout as No. 12, or larger still, and should stand exactly at right angles to the board. Put them far enough apart so the largest loaf will readily go between them, and have the opening in each wire standard just wide enough so the knife will slide up and down without "wobbling." The dotted lines show the position of the knife when

in place. Screw a little strip of wood in front of the wire, just far enough ahead to make the slice of bread the right thickness. Press the loaf up against this guide and cut off a slice, then press the shortened loaf up again, and repeat the process.

HOMEMADE WATER COOLER

It's a mighty nice thing to have a good supply of cold water at the barn when threshers, corn huskers, or hay harvesters are at work. A simple and effective arrangement can be made by using a flour barrel and a 10-gallon stone jar. Place the jar inside the barrel and surround it with charcoal, sawdust, or chaff, if nothing else is available. With a tight lid and a wet cloth spread over the top, water will keep ice cold in this arrangement.

WATER COOLER

The uses of such a cooler may be multiplied to include keeping many things cool in the house.

KEEP FOOD COOL IN SUMMER

A very convenient and serviceable place to keep dairy products may be formed by sinking a large

barrel in the ground. A shady spot should be chosen, or the heat of the sun will affect the temperature. Fill in around the barrel with small stones, gravel and sand, dampened in order to maintain coolness.

Construct a box around and above the top of the barrel, and bank up with solid earth, preferably

FOOD COOLER

clay. This drains off the water when it rains. It also makes the bottom of the barrel farther down from the top of the opening, which further promotes coolness. Next shape a light, inner lid to place on top of the barrel, and then make a strong, hinged lid for the box, and arrange it so it may be fastened down tightly.

Sprinkle a little dampened sand on the bottom of the barrel, and your little barrel cellar is ready for use. By being careful several vessels may be arranged one above the other in this handy little receptacle. Air out occasionally to prevent mold and odors from collecting.

A COOLER DUMMY

Where a deep, cool well is located near the house an arrangement may be devised that will serve the purpose of a refrigerator. Construct a frame of strong boards with a groove in which a board on the side of the box of shelves can run. Attach a rope to the top of the box of shelves, pass it over a wheel on the crank shaft and balance with a counter weight.

If the frame is 16 feet long and extended down near to the surface of the water the lowest temperature may be secured. A nice looking top may be constructed for the arrangement, with a door opening into the shelves when they are drawn to the top. Most wells are almost as cool as a refrigerator, and this sort of an arrangement serves the purpose with a great deal less expense.

A wire clothesline will serve as a cable. Any old pieces of iron will do for the counter weight, and it is well to have a ratchet wheel, such as are found on old chain pumps, to prevent the elevator dropping when it is well filled. Make as many parts as possible of wood to prevent rusting. One such elevator is 42 inches high and 18 inches square.

Turning the grindstone is hard work; but if you use it as a muscle developer it will help out.

AN OUTDOOR CLOSET

When the housewife has baked a pie or a pudding for dinner and wishes to cool it quickly in winter it has to be set out of doors; but there the trouble begins. It cannot be set upon the snow, since that would melt and engulf the hot dish. Moreover, the cat or dog, or some neighbor's cat or dog, is likely to be lurking about the door, ready for pie. Let the handy man make a little out-of-door cupboard for the use of the housekeeper, locating it beside the kitchen door. Get an empty grocery box of the right size and hinge the cover to the top, placing a knob on the other edge. Make a support for this closet by driving two strips of wood into the ground and screwing two crosswise strips of board to the tops. Lay the grocery box on its side on these supports and nail it to them from the inside.

Here anything hot can be placed to cool quickly, and with the cover down there will be no danger from cats or dogs or hens. If desired to give a freer access to the cold air, several holes can be bored in each end and in the bottom before putting the box in position on the supports. If the ground is frozen too hard to insert the strips of board, the closet can be placed against the side of the house, close to the kitchen door, and supported in place by two wooden brackets. Another plan to secure the same result would be to make the closet and screw a wooden handle to the middle of the top, with holes bored in ends and back. When it is to be used put the dish, or dishes, inside and set the closet out onto the snow beside the door.

Taste the joy
That springs from labor.—Longfellow.

HOMEMADE REFRIGERATOR

Take two large boxes, one 2 inches smaller than the other every way, and bore two 1-inch holes in the bottom of each box for drainage. Fill up 2 inches in the large box with powdered charcoal or coal ashes. Put the smaller box inside and fill the space all around with the charcoal or ashes. Fix the lids to both boxes to fit tightly. Put shelves on both sides of inner box. Leave a place in the center of the box of ice. A rack, made of lath, can be laid at the bottom for ice to rest on.

ICELESS BUTTER AND MILK COOLER

The accompanying picture shows how a well may be utilized during the warm months for cooling

COLD STORAGE FOR MILK

butter, milk and other perishable articles. It will be found very handy as a substitute for a refrigerator when the farmer has no ice supply. Anyone can make a triangular-shaped frame for the windlass, which is placed above the well; and anyone can also put the trap doors in the platform of the well. These doors should be pro-

vided with a lock, so children cannot fall in. A pin may be placed on the handle side of the windlass to prevent the crank from turning around when the box is lowered to the desired depth.

The picture is only suggestive. The shape and size of the various parts will depend upon the style of the well. Preferably, the box should be made of galvanized iron and have perforations in the bottom, so it may be lowered right into the water. Of course, this would not be feasible if the materials to be kept cold were not first placed in sealed receptacles. Where a well with a bucket pump or the ordinary wooden pump is the only available place to put such a cooler, the cooler may be at one side of the well. If necessary, the position of the pump may be shifted.

Knowledge is of two kinds. We know a subject ourselves, or we know where we can find information upon it.—Samuel Johnson.

Every addition to true knowledge is an addition to human power.—Horace Mann.

But now my task is smoothly done,
I can fly, or I can run.—Milton.

A VENTILATED PUMP PLATFORM

Here is a way to keep the well clean and pure at all times. Make the frame of the platform of 2 x 4's, allowing a space 2 to 6 inches between the top and bottom parts of the sides. This space is covered on the inside with a fly screen to keep out dirt and

insects, and outside of this with a larger meshed screen to keep out large vermin. This gives good ventilation to the well, which never becomes foul. In the winter cover the platform with straw and snow.

HELPS TO KEEP WATER PURE

CLEANING A WELL

To remove floating litter from a well, take an ordinary sand sieve, and, after marking off the rim into three parts, attach a wire to any of the two points and to this improvised handle attach a rope. Fasten the end of the rope to the third point in the rim and a weight to the sieve, so that it can be lowered into the well and will sink. When used, sink the sieve edgewise into the water and pull the

rope with a single attachment and it may be lifted out with all the floating sticks and timber on the surface of the water.

DOG POWER FOR PUMP

This sketch shows an arrangement for making use of the dog for carrying water. It simply consists of a wheel 8 feet in diameter and 18 inches

DOG POWER PUMPING DEVICE

wide, with room enough inside for the dog to walk around, where he acts as a tread power, which causes the pump to revolve. In southern Califor-

nia there are a number of these dog-power pumps, which cost less than \$15. A good-sized dog can easily earn his living in an arrangement of this kind.

FILTER FOR CISTERN WATER

The problem of keeping water in a cistern clean is most easily solved by not allowing it to get dirty, as can be done by the device shown in the drawing on page 69. Two barrels, each with a perforated false bottom, are set side by side beneath the water spout from the roof and connected with a pipe leading to the cistern. Above the false bottoms fine gravel and then sand are packed to the depth of 8 or more inches. On top of the sand rest stout floats as large as can be let down into the barrels. From near the margin of the floats two heavy wires extend vertically upward about 2 feet to engage loosely near their centers with a tilting spout by means of knobs on both the ends of the spout and the wires.

When the barrels are empty the floats rest on the sand. As the water begins to pour in one barrel it strikes the float, but is prevented from gouging a very deep hole at the outside of the barrel by striking a strip of wood about 1 inch high, 2 inches wide and 1 foot long. This spreads the flow. A layer of gravel at this place would also help prevent gouging. If the flow is too great to filter away readily, the float will rise and the knob on the wire will engage with the spout, which will be tilted until the flow will suddenly start into the other barrel. If the delivery pipe to the cistern be large enough there should be no danger of either barrel overflowing. When the sand becomes dirty

a few minutes will serve to remove it and put in fresh. This will insure clean water in the cistern, and greatly reduce the number of times the disagreeable job of cleaning out the cistern must be done.

TWO-BARREL FILTER

A HANDY WATER FILTER

Nearly every farm can boast of good water, but no water, either from well, spring or stream, is pure, as it all contains more or less animal or vegetable matter. The only way to make it pure is to filter it, just as is done in city supply reservoirs, or private filtering tanks.

A simple water filter is very easily made that answers all purposes for domestic use. The plan of its operations is identical with that employed in large reservoirs where water is filtered on a large scale for general distribution. This filter consists, primarily, of two flower pots, set one above the other. In the bottom of the upper pot is stuffed a large sponge. A sponge is also stuffed in the bottom of the lower pot, but it is more adequately supplied with filtering material by placing above the sponge a layer of smooth pebbles, then a layer of coarse sand, and still above this a layer of pounded charcoal 3 or 4 inches in depth. It is also best to place another layer of smooth pebbles above the charcoal, to prevent it from being stirred up during the circulation of the water.

The upper pot should be the largest, and if the lower one is strong, the upper one may stand in it, or two strips of wood will serve as a base support. The two pots thus arranged are placed on a three-legged stool with a hole in it, through which the water drips through the bottom of the lower pot into the mouth of a jug set underneath. The upper pot serves as a reservoir, and its sponge stops the coarser impurities, and thus the filtering layers of the lower one may be used for a year without being renewed, though it is necessary frequently to clean the sponge of the upper pot.

The layers of sand and charcoal of the lower pot are positively effective in stopping all animal and vegetable matter, as well as many smaller impurities in the water. The only trouble one may experience with it is in neglecting the upper sponge for too long a time, or in stuffing it in too loosely, thus allowing the water to pass from the upper pot faster than it can filter through the lower one. Only a little attention, once or twice a month, is sufficient to keep this simple filter in perfect running order.

DELIVERING MAIL BY TROLLEY

Where the house stands some distance back from the highway a trolley can be rigged up to save steps in getting the mail. The box is hung on two pulley door hangers, as shown in cut. A strong post, with a bent arm, is set next the highway,

TROLLEY MAIL BOX

a, suspended between it and the house, on which the box runs. A pulley is fastened in or to, the post, and over it runs a cord, *b*, *c*, to pull the box back and forth between the house and the road. The box is sent down to meet the carrier, who places the mail in it, and then it is quickly pulled back to the house.

BEAUTY IN A BARREL

A very nice ornamentation for the lawn is shown in the picture. It is made by sawing an oil barrel in two as shown, and mounting it on legs. Paint it and set one-half of the barrel on each side of the walk and use them for growing flowers in during the summer. Care should be taken to have the hoops thoroughly nailed to the staves and to have the heads solid. Dark green or dark red are good colors for the painting. If preferred, the barrel may rest upon the ground, but should be securely braced or blocked to prevent rolling.

HALF-BARREL PLANT HOLDER

STORAGE BIN FOR VEGETABLES

Instead of keeping the vegetables in barrels or boxes scattered all over the cellar, have a set of storage bins. Take six drygoods boxes and bolt them together as shown in the drawing. Put legs on them to hold them off the floor and a cover on the top. Then paint on the boxes the names of the

vegetables. It is most convenient to have the vegetables most frequently used in the upper boxes, which would not be true of the bin shown in the picture. If the upper row of boxes is attached to each other, but not to the lower ones, the top section can easily be moved enough to make filling the lower boxes a simple matter. Otherwise, the vegetables

VEGETABLE BIN

would have to be put in through the openings at the top of each box a few at a time by hand, instead of pouring them in.

Many people would not care to keep their potatoes in such a sectional bin, preferring a large separate bin. It certainly is all right for other root vegetables, and many other products of the farm that are stored might well be kept handy for use in such a labeled sectional bin.

AN INEXPENSIVE CELLAR

A temporary cellar is sometimes necessary in cold countries where that under the house is not sufficient for storing vegetables. A very effective and useful temporary cellar may be constructed after the following method, as shown by the drawings: Dig a pit 15 feet long, 10 feet wide, 4 feet deep

CROSS-SECTION

in a solid, dry place where the drainage is good. Put a gable roof of 1-inch board over the hole, supported by 2 x 4-inch strips at the eaves, gable and half way up the sides. Strengthen by crossbeams and a central support if the lumber is not first class. Over this place 8 to 10 inches of dry straw

TEMPORARY CELLAR

well packed and over the entire structure, excepting one end, pack earth 12 to 14 inches deep. The surface should be smooth to shed water. It is better if plastered with mud covered with sods.

The door end must be double-walled and the space filled with straw. The door must also be double and its margin packed with cloth strips, so as to be practically airtight. If possible, the pit should be drained by a tile, the end of which is covered with a piece of wire netting to prevent the entrance of rodents. Such a cellar will prevent freezing during usual winter weather. The door should be opened on mild days and the interior aired thoroughly. The size and depth of the pit may be varied according to needs.

CLOTHESLINE UP AND DOWN

Heavy posts should be set for the ends, 3 feet in and 3 feet out of the ground. It is not necessary for the center post to be as heavy as the end ones. Have the posts clean and smooth, so they will not soil the clothes when blown against them. Take a

ELEVATED CLOTHESLINE

piece of 2 x 4-inch hard wood 5 feet long for the lever. Fasten to the post near the top with a $\frac{3}{4}$ -inch bolt, 2 feet next to the line and 3 feet for the lever. A block holds the lever in position while the clothes are being put on. A button holds the lever upright when the line is hoisted.

A CLOTHES HORSE

There is no little thing that will save the household so much as a revolving clothes horse, so near the back stoop that the clothes may be hung on it without stepping out in the snow. A solid post should have a hole bored in the top and the arms may be beveled and spiked to a piece of plank through which a bolt passes into the post, or each arm may be bored to let the bolt pass through it. Three, four or five arms may be used as desired, and of any length, provided all are of one length. No skill is required in making it, as the rope holds the arms up simply by being tight enough. It is well to set the post before measuring for the arms, so that they may be sure to reach the veranda. Some laths may be nailed together at first to make a model, if you are not sure of your ability as a carpenter.

A TOILET CLOSET

A small closet in a home, for keeping medicines and toilet articles, is a great convenience. One consists of $\frac{1}{2}$ -inch pine, 4 inches wide, planed and put together so as to be 2 x 3 feet. It has four shelves. The door is of thin pine, free from knots, planed, hinged and with a back catch. The outside of frame and door is varnished. Being in the toilet room, it is indeed a very useful as well as ornamental piece of furniture. It has no back casing or boards; simply rests against the wall. It is held in place by four short pieces of band iron, one end of each band being fastened to back of frame, the other end fastened to the wall by a screw. All

kinds of medicines, shaving materials, soaps, wash rags, can there be kept. If there is no other looking-glass in the room, one may be fastened on the outside of door.

REVOLVING CELLAR SHELF

A handy cellar shelf that will save the housekeeper many steps may be arranged at the side of the cellar stairs, within easy reach upon descending a few steps. The shelf is contrived from an old axle and wheel. The axle is fastened to hang from the nearest beam to the stairway. The wheel is covered with thin, smoothly planed boards and the axle is kept well oiled, so the wheel will revolve readily, bringing all parts of the shelf within reach at need.

WATER SUPPLY FOR FARMHOUSE

Farmers can have running water, hot or cold, in their dwelling houses at a cost of fifty dollars and up, depending upon the size of the house and the kind of equipment needed. This makes possible the bath and toilet room, protection from fire, the easy washing of windows and walks, the sprinkling of lawns, the irrigating of gardens, and all the other conveniences which a few years ago were thought possible only in cities, where big water systems were available. This is one of the things that makes farm life attractive. It lessens the work in the house, insures a fine lawn and garden, reduces danger from fire, adds greatly to comfort and convenience in every direction.

The way to secure this is to install a water supply system, with a pressure tank in the basement.

This pressure tank is so arranged that by pumping it full under strong air pressure the water is forced all over the house, and is available for the bathroom, toilet room and the garden or fire hose. The water is distributed about the house exactly as it is in city homes, by means of galvanized iron pipes. Where a small building is to be supplied and the

HOUSE WATER SYSTEM

amount of water to be used is not large, the system can be installed for \$50. For the average house \$90 is a better figure. Where the house is large, and where considerable amounts of water are needed for the lawn and garden, and possibly also for washing carriages, automobiles and horses, a larger system should be installed, costing up to \$150.

Installation and Operation

Its installation is easy, and its operation is exceedingly simple. Any pipe fitter or plumber can

put in the plant so that it will work perfectly. All that is needed for operating is to keep the tank pressure up to the desired point. This may be 20, 40, 60 or 100 pounds. A few strokes of the pump, if the work is done by hand, is sufficient. If a lot of water is used, of course the amount of pumping will increase. By being economical in the use of water, that is to say, wasting none, this matter of pumping is not at all a serious problem.

The most satisfactory method of pumping, however, is to use a windmill, or what is much better, a gasoline engine. Every up-to-date farm ought to have a small gasoline engine, which can be utilized not only for operating this water supply system, but for churning, sawing wood, cutting feed and doing a dozen and one other jobs about the farm. It would take only a few minutes of pumping to raise the pressure in the tank the desired height. With the engine it will not be necessary to be economical in using water, provided the well is a good one, and the supply of water large.

Experience with Water Supply System

C. A. Shamel of Illinois, editor of the Orange Judd Farmer, has a system of this kind in his country home. It cost \$75. He put in a bathroom, a toilet, has a hot water tank in connection with the kitchen range, and no money ever expended on that farm has given anything like the amount of satisfaction and comfort as that paid for this water supply system. Arrangement is made to take care of the waste water and sewage by running a large tile from the bathroom, one-quarter of a mile distant, to a large cistern, located in the center of a big field. This is disinfected about

twice a year, and is easily handled. There is never any trouble with the water pipes, even during the coldest weather. Neither has there been any difficulty with the waste system. In fact, the water supply is practically perfect, and the people on that farm don't see how any farmer who can get together \$75 or \$100 can afford to be without it.

Up to date all the pumping has been done by hand. With the pump in perfect condition, this is not a laborious problem. On two occasions the pump valve became slightly defective through wear, and it was not convenient to fix it for a few weeks, being somewhat distant from the factory. With this condition it required a great deal more labor to do the pumping, but even with this disadvantage, it was not a serious proposition.

The illustration indicates the arrangement of a water supply system, and as can be readily seen, it is very simple. Notice the hand force pump tank in the basement to hold the water under pressure, and the arrangement of lavatories, bath and kitchen hot water service. The system can also be used for supplying water to stock tanks, and these may be located anywhere on the farm. The pressure developed in the tank is sufficient to force the water anywhere wanted. This use will, of course, depend entirely upon the wishes of the owner and is simply a matter of cost of pipes. It can very readily be used for delivering water to dairy or other stock barns, where it can be run into water troughs in the stalls, or elsewhere, as desired.

WARNING AGAINST FIRE

A handy device that will give an alarm in case the roof catches fire close to the chimney is shown

A FIRE ALARM

on the opposite page. Drive a nail in two rafters on a line with the face of the chimney, to which stretch a cord close to the chimney, so that, in case of fire, the cord will burn off and release the weight hanging to it, which in turn will drop on an electric button and ring a bell. A dry battery will cost 20 cents and a bell 50 cents. Place these on a shelf above the fireplace. Place a piece of heavy wire, *b*, 10 inches long, as shown, and fasten to the wall or chimney for the weight, *a*, to slide on. The weight need be suspended only an inch or two above the bell.

WHERE TO HANG A FIRE LADDER

A necessity on all farms and near all farm buildings are ladders and other means of getting on the roofs, and in and out of upper story windows in time of emergency. A scuttle should be left or made in the highest part of the house roof and a ladder should be at hand that will reach the eaves of the highest roof. A good place to store a ladder of this kind is under the eaves of the L or along the rear wall of the house. Have two hooks to hang it on. Make a good ladder and keep it painted.

If your cellar is dark, there is danger of accidents when going down the stairs. Have the last step whitened so that you may easily know when you are at the bottom. You can see this step plainly even in a dim light.

A HANDY FEED BASKET

PROVIDE a feed basket like this to strap upon the nose of a horse when giving the animal feed while away from the stable. It is simpler to make than the round basket, and has an added advantage. When not in use, the two sides press together and occupy scarcely any room. Cut out two semi-circular pieces of wood from a $\frac{3}{4}$ -inch board in the shape suggested in the cut. Setting them at the proper distance apart, tack a strip of canvas, or other stout cloth, around the curved partition, as shown in the accompanying picture. Nail a strap and a buckle at the sides, to go over the head, and the feed basket will be complete.

FEED BASKET

The form of this basket more nearly fits the shape of a horse's head, and besides, because of its oblong shape, gives the horse more freedom in opening his mouth than does the close-fitting round basket.

He who will not be counseled cannot be helped.

MAKE THE HORSE EAT SLOWLY

If your horse has the habit of bolting his feed you can easily remedy it by making a self-feeder on his box. The accompanying drawing shows how a feeder may be made similar to a poultry feed hopper. The contrivance may be made of inch boards large enough to hold one feed. The horse can get the grain only in small quantities and so cannot eat it more rapidly than he should. The bottom must be made with enough slant to insure all of the feed coming out in the trough.

HOLDS ONE FEED

I am only one,
 But I am one.
 I cannot do everything,
 But I can do something.
 What I can do I ought to do;
 And what I ought to do
 By the grace of God I will do.

STALLS BETTER THAN STANCHIONS

The only point in favor of stanchions is that they take up less room than stalls, but the increase in milk is a reward for allowing more space and convenience to each cow. The cut shows one kind of stall. The rack, *a*, is of hardwood 30 inches high, with the slats wide enough so the cow can thrust her nose through up to her eyes.

The bottom of the rack is 18 inches wide, extending into the stall toward the cow. The feed

box, *b*, slides through an opening in the stall on the barn floor. It can be drawn into the feedway, cleansed out and a new feed put in without being disturbed by the cow. The halter strap, *c*, is just long enough to allow the cow to lie down comfortably. The gutter, *d*, is 8 inches lower than the

PLAN OF COW STALL

stall floor. When she lies down she will put her head under the rack in kneeling and when she gets up, she will move backward so that she can look through the rack. The length and width of stall can be made to suit the cows. Small breeds, like Jerseys and Ayrshires, will need about 6 inches less each way than Holsteins and Shorthorns.

Knowledge is proud that he has learned so much;
 Wisdom is humble that he knows no more.

—Cowper.

The man who is always poking his nose into other folks' business rarely has any of his own worth attending to.

There is no knowledge that is not power.—
 Emerson.

GOOD TIES FOR COWS

The merits of stanchions and other forms of cow ties have been debated by dairymen for a long time.

SWINGING STANCHIONS

The mass of experience is in favor of the tying arrangement which will give the cow the most freedom of movement. The old-fashioned solid stanchion fails in this respect. In many cases it is difficult for the cow to lie down or get up with her head fast in one of these stanchions. The heavy swinging stanchions have advantages over this, but it also must be criticised in many cases, because of its weight and of the consequent lack of freedom on the part of the cow. A very light swinging stanchion is the best type of that form. It is easy to fasten, as the cows will in most cases put their heads in position as they go into the stall. There is not so much danger of the dairyman being struck by the horns of the cow in fastening these stanchions. Many modern barns are equipped with this kind.

The chain tie is favored in many sections. This consists simply of a crosschain with considerable slack, attached to a ring at each end which runs over a perpendicular iron rod about 18

inches long. In the center of this chain is a loop with a snap which goes around the cow's neck. This arrangement gives the greatest freedom, and allows the cow to lie down and get up without difficulty. If light partitions are used between the heads of the cows no difficulty will be experienced in their striking each other with their horns. This is by far the least expensive of cow ties, and is at the same time one of the most satisfactory.

NECK CHAIN

HANDY CALF-FEEDING DEVICE

To feed a half-dozen calves at once is entirely possible if one uses the device shown here. A man

STANCHIONS FOR CALVES

who has one reports no more trouble with calves since he has used this. He rattles a couple of

buckets together, the calves come running up to the fence and soon have all their heads through the stanchions, to which they are easily fastened by throwing down lever, *a*, which draws the bar, *b*, into position. Then one may feed each calf without difficulty.

Leave a 4-inch space for the calves' heads. Make the rack of 1-inch lumber and it can be moved from one pasture to another and attached to the fence or a couple of posts. It can also be used for holding ewes at lambing time.

MANAGEMENT OF KICKING COWS

Make a slatted stall just high enough so the cow can't jump out, and wide enough to hold her comfortably, with nothing to spare, and narrower at the end, where her feed box should be placed as high from the ground as is comfortable for her to eat out of. This slatted stall should be long enough to have cleats through which a bar or two should be run behind the cow to keep her from backing out, and also places to run a bar in front of her hind legs about the hock joint, or as high up as possible so as not to interfere with milking. A hole about 18 or 20 inches wide is left open for this purpose from the ground up to the cow's flank, which allows easy and safe access to the udder, while the cleat and post prevent the cow from kicking outwardly at the milker, thus insuring safety.

A HANDY MILKING STOOL

Milkers who have trouble with restless cows that invariably either upset the pail or get a quantity of

STOOL TO HOLD PAIL

dirt in it will find the stool shown here a remedy for their troubles. It is also very serviceable in fly time. The upright pieces forming the legs and ends of stools are made of 2 x 8-inch pieces about 1 foot long. The supports for the bucket and the seat are made of inch boards. To secure rigidity it is well to put three-cornered blocks under the seat and bucket board as brace stays. The most restless cow is not likely to upset the bucket from this stool.

THE EVER READY STOOL

A very convenient stool for use in milking the cow in yard or field is shown in the cut. It is merely a one-legged stool to which is attached four straps connecting with a broad strap that is buckled around the waist. The stool is quickly fastened to the milker and is always in a position so one can sit down anywhere. Such a stool with a short leg would also be useful in the garden. Of course, if one pre-

MILKING STOOL

ferred four legs instead of one, the stool could be so made, but experience proves that the one-legged kind serves well.

CHEAP MILKING STOOL

A cheap and very useful milking stool is made of the reel from which barbed wire has been removed. Saw off the ends so it will set level and

REEL STOOL

cut a board to fit on top. Make a hand hole through the board as shown in the illustration and the stool is ready for use.

KEEP STOOLS CLEAN

Much milk contamination is undoubtedly due to the careless handling of the milk stools. When the milker is through milking one cow he gives the stool a toss, then he picks it up again when he starts to milk the next cow and his hands become more or less contaminated from the stool and from

them the dirt drops into the milk pail during the milking.

When the milking is over, the stool is left in the yard or on the barn floor. It is so easy to make a small rack and to bore holes in the legs of the

STOOL RACK

stool, so that they may be hung up. This keeps them out of the dirt and it is only necessary to brush them off carefully once in a while to keep them scrupulously clean.

The man who is constantly changing his mind usually has little to change.

A USEFUL STOCK CART

Here is a handy transfer cart, made with wheels and crossarch of an old corn plow to carry a hog

or sheep, pigs or a calf. Raise the tongue, which lets the rear end on ground, then drive in the animal,

TRANSFER CART FOR SMALL ANIMALS

shut the gate, pull tongue down and you have your load ready to fasten to a wagon.

HOW TO STAKE OUT STOCK

A convenient and simple contrivance so that no harm can come to the animal is to drive two stakes several feet apart and stretch a rope or wire on

COW TIED OUT TO FEED

which a ring is placed. To this ring fasten halter strap. The animal can graze up and down on both sides without tangle or injury. The ring slides, and the stretched wire will give some.

FEED BOX FOR FIELD

A handy feed box for use in open lots or when steers are being fed upon grass is shown in the

TUB FEED BOX

cut. Cut a barrel in two and strengthen the halves by placing a frame of two boards across the inside, as shown in this sketch. This will prevent the tub being smashed and will allow four animals to eat out of the trough without bothering each other unnecessarily.

It is important that a very strong barrel be selected and that the hoops be nailed to each stave.

Be advis'd;

Heat not a furnace for your foe so hot
That it do singe yourself: we may outrun,
By violent swiftness, that which we run at,
And lose by over-running.—Henry VIII.

Have more than thou showest,
Speak less than thou knowest,
Lend less than thou owest,
Ride more than thou goest,
Learn more than thou trowest,
Set less than thou throwest.—King Lear.

Use or practice of a thing is the best master.

CHEAP SHEDS OF STRAW

It would pay every farmer to put up in the pastures some kind of protection for his sheep, hogs and cattle. Where labor is scarce and hay and straw is plentiful and cheap, a condition which prevails in many large sections, straw sheds and barns are very profitable. Put up a framework of posts 8 feet high, 16 feet wide and as long as needed; 30 feet is a good length.

The posts are hewed evenly on two sides and set so that a bale of straw will fit snugly between them. They are cut off at a uniform height and a 2 x 6 spiked securely on top. Rafters are nailed to this and covered loosely with poles. Baled straw is used for the sides.

After the sides are up the roof is covered 2 feet deep with loose straw held in place with a few poles that are tied together in pairs and placed over the ridge. Several of these sheds have been built for five years and have not needed any attention.

Life is made up not of great sacrifices or duties, but of little things, in which smiles and kindness, and small obligations given habitually, are what win and preserve the heart and secure comfort.—
Sir H. Davy.

You must cut your coat according to your cloth.

FEED TROUGH FOR SHEEP

For a sheep trough procure two 6-inch boards, *a*, about 3 feet long and at the bottom of each fasten another board, *b*. Make a flat trough and let the

ends project above the top. Bore a hole through each end and also through the standards, *a*, and hang the trough on bolts. After the sheep eat and

SWINGING SHEEP TROUGH

leave the cobs, or if it rains, the trough can be turned bottom side up and quickly cleaned.

The luck that I believe in
Is that which comes with work,
And no one ever finds it
Who's content to wish and shirk.
The men the world calls lucky
Will tell you, every one,
That success comes, not by wishing,
But by hard work, bravely done.

A NOVEL FEED RACK

An overhead manger, as shown in the sketch, is excellent for sheep or calves. It should hang just high enough so that they will pass under with-

out rubbing their backs. When filled with hay from above they will eat of it at their pleasure, and at the same time it will not take up floor space.

HANGING RACK

Such a manger is not suitable for grains or fine cut fodders, as too much may be wasted.

A WHEELBARROW SHEEP TROUGH

It very often happens that one wishes to run the sheep on several different pastures during the

PORTABLE RACK FEEDER

season. If heavy feed racks are used it is quite a task to move them. The drawing shows a rack that can be easily moved from one field to another by one person. It is simply mounted upon a pair of wheels and has handles on the other end.

If the rack is made very large, it can be easily attached to a wagon, and thus drawn from place to place. The one shown is mounted on old cultivator wheels.

PACKING THE FLEECE

One of the best ways to pack a fleece is to lay it upon a table, turn in the head and tail, then the

FLEECE TYING BOX

flanks. After this roll it up into a neat roll and tie firmly, using such a device as here illustrated.

The tying box is made from light lumber with slots, as shown, through which the rope is passed. The fleece is placed upon this rope and the roll easily tied. Wool buyers prefer to have the fleece

loose, light to handle and elastic and tied up so that it can be opened if needed.

EASY TO HANDLE HEAVY HOGS

The old fashion of having a lot of help around at hog-killing time is going out, owing to the use of better appliances for handling the animals after killing. You may rig up a simple arrangement so

ONE-MAN BUTCHERING RIG

that you can handle heavy hogs without assistance. Build a fire box with a flue, *b*, of three joints of old stovepipe. The vat is made of heavy galvanized iron 4 feet long by 2 feet wide and 18 inches deep.

Over this erect a frame of 2 x 4-inch strips, upon which place an old traveler from a hay carrier, or construct one similar to *d*. With the windlass arrangement, *a*, and the tackle, *e*, to which are attached the four feet of the hog, you can convey it from the vat to the bench. A rope, *c*, passing over the pulley at *g*, serves to pull the carrier, *d*, over the bench from the vat.

HEATING WATER FOR HOG KILLING

A device which is superior to the old iron kettle for heating water is shown in this sketch. Take a piece of 2-inch iron pipe 8 feet long and have it securely screwed into the bottom of a stout vinegar barrel. In the other end of the pipe screw a large wooden block.

SIMPLE WATER BOILER

By arranging the affair as shown in the sketch water in the barrel will be heated rapidly and can be removed as desired without bothering the fire. Do not make the mistake of putting a metal cap on the end of the pipe, or the steam may sometimes burst the piping before the cap will come off. The wooden block acts as a safety valve and will fly out if pressure is too great.

A FARM SLAUGHTERHOUSE

If one butchers his own stock on the farm he would do well to fix up a small building for a slaughterhouse. This can be done so easily and at such small expense that almost any farmer can afford one. It is generally most convenient to have

it near the hog yard, for then the refuse can be easily conveyed to the hogs. Indeed it would not be a half bad idea to have it in some instances a part of the hog house. The room in which to kill

CARCASS DERRICK

cattle and hogs should not be less than 15 feet square. This will give plenty of space for the work. As much of the room should be kept clear from fixtures as possible.

The floor should be made of concrete graded so that it will all drain to a central opening. A pipe should carry the liquid from this opening to a trough in the hog yard. The ideal way would be to make the walls of concrete for about 3 feet from the ground. This will make it much easier to keep the place clean. It is quite necessary that a good supply of water be close at hand. If possible, a water pipe with hose attached should be in the house. This will enable one to flood the floor at any time.

On page 99 is a picture of a very good device for handling the carcasses. It is made of a heavy roller, *c*, 5 to 6 inches thick, and long enough to reach across the width of the room. It is supported in the middle by a bracket, *d*, detail of which is shown in the drawing. This makes it possible to lift a carcass of any weight. A drum, *b*, is attached to the roller at one end, over which is run the rope that communicates with the crank, *a*, at the floor. Any man handy with tools can make this derrick.

In order to simplify matters one may use a barrel cart water heater. This barrel has a valve attached at the bottom. To this is fastened a rubber hose that communicates with a small coil of pipes. This coil of pipes in turn communicates with the top of the barrel by another rubber hose. The coil of pipes is placed over a fire built in a hole in the ground, and the valve is opened.

As soon as the water in the coils becomes hot it is forced through the rubber hose, and a circulation is started. This device will heat water very rapidly and easily. When the water is heated the rubber hose is detached and the barrel wheeled under the

derrick on which the hog is hung. By means of a crank the carcass is let into the water to be scalded.

With simple devices one man can very easily do the butchering alone. It will be found convenient to have a table that folds up against the side of the building on which to cut up the meat.

KEEP PIGS OUT OF FEED TROUGH

To prevent hogs crowding and getting in the trough with their feet the accompanying plan will be found practical. You can nail the Vs, or rick-

PARTITIONED HOG TROUGH

rack work, on any shaped trough. They fit on a pointed or flat-bottomed trough equally well. Nail a strip lengthwise along the top of the Vs to strengthen them. Stakes driven at intervals and nailed securely to the angles will hold the Vs and trough both solid.

MOVABLE HOUSE FOR BREEDING SOWS

Individual hog houses may be constructed with four upright walls and a shed roof, as shown below. The walls and the roof are separate and can be easily taken down and replaced. These small

houses can be moved about very easily. The size of the house will depend upon conditions. The

CONSTRUCTION OF THE HOUSE

construction is shown, so that any farmer with tools can easily put up one of these houses. With the individual houses the sow at farrowing time may be kept alone and away from all disturbance and there will not be too large a number of pigs in a

THE HOUSE SET UP

small lot if kept in this way. The danger of spreading diseases among the animals is also reduced to a minimum where swine are kept more isolated. When properly bedded and cared for no disastrous disease need be feared. Much depends upon the sanitary conditions.

WELL-ARRANGED HOG LOTS

An Indiana farmer keeps his pigs in long houses which are divided into compartments opening into small lots. The sketch shows how they stand. Breeding hogs and fattening shotes are allowed the run of their own lots, as well as occasional

PIG HOUSES AND PENS

changes into the larger field, shown at the bottom of the sketch, which is a timothy and clover pasture. It is better to have pigs in separate quarters in small bunches, for in this way they can be better attended to and the growths are more uniform.

HANDY PIG CATCHER

Here is a homemade device for catching small pigs which saves much time and annoyance. The net may be made from a discarded lawn tennis net, the rim from a bicycle wheel, and the handle is a heavy rake handle. The net is securely fastened to the rim with some copper wire, while the rim is fastened to the handle with two pieces of band iron. Small pigs caught in the net will not squeal and struggle as when chased around the pen and caught by one leg. The element of excitement is greatly reduced by use of the net, and some would find less fun in the net method. On the whole, however, we recommend it.

PIG NET

The weakest arm is strong enough that strikes with the sword of justice.

Our knowledge is the amassed thought and experience of innumerable minds.—Emerson.

STAIRS FOR THE BARN

A lot of time is saved if one has handy stairs which can be used for throwing down hay as well as a passageway. These steps are made of light

material and instead of putting on a lower step, use a block, *c*, and attach the stringers of the stairs to it at each end with a pin. A rope passes over the

pulleys at *d*, to a weight, which allows the stairway to be held upright while the hay is being put down. The rope, *e*, is handy to pull the stairs into position.

HANG UP THE LANTERN

Here is a good idea for hanging a lantern over the barn floor. Get two pulleys with screw stems, and screw on in beam over head, the other at top of post. Have a bracket lower on the same post. Take a piece of small but strong cord, and at

one end fasten a snap and pass the other end through the pulleys. Put your lantern on the snap and draw it high enough so it will be out of reach of forking hay, and you can see all over the barn floor. You can raise the lantern high enough to pitch hay from the top of the mow with no danger of turning the light over and burning the building and contents.

PULLEY-HUNG LANTERN

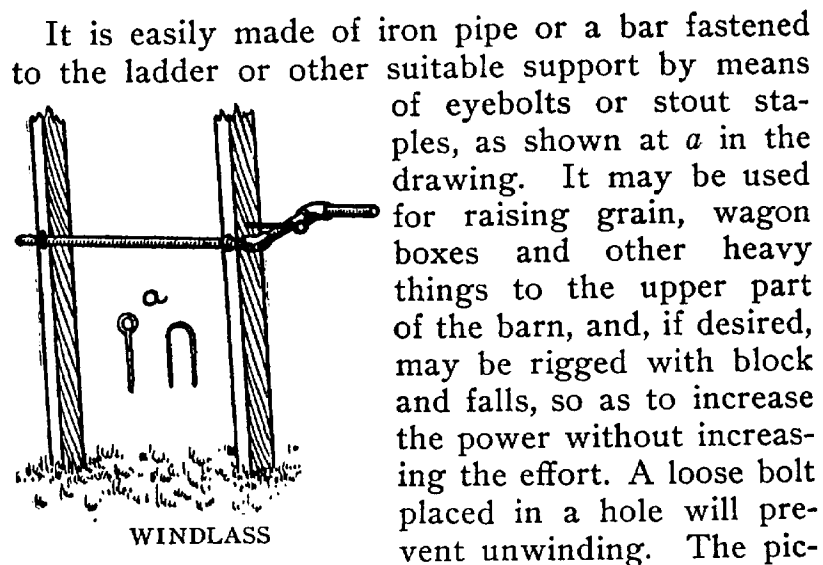

The end of the cord opposite the lantern may be fastened with a snap, or more length may be allowed for adjusting the height of the lantern, and the cord may be secured by a hitch or a few turns around a button or two spikes driven halfway in and bent over in opposite directions.

ARRANGEMENT FOR WEIGHING

A homemade balance may be constructed with a joist loosely attached, so as to just balance over the rounded top of a heavy block. It will be useful in weighing hay and other bulky substances for feeding purposes. For weights, use small wooden boxes or bags of stone and sand which have been weighed on other scales. Place the required weight upon the balance and then place feed on the other

end until it balances the weight, and it will be accurate enough for all ordinary purposes.

A BARN WINDLASS

It is easily made of iron pipe or a bar fastened to the ladder or other suitable support by means of eyebolts or stout staples, as shown at *a* in the drawing. It may be used for raising grain, wagon boxes and other heavy things to the upper part of the barn, and, if desired, may be rigged with block and falls, so as to increase the power without increasing the effort. A loose bolt placed in a hole will prevent unwinding. The picture shows how simple this device is. Every farmer knows how useful a barn windlass may be.

GRAIN BOX EASY TO EMPTY

The trouble with most grain boxes is to get out the last third of the grain. Bending over the edge jackknife fashion is neither pleasant nor healthful. A box or bin may be made with half its front on hinges, so that it can be let down and all the contents scooped out without difficulty. The bin may be made from a piano box with a partition in the middle for two kinds of grain.

Leave your son a good reputation and an employment.

EASILY CONSTRUCTED GRAIN BINS

Grain bins with compartments for different kinds of feed are handy in barn or stable. By procuring a number of dry-goods boxes, all of the same size and shape, and nailing them together side by side, so that they will appear as one, the bin is easily made. The cover should extend the entire length of the bin, and though leather hinges will answer, it is better to attach it with iron ones, for then, with a good staple and hasp, the contents can be kept under lock and key if desired.

A CONVENIENT BARN TRUCK

No dairyman can afford to ignore that which will lighten his labor in any way whatever. Be his stable ever so conveniently constructed, he has enough to do. Hence the importance of his considering a feeding truck or car if he does not have one. Made of good lumber, the only iron about it need be the handle at each end, by which to push or pull it along the feeding alley in front of the cows which are to be fed, and the small trucks on which it is mounted. The wheels procured, any good blacksmith can make these, so that the truck is by no means difficult to construct. The box body should be about 2 feet wide, 20 inches deep and 4½ feet long. Silage can be conveyed in it from the silo to the mangers very readily. If the silo is some distance away, it will save much hard work.

If little labor, little are our gains:
Man's fortunes are according to his pains.

—Herrick.

TAKES A MAN'S PLACE

In most cases it takes two men to fill a sack of

SACK HOLDER

man or enables a man to work twice as fast as he could without it is worth while.

A wise old owl sat on an oak,
The longer he stayed the less he spoke.
The less he spoke the more he heard.
Why are not more of us like that wise old bird?

There are but two ways of paying debt: increase of industry in raising income, increase of thrift in laying out.—Carlyle.

If it were done, when 'tis done, then 'twere well
It were done quickly.—Macbeth.

A HANDY BAG HOLDER

It is constructed with two good boards 1 inch thick and 15 inches wide. The perpendicular one is 3½ feet long, and the horizontal one 2 feet long. These are joined together and braced as

BAG HOLDER

shown in the drawing, and the hopper is attached, wedged out from the perpendicular board so the bag may wrap it all the way round. The hooks for holding the bag in place can be secured at a hardware store. As the whole affair, if composed of thoroughly seasoned lumber is light to handle, it can easily be carried to any spot where grain is to be put up.

Here is another scheme that saves time and labor and makes it possible for one man to do the work that usually requires two. This one is as good and perhaps better than any device that has been invented in the bag-holder line. In making it, an important point is to attach all parts very securely where they come together, especially the hopper and the braces. Otherwise, with hard usage the holder will get loose and break down.

A CORN HUSKING RACK

Many who husk their corn by hand find it very tiresome to sit on the floor or ground in a cramped position. A rack made as shown in the drawing

RACK FOR CORN HUSKING

will hold two or three shocks and gives a better place for the husker to sit. Place the stalks cross-wise of the bench in front of you.

A HOMEMADE FEED CUTTER

An old lawn mower can be arranged to make a fairly satisfactory straw or feed cutter. One must

WORKING THE LAWN MOWER

rig up a hopper, as shown in the sketch, and attach the mower to the lower end of it so that the straw or grain will just strike the knives where the grass usually comes into the mower. A crank and a belt arrangement makes it easy for one man to feed and turn the cutter. This is a good use for a lawn mower in the winter time when it is not working outdoors.

SAW ROOT CUTTER

Those who have cut roots in the winter time with a butcher knife or hatchet will fully appreciate something better for a root cutter. A Wisconsin farmer has found a serviceable homemade lever cutter very efficient for all roots. For hard ones, like rutabagas, it is about the best thing available.

ROOT CUTTER

His is made out of an old hand saw, sharpened on the back, fastened by means of a bolt passing through a hole punched at the small end, and held by a guide formed of two pieces of wood secured upright, so as to have a slit for the saw to work in. This contrivance is a success, and with a little practice the roots may be cut very rapidly. See accompanying illustration. The cutter may be mounted upon the wall wherever it will be most convenient. The bench or platform should be at about the height of a common table.

HOMEMADE CABBAGE CUTTER

A cheap and easily made cabbage and root cutter is shown in the drawing. Take two

CABBAGE CUTTER

12-inch boards and nail them strongly together. With dividers mark around a circle, then saw out and mark in quarters. Cut four slots 7 inches long on a slant, as shown by dotted lines, so the cabbage will fall through easily. Next cut two circles 4 inches in diameter. Nail one to the large wheel on the back and leave the other loose on the shaft to act as a bearing.

Make a frame to admit the wheel, leaving 2 inches clear, and just wide enough so the knives do not strike the side. Make a top over the wheel and put a hopper on the opposite side from the crank. The knives are 8 inches long and can be made from an old bucksaw and ground down sharp, with a bevel on one side. Screw these on the wheel at a slant according to the thickness the cabbage is wanted. A square hole should be cut through the center of the wheel for the shaft.

A SUBSTANTIAL DRIVEWAY

A plank driveway to the barn is usually made steep in order to save planks. It is continually wearing out and breaking. A substantial driveway with an easy grade can be made by driving down stakes close together on either side, and filling in between with stones, rubbish and earth, packing all down firmly. When full to the top, pack some earth against the outside of the stakes and sod over the sides. This driveway will form an easy rise and will prove very durable.

Kindle not the fire that you cannot extinguish.

FEEDING DRY GROUND GRAIN

SOME of our friends have found that a poultry feed hopper for feeding ground grain has proved very satisfactory. Make a box 18 x 18 inches and 6 inches deep, then take off one end and fasten to the back with hinges, which forms the cover.

Nail a strip, *a*, 3 inches wide across the open side at bottom, which forms the box for the poultry to eat from. Take a board, *b*, the width of inside of box, 14 inches long, and insert in front of box, nailing as shown in cut, with the upper end even with front edge of box and slanting in until a space of 2 inches is left between bottom of board and back of box to allow the feed to pass through.

FEED HOPPER

The feed is poured into this hopper and runs down into the box at the bottom as fast as needed. The size of the hopper can be varied to suit the size of the flock. It should be screwed to wall of poultry house about 12 inches from floor. By using this hopper one may keep a dry mixture consisting of wheat bran and middlings and occasionally corn meal, or a small amount of linseed meal, always before the fowls. In addition, some people feed a mixture of whole corn, oats and wheat in the litter morning and evening, also ground green bone and beef scraps.

KEEPING THE WATER CLEAN

Few drinking fountains are more successful than a large bottle or jug filled with water and inverted. It can be fastened wherever convenient with straps. If a small pan is placed close beneath it the water will flow out as it is used and will remain clean and cool. Place it high enough above the floor of the house so the fowls will not scratch litter into the pan.

A WATERING RACK FOR HENS

Build a crate of lath 2 feet square, 3 feet high, with a slanting cover to keep the hens off the top. Then tack an 8-inch board in front, level with floor of crate. Nail the rack to post or side of henhouse about 2½ feet from floor, and put your water pan in crate. The hens will quickly learn to fly up and drink by putting corn on the lighting board. This contrivance keeps the hens from spilling their water or scratching dust or chaff into it. Be sure to nail the rack securely to the wall or post where it is put up.

RACK IN PLACE

Keep your shop and your shop will keep you.

DRINKING FOUNTAIN

The best drinking fountain, in that it is impossible for small chicks to get drowned, and they cannot stand in the water to befoul it, is made by inverting a can or pail in a pan a trifle larger. Tomato cans with the edges pounded down, leaky pails with the ears bent up, in fact anything with a smooth top and in which a hole can be made, can be used. Punch a hole or holes in the side just a little less distance from the top than the depth of the pan to be used. Fill with water, invert the pan over the top, and turn over quickly.

CHICKEN FOUNTAIN

FOLDING CHICKEN ROOST

This roost is made of 3-inch boards cut any desired length. A small bolt fastens the upright

MOVABLE ROOST

pieces at their top ends, and the horizontal pieces are fastened on with nails. This roost can be kept at any angle, and may be quickly taken out of the house when it is time to clean up. This sort of roost will accommodate more fowls in the same space than the flat kind, but it should not be made very high.

A GOOD POULTRY NEST

A useful trap nest can be made of grocery boxes. They should be at least 12 inches each way. The illustration shows how they are made. In the cut the trap is set ready for the hen to enter. A cleat, *c*, is fastened to a small piece of cord, which is tied to a nail on the side of the box. Set the trap by raising it and resting the cleat on the nail, with the other end under the arm marked *a*. This leaves an opening from 4 to 6 inches wide, which is not enough for the hen to enter. In going into the nest she will be obliged to raise the trap door, which will let the cleat fall, thus closing the trap after the hen has gone in.

TRAP NEST

The trap door, the arms and the cleats may be made out of lath. Leave a little space between the boards in the walls, so the heat can escape, otherwise it will be too warm in summer. The bottom

board, *b*, in front should be 3 or 4 inches wide, and the lower piece of the trap door should rest against this so the hen cannot get her head through, raise the trap and get out.

TWO COOPS FROM A BARREL

Very good coops can be made at small cost from empty barrels, as shown in this picture. First, drive shingle nails through the hoops on both sides of each stave and clinch them down on the inside. Then divide the barrel in halves, if it is big enough, by cutting through the hoops and the

BARREL CHICKEN COOP

bottom. Drive sticks into the ground to hold the coop in place, and drive a long stick at each side of the open end just far enough from coop to allow the front door to be slipped out and in. The night door can be made of the head from the barrel or any solid board, and the slatted door, used to confine the hen, by nailing upright strips of lath to a crosslath at top and bottom.

Weak men wait for opportunities; strong men make them.—Marden.

A BOX CHICKEN COOP

The diagram shows a convenient way to make a coop for the poultry yard, of which the special feature is its door. Procure a box of the right dimensions and saw a hole, *d*, in one end. Then strengthen the box with narrow strips of wood, *b*, *c*, on each side of the hole *b*, *c*. This acts as a

HINGELESS DOOR IN COOP

groove for the door, *a*, to slide in. Thus you have a sliding door, which opens and shuts with the greatest ease. The front of the coop is inclosed with lath, or narrow strips, placed $2\frac{1}{2}$ to 3 inches apart. The top should be covered with a good grade of roofing paper to make it waterproof. A coop of this sort should be 2 to $2\frac{1}{2}$ feet long, 16 inches deep and 2 feet high.

A LOW POULTRY RUN

A safe and secure run that requires less material than a high pen can be made from laths sawed in two, which would make the sides 2 feet high, making the frame of scantlings and the top of sawed laths, box boards or similar material. The top of

the run should consist almost entirely of trap doors, using bits of old harness for hinges, which will look well if cut neatly. The picture shows one of the doors propped up to show the construction more plainly. The doors are 4 feet long, the length of a lath, and may be 8 to 10 feet the other way and still not be clumsy, being constructed of such light material. This trap door is an important feature,

TRAP-DOOR POULTRY COOP

as it permits the tender to enter easily for removing top soil and replacing with fresh earth, or otherwise caring for the birds. The frame material is of 2 x 2-inch scantling at the corners, while the side strips are made of inch boards sawed 2 inches wide. The earth under this run should be slightly mounded for the sake of dryness.

Whatever is worth doing at all is worth doing well.—Earl of Chesterfield.

A PORTABLE CHICKEN COOP

One of the annoyances about an ordinary chicken coop is that it is not easily moved from place to place, nor provided with a yard. To obtain a yard the coop must be moved separately, and thus require the loss of more or less time. In the drawing shown herewith is a simple, homemade coop,

COOP EASILY MOVED

which can very easily be moved by the aid of the handles at the apex at each end. The coop is built of ordinary material on a base frame, and with a V-shaped roof and side frames. The ridge pole is extended, as shown at each end, to form a handle. A convenient length is about 2 feet for the coop and 3 or 4 feet for the yard. If desired, the hen may be allowed the freedom of the yard or may be held in by slats, as shown in the drawing.

A HOMEMADE BROODER

The material costs about \$2 and a handy person can build one in a day. The gas from the lamp does not go into the chick apartment at all, but filters around under the floor, making it dry and warm. The lamp flame is about 3 inches from the

sheet iron. The heat flows up gently through the drum, *f*, which is perforated with holes in the side, thus letting part of the heat out into the hover and the balance in the brooder above. The heat reservoir, *g*, between the sheet iron, *k*, and the floor, *c*, is about 1 inch deep. The tube, *f*, should not touch the sheet iron, merely extending through the floor, *c*. It takes very little oil.

DETAILS OF BROODER

In the cut, *a*, is the paper roofing over inch-matched boards, *b*; *c* is board floor of same material; *d* are small windows, *e* is the hover, *h* are holes in each side of the brooder for the escape of gas and fumes, *l* shows door to reach the lamp, *n* air space below the floor.

MOVABLE BROODER HOUSE

The type of house shown in the cut is one of the best for raising poultry. It may be built on runners, with a tight board floor of matched boards. A convenient size is 6 feet wide and 10 feet long, 6 feet high in front and 4 feet at the rear. The

door is in the middle, and there is a window on each side, with two openings below. The roof should be covered with a good quality of prepared roofing.

HOUSE ON RUNNERS

The same material used to cover the sides will make the house warmer. Roosts may be put in after the brooders are taken out, and the chickens easily protected from foxes and other animals.

A VERY CHEAP HENHOUSE

It was built by a "down east" Yankee. The studs and rafters were made of two pieces of 1 x 2-inch stuff nailed together T shape. These were set up 2 feet 10 inches apart on centers and covered with wire netting drawn taut. This was then covered with tarred paper, which made the only material between the fowls and the outside air. They have wintered in these houses without discomfort, and gave a good egg yield. The wire netting prevented the paper from sagging when the house was covered with snow.

They can who think they can.

A DAYLIGHT CHICKEN CATCHER

Do you, when you want fried chicken on short notice, run it down, provided it doesn't run you down? Here is a better way. Fasten a barrel hoop securely to a handle about 6 feet long, and to it fasten a bag about 3 feet deep. A piece of an old hammock is fine for a bag, or horse net or fish net—anything the chicken cannot get out of. Lay it on the ground, call the chicken and throw the corn over the bag, and when one suitable goes on lift up the hoop and you have it. If the bag is made not over 1 foot deep it can be dropped down over the chicken while eating.

A SIMPLE HAWK TRAP

Make a box 4 inches deep, 6 inches square and nail to a 4-foot pole with cleats at the bottom to keep from turning over. Cover top of box with 1-inch mesh wire. Place a little chicken in the box; then put a steel trap on top of box and set it out under the trees where the hawks lodge to watch for the chickens. If there are hawks around, it is pretty sure to catch them.

SCARE AWAY CROWS AND HAWKS

For keeping hawks and crows away from the poultry yards, get a few bright tin shingles, link them together with wire, and hang upon an arm extending from the top of a high pole, where sun and wind strike fairly. The jingle and glitter is sufficient to keep these pests at a safe distance. You will also find them useful in the corn and melon fields where crows are troublesome.

PRACTICAL HIVES AND HIVE MAKING

EVERY apiarist knows that there is no item in bee keeping of more practical importance than the hive and brood frame. The Langstroth, or Simplicity size of frame has become almost standard, for there are more frames of this size in use than all others combined. The frame proper is $17\frac{5}{8}$ inches long, $9\frac{1}{8}$ inches deep, and the top bar is 19 inches long. There are several styles made, but many prefer what is known as the Hoffman. This has a heavy top bar in depth, as well as width. The ends, or end bars, are made $1\frac{3}{8}$ inches wide for about 3 inches down and one side is worked off to a knife edge, which comes against the square edge of the next frame, making them self-spacing, but not a closed-end frame, and allowing the proper bee space between the top bars. This works fairly well without the use of the honey board, though one is preferable.

The hive for this frame, to be best adapted to the production of comb or extracted honey, should contain 10 frames, the inside dimensions being 15 inches wide, 10 inches deep and $18\frac{3}{8}$ inches long. A follower can be used at one side to assist in removing frames by first removing the follower or division board. This arrangement leaves $\frac{3}{8}$ inch between the top of the frames and the top of the brood nest, so that when the surplus cases are put on the proper bee space is

DOUBLE-WALLED
HIVE

preserved. This hive is made of scant $\frac{1}{2}$ -inch lumber for the outside, ship-lapped together in a manner to make a perfect joint. It is 20 inches wide, 24 inches long, about 20 inches high to the eaves, or roof, outside measurements, and weighs complete about 50 pounds. The inside dimensions of the brood nest should be the same as any 8 or 10-frame hive, as the bee keeper may prefer. The brood nest is raised sufficiently to admit of packing between it and the hive proper, also a space for packing at ends and sides.

DOVETAILED HIVE

The lower portion of the hive being well protected against the cold, the warmth of the bees will care for the upper portion. To avoid condensation cover the brood nest after removing the surplus cases with a porous substance, or chaff cushion. Make a wooden rim about 4 inches deep, covering the top and bottom with burlap and filling with wheat chaff or cut straw. Many prefer the cut straw both for cushions and packing the

hives. This rim should be made a little smaller than the inside of the hive.

In extremely warm weather the cover can be raised a few inches in front, giving a circulation of air all around the surplus department, and shading it at the same time. The cover is hinged at the back end, and when raised, as shown in cut, makes two shelves for the use of the operators, which are highly appreciated; besides, there is no lifting on or off of covers, as is the case in other hives. The alighting board is hinged and can touch the ground, which is of great advantage to the bees during a heavy flow of honey.

Perhaps there are more single-walled hives used in the United States than double-walled or chaff hives, but in northern states a double-walled hive is preferable.

DEVICE FOR EXTRACTING BEESWAX

Wax, as produced by the bees and worked into comb, is almost pure white, but, on being melted

SOLAR WAX EXTRACTOR

and cooled, is yellow. A man who knows advises every beekeeper to use the solar wax extractor.

All that is necessary is to have a box with glass to fit over it, as shown in the drawing. To melt combs, put in the box an old dripping-pan, having a hole at one corner, and that corner the lowest, with some kind of a dish set under to catch the wax. Set in the sun. To get the most out, break up the combs into fine pieces, then soak in water for a day or two longer before rendering.

SELF-FEEDER FOR BEES

A very simple device for feeding bees on syrup may be made if you take an ordinary fruit can, fill it full of syrup and over the top tie a thick rag with a string. Then invert the can in a small pan or dish. The syrup will seep out through the rag around the edges of the jar just fast enough for the bees to keep it cleaned up.

A HANDY DEVICE OF THE ORIENT

QUICK DELIVERY FROM THE FARMS

Hundreds of farmers are today making profitable use of automobiles, although their first appearance upon country roads caused only fear and anger.

SAVE THE BARRELS

Barrels, barrel hoops and barrel staves may be worked into many useful things upon a farm. From the few described in this book your ingenuity will lead you to others.

AS IN DAYS OF YORE

Modern harvesting machinery has come to take the place of old-time hand tools on the big farms; but many a reaper of the ancient type still swings through the golden grain, a relic of the days when men worked harder and accomplished less than they do today.

KEEP THE HAMMER BUSY

A NAIL IN TIME

A TIME-HONORED HANDY DEVICE

AN IRON HOOP TRELLIS

THE BIG BROTHER TAKES A HAND

He's a city chap now, but when he comes home, he proves that his early training has not been forgotten. Teach your boy to use tools and use them right.

THIS trellis is made of the iron hoops that are now used so commonly upon sugar and other barrels. They are of stout wire, welded into a complete circle, and, as barrels are constantly going to pieces, one can get together quite a collection of these, when they can be assorted into uniform sizes.

An attractive trellis is shown. Three strips of wood, pointed at the lower end and finished with a knob at the top, are provided, the length being a matter for individual taste. A trellis for tomato plants will need not more than two hoops, while one for sweet peas may require a half dozen. The strips of wood should be of inch board, 2 inches wide. The hoops are secured to the uprights by small staples made for putting up wire fencing. The wooden posts may be oiled or painted some attractive color. This trellis will be greatly appreciated both in the vegetable and flower gardens, for its strength and attractiveness.

THE TRELLIS

Diligence is the mother of good luck.—Franklin.

PLANT SUPPORTS OF BARREL HOOPS

The ordinary wooden hoops from barrels may be made into an attractive trellis for grapes or a support for smaller twining plants by being arranged

HOOP TRELLISES

as shown in the sketch. Attach them firmly to heavy stakes with some No. 7 smooth wire and you have an arrangement which will last for several years and is not unattractive to the eye.

A FOLDING TRELLIS

A good way to pole beans is to make a folding trellis out of plastering lath, as shown in the cuts.

TRELLIS FOLDED

Bore three small holes through each lath, as shown in the first cut and fasten them together with common wire nails well clinched.

Five-foot posts are set 1 foot in the ground and a wire strung at top and bottom. The lath are fastened to the wires with string, as shown in the second cut. The trellis is made in sections so as to be

TRELLIS IN PLACE IN THE GARDEN

easily handled. When not in use it is folded up and laid away under shelter. The posts are spaced evenly so that one section of trellis will just go between two posts.

EASY WAY TO POLE BEANS

Set posts at convenient distances apart and stretch a wire at the top. This may be done as soon as ground is plowed. Plant and cultivate one row each side of line until beans begin to vine, then

TRELLIS FOR BEANS

set poles slanting, tying them together where they cross at the wire. This braces the whole row and beans can be cultivated with hoe. Hills 3 feet apart in row with one vine to hill are better than two vines.

TRELLIS THAT STANDS ALONE

A plant support or garden trellis, such as shown in the drawing, is very handy in the garden. This

DOUBLE FORM OF TRELLIS

double form of trellis can be folded up and takes very little room in storage. All trellises and stakes should be gathered as soon as the crop is harvested and stored under cover until the next season.

They are useful for tomatoes, beans, peas, cucumbers and other plants that need some support. The double trellis is built of narrow $\frac{1}{2}$ -inch slats and pieces of 2 x 3, which are bolted together for the legs. The top may be held in place by pieces of string or wire attached at the points indicated in the drawing. The length, width and height of this trellis should depend upon the use to be made of it. A large one will be wanted for a large spreading plant and a small one for a small plant. It is important to have trellises just the right size to give proper support.

PROTECTING NEWLY SET PLANTS

Plants newly transplanted always demand more or less protection from the blighting effects of too much sun and wind. It is best achieved by making a shelter such as is shown in the cut. Two 10-

foot poles and two 3-foot pieces of any convenient thickness for the crosspieces, with four 14-inch weather-strips for the legs, constitute the frame. In the middle of it two hooks should be inserted on each side, and upon these the covering fastened, which can thus be adjusted very quickly. The covering may consist of burlap or any kind of rough sacking.

FRAME OPEN AND COVERED

Being so simple and economical to make, it is advisable to have enough frames to protect the number of tender plants that are set out in a garden at one time. They possess other advantages than sheltering the young things from the direct rays of the sun. They allow slow evaporation, and so keep newly watered ground moist for hours, whereas if exposed to the sun and wind it would soon become dry and caked. On windy days it is only necessary to let the sacking down on the windward side of the shelter. In case of frost the protection that they afford is of inestimable value.

Love thy neighbor, yet pull not down thy hedge.

MAKING THE HOTBED

The value of every vegetable garden can be greatly increased and the time during which a supply of fresh vegetables may be secured for the table greatly lengthened by the use of the common manure hotbed and the cold frame. These indispensable adjuncts of the good garden are so easily made and cost so little that it is surprising they are not more common. A good hotbed made the latter part of February or in March can be made to yield an abundant supply of lettuce, radishes, spinach, etc., for table use by the time such crops are being planted out of doors, and the supply of cabbage, tomatoes and other plants for the home garden can be secured ready to transplant several weeks earlier than if plants grown in the open were depended upon.

As a source of heat fresh horse manure is used. About half manure and half fine straw mixed together should be piled in square piles 2 or 3 feet in depth, and 4 or 5 feet in width and long enough to contain the amount necessary for the beds desired. After heating has well started, the piles should be forked over, turning the outside of the old pile to the inside of the new, and when heating again is well under way the material is ready for use. In the meantime select a well-drained spot, sloping to the south, if possible.

Dig a trench $6\frac{1}{2}$ feet wide, 2 feet deep and as long as desired, running east and west. Now place the manure in the trench, tramping and packing in thin, even layers until level with the surface. Make a frame 6 feet wide and as long as desired, but some multiple of three, because the hotbed sash are always made 3 feet wide. The end piece should

be 9 inches high in front and 15 inches high in the back. The front side board should be 9 inches wide and for the rear it will require two boards, preferably 12 and 3, with the wide one at the top.

A frame 12 or 15 feet in length will be quite large enough for the ordinary farm garden. Set this frame on top of the manure with the slope facing the south and secured by stakes. On top of the manure put 6 inches of good garden soil and cover the frame with common sash or windows 6 feet long by 3 feet wide. At first the heat will run very high, but in a few days it will fall to 80 or 90 degrees, when it is safe to plant the seeds.

MAKING PERMANENT HOTBEDS

Hotbed sash should be constructed of white pine or of cypress, and the sash bars should run in one direction only, and that lengthwise of the sash. The bars may be braced through the middle by a transverse bar placed through the long bars below the glass. The two ends of the sash should be made of sound timber, 3 inches wide at the top and 4 inches wide at the bottom end, mortised to receive the ends of the sash bars, and with a tenon at the ends to pass through the side pieces, which should be $2\frac{1}{2}$ inches wide.

A permanent hotbed should be so constructed as to be heated either with fermenting manure or by radiating pipes from the dwelling or greenhouse heating plant. For a permanent bed, in which manure is to supply the heat, a pit 2 to $2\frac{1}{2}$ feet deep, according to the latitude in which the work is to be done, should be provided.

The sides and ends may be supported by a lining of plank supported by posts 4 feet apart, or, what

is better still, a brick wall 9 inches thick, as shown in the drawing, may be used. In either case the pit lining should come flush with the surface of the soil. The site for the pit should be on naturally well-drained land, and a tile drain from the bottom of the excavation should be provided to prevent the

HOTBED WITH BRICK WALLS

water from accumulating in the pit and stopping the fermentation of the manure during the period the hotbed is in use.

Standard hotbed sashes are 3 by 6 feet. The pit, therefore, should be some multiple of 3 feet in length, and the width should be the same as the length of the sash, 6 feet. The plank frame, or the brickwork of the pit, may be extended above the surface of the ground sufficiently to allow for placing the sash immediately upon these permanent structures.

HEAT FOR HOTBEDS

Make an excavation 5 x 16 feet on the surface, and about a foot deep. Lengthwise along this

space lay three rows of tiling, one along the center and one about a foot from each side. The tiles should be 4 inches inside measure, and 1 foot long. These are placed end to end so as to fit closely, and earth is pressed around them so as to hold every piece exactly in place. Then the excavation is filled with rich soil until level with the surface, excepting at the end the tiles are left bare for a few inches. The board frame, 5 x 15 feet, is next put in place so as to leave 6 inches of each row of tiles projecting beyond the ends of the frame.

At the east ends of the bed, a hole should be dug 3 x 4 feet on surface and 2 feet deep; in this hole a crude fireplace may be made of loose brick and the flue connected with the three ends of projecting tile. At the west end of the frame a brick chamber should be made into which the three tiles enter, giving them a common flue for outlet. Cover the top of this chamber closely, excepting a 6-inch circular hole, into which a single length of stovepipe is fitted. A sloping door is hung over the fireplace cavity to keep out the rain; and the earth raised high enough around to prevent surface water from running into the hole. Bank soil about the frame. You may happen to have on hand six old storm window sashes of that size. Of course the sashes slope to the south in the usual way.

When the fire is kindled in the fireplace the smoke comes freely from the stovepipe. The tiles are covered with soil to a depth of about 6 inches. With a good fire, you can quickly warm up the earth on the coldest days of spring. And when once well heated, the earth and tiling hold the heat for a long time, provided the draft is closed. Unlike beds heated with manure, the heat supply can thus

be regulated to suit the demand of the prevailing weather.

COLD FRAMES AND THEIR MANAGEMENT

In the South cold frames are in use all winter. The principal winter crops grown are lettuce, radishes, beets, cauliflower and occasionally cabbage, while these crops are commonly followed in spring by cucumbers, cantaloups and sometimes Irish potatoes. The frames are easily made. Rough inch lumber (heart pine is best in the South, and hemlock in the North) and 2 x 4 or 2 x 3-inch scantling are all that is required. For the double frames, strips 3 inches wide and $\frac{3}{4}$ or $\frac{1}{2}$ inch thick, long enough to extend across the frame, should be provided for rafters. The back or north side of the single frame should be 12 or 15 inches high, while the front should slope down to 8 inches. In Southern practice, where canvas covers are used, the back should be $2\frac{1}{2}$ feet and all cracks should be well covered with building paper, held in place by laths tacked over it.

Good treatment for the posts used in construction is to dip them in kerosene over night. This will preserve them indefinitely. Drive the posts into the ground 18 inches and let them extend upward to the top of the boards, putting a post at the union of each pair of boards and nailing them to it. All ends and rafters may be made so that they can be quickly removed, so that the frames can be plowed and the ground prepared with a mule. The sides of the double frames are best made 1 foot high, with the ends sloping upward to $2\frac{1}{2}$ feet. Down the center of the frame, a row of 2 x 4-inch posts $2\frac{1}{2}$ feet above ground are set 8 feet apart.

Over each one of these a rafter is bent and fastened to the sides of the frames.

For cold frames in the North, glass is the only covering to be thought of. By all means, put the frames up facing the south or southeast and to afford protection against the north and northwest winds, cold the country over, a high wall, a thick hedge, or a piece of thick woodland should be close at the back of them.

The soil in the frames should be thoroughly prepared, rich and pulverized thoroughly. An abundance of well-rotted stable manure should be used; if thoroughly decomposed, at the rate of 75 to 100 tons an acre is not excessive, unless the soil is already very rich. Whether glass or canvas is used as a covering great attention must be given to water and ventilation. The land should be well drained that no water will stand, or the soil become water logged; that is one side of the water question, but in addition, the plants should be carefully watered from time to time to provide sufficient for their needs.

If the coverings are kept down too constantly, the growth of the plants will be weak and spindling and such diseases as damping off, Botrytis and drop will work havoc with them. Careful attention to watering, ventilation and keeping the surface of the ground stirred are the genuine secrets of controlling these pests. Watch the temperature, do not let it rise too high, lower it by raising the sash or drawing back the covers. The canvas covers should be drawn back a portion of every day when the temperature is not too low, and at other times the ends may be raised, to allow the air to circulate under them. A sharp eye must be kept on the

frost item. Sometimes steam heat is provided, oil stoves may be used and glass covered frames should be covered with burlap or straw mats, securely held down either by tying them in place or by weighting them down. Both canvas and the glass covering should be well fastened to prevent their being lifted off by strong winds.

The upper end of glass sash may be held down with a hook and staple, a hook being placed on the back of the frame at the center of each sash with the staple in the end of the sash. Canvas covers are best held down by nailing along the center to a board run lengthwise on the center of the rafters, in the case of double coverings, or along the back in the case of single ones and by placing marbles or small pebbles in the cloth and tying about these every 4 or 5 feet, along the ends and sides, slipping the looped ends of the twine used in tying them over nails driven into the ends and sides of the frame.

A HAND GARDEN CULTIVATOR

Now that garden crops are planted almost exclusively in rows a tool that will clean out the weeds, stir the soil around the plants, and, by making a good surface mulch, prevent the loss of moisture to some extent, is essential for the proper care of the garden. The wheel hoe of our cultivator is usually used for this purpose by the professional gardener, but the price is generally considered rather high by the ordinary farmer or amateur.

This machine, although homemade and not very handsome in appearance, does the work as well as a \$6 or \$8 tool, and cost not more than 40 cents

to make. For a wheel, take the fly wheel of an old sewing machine, about 1 foot in diameter, and put a round bolt tightly through the axle. Then a piece of plank, *a*, 20 x 10 inches, and cut as shown, boring holes for the axle where marked. After the wheel is set in place, it should turn easily and steadily, if balanced properly. For the handle, *c c*, cut out and round from a piece of plank two pieces, or use any that may be otherwise obtained. Then get a blacksmith to make three teeth, *b*, out of a

HAND CULTIVATOR

piece of spring steel 1 inch wide and 8 inches long, bent as shown. Two-inch holes are drilled through them for screws.

One tooth should be placed about 6 inches behind the wheel and directly in the center, the other two being 4 inches behind the first, and the same distance from the center tooth. When this cultivator is pushed through the rows it should run with little pressure from the operator, clearing out the weeds and stirring the soil at the same time. This contrivance does the work well, and if given two coats of brown and green paint it will be improved in appearance.

Know thy opportunity.—Pittacus.

A CONVENIENT GARDEN STOOL

This device will prove useful in doing hand work in the garden. It is made from two barrel staves upon which is mounted a low stool. This should be narrow, so that it may be drawn between the rows of vegetables. The holes in the seat are large enough for the fingers to go through and render the stool more easily handled. The device is especially convenient for the women.

WEEDING STOOL

WATERING SEED SOIL MADE EASY

To avoid disturbing small seeds by watering, when planted in forcing boxes, a plan has been devised which not only insures against the disturbance of the seed, but keeps the soil of the entire box in a moderate state of moisture, which is an essential feature in early growth.

Make a box of any desired size to suit the occasion, and about 3 inches deep. Then get a few small unglazed flower pots and place same on stove until quite hot. With a short piece of candle, seal drain hole in bottom of pots, taking care not to put wax over the entire bottom of pot. Place pots in box about 9 inches apart on a thin layer of sand, and overlap pieces of broken pots, to convey by capillary attraction the water to the entire soil of the box, which soil should be sifted and box filled to within $\frac{1}{4}$ inch of the top of the pots.

Cover the box with glass, and heat from above will draw the water up to the roots. By this method you will not have surface baking, which is so troublesome with surface watering. If so desired,

you can cover the pots with circular pieces of paste-board or tin, and avoid surface evaporation from the pots. Always fill pots with warm water.

CATCHING OWLS AND HAWKS

A friend of ours captured a large owl and fastened him securely with a small chain to a stake in the middle of an open field. He set three posts 5 feet tall and 4 to 5 inches in diameter 20 to 30 yards from the owl, and on each post placed a small steel trap with a bunch of hay or grass tied to the post just under the trap, to hide it, as shown in cut. At night, the owl called. Others came, and seeing nothing near, alighted in the trap on the post. During the day hawks came, and were caught in the same way. In two months two owls and 17 hawks were caught. In some places a bounty is paid, so there is a profit in two ways. The owl may be fed on the hawks caught and on rabbits or chickens that may die around the premises. The most difficult part of this scheme is often the capture of the first owl, but if you are a good hunter you will find a way.

TRAP ON POST

Make no absolute promises, for nobody will help you to perform them.

Money is a good servant, but a bad master.

MOVING A LARGE TREE

To move a large tree one may find it very satisfactory to use a rig similar to that shown in the picture. Make a three-sided standard of 2 x 4-inch stuff. Loosen the dirt around the roots of the tree

RIG FOR MOVING TREE

and wrap the tree firmly at the base with old carpet or burlap to prevent injury. Place the standard firmly in the ground and tie the cross-piece to the body of the tree with strong rope to each side of the standard and hitch a horse to the

other end. With a slow pull the tree can be drawn onto the drag and then hauled to the new location. It can be placed in the ground again by using the standard in the same way it was used to load it upon the drag.

A penny saved is two pence clear,
A pin a day's a groat a year.—Benjamin Franklin.

The man who builds, and wants wherewith to pay,
Provides a home from which to run away.—Young.

TRANSPLANTING TREES

Here is a way to transplant large trees that is not so difficult as such transplanting is by many supposed to be. The first move to make is to dig all round the tree, leaving a large ball of soil, which is carefully wrapped in sacking or canvas to hold it on the roots and prevent drying. When this is well tied in place a chain is passed round the ball two or three times and hooked, as shown in Figure 1.

FIGURE 1—BALLED

Then with a pair

FIGURE 2—HOOK AND TRUCK

success in transplanting trees is to injure the roots as little as possible.

The manly part is to do with might and main what you can do.—Emerson.

Many things difficult to design prove easy to performance.—Samuel Johnson.

HOMEMADE FRUIT PICKER

This is a device that is hard to beat for reaching fruit at the top of tall trees. After a little

of heavy wheels on a short axle and a strong pole laid across it, with a massive iron hook fastened to the pole, it is easy to back up to the tree. The sketch, Figure 2, shows the truck with its lever raised ready to hook into the chain. The rope at the end of the pole brings it down and the tree up, when the pole is fastened under a second pair of wheels. The young trunk must be kept from contact with the machinery by the free use of blankets and bags. The secret of suc-

cess in trans-

practice, a man can operate it rapidly, far outstripping hand pickers and at the same time not

WIRE DETAILS

injuring the fruit. The construction is shown in the upper drawing. The main frame is of heavy copper wire, to which is attached the strong spring, *d*. The end, *a*, is inserted into a wooden handle as long as

THE PICKER IN USE

needed. When the muslin sack is attached, as shown in the picture of the picker in use, the jaws of the picker are easily closed by pulling slightly on the cloth. The fruit falls through the sack or long cloth tube into the hand of the operator. Many

devices have been made for this sort of service, but it will be hard to find one that works better than this one if constructed in the exact shape indicated.

A TRUSS LADDER

For a 14-foot ladder select four pieces of 1 x 2 hard wood, using two pieces for each side. Place rungs of 1 x 2 between the side pieces. Make ladder 12 inches wide at top, 14 inches at center, and 30 inches at the bottom. Put a 1/4-inch bolt through the side pieces just below the rungs, and a 6d nail through the end of each rung to prevent them from slipping out. Keep all bolts tight. A ladder made as above, of Oregon pine, 14 feet long, supported on trestles at each end, deflected but 1 inch when 150 pounds were placed on the center. It is light, yet strong, and it is almost impossible to spring it. The special advantage of a truss ladder is lightness, which is a very great advantage, when strength is combined, as in the case of this particular ladder.

THE LADDER

Let us have faith that right makes might; and in that faith let us to the end do our duty as we understand it.—Lincoln.

Never spend your money before you've earned it. Never buy what you do not want; it is not cheap.

ORCHARD LADDER ON WHEELS

The accompanying sketch shows the manner of construction. Any farmer or orchardist can build it. Secure two old mower wheels and one piece of 2 x 4 scantling for an axle. Place the ladder upon this scantling. To keep it upright use poles, two at the bottom and one near the top of the ladder, extending to the ground. The upper one should be forked at the top so as to hold the ladder firmly. This ladder is 18 feet high, and as the foundation is broad, there is no danger of it falling over. The brace is so made that it can be adjusted, thus enabling one to place the ladder at any angle.

LADDER FOR FRUIT TREES

CONVENIENT SORTING TABLES

Where fruit is packed from the trees a sorting table will always be found convenient. It generally saves time and labor to do the packing right in the orchard. A handy table is one mounted on wheels which may be of any size desired and should be large enough to hold at least four barrels. The

wheels can be picked up from discarded machinery or quickly made by nailing together crosswise two boards to prevent them from splitting, boring a hole in the center for the axle and rounding them off with a key hole saw. One end of the table should be made several inches higher than the other, so that the culls will roll into a pile at the lower end.

OREGON SORTING TABLE

In the Hood river district of Oregon a table such as shown here is commonly used. This is made to accommodate two packers. To make such a table take four standards about 3 feet high. It is made 3 x 4 feet in size, the top covered with strong burlap or canvas and allowed to hang rather loosely. Saw off the tops of the legs on a bevel so as not to have the sharp corners push into the burlap, and make points that will bruise or cut the fruit.

A piece of old garden hose is generally nailed around the top of the table to protect the fruit. Besides the braces shown in the cut it is also well to wire the legs and braces together firmly, as there is a heavy load to support. The shelves on each side are for holding the boxes, as all the good fruit in this region is boxed. The height is only relative, the point being to construct it so each packer can work with the greatest comfort, avoiding back bending in all cases. The top should not be greater than 3 x 4 feet, as anything larger would not allow two packers to reach all points of it without unnecessary stretching.

PORTABLE HAY DERRICK

A VERY satisfactory derrick for stacking hay is shown in the sketch. The base pieces are 6 x 6 inches by 16 feet. For the center pole we use a straight round pole 7 inches in diameter at the base and 5 inches at the top about 24

feet long. We put an iron band around the base and insert the peg upon which it turns. About half-way to the top is an iron collar, which has three loops to it that form an attachment for the braces, which are fastened about 15 feet from the bottom of the central pole. This allows the pole to turn readily when in upright position. The top framework is made of 2 x 6-inch pieces

HAY DERRICK

12 feet long. The rigging, consisting of three pulleys and the hay rope, is attached as shown in sketch. By having the lower pole attached near the base of the upright the arms will make half a turn when the hay fork is lifted, thus swinging around from the ground or wagon onto the stack.

A WIRE TIGHTENER

Here is a device easily made and very convenient to use in tightening barbed wire when stringing it upon the posts. Cut out a piece of inch board in the shape shown in the picture with a notch to let in the face of a hammer. Insert a long bolt at the point indicated by the light dotted lines, to prevent splitting. Fasten on the hammer with leather straps. The sharp brads should stick out about half an inch. Carefully finish the handle so that it will be smooth and not hurt the hands when you are using the device. It should be made of tough hardwood.

TIGHTENER IN USE

FENCE WIRE REEL

Here is a device on which one can wind barbed wire that is much better than an old barrel. The reel is mounted on a truck made of old buggy wheels with short shafts. The cart may be drawn

along by a man while a boy steadies the reel to keep it from unwinding too rapidly. For winding up wire, the machine is best pushed just fast enough

WIRE REEL ON WHEELS

to keep up with the wire as it is being wound on the reel. A crank placed upon the reel proves serviceable in winding up.

Never sign a writing till you have read it; neither drink water till you have seen it.

One part of knowledge consists in being ignorant of such things as are not worthy to be known.

Get the work habit.

SAFE WAY TO STRING BARBED WIRE

One of the most satisfactory ways to unreel barbed wire is to make a contrivance similar to the one shown on page 157. Fasten a short piece of plank to the front end of a stone boat. Bore a 2-inch hole in this plank and set the spool

of barbed wire on top. Run a piece of gas pipe about 5 feet long through the spool and let the bottom end rest in the hole made in the plank.

Attach the stone boat to the rear end of the wagon and have an assistant sit in the wagon and hold the top end of the pipe. If the wire becomes kinked the assistant simply lets go of the pipe and the spool rolls off the boat without breaking the wire.

WIRE REEL ON BOAT

A BOXED STONE BOAT

A flat stone boat or drag is convenient for many purposes, but its uses are limited because it has no great capacity. On page 158 is shown an arrangement for increasing the utility of a stone boat 100 per cent. It is made of plank and has sides 1 foot high. It may be used for the purpose for which the ordinary drag is employed, and in addition is very convenient for hauling apples, potatoes, or other root crops from the field.

By increasing the size of the box, manure can be

hauled out from stables as it is dumped into it from wheelbarrows without having to reload or wheel up an incline. It is low on the ground and very convenient for loading. All light, bulky articles, as well as heavy stones, bags of fertilizers and seed, can easily be hauled on this contrivance.

CAPACIOUS DRAG

A HOMEMADE ROAD ROLLER

If you need a road roller get a heavy sheet iron cylinder, stand it on end and place a length of $1\frac{1}{2}$

ROAD ROLLER

or 2-inch pipe through the center. The end should be placed on planks which are well soaked or are

well oiled, and the pipe braced to keep it exactly in the center. Fill the cylinder with good concrete, and when it has set tip it over and build a frame for it, so you can hitch a removable tongue at either side. The frame should be made of good strong hardwood well braced. The cuts show plainly just how the roller is made and put together.

AN OLD-FASHIONED DROGUE

Drogue is an old-fashioned word applied to a low drag or sled, something like the stone boat in general use now. The word is seldom heard today.

HOMEMADE HANDY DROGUE

So accustomed are we to the regulation stone boat that most of us do not know that there is still a more handy arrangement that is fully as easy to build and better to use, because it cannot slide sidewise on a hill. Select a small tree that has a bend in it the shape of a sled runner and split it with a sharp saw while it is green. It saws fastest and easiest while frozen. Saw or hew the bottom and top flat, so planks about 4 feet long may be pinned to it. Bore the front ends so a heavy stake with a shoulder may be inserted to prevent the runners from drawing together, and the drogue is done. It is handy for all work, but may need side rails spiked to it, if small stones are to be drawn.

Regular boat planks are not easy to obtain now that the old up and down saws are not in use.

A DITCHING SCRAPER

There should be a ditching scraper on every farm. They can be purchased made of steel, but a homemade one costs little and is quite serviceable. Take two planks, each 10 inches wide and 3 feet long, of good 2-inch hardwood. Bolt to them securely a pair of old plow handles. To the bottom bolt an old crosscut saw blade which will make a sharp edge. Let this project about an inch at the bottom. Attach two singletree hooks near each end of the lower board and your scraper is ready to use. With this scraper and two men a ditch can be cut one-quarter mile long and as deep as it could be plowed with a turning plow in two days' time. It is also very useful in filling holes in the highway.

BRIDGE FOR A SMALL STREAM

For crossing a small creek or deep ditch a cheap bridge can be built as shown in the illustration. The lumber used is 6 inches wide and 2 inches thick, except for the floor and four side braces.

A BRIDGE OF TRIANGLES

Saw 11 pieces the length required for each of the two sides, then bore bolt holes $1\frac{1}{2}$ inches from each end. Use $\frac{5}{8}$ -inch bolts $8\frac{1}{2}$ inches long where four pieces come together and $6\frac{1}{2}$ -inch bolts where

FRAMEWORK OF BRIDGE

three pieces meet. The A-shaped supports and the pieces for the approaches are bolted on at once, and then the side braces are put on. The sides of the bridge are made entirely of triangles. The first triangle is made of pieces, *a*, *b* and *c*. The second triangle of the pieces, *b*, *d* and *e*. The piers may be posts, stone or concrete.

DAM FOR FARM POND

A small pond held by a good-sized hydraulic dam supplies water for house, barn and two acres

EASILY BUILT DAM

of garden and fruit, also floods a cranberry meadow when needed. A section of the dam is placed 6 feet apart and covered with plank fitted tight. The apron is of 12-foot plank spiked to the sills so as to break joints. The bottom is made tight with brush and clay. Stones are piled in behind the plank coverings, as shown in cut.

SOWING SEED EVENLY

These drawings show the construction of a wheel seeding device that can be easily made at home.

THE SEED BOX

The axle is tightly fitted into the wheels so that it turns when the wheels do. This agitates the grain or other seed and helps to keep the seed running out of the holes at the lower back side of the box. The quantity of flow may be regulated at pleasure by making the holes large or small and increasing or diminishing the number of holes.

A SOWING MACHINE

It may be found desirable to have a considerable number of holes and then having plugs, for alternate ones, perhaps, which may be removed to make the seeding thicker. From 4 to 6 feet is suggested for the length of the box. Any old wheels will do if they are not too heavy to be easily drawn by hand.

BERRY CRATE CARRIER

One of the most convenient appliances for use in the strawberry field is illustrated in the picture shown herewith. It shows a novel use for the old-fashioned yoke used so commonly on the old-time farms. The picture is so readily understood that no description need be given. This also suggests the many purposes for which a yoke may be used on a farm. Every farmer ought to have one, to make more easy the task of carrying things. In

YOKE CRATE CARRIER

some places yokes may be found for sale, but if you cannot buy one, make one yourself. Take a piece of strong, tough wood, shape it out to fit around the neck and shoulders and taper off the ends to what you consider the right size. Usually a groove is cut around about $1\frac{1}{2}$ inches from each end and

a rope is securely tied. At the other end of the rope a hook is attached the right size to go around the bail handle of any ordinary pail. The hook may be iron or may be formed from a strong, branched stick.

HANDY LOADING DEVICE

Here is a rig simple and strong that works well for loading corn in the field. The picture shows

LOADING RIG IN USE

the construction of the rack and hoisting device with pulley attachment. Such a rig will be found useful for loading many things on a farm.

RACK FOR HAULING FODDER

A handy rack for hauling fodder from the field is shown in the drawing. It may be used for any kind of corn, of course, for sorghum, and may be found useful in moving brush. Each end of the

rack is hung from the axles by two straps of iron that can be obtained from any blacksmith at very little expense.

FODDER RACK

PULLING FENCE POSTS

An easy and practical method of pulling fence posts, by which all digging and hand labor is eliminated, is here shown. Take a plank 4 feet long,

POST PULLER IN POSITION

1 foot wide and make a V-shaped notch in one end, nailing on several crosspieces to prevent splitting. This plank is used to change the horizontal draft to the vertical.

Place one end of chain around the post close to ground. Incline the plank against the post so the lower end of the plank will be about $1\frac{1}{2}$ or 2 feet from the base of the post. Place the chain in the notch of the plank, start the team and the post in a few seconds will be clear of the ground.

In moving fences the chain should be attached to the rear axle of the wagon, so the posts may at once be loaded and hauled to the new location of the fence.

ONE WAY TO PULL STUMPS

A Connecticut man has a very handy device for pulling peach stumps from old orchards, and can

TACKLE FOR STUMP-PULLING

pull 200 or more a day by this means. The limbs are cut off and the stumps, E, left as long as possible. A short rope or chain with a single pulley is attached to the top of the stump. The anchor rope, B, which runs through the pulley, is fastened to the bottom of a stout stump, A.

A pair of steady horses is attached to the rope and always pull toward the anchor stump. With

a steady pull there is no jumping or jerking, and they will walk right off as if pulling a loaded wagon. Use about 60 feet of 1-inch rope, which costs \$2.40, and the pulley, \$1.75, making a total cost of \$4.15.

SIMPLE LAND MEASURE

Having much land measuring to do that requires greater accuracy than just "stepping it off," make a simple affair like this.

The manner of construction is made plain. Use hardwood pieces; $\frac{5}{8}$ or $\frac{3}{4}$ x 1 inch is heavy enough. Have lower points exactly 5 feet 6 inches apart. Make a round head on the handle. Grasp the top lightly in hand, holding at the side, whirl handle to bring rear point to front, moving off in direction to be measured. Continue to revolve measure, changing points in advancing. It takes three lengths to the rod.

THE MEASURE

STORING WATER

An easy way to make a reservoir at the spring is to throw up a bank, perhaps laying a wall first, founding it below the surface. Should the soil be such that water percolates through it, face the soil with loam on top and puddle it well. If this leaks, face it with clay and puddle the clay. These rules apply to all dams made of stone and earth.

Pipes entering reservoirs should enter at the bottom and the soil be well puddled around them

to prevent the water working through beside the pipe. Each pipe must have a strainer over its supply end and have no air holes in its entire length.

A good strainer can be made from a piece of large lead pipe punched full of holes. One end may be flattened or turned over and the other drawn on over the end of the water pipe. Let nobody suppose that simple, inexpensive arrangements are faulty because primitive. If constructed correctly and in line with natural laws, they are not only all right, but are preferable to fancy, complicated devices that get out of order easily or in a year or two and require a master mechanic to put them into working condition again.

GETTING A SUPPLY OF FUEL

A PLAN for getting up the year's supply of fuel is suggested as follows: Fell the trees on the ground with a small sapling under them, so a log chain can be passed beneath. Then a logging bob (Figure 1) is tipped up on its side near the end of the log; a chain is hooked to the bolster near the ground, passed under the log and over the top runner of the bob and the team hitched to the end of the chain. A quick pull of the team and the bob comes down on both runners, with the log on the top of the bolster.

The log is now drawn to some sheltered place near the woodhouse and sawed into stove lengths with a 6-inch crosscut saw on the skidway shown in Figure 2. The limbs are trimmed in the woods, drawn on a pair of bobs to the shop, where there

is a three-horse power boiler and two-horse power engine, and are sawed at the rate of $1\frac{1}{2}$ cords an

FIGURE 1—LOGGING BOB

hour with a buzz saw. A handy device can be made of two crotched limbs, as shown in Figure 3, to saw large limbs on. A 2-inch auger hole is

FIGURE 2—SKIDWAY

bored where the limbs branch, and a hardwood limb driven tightly into the hole.

The following described device (Figure 4) is very handy to hold and lower the tree after sawing

the stump off. [*a*, planks with holes bored in them; *b*, log; *c*, chain; *d*, crotched limb; *ee*, lever; *f*, iron pins.] It is made of two hardwood planks about 8 x 5 inches and 1½ inches thick bolted together at the top and bottom, with a 2-inch space between

FIGURE 3—HANDY SAWHORSE

for the lever to work in. One-inch holes are bored through the sides of both planks, in which iron pins are placed for the lever to pry over. The lever is made of white ash, and has two notches near the large end, with a chain link attached midway be-

FIGURE 4—LOG JACK

tween notches. A stout chain is hooked in the link, passed under the log, and attached to a crotched limb leaning slightly against the opposite side of the log. By working the small end of the lever up and down and moving the pins up one hole at a time, a good-sized tree can be raised from the ground high enough to be sawed easily without a backache.

SIMPLEST OF ALL CAMPING TENTS

The great trouble with camping-out tents is the weight of the frame, but the weight of the latter in

Fig 1

Fig 2

DETAILS OF TENT

the case of the tent figured herewith will hardly prove a burden to anyone, as only two light sticks are used, such as are shown in Figure 1. These

are pressed into the ground 8 or 10 feet apart, according to the size of the tent, and brought together and fastened at the upper ends with such a joint as is shown, or with a string passing through a screw-eye in each pole, if a simpler method is preferred.

The tent is made from four triangular pieces of cloth, as suggested in Figure 2. One of these is cut up the center and hemmed, to afford an entrance to the tent. The triangular pieces are sewed together at the edges and at two of the opposite

THE TENT SET UP

corners pieces of stout cord are sewed into the corners of the cloth, the cloth being reinforced as suggested in the cut.

Two stout pegs of wood and two lighter ones are provided. To pitch the tent, put up the two frame poles A-fashion and draw the tent cloth over them, opposite seams and corners fitting over the poles. Draw out the other two corners and tie by the ropes to the stout pegs which have been driven into the ground. The two lighter pegs are

used to fasten back the flaps of the front. It may be found well to hem a light cord into the bottom of the side having the opening, leaving the flaps free from the cord. The position of the cord is shown by the dotted line. It will not be in the way when lying across the opening of the tent on the ground and will strengthen the whole when the outer corners are drawn tightly up to the stout pegs.

This makes a practically square tent and the size can be as large or small as may be desired. To cut the side pieces, decide on the width of the sides and the height you wish the tent to be. Then draw a triangle (Figure 2), having the base as long as desired for the side of the tent, and a perpendicular 2 feet longer than the height desired for the tent, since the four sides of the tent are to be inclined, and must, therefore, be enough longer to make up for this.

This will prove a very satisfactory tent for boys who are camping out, and it has the merit of being easily made and very easy to carry about.

KEEPING A GATE FROM SAGGING

THE average farm gate is heavy, and after a little time it sags. When they get this way it takes a strong man to open and shut one. Here is a remedy. Get a wheel, either big or little, from an old piece of machinery, and bolt it to the front end of the gate in such a way that the gate will be held level. Now the smallest child can open

OLD PLOW WHEEL DOES THE TRICK

the gate for you. Try it, for it is a saver—saves your patience, your back and the gate.

AN EASILY OPENED GATE

Take an old buggy wheel and fasten it as shown in the drawing to the gates that are opened often. The piece of board indicated by *c* drops between

GOOD USE FOR A WHEEL

the spokes of the wheel and holds the gate either open or closed. A child can easily operate the heaviest gate with this attachment.

A GATE THAT NEVER SAGS

A farmer has used this gate for many years and never spent five minutes repairing it. Countersink

CROSSPIECE

two pieces and pin them together. Then set up two 2 x 4 pieces 2 feet higher than the gate so it can be raised in winter. Mortise and set in between the crosspieces, which are 12 inches apart, the board, *a*, and fasten a cap to the top of the frame. The gate is 16 feet long, 12 feet being for the gateway and 4 feet for the weights to balance it. The frame is of 2 x 4s. Cover the 4-foot end with boards and fill with enough stones to balance it when hung.

BALANCED WIRE GATE

Cover the gate with wire fencing and hang by a chain. Put a bolt through the lower part of the frame into the crosspiece, *a*.

WIRE GATE THAT SPEAKS FOR ITSELF

A CHEAP GATE

A light, useful and durable gate can be made of sassafras poles and barbed wire, as shown in the

cut. Set a strong post 4 feet in the ground in the middle of the gateway and balance the gate on it.

POLE AND WIRE GATE

The lower rail is made of two forked sassafras poles securely nailed together so as to work around the post.

A SIMPLE FARM GATE

Many like such a gate as that shown in the cut. Material to be used depends largely on the purpose for which the gate is made. For a paddock or pasture gate, make it out of seasoned boards 1 x 6 inches, 12 or 14 feet long. The posts supporting

GATE SIMPLE AND STRONG

the gate are about 5 inches apart, the one on the inside being about 8 inches ahead of the other. They are joined together by cleats or rollers which support the gate and allow it to be pushed back and swing open. If rollers are not obtainable, cleats made of any hard wood are good. They need not be heavier than 1 x 4 inches. If the gate is to be used for a hog pasture, the lower cleats on both sets of posts should be placed just above the lower board to prevent the hogs from lifting it up.

AN EASILY REGULATED GATE

The gate hanger illustrated in the drawing is very handy for use where it is desired to let hogs

ADJUSTABLE HANGER

pass from one pasture to another while cows are confined to one. As shown, the hanger is a piece of strap iron bent around the post and supported by pegs. These pegs may be inserted in holes at varying heights. Raise the gate to let the hogs through and lower it to keep them in, of course. This is also a good device for raising the gate above the snow in winter. Many would find this use of the adjustable hanger prefer-

able to the gates made to raise only one end for snow. Of course it is desirable that there should be the least play as possible while the hanger

slides up and down freely, and special care should be taken to set the post firmly. Otherwise the gate would sag.

GATE TO OVERCOME SNOWDRIFTS

In the picture is shown a gate which can be readily adjusted to swing over snowdrifts. It is easily made from ordinary lumber. A 1 x 6-inch upright is used for the lower boards, 1 x 4 for the upper ones. The uprights at the hinge post are double 1 x 4, one piece outside and the other inside

GATE SHUT AND OPEN

the bars. The upright at the latch side may be the same weight of stuff or slightly lighter, and fastened in the same way. Instead of nailing the bars to these uprights, bolts are used, one for each bar at each end. The lowest board is notched as shown, and the double brace used from the top of the latch post to the bottom of the hinge post. For the brace, 1 x 3 stuff is strong enough. They are joined near the bottom with a bolt, which engages with the notches when the gate is raised, as shown at the right.

A TIME SAVER

To open and close gates that stock may be kept within bounds the year round is one thing which uses up a great deal of time, and makes no return. Every gate should be so made that it will fall into

TURNSTILE GATE

place of its own weight and stay closed and open without hitch or bother. The cut illustrates a convenient thing that should be in larger use on farms. It is always open and always closed against stock. Put up and well painted, it will last for many years.

He who keeps company with great men is the last at the table and the first at any toil or danger.

KEEP THE GATE OPEN

A simple and handy device which serves to hold the gate open is shown in the cut. To make it, procure a board, *a*, 1 x 4 x 12 inches and saw out a portion in the center, leaving a space on each side $\frac{1}{2}$ inch wide, and bore holes for a bolt. Next get an 8-inch stick, *b*, and bore a hole through it 3 inches from the top. Bevel the top so that the gate will pass over it, and it will then fall back and hold the gate open. When one's hands and arms are full of things, as they often are on a farm, it is a great convenience to have a gate or door held open automatically. No simpler or more effective device for the purpose can be found. A similar device can be adapted to use as a latch to catch and keep a gate or door closed.

GATE CATCH

GOOD BARS FOR THE FARM

It is an important matter to the farmer that his farm should be well equipped with good, substantial bars. Some farmers go to as much trouble in a year's time in moving a poor gate or bars back and forth as they drive in and out of fields, and in chasing cattle about, as making dozens of such bars as are represented here. Use round poles about $2\frac{1}{2}$ or 3 inches in diameter. Set two good-sized posts one on either side of the barway, and to each one, an equal distance apart, nail large horseshoes, al-

lowing the round part to stand out far enough from posts to admit the bar poles easily.

BAR WITH HORSESHOE CATCH

DURABLE FLOATING FENCE

This is a cheap and easy way to make a good, strong cable on which to hang a water gate, when it becomes necessary to have a fence cross a stream: Set two good, large posts about 3 feet deep in the ground and about 6 feet from the banks of the stream. Get a piece of wire (barbed wire will do, but smooth wire makes a much better looking job), long enough to go from one post around the other and back again about six times, being careful to fasten each end securely at the proper height from the ground. Then get a strong piece of wood about 1 x 3 inches and about 4 feet long, stand as near the middle of the space between the two posts as possible, and place the stick between the two sets of wires. Turn around until all the wires are well twisted together, being careful not to twist too much.

On withdrawing the stick, the wires will only untwist two or three times. After the gate is hung, the stick may be again inserted in the same place

and several more twists given to take up the sag caused by the weight of the gate. Then fasten one end of the stick to the top of gate and it will be im-

SUSPENDED GATE

possible for the cable to untwist any more. This has been found to answer all the purposes of an expensive cable and looks and lasts just as well.

FENCE ACROSS A STREAM

To construct a fence across a creek or small stream, set a post on each bank and brace well. If a tree happens to be near at the right place, so much the better. Then fasten wire securely on posts, leaving enough slack so a weight in the middle will draw the wires toward the bed of the stream, thus making it impossible for stock of any size to get through. A large stone makes a good weight. It can be blocked up to desired height and fastened in position with smooth wire.

TEMPORARY SHEEP FENCE

One of the best portable fences for use in soiling sheep is made in panels with supports, as shown on next page. Panels are 10 feet long, made of 4-inch board solidly nailed together. After this fence is once put up, sheep are not likely to overturn it. A fence 3½ feet high will turn most flocks.

MOVABLE FENCE AND PARTS

FASTENING HEAVY DOORS

There is little difference in the effectiveness of these two locks for heavy doors. The left-hand

TWO BIG DOOR LOCKS

device is extremely quick and handy; the other very neat and substantial. The lock to the left has both bars pivoted to a lever handle, which is pivoted to the door midway between the ends of the arms. Moving the lever handle up moves both arms out of slots above and below the doors. The fastening may be also worked from the inside by cutting a slot through the door and setting a pin in one of the arms, so that it can be moved in the slot.

The right-hand fastening is worked by raising the lower arm so that the notch incloses the middle staple at *d*. Then the upper arm can be pulled down. Both arms stay firm and snug whether the door is shut or open.

HOLD THE BARN DOORS SHUT

A latch that will hold double doors shut is shown in the cut. This is put on the inside of the door that is closed first. It is made of hardwood 4

LATCH FOR DOUBLE DOORS

inches wide and 1 inch thick. To open the door, turn the piece, *a*, to the right and pull down on the crosspiece which is fastened to the door by a bolt in the middle. This will raise the latch, *c*, and lower the latch, *d*, as shown in the cut to the right.

Open your doors to a fine day, but make yourself ready for a foul one.

Prosperity is the thing in the world we ought to trust the least.

FASTENING THE STABLE DOOR

A handy stall door fastener is shown in Figure 1. It consists of a piece of oak or other hard wood 4 inches wide by $\frac{7}{8}$ inch thick and 2 inches longer than the width of the door. It is fastened to the door by a $\frac{3}{8}$ -inch bolt through the middle and it works like a button. Cleats, *b*, are sawed out and fastened to the door jamb on each side to hold the fastener in place. Another handy fastener that can be worked from either side of the door is shown in Figure 2.

FIGURE 1—LONG FASTENER

There are three upright pieces, *a*, two of which are on the door and one on the door jamb or casings. Another piece, *b*, slides through these and holds the door shut. A pin, *c*, goes through the bolt and through the door to open or shut it from the opposite side. The bolt is kept shut by the spring, which can be made from a piece of hickory, or other tough hardwood, whittled down to the proper thickness. The spring feature is the chief advantage, and a very important one it is, of this excellent fastener. It is also a good point that the fastener works nicely from the opposite side of the door.

FIGURE 2—SPRING FASTENER

Sell cheap and you will sell as much as four others.

They must hunger in frost that will not work in heat.

'Tis easier to build two chimneys than to maintain one.

HOMEMADE DOOR LATCH

This consists of three pieces of oak or other good hardwood, as shown in the drawing. For the handle use a piece 8 x 2 x 1 inches. Shape a flattish knob on one end 3 inches long. Work down the rest so as to pass through a 1-inch auger hole. Shape a knob on the other end by flattening the sides.

DETAILS OF LATCH

The latch is made of a piece 5 x 1 x $\frac{3}{8}$ inches. The catch is 8 x 2 x $\frac{3}{4}$ inches. Bore a 1-inch hole for the handle 3 inches from the edge of the door. Push the handle through the hole and mark on it the thickness of the door; then bore in the handle a $\frac{3}{8}$ -inch hole for the latch. Now assemble the parts according to the finished figure, which shows the latch thrown back. A little peg may be used to keep the latch from falling down when the door is open. By taking pains to shape and finish this latch nicely it will look well enough to please the artistic eye of the most fastidious.

LATCH IN PLACE

IMPORTANT POINTS IN HOUSE BUILDING

THE following points in building a house are considered of the greatest importance by a well-known architect: Carefully watch that the foundation walls are substantially laid, and accurately leveled on their upper surfaces, so that the doors shall not strike the floor or carpets in opening, nor the tables, chairs, or other furniture be obliged to stand on three legs.

The framework, when raised, should be plumb, so that all on or in the building can be cut square, and applied without tedious fitting. The siding should be thoroughly seasoned in the open air before using, and carefully applied with close joints, and well nailed. The edges of all water tables, corner boards, and window frames should be painted before setting.

The shingles should be carefully laid, breaking their joints at one-third of their width and double nailed. The flooring should be dry, close laid, and nailed with two nails to each beam. The partitions should be set with studding of selected width, and their angles or corners should be anchored firmly together to prevent the walls from cracking in those parts when finished. The chimneys should be carefully constructed, all points between the brickwork should be well filled with mortar to prevent sparks from passing through to the framework.

All mortar for plastering should be properly mixed, and allowed sufficient time (at least a week) for the thorough slacking of the lime, and a complete permeation of the caustic properties. Thin coats of plastering are better than heavy ones. A mortar that does not crack in setting or drying is sure to be good.

The interior wood finish should not be begun until the plastering is completely dried out, and all loose mortar is removed from the building. All woodwork usually painted should be primed as soon as in position.

A VERY CONVENIENT HOUSE

The accompanying picture and plans show the outside and interior arrangements of a very convenient home built the past year by one of our

AN ATTRACTIVE HOME

agricultural editors. It is 34 feet wide by 30½ feet deep, with a 7-foot cellar underneath. The house

contains 10 rooms, including two in the attic, besides a storeroom in addition to those shown. All the rooms are of good size and have two or more large windows, which make them light and sunny and supply plenty of good air.

PLAN OF FIRST FLOOR

Economy of construction, as well as of doing the work, was kept in mind in the planning. The location of the stairs is somewhat unusual in a house of this sort, but is such that only one light

is necessary from first to second floor. There are plenty of large closets on the second floor, which are greatly appreciated.

The porch is not roofed except over the door, but

PLAN OF SECOND FLOOR

an awning, which is taken down in the fall, makes it cool and shady in summer, and allows the sunshine to reach the living room in winter. The first story is 9 feet from floor to ceiling, the second 8 feet and the third 7 feet 6 inches. The house

is piped with gas and wired for electricity, provided with the best quality of sanitary plumbing

FIRST FLOOR COTTAGE PLAN

and heated with hot air furnace. A similar house can be built for about \$4,000, more or less, according to finish and locality. Occupancy proves it to be a model of convenience.

If a bigger kitchen is desired, it can be obtained by going back farther. Many would prefer a

SECOND FLOOR COTTAGE PLAN

wider bathroom. A foot taken from the back chamber on the right would greatly improve the bathroom and still leave a large chamber. If desired, a large roofed piazza can be added.

BUILDING A BLOCK HOUSE

A Kansas farmer needed a house on his farm, but had very little money. He found that only a little was needed for a cement block house. He ordered a cement block machine and bought 12 boards 10 inches wide and 12 feet long, which were cut in seven pieces of equal length. Two cleats were

\$400 CEMENT BLOCK HOUSE

nailed on each, about 3 inches from the ends. These were for pallets and cost about 7½ cents each. The cement blocks were 8 x 9 x 18. As the block machine had no attachments, some contrivances were made for making half stone, three-quarter and others.

For caps and sills for doors and windows 9-inch boards were taken, using three for each mold, and

two holes 2 inches from the edges and 3 or 4 inches from the ends of two of them were bored. Then the farmer made cement blocks for the ends 9 x 8 inches, laid the other board on the ground, placed one of the others on each side of it edgewise, put in the end blocks, and through the holes put long bolts and bolted it tight together. Then it was ready to fill with concrete. These boards were as long as were needed to make the caps or sills. A sprinkler, sand shovel, plasterer's trowel, and a wire sieve of $\frac{1}{4}$ -inch mesh were obtained.

FIRST AND SECOND FLOOR PLANS

The sand cost nothing except hauling. The machine was set up near a spring. A box something like a wagon bed with both ends out was made of boards, the block machine placed in one end and the pile of sand at one side. Three shovels of sand and one of cement were placed in a tub and mixed thoroughly. Then a boy took the sprinkler and sprinkled it while another mixed, until it was dampened evenly all through. Then they spread 35 shovels of sand in the mixing box and shook one sack of cement over it, which made a five-to-one mixture. This was thoroughly mixed

by shoveling and sprinkling until it was good and damp, but not wet. This quantity made ten blocks.

A pallet was placed on the open machine, the machine closed, and some of the richer mixture of concrete placed on the face about 1 inch thick. The mold was then filled with the five-to-one mixture, while one of the boys tamped it, put in the core, and smoothed off the top with a trowel. The core was then carefully lifted out, the machine opened, and the pallet with the stone on it placed on a level piece of ground.

In three or four hours the blocks were ready to sprinkle. When 30 hours old they were placed on end and the pallets used for more stone. After standing for two days, during which time they were sprinkled frequently to keep them damp, they were dumped in the creek, where they were left until ready for use. The foundations were made by first putting into a trench about 6 inches of broken rock, then 4 inches of concrete.

The house is 26 feet square, the walls 12 feet high, with gables north and south. The picture of the house and arrangement of the two floors are shown in the illustrations. We used 12,400 pounds of cement, which cost 60c per 100, or \$74.40. Doors and windows were brought at a cost of \$33.75. Chimney, plastering and lumber for floors, roof, partitions and finishing, all of the best, cost \$240. The hardware was \$30, making the total cost of house \$378.15, not counting cement machine or labor, all of which was done by the family.

Art imitates nature, and necessity is the mother of invention.—Richard Franck.

Consider the end.—Chilo.

A PRACTICAL ROUND BARN

There is no economy in building a round barn, that is, strictly round. The barn here illustrated has 26 sides nearly 12 feet long, making a barn 94 feet in diameter. The sills, plates and roof in a strictly round barn are very expensive, and the work will not last as well as when built as shown. The floor space of the first floor is nearly the same as if round, and the hay loft is very little smaller. If the building is round, the walls should be lathed

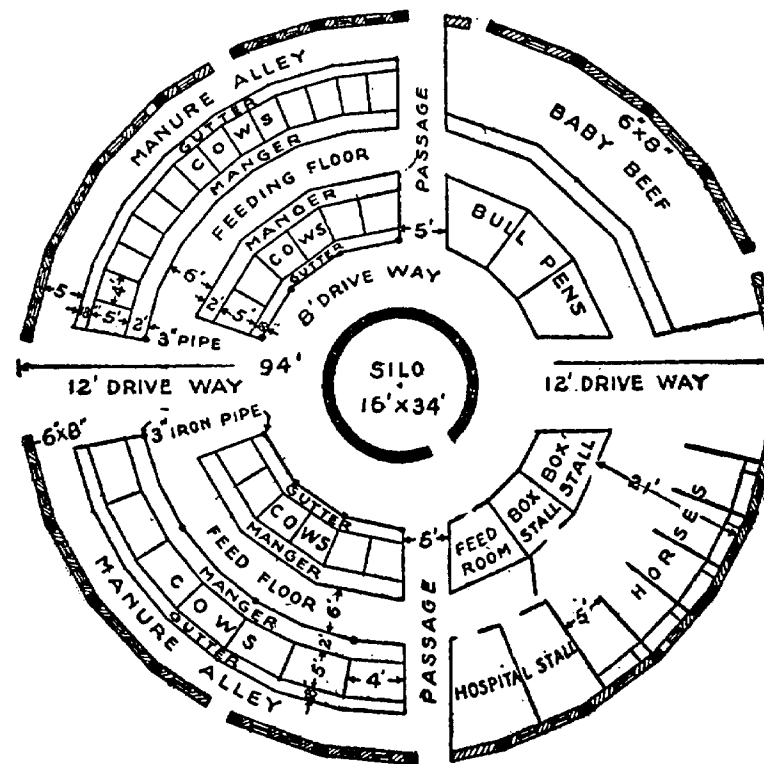

CROSS-SECTION OF BARN

with metal lath, over rough boxing, and plastered with two coats of portland cement. In fact, this finish is to be preferred in building any shaped barn, as it requires no paint and practically no repairs.

The floor plan of the barn shown is self-explanatory. It has stalls for 40 milch cows, three bull pens, two hospital stalls, pen for baby beef that will accommodate about $2\frac{1}{2}$ cars of calves, stalls for seven horses, including the two box stalls, and the feeding room and silo. The silo is 16 x 34 feet, will hold about 140 tons of silage, and requires about ten acres of average corn to fill.

The hay loft has 166,500 cubic feet of space, and deducting the silo and bins for ground feed will hold 300 tons of loose hay. The ground feed is stored in hopper-shaped bins above the feed room, and drawn down through small spouts as wanted. The hay is handled with hay forks, and to locate

FIRST FLOOR PLAN

the trolleys as near the roof as possible, trap doors are left in the loft floor, and the hay hoisted from the driveways. A circle trolley may be installed, or two straight ones. Several large hay doors are also built in the outside walls above the loft floor. The silo, the floors of the cow stalls, including

the gutters and mangers, also the 8-foot driveway around the silo, are of cement, and, while it is intended to install litter and feed carriers, it is also intended to drive around the entire barn, or the feed floor with a cart if desired. The interior arrangement of first floor may, of course, be changed in several ways, and the cows faced in the opposite direction, etc., or stalls and other equipment arranged for different stock.

The barn, as shown, has about the same floor space as a barn would have 36 feet wide and 180 feet long. The ventilation is always much better in the round barn, the work of caring for and feeding may be accomplished with less labor, there are never any drafts on the stock, the building may be built for less money, and is much stronger. As shown, the barn has a stone foundation, the roof is covered with asbestos roofing felt, and the walls covered with 6-inch drop siding. Everything is of the best, and all exposed woodwork painted two coats. This building would cost about \$4700 without the cow stanchions. Where home labor is used, and the lumber can be secured for less than \$30 per thousand, the barn may, of course, be erected for less.

A WELL-ARRANGED BARN

This Kentucky barn has a frame of oak, 6 x 6 inches. Center posts 23 feet 9 inches; shed posts 16 feet tall; studding and braces 2 x 6-inch poplar; joists 2 x 10-inch poplar, oak and pine. The sheeting is of poplar, beech and ash. The bevel siding is select poplar. Cornice and base, white pine. All doors are two thicknesses, front is dressed cypress and the back dressed white pine. The

lower windows are 10 x 12-inch, 12 lights and upper ones inside the building. The joists are set 20 inches from center to center. The loft is 8½ feet from lower floors.

The floor plan shows the arrangement as follows: Number 1, icehouse, 18 feet deep, walled up with stone; 2, carriage house, 16 x 18 feet; 3, stairs, leading to lumber room over carriage room; 4, corn

GROUND PLAN OF A KENTUCKY BARN

crib, 8 x 16 feet, over which are the grain bins for wheat and oats. These bins have chutes running down into the corn crib, from which grain is filled into sacks. Numbers 5, 5, are box stalls, 8 x 12 feet; 6, driveway, 12 x 38 feet; 7, 7, 7, 7, box stalls, 6½ x 12 feet; 8, harness room, 6 x 8 feet; 9, feed mixing room, 6 x 8 feet, with spouts running from cutting box and bran bins overhead; 10, alleyway running from driveway to feed alley; 11, 11, 11, hay

chutes, with openings near the bottom, 1 x 2 feet. These openings are directly over the feed boxes and any hay that falls while horses are feeding goes into the boxes and none is wasted. Number 12, feed boxes, 1 x 2 x 2 feet; 13, feeding alley, 4 x 38 feet.

Overhead at X is an opening from the hay loft where alfalfa, clover, cowpeas and hay are kept for the cows; 14, cow shed, 8 x 38 feet. Cows are fastened with stanchions and fed out of boxes on alley floor. The cow shed has concrete floor, with a fall of 2 inches from stanchion to Number 15, the drain basin, which is 1 foot 2 inches wide and 1 foot deep at A, where it runs into a basin made of concrete, 6 x 6 feet and 2 feet deep; 16, driveway into carriage room; 17, openings in which siding doors hang when open; 18, windows.

The roof is of tin, standing seams, with Yankee gutters made on the lower edge of the roof. An opening 10 x 10 feet in the center of the driveway loft is allowed for hay and other feed taken up by an unloader that runs on a track in comb of roof. The barn will cost about \$1500—more or less, according to cost of building material where it is erected.

A HANDY SMALL BARN

This barn is arranged to meet the needs of a small farm. It can be built in most localities at a cost not to exceed \$500, and if a farmer has his own timber, at even less cost. The outside dimensions are 36 x 48 feet, and it is 16 feet to the eaves, with a curb roof. The stables should be about 8 feet high, which allows plenty of loft room above for hay.

In the floor plan the cow stalls, A, can be made of any width desired, 3½ feet being best for general purposes. At B are two large box stalls for cows with young calves. The mangers, C, are 18 inches wide, with a rack for hay or fodder above. At D is the feed room and alley, which is 8 feet wide. At E are the mangers for the horses, with

GROUND PLAN

a feed box at the right side. At F are three horse stalls 4 feet wide, in which horses can be tied. At G is a large box stall for mares and colts.

At H is provided the granary, which can be subdivided into bins as necessary. The portion I is the driveway, which affords ample storage space for tools, wagons, etc., and is used as a driveway when hay is being elevated into the loft above.

There is a large corn crib, J, at the end, which can be filled from the outside and emptied from the inside. It is narrow and so arranged that the

corn will dry out quickly. Chutes from this bin should be provided at L. A ladder to the hay loft at K is a convenience which should not be omitted.

VIEW OF COMPLETED BARN

THE FARMER'S ICEHOUSE

In a properly constructed icehouse, and when the ice is properly packed and cared for, no waste should take place from the inside of the pile of ice. The melting from the sides, bottom and top is caused by insufficient insulation. The waste from the bottom is generally the greatest. The amount of ice melted in the bottom of the icehouse varies from 1 to 6 feet during the year, depending upon the construction of the floor. If the icehouse is provided with an airtight floor, with the ice laid on at least 18 inches of dry sawdust, the bottom waste rarely exceeds 12 inches during the year; on the other hand, if the ice is piled in the icehouse on the bare ground without any insulation under it, or any provision made for drainage, the meltage fre-

quently is 6 feet. The side and top meltage is not so great, but it frequently ranges from 1 to 3 feet, depending upon the insulation.

Location and Building

The location should be where the ice can be removed and delivered with the least amount of labor; however, it is very important that the icehouse should be located in the coolest place, in as dry a place as possible, and always above ground. The lowest layer of ice should always be at least 6 inches above the outside level of ground.

The size of the building must be determined by the amount of ice used during the year. For instance, a dairy farm upon which 35 cows are kept, and from which the milk is sold, needs an icehouse 16 x 16 and 14 feet high. If the cream is to be sold and skim milk fed to the calves, immediately from the separator, an icehouse 14 x 14 and 12 feet high is of sufficient size. In both cases we make allowance for the use of 25 pounds of ice per day during the summer months for household purposes. For a man who keeps about 20 cows and sells the milk, an icehouse 14 x 14 and 12 feet high is of sufficient size; however, in no case should an icehouse be smaller than 12 x 12 and 10 feet high, because the outside surface is too great, compared with the volume, and, therefore, too much ice is wasted in proportion to the amount used.

The building should be as near the shape of a cube as possible, for the cube contains the greatest amount of volume with the least amount of surface exposed other than circular forms. It is not always practical to build as high as we build square,

owing to the amount of labor and the inconvenience of storing the ice; therefore, the dimensions given are really the most practical.

If the icehouse is not built upon a sandy surface and where rapid drainage is natural, it is

CROSS-SECTION OF ICEHOUSE

necessary to cut a space to a depth of 12 to 18 inches, where the icehouse is to be located, lay a tile drain to drain this, and fill it with sand or finely crushed stone. Put a 6-inch foundation of concrete of the size you wish to build your icehouse in this pit, and fill around the outside.

Framing the Icehouse

The framework is made by laying 2 x 4-inch sill on the concrete foundation; fasten this to the foundation by cementing a few bolts into the concrete and allowing them to extend through the sill; 2 x 4 studding are then placed upon the sill, 16 inches apart from center to center. The rafters for the roof are likewise made of 2 x 4's, placed the same distance apart as the studding, but the purlin plate upon the studding should be at least 6 inches wide. The outside of studding may be boarded either with common sheeting and paper, upon which poplar siding is nailed, or with patent siding or ship-lap siding, the latter being the cheapest and requiring only a single thickness of board.

The roof should be made with not less than one-half to one-third pitch, and preferably covered with shingles, for shingles are better insulators than either slate or metal. Paper may sometimes be used to good advantage. A cupola or flue should be built upon the roof to allow for the removal of the warm air from the top of the ice. A ventilator may be placed in the gable end,

A continuous door should be cut in one end to allow the ice to be put in. This door may extend from the gable down to within 5 feet of the bottom.

Before putting in the ice place from 18 inches to 2 feet of sawdust or dry peat upon the floor. The ice should be harvested in regular shape, oblong, rather than square, and not less than 18 inches in width and 30 inches in length.

Ice and Milk Houses Combined

The side elevation of an icehouse with milkhouse attached is presented in the drawing. It shows the

advantage of utilizing the water from the icehouse for cooling the milk. No ice needs to be removed from the icehouse. It operates automatically. If the weather is warm the ice melts more rapidly and keeps water in the tank at the required temperature.

A GOOD COLD COMBINATION

SMALL GREENHOUSES

The farmer who would make his crops of vegetables most profitable, or the small gardener who would have an early supply of early vegetables for home use or market must employ some kind of glass structures to hasten these crops. The hot-bed or cold frame have been much in use in the past, but the cost of sash, shutters and mats is nearly as much as the materials needed for a permanent structure, while the labor of caring for cold frames or hotbeds is often much more than that of the small greenhouse. In the latter one may work with comfort no matter what the weather may be outside. It requires much more skill to run hotbeds successfully.

Small greenhouses may be built against the south side of the house or stable, Figures 1 and 2, or they may be built entirely away from other buildings, but the shelter of larger buildings on the north or west will be found of great advantage. If one has a basement to the house or stable, a lean-to house may be built, and heat from the open cellar in a large measure will heat the greenhouse in the mild weather of fall and spring.

Material for Construction

A cheap and efficient house may be made by setting chestnut or cedar posts in the ground, covering the sides with lining boards, then two thicknesses of tarred building paper and sheathing

DETAILS FOR SMALL GREENHOUSES

outside, Figure 3. Cement, stone or brick will be cheaper in the end. The durability of glass structures will depend much upon the form of the materials. Clear cypress is now more used than any other material. Sills should be of the form shown in Figure 4. Plates may be made of plank as in

Figure 3, or as in Figure 5. Sash bars should have grooves along the sides to catch the drip from the glass, as in Figure 6.

The glass for ordinary work may be No. 2 double thick, large sizes, 16 x 20 inches or 20 x 24 inches, being much used. Smaller sizes will be cheaper in price, but more sash bars will be needed, and they cut off much of the sunlight. The glass should be put in with putty, made with about one-third white lead in it, and firmly tacked with triangular zinc tacks of large size, or the double-pointed tacks, which are so bent as to prevent the glass from slipping down.

Set Glass in Warm Weather

Glazing should be done during the summer or early fall, as putty will soon become loose if frozen before well hardened.

In building there should be no mortises, but all joints be made by toeing in with long, slender nails. All woodwork should be thoroughly painted before fitting, and all joints filled with white lead paint. After all is done the frame should be painted before the glass is put in.

The most important and expensive feature of the small greenhouse is the heating. If one has a hot water or steam heater in the house, to which the glass house is attached, it will be a very simple matter to carry pipes through, as at *a, a*, Figures 1 and 2. Hot air also may be let into such houses, or a small kerosene heater in very cold weather may be used, if the house is built opening into the cellar.

Ventilators must be located as shown in Figures 1 and 2, at *b, b*. Very small structures may be

run without much heat if opening into cellars or other heated rooms by having shutters or curtains to draw down at night and in very cold, cloudy weather.

Covering with Hotbed Sash

Houses of small size may be made by building a frame upon which hotbed sash may be screwed. If one has the sash this is a cheap way of building, and such a house has the advantage that the sash may be entirely removed during the summer, but it is very difficult to make a close house with such sash.

The woodwork of greenhouses and hotbed sash should have a coat of thin linseed oil paint every second year. Much of the success to be obtained from any glass structure will depend upon the skill of the operator, and the thermometer, both outside and in, must be watched very closely. The temperature should be maintained as nearly as possible like that in the open air under which the plants grown thrive the best.

WIRE FENCE CORN CRIB

In the drawing is shown a handy, inexpensive corn crib, which possesses several advantages not possessed by the ordinary slat corn crib. It is made on 4 x 4-inch posts, with pans at their tops, to prevent rats from climbing in. The sills are 4 x 4-inch, the scantlings 2 x 4, and 2 feet apart. The fencing is nailed to these on all sides, and the door frame is similarly covered. The roof is made wide, so as to shed all possible water. The height, length

and width may suit the farmer's convenience. A convenient width is about 5 feet at the floor, widening to 7 feet at the eaves. Owing to the very open

THE CORN CRIB

nature of this crib, corn dries more quickly than in a slat crib, and as there is less chance for water to lodge in the cracks, the crib will be more durable than if built entirely of wood.

Want of cure does us more damage than want of knowledge.

HOW TO LAY A FLOOR

To lay a floor or board ceiling just right, and do the work fast, use a good lever, as in the illustration, taking for the supports two 1 x 4-inch pieces as long as the width of the room. The upright arm is 4 feet long with a hole 4 inches from the lower

FLOORING LEVER

and through which it is pinned loosely between the ends of the supports. With a little practice, a good carpenter's job can be done on floor or ceiling.

AN INEXPENSIVE VERANDA

A vine-covered veranda is a great comfort, but in many cases the expense seems greater than the owner of the plain little farmhouse feels able to stand. A farmer in Arkansas wanted one, and he set to work in this fashion. First he went to the woods and got a load of straight poles about 1½ inches in diameter and from 8 to 12 feet long. He next procured a number of nice, smooth boards for the flooring of the veranda, making it about 6 feet wide and 10 feet long and strengthening it with the necessary timbers. He securely nailed the poles about 8 inches apart around the flooring to form an inclosure, leaving an opening in front about 5 feet wide.

The poles in front were 7 feet from the floor to the roof and 12 feet at the house. About midway of their height the poles were straightened by a row

of poles nailed horizontally and another row was placed at the top. To make all secure against rain, the slanting roof poles were next carefully covered with overlapping rows of bark. All this required but small outlay of cash and even less of work. It was then ready for the vines.

Being in haste for immediate results, the builder planted some roots of the hard native woodbine, which will soon cover any space with its rapid growth. It is an easy matter to sow seed of the morning glory, hardy annual gourd, or any one of several hardy climbers and the result will soon be a mass of shade and lovely blossoms besides, all of which makes the summer evenings pass far more pleasantly.

CONCRETE ON THE FARM

The progressive farmer must not overlook the economic value of portland cement concrete. Today is the age of concrete. It is crowding wood and steel into the background, and bids fair to become the most universal of building materials. Concrete is extensively used by the largest landholders, and can be used by the men of more moderate means to equal advantage. It is to be recommended for general use by reason of its durability, sanitary qualities and moderate cost. Molded solid, it has no joints nor seams to afford a lodging for dirt and foster the growth of noxious fungi; it can be swept, washed, scrubbed and scalded, without injury to its texture. Further, it does not possess the disagreeable quality of absorbing gases and odors. Add to these qualities, coolness in summer, warmth in winter and we have one

of the most logical building materials in present-day use.

Concrete is not expensive when compared with other materials of construction, such as stone, brick and wood. To be sure, the initial cost of wood is less than that of concrete, but when we consider the life and quality of the finished product, concrete is easily cheaper than wood.

Portland cement of the most approved brands costs about \$1.60 per barrel, $1\frac{1}{4}$ barrels of cement being required for each cubic yard of concrete. Sand and gravel may be had from the farm or bought nearby at 10 cents a load. Add the cost of the forms and the labor of mixing and laying the concrete, which should be done at an expense not exceeding 75 cents per yard, and we have a total expense ranging from \$2.75 to \$3 per cubic yard, but under very favorable circumstances the cost may be reduced close to \$2. Experience both in practical work and in the laboratory has proved beyond a doubt that the best brands of cement, as in all other goods, are the cheapest in the end, and should be insisted upon by all prospective purchasers. Atlas, Alpha, Saylor's, Edison and Giant cements are among the leading brands. The sand should be clean, coarse and sharp and free from all foreign matter that would in any way tend to weaken the concrete. Broken stone with sand and cement makes an ideal mixture, but it is objected to on account of the cost of the broken stone. Gravel may be substituted for the stone, however, with excellent results. The gravel should be washed and cleaned, and, if very coarse, passed through a screen. The gravel should range from $\frac{1}{4}$ inch to $2\frac{1}{2}$ inches in diameter, but should not exceed $2\frac{1}{2}$

inches and to obtain the very best results the major portion should be between the limits of 1 and 1½ inches.

MIXING THE CEMENT

In mixing concrete for general use the following proportions are perhaps the best: One barrel cement to 3 barrels sand and 5 barrels gravel. In this mixture the spaces between the stones are entirely filled and when hardened the concrete virtually becomes a solid monolith.

To secure the best results mix the concrete as follows: Have the gravel washed and in readiness, usually on a platform of planking or boards, to permit easy shoveling and insure against waste. Add enough water to the cement and sand, which have been thoroughly mixed in a mortar bed, to make a thin mortar, not too thin, however, to permit easy shoveling. Spread the mortar on the gravel and thoroughly mix by turning with shovels. Then, without delay, shovel the batch of concrete into the forms or spread it on the floors as the case may be, being careful not to exceed layers of 8 inches at each filling. Each layer must be tamped and rammed till water flushes to the top.

Proceed in this manner till the forms are filled. In hot weather damp cloths or boards should be placed over the top of the concrete to keep it from checking after the final layer has been placed in the forms. The forms must necessarily be water tight and the concrete worked back from the boards with a spade, so the softer material may flow to the outside and insure a smooth surface. If this last is not done holes will surely result and the work will be disappointing. Let the concrete rest four to six days before removing the planking, concrete

being somewhat brittle until thoroughly hardened, and while in the "green" state easily broken.

MAKING CONCRETE BLOCKS

Concrete building blocks are ideal as building material on the farm. The cost to purchase these blocks has been beyond the reach of the farmer who desired to use them for all purposes; but by the use of the simple machine or mold described anyone can make the best quality of hollow concrete building blocks at an average cost of less than 6 cents each, the mere cost of sand and cement.

As the standard size block is 20 x 8 x 7½ inches, instructions are given for making the machine to build that size, but it can be constructed to turn out any size of block by changing the dimensions accordingly.

Take two boards 20 inches long by 7½ inches wide and 1 inch thick. These are for the sides. For the ends use lumber 10 inches long by 7½ inches wide. Care must be used to have the boards free from large knots and with an even grain, so as to avoid warping.

The above four boards were joined at three corners with six hinges; two hinges at top and bottom of each corner. In putting together have the two end boards set up against the sides as shown in Figure 1. At the fourth corner place a strong hook and eyelet to hold the machine together when making block, and by unhooking this allows the machine to be folded back away from the finished work, etc.

This makes a mold or form that is, inside measurements, 20 inches long, 8 inches wide and 7½ inches high, with top and bottom open.

For the core, take two boards of 1-inch lumber, cutting them 13 inches at the top and slanting to 11½ inches at the bottom with a width of 7½ inches. These make the sides of core. For the ends, use 2-inch strips cut 7½ inches long. These are fastened together,

as shown in Figure 1. This makes a slanting box which is set inside of the machine, as illustrated in Figure 2, and forms the hollow in the block. To the top of the core a round stick is fitted into place the length of the core, so it will set down level with the top for a handle to lift the core from the block when operating the same.

To Operate the Machine

First set it on a board somewhat larger than the machine, as shown in Figure 2. This makes the bottom of machine and holds the block until dry. Enough of these boards must be provided for the

FIGURE 2—CEMENT BLOCK MACHINE OPEN

blocks made each day. Close the machine and fasten catch, then set the core in the center and fill the space around the same with the concrete mixture, tamping it in thoroughly. When full level off the top with a flat stick and carefully lift out the core, setting it on another board ready for the next block, unhook the catch and fold the machine back away from the finished block and you have the completed block ready to dry and cure. This method requires no handling and so has no danger of breaking while the block is yet "green," as it remains on the board or "pallet" until dry enough to be piled up, which they will be in three or four days.

When the blocks are to be laid in a side wall, between corners, take two 1½-inch strips 7½ inches long and attach with screws to the center of each end of machine on the inside. This molds a groove in the block, which is filled with mortar when laying the block in the wall and so securely ties it. By fastening with screws these strips can be easily removed when molding corner blocks.

Blocks of Different Shapes

A neat panel block can be molded by taking the common half-round strips, cutting to the right lengths and fastening to the outside of the face of machine, as shown in Figure 1. For corner blocks they can be attached to either end of machine. By using small screws these can be removed when not desired and also enable you to panel either right or left end of block as needs require.

For making half-size blocks, have a piece of board that is exactly 8 inches wide and 7½ inches high, or so it will just fit into machine when core

is removed. Set this in place in the middle half-way between the ends and fill with material. This will make two half-size blocks for use in breaking joints when laying wall. If desired to have these hollow, two small cores of proper size can be made to set in place when molding blocks of this size.

Rock face effects can be produced very easily by taking a 2-inch plank the size of the face of machine or the end as desired. On this draw a border $1\frac{1}{2}$ inches all around, then take several irons, heat them red-hot and burn out the center in irregular shape, at least $1\frac{1}{4}$ inches deep. By making ridges and hollows in this burning process of different depths and as broken as possible, you will secure a face plate that will mold a very excellent imitation of a rock face. This, of course, can be made to suit any fancy.

One may follow the practice of making several faces and ends from plain and panels down to different rock effects, having these extra face plates the same size as given for the machine above. Then by using hinges as used on doors or any pin hinge, you can easily change the style of block by putting one face plate or end on machine in a moment's time. One machine can thus be used for any style of block and a great amount of time be saved in changing from one style to another.

This machine, in addition to being simple in construction and operation, is very rapid. With but little practice one man can make from 75 to 100 blocks daily and have each one perfect, as he does not break any by handling them after they are molded

According to her cloth she cut her coat.—Dryden.

ANOTHER STYLE OF MOLD

All the lumber necessary to make this mold should be selected white pine or hardwood, free from knots and sap. The platform on which this mold rests should be 14 x 24 inches and be well battened together. The sides are made as shown

THE FINISHED MOLD

by the drawings, with a cleat on each end, which overlaps the end pieces and holds them in place. Both ends and sides are fastened to the platform as shown, with hinges, which permit them to be turned down to take out the completed block.

On each end is placed a flat iron bar with a notch in to fasten the whole mold together. These

bars are the same as hooks, only the ends are prolonged to act as handles for convenience.

Regulating the Height of the Blocks

The bottom board is intended to be fitted in the bottom of the mold loosely and should be blocked up from the bottom to give the required height of

the finished block. The end pieces of mold have a thin piece of board running up and down to form a key between blocks and should run down to top of bottom board.

The plugs are made as shown, with a taper both sides, so that when they are removed they clear all the way out. The pins in the bottoms of the plugs

are to fit in the holes in the bottom board, which will steady them and hold them in place.

When the plugs are removed the board with the two square holes is placed over the top of mold and the handle of tamper is run through the rings in top of plugs and they are lifted up. This board is used as a guard and prevents the block from being broken when plugs are removed, and should not be used until the block is finished and ready to take out of mold. The tamper is made of a large iron nut and a piece of iron rod about 18 inches long.

Filling the Molds

To make these blocks use one part of portland cement and three parts of good sharp sand, mix well and put enough water on to simply dampen the whole. Now close up the mold, put plugs in place, fill the mold one-fourth full and tamp down hard. Repeat this until the mold is filled. Scrape off surplus material, remove the plugs, then turn down sides and lift out finished block which is to remain on the bottom board until hard enough to lift off.

It will be necessary to have a number of these bottom boards. After a number of blocks are made they should be sprinkled from day to day for from 15 to 20 days to properly cure them before using. A barrel of cement will make about 50 blocks and one man can make a block in 12 minutes.

MIXING CEMENT FOR BRICK

Many have found mixing the sand and cement the hardest part of cement brick making. An old

vinegar barrel may be put to use by placing a grindstone crank on one end and a pinion on the other. Two strong posts are set in the ground and the barrel hung over two pieces of round iron driven into the posts. A square hole is cut on side of barrel and covered with a piece of sheet iron hinged and a bottom to fasten.

The sand and cement are dampened, shoveled into the barrel and a boy may turn the crank. The mixing is done as fast as two men can mold, with a boy to sprinkle the brick to prevent drying too fast.

REINFORCEMENT FOR CONCRETE

For heavy construction work involving beams and columns, reinforcement with steel rods is needed. Reinforced concrete is rapidly coming to be the most approved kind of construction of large

DETAILS OF REINFORCEMENT

buildings. Our own great building is one of the most noteworthy examples, being of reinforced concrete throughout. For any building where reinforcement seems desirable the following details will be found useful:

Plan of the footing or foundation of each column is shown in *f*; *g*, side view of footing and part of column above. The steel rods that run up through column are shown by dots in *h*, and the wire spiral by diagonal lines in *g*. *h* is cross-section of column filled with cement, the shaded part being the concrete. *a*, section of floor slab, $4\frac{1}{2}$ inches thick; it is also shown on top of the floor girder and floor beam (crossbeams between girders). *b*, girder; *c*, cross-section of girder, the dots showing twisted steel bars that take up the tensile stress—compression stress is carried by the concrete. The steel bars, *d*, stuck into the column at an angle, are to prevent the girders from breaking off or “shearing” at column.

MAKING A FROSTPROOF CELLAR

Some farmers build their own concrete cellar walls and chimneys with inexperienced help. Lay out your foundation the same way you would for any building. Have outside line of excavation plumb. Then use 2 x 4-inch studs the length required. Point one end, drive in ground, on line of inside of cellar wall, brace top of stud by driving stake in ground, and nail brace to stake and each stud. You must make everything firm. Then take square edge boards and place horizontally against the studs. (See illustration.)

Do not try to go around the whole cellar wall, take one side at a time to the height of earth sur-

face, but turn your corner. Pay no attention to outside, let the stone and cement push up against the earth. It is the best plan to finish the whole wall up to the earth surface line before making the elevation above the ground line.

Above the earth surface line do just the same on the outside as you have been doing on the inside, but now you must use boards and studs, as up to

CONCRETE CELLAR WALL

this point the earth took the place of them. Plumb every stud you drive, and place them 24 inches apart. Have cellar window frames ready and place them as you come to them. Be sure and make extension for hatchway when building your main wall. For the corners use baled hay wire in wads, bending it around the center of wall, and a reinforced concrete corner will be the result.

Get cobblestones or any stone from the size of a goose egg to the size of your head, and put them in bottom of wall to depth of 1 foot. Make a mixing bed, say, about 12 x 36 x 72 inches. One man

used an old wooden sink as near watertight as possible. Use one water pail of cement to three of fine gravel sand. Put one and one-half pails water in the mixing bed, then add the cement. Be sure and mix water and cement well before using sand. Throw sand in one shovelful at a time. Have one person mixing with a good-sized hoe, while another throws in the sand. Mix well.

Have it about the same as thin mortar, so it will leave the pail easily when pouring into the foundation. Cover the stones and then put in another lot and do the same to height of wall up to within a couple of inches. Do not put stones to full height of wall. To bring wall up to line, mix cement and water together (or one part sand and one cement) so it will run, and after wall is hard pour it on top and it will find its own water level and your sills will fit exactly. It is a good plan to have wall thicker at bottom than at top—perhaps 18 inches at bottom and 12 inches on top.

Now for hatchway steps. Put in the stones, as they save cement. Before the cement gets hard, drive in some large spikes, leaving them projecting about 2 inches on line of hatchway sills. Your hatchway doors will stay in place if sills are well-fitted on to spikes. One of the most important things is to be sure of the sand you use. If there is more than 10 per cent loam in the sand, your work will be a failure.

A SUMMER COOL ROOM

A simple method of constructing a cool, outdoor cellar in localities where the common house cellars are too warm for use during the summer time, is shown in the accompanying sketch. It is a cellar

made under the pump, so that the water pumped by the windmill has a very cooling effect. In places where it is difficult to obtain ice, it will prove indispensable to the dairyman who keeps a few cows. Another important item is the fact that a man does not have to pull up all of the pipes every

CONCRETE OUTDOOR CELLAR

time that he finds it necessary to repair the pipes and pump.

It is constructed of concrete. The top is reinforced with $\frac{1}{2}$ -inch steel rods placed 1 foot apart each way and the concrete work is about 6 inches thick. The sides are made by using a form, and the stairs are also made of concrete and are reinforced by small steel rods. The cost, including the labor, is about \$50. In the west and southwest it will also answer the purpose of a storm cave, which is considered a fixture on all farms.

A CONCRETE SMOKEHOUSE

The structure is about 8 x 10 feet and 7 feet high. It will keep the meat inside and thieves out. For a building of this sort 8-inch walls will be thick enough. Excavate to the proper depth below frost, which will be two feet or less, and use a mixture of one part portland cement, three parts sand and six parts gravel or broken stone.

Make the forms of matched boards, although square-edged boards could be used for this purpose. The forms must be well braced and may be raised as the work of laying the wall progresses. Space for a doorway must be left and two eye-bolts inserted in the concrete for the door to swing on. The door jamb can be molded in cement if it is desired. An eyebolt for the lock and latch should also be placed in the wall.

The roof will no doubt be of boards or shingles. The plates should be placed on the concrete and held to it with bolts properly imbedded. An arched concrete roof can be made if desired, in which case it will be necessary to leave suitable vents in each end, or build a small flue to allow the smoke to escape. To make the house absolutely proof against fire a steel or iron door should be used.

LAYING A CONCRETE FLOOR

A concrete floor should be level with the top of the sill, where there is much passing in and out with stock or wagons. There should be about 4 inches of concrete. If the earth is leveled off and tamped down hard, it would be unnecessary to put any crushed stone under the concrete in a building

where frost or water does not get underneath. It is generally recommended to put several inches of stones, gravel or cinders on top of the earth, but many floors are laid without such a bottom. Partitions for horse stalls and cattle stanchions can be held in place on a cement floor by putting down iron belts or pieces of gas pipe when the floor is laid. Let them project 2 or 3 inches above the floor.

MAKING A CONCRETE WALK

The best way is to dig a trench 16 inches deep, put in a foot of loose gravel or stone, leveling it off with fine material. On top of this spread 3 inches of concrete made of one part portland cement, two parts sand and four parts crushed stone or gravel. On this put a granolithic finish 1 inch thick mixed in the proportions of 1-2-3. Trowel it down smooth and hard. Joints $\frac{1}{4}$ inch thick and filled with sand should be left every 5 feet to prevent walk from cracking

CEMENTING A CISTERN WALL

In making a surface waterproof, a mixture of about one part portland cement to two of sand will shed water from a roof or wall, but to make a surface perfectly watertight, so that it will keep out standing water, it is better to use neat cement only, that is, cement with no other material but the water with which it is mixed, and it will cost less to put on a coat $\frac{1}{4}$ inch thick of neat cement than one 1 inch thick, one-half or two-thirds sand, as the neat cement mixed with plenty of water is waterproof.

SPECIAL USES FOR CEMENT

A sack of portland cement is a very useful thing to have for making quick repairs about the farm. A hole in a drain pipe can be stopped in a few minutes with a little cement, mixed with water, thick as putty. A crack in a barrel can be stopped this way. Hardwood floors may be patched and nail holes filled so they will not leak.

A waterproof floor can be laid over an old board floor in a short time. Sweep the old floor clean and dry and nail down all loose boards. Cover with a layer of heavy wire netting, tacking it down occasionally. Over this lay a layer of concrete of one part portland cement, three parts clean sand, mixed with water to a thin paste.

Smooth thoroughly, but if it is to be used by stock, brush with an old broom to make it rough, then let it dry thoroughly before using the floor. Gutters may be put in where necessary. Holes in an old shingled roof can be quickly stopped by forcing a little cement putty under the shingle where the leak appears.

Some special uses to which cement is being put are the making of bee hives, brick for pavement and ordinary foundations, cement shingles for roofing, grain bins in the form of square boxlike and round barrel-like receptacles. The use of this excellent material for farm structures is only just opening up and it is destined to become the most important material for general farm building.

A wooden reinforcement in the center of a concrete fence post is worse than useless. It does not make a bond with the concrete, and thus weakens,

instead of strengthens, the post. Of course, the same is true of wooden reinforcement of any concrete work.

A TIME-HONORED HANDY DEVICE

(SEE FRONTISPIECE)

How dear to my heart are the scenes of my childhood,
 When fond recollection presents them to view!

The orchard, the meadow, the deep-tangled wild-wood,
 And every loved spot that my infancy knew!

The wide-spreading pond and the mill that stood by it;

The bridge, and the rock where the cataract fell;
 The cot of my father, the dairy-house nigh it;

And e'en the rude bucket that hung in the well—
 The old oaken bucket, the iron-bound bucket,
 The old moss-covered bucket that hung in the well.

How ardent I seized it with hands that were glowing,
 And quick to the white-pebbled bottom it fell!

Then soon, with the emblem of truth overflowing,
 And dripping with coolness, it rose from the well.

—Samuel Woodworth.

FREEZING ICE IN BLOCKS

HERE a pond or stream is not handy from which to get the year's supply of ice, blocks can be frozen in forms with comparatively little labor. A supply of pure water is essential. The forms are best made of galvanized iron of any size desired. A convenient size is 16 inches wide, 24 inches long and 12 inches deep inside measure. The sides and ends should be made to taper $\frac{1}{4}$ inch, so

HOMEMADE ICE MOLDS

that the frozen block will drop out easily. The top of the mold should be reinforced with wire for the sake of strength and durability.

With a dozen or 20 forms one can put up quite a supply of ice during the winter. The forms should

be set level on joists or boards and placed a few inches apart. Fill them nearly full with pure water and let them freeze, which they will do in one or two days and nights in suitable weather. When frozen solid, turn the forms bottom side up and pour a dipper of warm water on them, which will release the cake of ice. The form can then be lifted off, the ice put away in the icehouse and the form filled with water again.

SAVING THE SEED CORN

Here is a handy device for preserving select ears of seed corn. It consists of a wide board

SEED CORN RACK

fastened between two supports nailed to the edges. The board stands upright on one end and may be as long as desired. Drive heavy spikes through it from the opposite side and stick an ear of corn upon each spike. This allows for the passage of air, and the ears can be examined without removing them from the rack. It

is much to be preferred to expensive wire racks, as each nail may be numbered and a record kept of the ears in this way. This rack was designed at the Idaho experiment station.

RACK FOR SEED CORN

Here is a simple arrangement for keeping choice ears of seed corn. Take a 2-inch square timber for the upright, and make a solid base by boring a hole through the two base pieces, then drive the timber into it. Drive 4-inch spikes through the upright at intervals of 6 inches from four sides, and stick the ears of corn on these spikes by thrusting the same into the butt of the cob. Numbers may be placed above each spike, so that records can be kept of all of the corn. The corn should be placed on this rack as soon as picked and husked, and may be left there until planting time if the rack is placed in a dry room where rats and mice cannot get at it. A large post strongly mounted on a heavy pedestal may be used in a manner similar to the small upright described above. The bigger the post and the larger the number of spikes used, the greater the capacity of the rack, of course. It is a good plan to make the pedestal heavy and strong in order that it may not be tipped over too easily.

RACK

The first years of man must make provision for the last.—Samuel Johnson.

Put your trust in God, my boys, and keep your powder dry.—Colonel Blacker.

DRYING AND KEEPING SEED CORN

Never let it freeze before it is dry. Farmers have had seed corn exposed to a temperature of 30 degrees below zero without injuring its vitality, and have had it ruined at 10 degrees above zero. We would not recommend kiln-drying for the general farmer, as this is only practicable where a grower is in the seed business. A very convenient way is to take four pieces 4 x 4

CORN DRYING RACK

6 feet long, set them up in a square, and nail laths on them two and two opposite. Leave a 6-inch space between the laths, so the corn will have plenty of ventilation. Lay your corn on this to dry, and if thoroughly dry it can lay there all winter.

Knowledge is worth nothing unless we do the good we know.

It is better to give one shilling than to lend twenty.

Keep your mouth shut and your eyes open.

FIG. 1

FIG. 2

FIG. 3

FIG. 4

WEIGHT LIFTER AND DETAILS

The drawings show the different parts and one of the many uses of this device.

STRONG AND SIMPLE WAGON JACK

Here is a good, practical wagon jack suited to almost all kinds of vehicles. The whole thing is made of wood with the exception of the curved piece, *b*, which is of iron and hooks over an iron bolt, *e*. It is well to have a strong $\frac{1}{2}$ -inch bolt at *f*, so as to support the heavy weight on the lever, *a*. The bottom, *d*, and the piece, *c*, are each 2 inches thick. In using the jack, the axle is lifted by simply pressing down on the handle of the lever. The teeth of *b* catch and hold on *e* automatically. The height of lever is regulated by moving *f* up and down.

WAGON JACK

Write down the advice of him who loves you, though you like it not at present.

A JACK FOR HEAVY WAGONS

Many lifting jacks which are designed for light vehicles would not work well in the case of a heavy log wagon. Here is one that will stand a lot of hard usage and is simple and effective. Make the base and upright of heavy 2-inch oak plank and insert a $\frac{3}{4}$ -inch bolt through the lever for a support. Have a good, strong hemp rope attached to the base, pass-

ing over the handle end of the lever, so that as it is drawn down and the wagon is lifted it can be hooked in a notch to hold it in position.

HOMEMADE WAGON JACK

A CHEAP WHEELBARROW

The construction of this barrow is very simple. Get a pair of old plow handles, two gate hinges about 1 foot long, and a wheel, which may be found at the junk dealer's. The legs of the wheelbarrow

MADE FROM OLD MATERIAL

are those of an old chair, braced with a piece of iron. These articles in themselves are worthless, but in their combination we create something very useful.

A WHEELBARROW CHEAP AND STRONG

Here is a picture of a handy, strong wheelbarrow that any farmer can make on a rainy day. Take a dry-goods box 30 inches long, 24 or 26 inches wide and 20 inches deep, and two sticks $5\frac{1}{2}$ to 6 feet long and $3 \times 3\frac{1}{2}$ inches for handles. Nail or screw

BOX WHEELBARROW

on crossbrace in front and rear, and pieces with brace as shown for legs. Cut four half circles from inch hardwood board and a notch in center to fit around axle. Nail these securely together for the wheel.

For the axle, take a stick $3\frac{1}{2}$ inches square. Trim and band each end or wrap with wire. Bore holes and drive a 6d. wire nail in each end. Just 2 inches apart in center, bore two 1-inch holes on opposite sides to hold the wheel in place. A band of hoop iron around the wheel will make it last longer. When it is put together, you have a very substantial wheelbarrow that cost but little.

HOW TO HANG A KETTLE

Using stones for a kettle support seems handiest oftentimes, but let the heat crack one of the stones and tip the kettle over, as it frequently will, does not tend to improve a man's language, let alone the loss sustained. It is much better to make a support such as is presented in the cut. The three uprights, of suitable length to correspond with the size of the kettle, may consist of any good wood. Through the top of these a hole is bored for the bolt to hold them together, which

TRIPOD-HUNG KETTLE

must be long enough so they will have play to set up easily. All that is necessary then is to suspend two chains from the top and letting them extend downward to the proper distance, attach the ears of the kettle into the hooks on them. When not in use, the device can be folded together and laid away.

A SNOW PLOW

No person not owning a snow plow can appreciate how useful one is after every storm. A horse, or if the snow be a heavy one, a span or a yoke of cattle and this simple homemade arrangement, and

in less time than is required to tell it there is a path, and no back-breaking work either. It is only a big V braced so the snow is pushed both ways by it. It must be made of 2-inch planks at least 1 foot wide and not less than 6 feet long. If shorter it wobbles and does not stay on the ground well.

To make a good road for teams, chain it to one side of the wood sled and drive up and down. It spreads 2 feet, and will make your farm front look as if somebody of pluck lives there. For foot-paths draw it from a ring at the top of the front so it will root.

SMOKEHOUSE SUBSTITUTE

TEMPORARY SMOKING DEVICE

If one butchers only once a year it is not necessary to build an expensive smokehouse, for almost as good results can be obtained from a device such as that shown on page 242. It is made by taking both ends out of a barrel and mounting it upon a box or above a fireplace in the ground. The meat to be smoked is hung from the sticks laid across the top of the barrel, the fire built underneath and the lid put on.

HOMEMADE HEATER AND COOKER

A cheap and economical heater may be of home construction. Make a frame of 2 x 8-inch pine 7 feet long and 27 inches wide. Put a bottom on

TANK AND COOKER

this of No. 18 galvanized iron, letting it project $\frac{1}{2}$ inch on each side and 14 inches at one end for a stovepipe fitting. Spike the frame together and

cover the corners with heavy tins to prevent any leaking. Nail the bottom on with two rows of nails.

Make a fireplace on the ground of stone and blue clay or brick and cement of mortar if preferred, 2 feet wide by 3 feet long and 18 inches high. Pile up dirt 1 foot high and 3 feet wide at the end of the fireplace for a flue, put stone on the earth the length of the galvanized iron, place the tank on this foundation and bank it up with dirt. In cutting a hole for the stovepipe, turn up strips of the galvanized iron for a collar, then drive an iron rod into the ground, put on two lengths of stovepipe and wire it fast to the rod.

A piece of sheet iron should be set up before the fireplace to control the draft and keep the fire. Such a heater, on one farm, is located near the windmill and storage tank and can be filled from either. The water can be heated quickly with cornstalks, straw, cobs or brush. One may boil pumpkins and small potatoes for fattening the pigs, and cook ground feed by pouring scalding water on the meal in barrels and covering with old blankets or carpets. A light fire will take the chill from ice water for the milch cows.

USE FOR A TOUGH LOG

Most farm wood piles have two or three old logs lying about which nobody cares to tackle with an ax or blasting powder, and are too short for the sawmill. If straight, they will make good water troughs. Square the ends, mark off about 10 inches from each end, chop out the inside and trim the edges. An inside coat of oil or pitch tar will increase wearing qualities.

A HANDY WOOD SPLITTER

For splitting wood a farmer in eastern Massachusetts uses a device as shown in the cut. Take a 2 x 8-inch plank about 3 feet long and an upright of the same material about 20 inches long. Set this upright at an angle of 20 degrees and use a brace of

WOOD SPLITTING DEVICE

the same material. The sharp points shown in the cut are 40d wire nails. Set the wood against these spikes in splitting it.

HOW TO SPLIT WOOD

Wood splits much more readily in the direction up from the root of the tree than when the blow of the ax is downward. In other words, to split a chunk place it upside down—contrary to the direction in which it grew. It is much easier to split by slabs than to try to cleave through the center. This means to split off pieces near the edge.

A PULLING HAMMER

If you want to make your old claw hammer do more work and do it better and easier, have the handle projecting a little beyond the head. You will find it much more convenient in drawing a nail, as it makes a right angle for pulling the nail without bending it to one side. It takes the place of a block and is always on hand and ready in the right place for immediate use. The handle is simply whittled a little more than usual and driven through to the required distance. Don't drive it through too far, but about as shown at *a* in the picture. If it sticks out too much, it will be in the way when driving nails. Whittle it off rounding, and give it a finished appearance.

MOUNTING THE FARM ANVIL

To make a solid foundation for an anvil, build a form of boards 14 x 18 inches square at the base, 18 inches high, tapering to 8 x 10 inches at the top. Fill this mold with rich concrete and fix a bolt in the center of the top of it to fasten the anvil. Afterward, melted lead can be poured around the base of the anvil, completing a very nice pedestal.

SORTING POTATOES QUICKLY

The sketch shows a homemade potato cleaner and sorter. It consists of a number of hoops to which are fastened $\frac{1}{2}$ -inch slats so as to make holes

$1\frac{1}{2}$ inches square. Two heavy pieces, *a*, are placed inside the cylinder to hold the axle, *b*, which extends entirely through the machine and is turned by a crank, *c*. The frame made is 4 inches lower at the opening end of the cylinder so that the potatoes will run through freely.

At the crank end is a hopper, *f*, into which the potatoes are poured. The cylinder is $2\frac{5}{8}$ feet long

POTATO SORTER AND CLEANER

and 3 feet in diameter. It will not bruise the potatoes, and the dirt and small ones run through on to the floor or crate and the marketable ones run out at the open end of the cylinder into another crate. With one man to turn the crank and another to fill the hopper, from 700 to 800 bushels can be sorted in a day.

An indiscreet man is more hurtful than an ill-natured one; for as the latter will only attack his enemies, and those he wishes ill to, the other injures indifferently both friends and foes.—Addison.

HANDLING POTATOES EASILY

A bushel crate is often more convenient to use in handling ear corn, potatoes or other vegetables

STORAGE BOX

than a basket. Crates that will hold a bushel when level full may be piled upon one another and thus stored in less space than baskets. At the same time they can be just as easily and just as quickly

moved. They may be of light material. Pieces of wood 2 inches square are used for the corner posts. The slats may be made of $\frac{1}{2}$ -inch boards 3 inches wide nailed securely to the corner posts. There should be just room enough between the two upper slats so that the fingers can be inserted when lifting the box. The box will be more durable if the upper slats are an inch thick. A handy size for the completed box is 16 inches long, 14 inches wide and 12 inches deep, outside measurements.

CUTTING SEED POTATOES

In the principal potato growing sections, medium to large seed is used for planting and cut to two eyes. In the famous Greeley district of Colorado, cutting is done by hand. Potatoes are shoveled into a bin or hopper, made of a dry-goods box raised on legs. The back is made higher than the front, so that potatoes will run down to the open-

ing and the bottom is slatted to let out the soil shoveled up with the potatoes.

The cutting is simple. An old case knife, *a*, is fastened to the end of a plank or board, *b*, in such

SEED POTATO CUTTER

a way that potatoes can be pushed against the knife and fall from it into the basket beneath. The operator sits on the box to which the board is fastened and can work very rapidly.

ANOTHER SEED POTATO CUTTER

A wide bench is boxed in on both ends and one side. It is divided into two or three compartments, these being open in the front which corresponds to the side boxed in. To each of the compartments is attached a sack on hooks, and along one side of the bench in the middle of each compartment and right over the opening of the sack is fixed, in an upright position, a shoemaker's or common steel table knife.

Potatoes to be cut for planting are shoveled into the compartments of the box and in front of each compartment a man takes his position, being seated

on a box or stool for comfort's sake. He seizes the tubers in rapid succession and by pulling them against the blade quickly cuts each one into as many pieces as desired; the pieces are then dropped into the open sack. It is claimed that by this indirect method of using the knife two fairly good cutters can cut each day all the potatoes ordinarily required for the use of one planter.

HOW TO TEST SEED CORN

Of the different methods for testing seed corn, the most convenient and satisfactory is a shallow box provided with wet sawdust to furnish the moisture and a marked cloth on which to lay the kernels. The most convenient box is one 2 feet square. This will accommodate 100 ears. It is best to make it about 6 inches deep. Fill a sack half full of clean sawdust and soak it for three or four hours in water. Then spread this sawdust in the bottom of the test box to the depth of 1 inch. Take a smooth brick and pack the sawdust down all over the box, making it as level as possible. Be sure to get it packed firmly around the edges and in the corners.

Then take a piece of white muslin 25 inches square. Stretch this tight on a table so that it can be marked. Rule off on this cloth with a heavy blue pencil 100 squares 2 inches each way. Beginning at the upper left-hand corner number these squares in rotation from left to right. When the ruling is done, pack the cloth in the germination box so that it will rest firmly on the sawdust. This can be done by pointing the tacks in the edge of the box downward, and as the tack is driven in it will draw the cloth tight over the sawdust.

Of course, there is no advantage testing any ears that are of undesirable shape or conformation, therefore the first step is to pick out those nearest to the type wanted. Lay these out in rows upon a plank or upon the floor, separating each ten ears with a nail driven into the plank or floor. Starting at the left-hand end of the row call the first ear No.

GERMINATION BOX

1, then the first ear beyond the first nail will be No. 11, the one beyond the second nail No. 21 and so on.

Remove six kernels from ear No. 1 and place them in square No. 1 in the test box. Put six kernels from ear No. 2 in square No. 2 and so on through the row. In removing the kernels from the ear take a pocketknife in the right hand and the ear in the left. Place the blade at the side of the

kernel you wish to remove and pry it gently. The kernel will come out easily and should be caught in the palm of the left hand. First remove a kernel from near the butt of the ear; turn the ear a quarter turn in the hand and remove a kernel from the center; turn the ear another quarter turn and remove a kernel from near the tip; another quarter turn and remove a second kernel from near the butt; another quarter and remove the second kernel from the center; another quarter turn and remove a second kernel from the tip. This makes six kernels from six different rows and representing the butt, middle and tip.

In placing the kernels in the box it will be found of advantage to point the tips all in the same direction, and also to lay the kernels with the germ uppermost. If the kernels are laid in the squares promiscuously, they may be thrown out of their places when the sprouts begin to grow. When the kernels are all in place, take a second piece of white cloth fully 24 inches square, moisten it and lay it carefully over the kernels. This will hold them in place while the top layer of sawdust is being put on. Take a third piece of cloth about 48 x 30 inches and lay it over the box so that the edges lap about equally. Then in this cloth put another inch of wet sawdust and pack it down firmly, especially around the edges. When this is done turn the edges of the cloth over the sawdust to keep it from drying out too rapidly and place the test box where it will not be subjected to cold below a living-room temperature.

Reading the Results

After seven days carefully roll back the cloth containing the top layer of sawdust and lift the

second cloth off the kernels. This must be done with care, because sometimes the sprouts grow through the cloth and the kernels will cling to it.

Observe the results in square No. 1. If all six of the kernels have vigorous sprouts, from $\frac{3}{4}$ to 2 inches long, you can be sure that ear No. 1 is thoroughly good. If in square No. 2 only two of the kernels have sprouted, you may know that ear No. 2 will make much better hog feed than seed corn. As soon as you have determined that ear No. 2 is really bad, pull it out from the row about half its length, leaving the other ears in place. After you have gone through the whole line, you may then go back and pick out the bad ears and discard them.

Of course, we would all prefer to use only those ears that gave a perfect germination, and if one has enough, that is the thing to do. But experience has taught that it is quite safe to use an ear, four of whose kernels grow strong sprouts. Or, if seed corn is scarce, one should not hesitate to use one that gave three strong sprouts and two weaker ones.

This testing may be done at any time after the ears are dry. It is generally more convenient to do it in winter, when there is not much outside work to be done. The box may be set behind the stove or any other convenient place, where it is sufficiently warm; in many cases, where there is an attic above the kitchen that room is a sufficiently warm place for testing.

Some put sand in an ordinary dinner plate, flood with water, and then drain the excess water off, place the seed on top of the sand, and cover with another dinner plate. Others use a saucer made

of porous clay. The seeds are placed in this, the saucer set in a pan of water, and the pan covered.

These methods may be used for other grains as well as corn. In case of sowing grasses, alfalfa or wheat, it is often of great advantage to test the seed.

Every man has two educations—that which is given to him and the other, that which he gives to himself. Of the two kinds, the latter is by far the most valuable. Indeed, all that is most worthy in a man he must work out and conquer for himself. It is that that constitutes our real and best nourishment. What we are merely taught, seldom nourishes the mind like that which we teach our selves.—Richter.

KILLING INSECTS IN GRAIN

If one has not time to make a substantial box for fumigation of seed grain for insect destruction, barrels may be utilized for the purpose. Get two tight, strong barrels, such as coal oil barrels, and make water tight. Put in the seed to be fumigated, cover with a blanket and close-fitting cover. Before covering pour carbon bisulphide, which is explosive, over the grain, at the rate of 3 to 4 ounces for 5 bushels of grain. If it is not desirable to pour this poison on grain, set a saucer on it, and pour the poison in the saucer. Place a small block near the saucer to hold up the blanket 1 or 2 inches higher, lay blanket over the

barrel, and place cover securely in place and weight with stone. This will kill the weevil in peas and beans.

BINDING PINS FOR HAY

Every person moving hay ought to have a set of binding pins. They are made in a minute and serve an excellent purpose for a lifetime. The sketch shows a rope stretched over the top of a load of hay or straw. The upright pin is worked down into the load and the other twisted in the rope and turned around the upright until the load

BINDING LOAD OF HAY

is tightly bound. Then a small rope that is kept tied in end of the horizontal pin is tied to the binding rope and the pressure is held. Each pin is $3\frac{1}{2}$ feet long. One is sharpened and the other has a $\frac{1}{2}$ -inch hole bored through one end. Old fork handles are just the thing to make them of. One pin only may be made and a fork used to bind in the manner shown after the load is on.

Nothing is impossible to industry.—Periander.

COMBINED DRAG AND HARROW

This road drag is all right. The front piece consists of a 4 x 4 oak strip, *b*, 10 feet long, through which are driven ordinary harrow teeth about 3 inches apart. This is attached to the rear piece, *a*, which is a 2 x 6 oak timber 10 feet long faced with

HARROWS AND LEVELS AT ONCE

3 inches of $\frac{1}{4}$ -inch metal on the bottom, *e*, which projects 1 inch. These pieces are kept apart by wooden blocks, *d*, upon the bolts, *f*, and by the top strips, *c*, each 2 x 6. This makes a fine level road, as it harrows it and scrapes it at the same time.

HOW TO HANDLE A ROPE

A rope is one of the most useful articles that are constantly needed about the farm; but too many farmers are not familiar with the many uses to which the rope may be put. The various sailors' knots may often be used to great advantage. To sling a plank for painting or other purposes make

a bight of rope as shown in Figure 1, bringing the rope entirely around the plank, so as to prevent its turning and throwing the workman down. One-half to $\frac{3}{4}$ -inch rope is usually sufficient for all practical purposes. A hemp rope is more generally used and stands wear better than other kinds.

SOME ROPE HITCHES

A useful way to sling a can or pail from the end of a rope is shown in Figure 2. Prepared in this way the vessel is secure so long as the rope is not slipped off from the bottom. Secure the knot firmly at the top to allow no slipping and so that the pail may not become lopsided.

Scaffolding may often be erected by tying poles together as shown in Figure 3. This sort of lashing will not slip if made tight. In many cases a chain may be used as shown in Figure 4, in which case the weight should be on the side of the upright where the chain is lowest. All of these lashings must be drawn very tight so as not to allow any play, which may result disastrously.

An excellent hitch knot is shown in Figure 5, readily made, easily loosened and valuable for many purposes on the farm. This knot is readily untied by slackening up the drawing strand. It does not become tight and hard as many ordinary knots after heavy usage.

In many cases where heavy hooks are used they are liable to come unfastened unless a cord is affixed, as shown in Figure 6. A few turns of heavy twine or light wire in the middle will frequently prevent any loosening of the chain.

A ring hitch, shown in Figure 7, is a very effective and safe method, which may be made on short notice. The loose end of the rope is allowed to hang free or may be tied with a slip knot to the drawing strand.

TYING SOME USEFUL KNOTS

A sailor judges knots for their holding qualities and also their ability to be quickly unfastened, without regard to the strain they have been sub-

jected to. A knot's main office is to hold, without working loose or slipping, yet they do occasionally fail absolutely to accomplish this, when made by inexperienced hands. The accompanying diagrams show some of the simpler knots that may be of everyday use. In these, the mode of formation can be readily discerned, because the rope's position is shown before tightening. The overhand knot, Figure 1, is probably the simplest of all. It is used only for making a knot at the end of a rope to keep it from fraying or to prevent another knot from slipping. If a slight change in formation is

A FEW GOOD KNOTS

made, as in Figure 5, it develops into a slip knot or, as it is sometimes called, a single sling, and its purposes are obvious. A double sling is represented in Figure 6, and though it is slightly more complicated, it is considerably more useful for any purpose where a rope is to be attached to a bar or beam and stand a steady strain.

Probably for convenience and emergencies no knots equal the bow-line, Figure 7, because it will not slip or give, no matter how great the tension; in fact, the rope itself is no stronger, and the instant the strain ceases it can be untied as easily as

a bow. When the end of a rope is to be secured, the two half-hitches or clove hitch, Figures 2 and 3, are of great importance, for either of these bends can be attached instantly to almost anything, and their holding powers are exceeded by none. The square knot, Figure 4, can be used for infinite purposes, from reefing a sail to tying a bundle, the advantage being, if made properly, of resisting any separating strain on either cord, and yet can be untied immediately by pulling one of the short ends.

One of the best and safest slip knots is shown in Figure 9, made with the overhand at the end, which, until loosened by the hand, maintains its grip. When a rope requires shortening temporarily the sheep shank, Figure 8, affords a means of so doing. This knot can be applied to any part of the rope without reducing its strength of rectilineal tension.

CARRYING A BARREL MADE EASY

In the cities the ash collectors use a simple device, which farmers might make and often find handy, as barrels often become dried, weak and will not stand rough handling. The device is made of six pieces of wood; four pieces are about 2 feet long and 4 inches in thickness and width. Handles may be whittled on one end of each. About 10 inches from the other end, boards about 2 feet long and 8 inches wide are nailed as shown at *c, c*, in figure. Pieces *c, c*, are then cut in circular form so as to fit the outside of a barrel.

An old wheel tire may be straightened and four pieces cut to be fastened to the ends of each of the four handle pieces, as at *d*. These are then riveted

together so as to make hinges as shown at *d, d*. The tire need be only long enough to fasten securely to the handle pieces. Of course, the blacksmith should drill holes in them, that they may be securely riveted.

To use this device, drop it over the barrel. One man lifts on the two front handles and another

BARREL CARRIER

man on the rear handles. Boards *c, c*, close up in circular form, just beneath the lowest hoop round the upper end of the barrel, and cling tightly. The barrel is then lifted and readily carried without jar to its contents or straining the barrel. Of course, if all the barrels on the farm are of uniform size, the device could be made without hinges, and the barrels headed up could be rolled on pieces *c, c*.

The best part of one's life is the performance of his daily duties. All higher motives, ideals, conceptions, sentiments, in a man are of no account if they do not come forward to strengthen him for the better discharge of the duties which devolve upon him in the ordinary affairs of life.—Henry Ward Beecher.

HARNESS CLAMP

The accompanying drawing represents a very handy harness mender which anyone who can use

THE CLAMP

a saw and hammer can make in a few minutes. It is made of lumber of the dimensions indicated in the drawing. The clamp is tightened by the worker sitting upon the seat, which should extend at least 2 feet from the clamps. The drawing shows the device with a shorter seat than that. It would doubtless be better to have the seat extended to twice the length shown from the left of the clamps and to have the base extended in a similar manner, so that the device will not tip over too easily. The joint at the upper right-hand corner may be hinged with heavy wire run through holes and twisted together underneath, or real strap hinges of iron may be attached.

They who provide much wealth for their children, but neglect to improve them in virtue, do like those who feed their horses high, but never train them to the manage.—Socrates.

a saw and hammer can make in a few minutes. It is made of lumber of the dimensions indicated in the drawing. The clamp is tightened by the worker sitting upon the seat, which should extend at least 2 feet from the clamps. The drawing shows the device with a shorter seat than that. It would doubtless be better to have the seat extended to twice the length shown from the left of the clamps and to have the base extended in a similar manner, so that the device will not tip over too easily. The joint at the upper right-hand corner may be hinged with heavy wire run through holes and twisted together underneath, or real strap hinges of iron may be attached.

SUBSTITUTE FOR PIPE WRENCH

The drawing shown here illustrates a useful device for twisting pipe off or on its connections.

Three or 4 feet of new rope is frayed out at both ends, which are put together and wound tightly around the pipe to be turned, so that the first coil twists over the loose ends and continues around the pipe, two or three times, ending in a loop, through which a bar of iron is slipped, to be used as a lever. This simple plan will be found very effective in ordinary requirements for the pipe wrench, and is worth a trial. A more durable wrench may be made by using wire instead of rope. The loop can be formed by closely twisting the ends of the wire with pincers. The rope is rather easier to handle because more flexible.

PIPE TWISTER

MARKET WAGON CONVENIENCES

Farmers who regularly haul produce to market or deliver direct to customers will find the conveniences described to be of much value.

REIN CLIP

They save much time and considerable trouble and cost but little effort to make them. Instead of wrapping the reins about the whip, or letting them lie over the dashboard, a hook, such as shown in the first sketch, may easily be made of stiff fencing wire and secured to the top of the wagon or the dashboard.

Two other hooks may be arranged at the sides of the wagon to hold an umbrella, which would be kept there rain or shine, and never forgotten and left at home. This will save a drenching some time and perhaps some valuable produce.

Another convenience is a rear curtain of oilcloth stretched over a light board frame and hinged at

REAR SHADE FOR WAGON

the top, as illustrated. Two old stays from a buggy top will serve to support it, when it must be left open, and it will protect the driver from sun and rain while taking things from the wagon.

CARRYING BUTTER TO TOWN

A refrigerator that one farmer uses in which he takes butter to town nine miles away in hot weather

is made thus: Get two clean, tight boxes of some odorless wood, one 12 x 15 x 13 inches deep, and the other 9 x 12 x 10 inches deep. Slip one inside the other with a notched block in each corner to hold the inside box in place. Fasten the covers together so as to leave an air space of about 1 inch between them all around. The inner box will hold 20 pounds of butter nicely. It will carry butter solid in wagon all day in 90-degree weather.

TO SHARPEN SCISSORS

Do you know that you can sharpen scissors, and easily, by passing the blades over glass jars? Take a bottle or jar, make believe you are trying to cut it (have one blade in and the other outside of the top of the bottle) and then allow the scissors to glide off the hard surface naturally, just as if you were trying to cut the glass. Use firm but not too hard pressure, and repeat the operation several times.

HOW TO PAPER A ROOM

If a room has been papered several times, tear off all the loose parts you can and with a sponge and water loosen what remains on the walls, removing as much as possible, so as to have a smooth, even surface. If the room has never been papered, first go over it and fill all large cracks and holes with a paste made of whiting and water, or plaster of paris and water. When using the latter, mix only a little at a time, have it rather thin, and use quickly. Then, give the room a coat of sizing, which is made of common glue, three or four handfuls dissolved in a pail of boiling water. The sizing is applied with a large brush and should be allowed to dry overnight.

Choose Judiciously

For very sunny rooms, select cool-looking papers, such as blues, greens and browns in various shades,

HANGING WALLPAPER

while for dark rooms pinks, reds, terra cottas and yellows are best. When selecting papers, pay care-

ful attention to the color scheme of your room, and don't have an inharmonious mixture, which will offend good taste. Small, plain patterns are the most economical, and the easiest to match. The cheap, trashy papers, costing only a few cents a roll, are not worth the trouble of putting up. Gold paper is not to be recommended for wear.

No borders should be used for rooms having a low ceiling. For such, a striped paper of pretty design running right up to the ceiling is best. The ceiling may be papered in a plain or very small-patterned design, to harmonize with the side walls, or treated with several coats of tinted kalsomine or paint. A picture molding of appropriate color is used to finish the side walls, being placed scarcely 1 inch from the ceiling. The ceiling whether papered, painted or kalsomined, should be done first. It is a very difficult matter to paper the ceiling, and, unless you can have help, it would be better not to attempt it. Plain tints in paint or kalsomine are always pretty and in good taste. If, however, you want to risk papering the ceiling yourself, get some handy body to help you.

Paste and Tools

The paste is made by simply boiling flour and water together, and adding a very little alum, salt and glue—about a tablespoon of each to a pound of flour. It should be of a consistency thick enough to apply easily, and not so thin that it will run.

Provide yourself with a good-sized paste brush, another one (a whitewash brush will do) to use dry over the paper, sharp scissors and a knife,

plenty of clean rags, two barrels, two long, smooth, clean boards, each about 10 inches wide, and a step-ladder.

Make a long table by placing the two barrels about 8 or 9 feet apart and on top of these the boards.

Trimming and Cutting

The first thing to do is to cut the necessary number of strips of paper long enough to allow for waste in matching, and lay them all face downward on the "operating" table, one on top of the other. Next spread the paste evenly over the top or first strip of paper, being very sure to have the edges well pasted. Then turn top and bottom parts down, bringing pasted sides together, so that they meet, and none of the paste part is exposed, and carefully trim off edge on one side, with large, sharp scissors. Lift up the part thus trimmed and folded, and mount the ladder, which should previously have been placed convenient to the place where you intend to begin operations—the largest wall space is best, next to a door or window.

Hanging the Paper

Now take hold of the top end which was doubled over (it will open and hang by its own weight) and adjust to its proper place on the wall. Then, with a large clean rag in your hand, rub downward, never up or sideways, and take great care to keep the edge straight. If you find that you didn't start straight from the top, loosen paper and do it over again. A "straight eye" is needed to do the work neatly. Don't rub too hard and always rub down-

ward, doing a little part at a time, and lifting paper occasionally, so that no air bubbles are left under it. When the upper part is done, dismount from ladder, undo the folded part at the bottom of the width, and proceed in the same manner to adjust to the wall. When you are sure it is on straight and smooth, trim with a sharp knife along the base-board. Then give the strip another smoothing by going all over it again with a dry, clean brush. Proceed in this way until all the full length parts are covered, and then match in the small spaces over and below windows and doors. All the matching must be done with great care.

Practical and Economical

Wainscoting in living or dining rooms are nice, and very practical, especially where there are small children. For this purpose burlap, or the less expensive dark, heavy papers that come in wood-grain imitation are good. Matting is sometimes used with very good effect, too. A narrow wooden molding is used to finish the top of the wainscoting, and in that case the work of papering the side walls is so much easier, the lengths being short.

THE FARM BLACKSMITH SHOP

A blacksmith shop is of immense practical value on a farm. To those who have one it is almost as essential as live stock, farm tools and crops. One does not need to be a professional blacksmith. The elementary practice in welding, upsetting and tempering is easily learned with a little practice. Nor is it necessary to have many tools. An entire equipment may cost but a few dollars.

An old railroad rail will do for an anvil. But after getting the real article one is better satisfied and can do the work with greater ease. The forge should be obtained at the start. With it almost anyone can heat any small iron to welding point with as much ease as a regular blacksmith.

In the equipment of an Ohio farmer are a pair of tongs that he made himself, two other tongs and a large pair of pinchers picked up in a junk shop. He got the hammer and sledge from a hired man who had worked in a car shop. The anvil and vise also came from the junk shop, and both were in good repair. These cost \$8, the hammer and sledge, \$1.15, and an old, second-hand forge, \$1.80. Not a large outlay to be sure, but a wise expenditure. If purchased at first hand the cost would be greater, but cheap at any price when you consider what you can do in the way of making and repairing with such a list of blacksmith tools.

In addition to the above list this man, Frank Ruhlen, has chisels, pinchers, fullers and other small tools, all of which he has made out of old pieces of steel taken from old worn-out machines. By figuring and planning just a little, any farmer can make the greater part of his own tools and at a very small cost for materials and labor.

Why the Shop Pays

Mr. Ruhlen says: My shop was not started to replace the town blacksmith shop; and it will never do so. But it does serve for repair work, and it saves many trips to town. It is helpful in other ways, also. Last winter a sudden ice spell came on, so severe that I could not get the horses out to the field to feed the flock. Only one thing was

possible: to have sharpened shoes put on the horses. But it was a disagreeable trip ahead to walk and lead the horses to town; so I decided to do the work myself. I had never set a shoe myself, but that trip before me quickly decided. The horses were brought into the shop, the old shoes pulled off and sharpened, and within an hour the feeding was done. Had I gone to town for the work it would have required time going and coming, and then, maybe a long wait ahead for my turn at the shop.

Last year I sharpened the shoes on the corn planter, and both cultivators, six shovels each. We wore out a steel point or shear, and never had it to shop but once, and then it was to get a new nose or point. I do not try to put steel points on anything, as it is too particular work for anyone who just picks tools up when something breaks. A sharp harrow is a luxury on most farms, because the average smith does not draw the teeth out enough, and they are dull in a few days.

And I do not believe the average smith can harden the farm tools as good as a farmer who has had some experience in tempering, as the farmer is the one who works with the tools, and soon learns when they are too hard or not hard enough. I sharpened my smoothing harrow last year before we commenced on our corn crop of 64 acres, used it on all the land, on some more than once, and my harrow is sharper now than my neighbor's, who paid \$1.50 at the shop for the same work. We never use a dull mattock or pick now as we did before we had a forge. Welding chains, making chain hooks, open rings, clevises, are all easy to do on rainy days. I could not tell all the different uses I make of my shop.

Blacksmithing Not Hired Man's Work

I do the work in the shop myself, finding other chores for hired men. You cannot afford to break them in, for the reason that they may soon leave and all the teaching and trouble would be for nothing. By doing the work myself, I have learned a little more each year, have acquired the knack of it, and really enjoy doing what is to be done. Had we had a shop when I was a boy all of the repair work could have been done by the boys, and I would at the same time have had splendid training for my own needs now.

My experience is all in favor of the shop on the farm. It pays well. Get the forge first, and then gradually add other tools as you can. I used a claw hammer for some time before getting a smith's hammer. I did not equip my shop all at once. Start in a small way, build up gradually, learn slowly, and the shop will develop itself. Get a shop, and you will believe in it because of its help to you.

HORSESHOE LEVER

A handy lever for prying up boxes or barrels may be made by nailing an old horseshoe on the end of a 2 x 4, letting the ends of the horseshoe extend about an inch or two beyond the end of the timber. A more finished device may be constructed by cutting the upper part of the lever down to the form of a rounded handle. A horseshoe should be selected with fairly long and well-sharpened heel calks.

HORSESHOE FOR A TOOL

HOW TO PAINT TIN ROOFS

Remove all rosin and other loose substances from seams and have roof clean. Paint immediately after laying is finished; do not allow the tin to rust—you coat the base plate with tin and lead to prevent rust, and paint the finished goods to prevent oxidation of the coating. Use only the best red or brown oxide of iron, mixed with pure linseed oil all raw, or half raw and half boiled. Use litharge only as a drier. Litharge makes paint adhere hard to coating, so that when thoroughly dry you cannot scrape it off. Don't use any turpentine or patent driers.

Apply all paint with hand brushes and rub in well. This is very important. Don't put paint on thick—one coat that covers well, and is thoroughly rubbed in, is better than three put on thick. Let roof stand two weeks to a month before applying second coat. Six months or so after applying second coat put on a third coat. After this you do not have to paint roof more than once every two or three years. Too much paint injures a tin roof.

Keep paint well stirred up; put on thin and rub well in. By following these directions you will have a roof that will last many years.

PRESERVING WOOD

Creosote, or sulphate of copper or iron, are effective for preserving wood. There are objections, however, to their use for floorings or ornamental woodwork. Creosote leaves a permanent, disagreeable smell. The sulphates discolor the wood. Borax is excellent for keeping wood from decay. The preparation of it is simple, and consists in immersing the wood in a saturated solution of borax, which is then heated to 212 degrees Fahrenheit. The wood is left for 10 or 12 hours, the time depending upon the density and size of the pieces of wood. When taken out, the wood is stacked until dry, then reimmersed in a weaker solution of the borax for a brief time, dried again, and are then ready for use. Boards thus prepared are practically indestructible from rot, and are nearly incombustible.

Another preservative is a compound of one part silicate of potassa and three of pure water—the wood to remain in the solution 24 hours, then dried for several days, then soaked and dried a second time and afterward painted twice with a mixture of one part water-cement and four of the first-mentioned mixture. Thus prepared, it will not decay in the ground, and will be incombustible out of it.

Another process for preventing decay of wood is by use of a paint which possesses the advantages of being impervious to water. It is composed of 50 parts of tar, 500 parts of fine white sand, 4 parts

of linseed oil, 1 part of the red oxide of copper in its native state, and 1 part of sulphuric acid. The tar, sand and oil should be first heated in an iron kettle; the oxide and acid are then added very carefully. The mass is thoroughly mixed and applied while hot. When dry, this paint is as hard as stone.

Decay in wood may be prevented by the following method: Take 20 parts of resin, 46 parts of finely powdered chalk, some hard sand, and a little linseed oil and sulphuric acid; mix and boil for a short time. If this is applied while hot, it forms a kind of varnish, thereby preserving the wood.

TO PRESERVE SHINGLES

Following is an effective method to prevent the decay of shingles: Take a potash kettle or large tub and put into it one barrel of lye of wood ashes, 5 pounds of white vitriol, 5 pounds of alum, and as much salt as will dissolve in the mixture. Make the preparation quite warm, and put as many shingles in it as can be conveniently wet at once. Stir them up with a fork, and, when well soaked, take them out and put in more, renewing the preservative solution when necessary. Then lay the shingles in the usual manner.

After they are laid, take more of the preservative, put lime enough into it to make whitewash, and, if any coloring is desirable, add ocher, Spanish brown, lampblack, or other color, and apply to the roof with a brush or an old broom. This wash may be renewed from time to time.

Salt and lye are excellent preservatives of wood. Leach tubs, troughs and other articles used in the

manufacture of potash never rot. They become saturated with the alkali, turn yellowish inside and remain impervious to the weather.

TO RENDER WOOD FIREPROOF

Rendering the woodwork of houses secure against catching fire can be done at an insignificant cost, and with little trouble. Saturate the woodwork with a very delicate solution of silicate of potash as nearly neutral as possible, and when this has dried, apply one or two coats of a stronger solution.

Another method is simply to soak the wood with a concentrated solution of rock salt. Water-glass will act as well, but it is expensive. The salt also renders the wood proof against dry rot and the ravages of insects. Still another method is to immerse the wood in a saturated solution of borax, heat being gradually applied until the solution reaches 212 degrees Fahrenheit. It is then left for 10 or 12 hours, according to the nature and size of the wood.

FIREPROOF WASH FOR SHINGLES

A preparation composed of lime, salt and fine sand or wood ashes, put on like whitewash, renders the roof 50 per cent more secure against taking fire from falling cinders, in case of fire in the vicinity. It pays the expense a hundredfold in its preserving influence against the effects of the weather. The older and more weather-beaten the shingles, the more benefit derived. Such shingles generally become more or less warped, rough and cracked; the application of the wash, by wetting

the upper surface, restores them at once to their original form, thereby closing up the space between the shingles, and the lime and sand, by filling up the cracks and pores in the shingle itself, prevents warping.

PETRIFIED WOOD

Mix equal parts of gem salt, rock alum, white vinegar, chalk and Peebles' powder. After the mixture becomes quiet, put into it any wood or porous substance, and the latter becomes like stone.

HOW TO SEASON WOOD

Boiling small pieces of non-resinous wood will season them in four or five hours—the process taking the sap out of the wood, which shrinks nearly one-tenth in the operation. Trees felled in full leaf in June or July, and allowed to lie until every leaf has fallen, will then be nearly dry, as the leaves will not drop off themselves until they have drawn up and exhausted all the sap of the tree. The time required is from a month to six weeks, according to the dryness of the weather.

BLEACHING WOOD

Sometimes it is more feasible to bleach a small part of a wood surface, especially in repairing, than to darken a larger portion of the work. This can be done by brushing over the wood a solution composed of 1 ounce oxalic acid in a pint of water, letting it remain a few minutes and then wiping dry. The operation may be repeated if necessary. A few drops of nitric ether, or a quarter of an ounce of tartaric acid, will assist the operation; or

a hot solution of tartaric acid may be used alone. Lemon juice will also whiten most woods. Cut the lemon in half and rub the cut face upon the wood.

When the bleaching has been done and the wood is dry, give a thin coat of shellac or French polish, as the light and air acting upon the bare wood will bring back the original color.

If the wood obstinately resists bleaching, it may be lightened by mixing a little fine bismuth white, flake white or ball white (the cleansing balls sold by druggists) with the shellac, and give it a thin coat. This whitens, but it also somewhat deadens or obscures the grain and is, therefore, not so good as the bleaching method.

WOOD POLISH

Rub evenly over the wood a piece of pumice stone and water until the rising of the grain is cut down; then take powdered tripoli and boiled linseed oil and polish to a bright surface.

FURNITURE POLISH

Take equal parts of sweet oil and vinegar, mix, add a pint of gum arabic finely powdered. This will make furniture look almost as good as new and can be easily applied, as it requires no rubbing. The bottle should be shaken, and the polish poured on a rag and applied to the furniture.

SIZE STAINS

By the aid of glue in the solution, the colors are fixed in size stains. They are employed for the

purpose of giving a color to cheap work in soft woods, such as chairs, bedsteads and common tables and ordinary bookcases. The colors usually wanted are walnut, mahogany, cherry color, oak and even a rosewood.

For Mahogany—Dissolve 1 pound of glue in a gallon of water, and stir in $\frac{1}{2}$ pound venetian red, and $\frac{1}{4}$ pound chrome yellow, or yellow ocher. Darken with the red and lighten with yellow, as desired. If the venetian red does not give a sufficiently dark look put in a pinch of lampblack. Apply hot.

For Rosewood—Same as mahogany, omitting the yellow, and using $\frac{3}{4}$ pound venetian red (or more) instead of $\frac{1}{2}$ pound. Give one coat of this and then add lampblack, one pinch, or more, to the color; with the latter put in the figure or dark parts of the rosewood.

For Oak—In a gallon of glue size (as above) put $\frac{3}{4}$ pound powdered burnt umber. Lighten with yellow (chrome or ocher), if need be. Hot.

DARK WOOD STAIN

White woods may be given the appearance of walnut by painting or sponging them with a concentrated warm solution of permanganate of potassa. Some kinds of wood become stained rapidly, while others require more time. The permanganate is decomposed by the woody fiber; brown peroxide of manganese is deposited, which afterward may be removed by washing with water. The wood, when dry, may be varnished, and will be found to resemble very closely the natural dark woods.

RED STAIN FOR WOOD

Boil chopped Brazil wood thoroughly in water, strain it through a cloth. Then give the wood two or three coats, till it is the shade wanted. If a deep red is desired, boil the wood in water in which is dissolved alum and quicklime. When the last coat is dry, burnish it with the burnisher and then varnish.

LIQUID GLUE

Dissolve 1 pound of best glue in $1\frac{1}{2}$ pints of water, and add 1 pint of vinegar. It is ready for use.

CEMENT FOR METAL AND GLASS

Take 2 ounces of a thick solution of glue, and mix it with 1 ounce of linseed-oil varnish, and half an ounce of pure turpentine; the whole is then boiled together in a close vessel. The two bodies should be clamped and held together for about two days after they are united to allow the cement to become dry. The clamps may then be removed.

CEMENT FOR BROKEN CHINA

Stir plaster of paris into a thick solution of gum arabic till it becomes a viscous paste. Apply it with a brush to the fractured edges, and draw the parts closely together.

CEMENT FOR CROCKERY AND GLASS

Take 4 pounds of white glue, $1\frac{1}{2}$ pounds of dry white lead, $\frac{1}{2}$ pound of isinglass, 1 gallon of soft water, 1 quart of alcohol, and $\frac{1}{2}$ pint of white

varnish. Dissolve the glue and isinglass in the water by gentle heat if preferred, stir in the lead, put the alcohol in the varnish and mix the whole together.

MENDING GLASSWARE

Broken dishes and glassware may be easily mended as follows: Fit the pieces in their proper places and tie a string around the vessel to keep the parts from slipping out. Then boil the entire dish for two or three hours in sweet milk. This will firmly glue the vessel together and it will last for years with proper care.

ARMENIAN CEMENT

This will strongly unite pieces of glass and china, and even polished steel, and may be applied to a variety of useful purposes. Dissolve five or six bits of gum mastic, each the size of a large pea, in as much rectified spirits of wine as will suffice to render it liquid; and, in another vessel, dissolve as much isinglass, previously a little softened in water (though none of the water must be used), in French brandy or good rum, as will make a two-ounce vial of very strong glue, adding two small bits of gum galbanum of ammoniacum, which must be rubbed or ground till they are dissolved. Then mix the whole with a sufficient heat. Keep the glue in a vial closely stopped, and when it is to be used set the vial in boiling water.

JAPANESE CEMENT

Thoroughly mix the best powdered rice with a little cold water, then gradually add boiling water until a proper consistence is acquired, being par-

ticularly careful to keep it well stirred all the time; lastly it must be boiled for one minute in a clean saucepan or earthen pipkin. This glue is white, almost transparent, for which reason it is well adapted for fancy paper work, which requires a strong and colorless cement.

ROOFING PREPARATION

Take 1 pint of fine sand, 2 of sifted wood-ashes, and 3 of lime ground up with oil. Mix thoroughly, and lay on with a painter's brush, first a thin coat, and then a thick one. This composition is not only cheap, but it strongly resists fire.

FIRE KINDLERS

Take 1 quart of tar and 3 pounds of resin, melt them, bring to a cooling temperature, mix with as much sawdust, with a little charcoal added, as can be worked in; spread out while hot upon a board, when cold break up into lumps of the size of a large hickory nut, and you have, at a small expense, kindling material enough for one year. They will easily ignite from a match and burn with a strong blaze, long enough to start any wood that is fit to burn.

MENDING PIPES WITH WATER ON

Many farmers have had trouble in repairing pipes where the water could not be shut off conveniently. A lead pipe which has been cut off accidentally in making an excavation, for instance, may be repaired by the following plan: The two ends of the pipe are plugged, and then a small pile of broken ice and salt are placed around them; in five minutes the water in the pipe will be frozen, the

plugs removed, a short piece of pipe may then be inserted and perfectly soldered. In five minutes the ice in the pipes may be thawed and the water set to flowing freely again.

TO JOIN WATER PIPES

Water pipes may be united by using a preparation made by combining four parts of good portland cement and one part of unslaked lime mixed together in small portions in a stout mortar, adding enough water to permit it to be reduced to a soft paste.

WELDING METALS

Welding together two pieces of metal of any kind can be accomplished only when the surfaces to be joined are equally heated, and both surfaces must be brought to such a temperature that the particles will form a perfect continuity between the pieces united. This embraces the entire theory of welding, soldering or brazing metallic substances of any kind. In addition, however, to the equal and adequate heating of the surfaces to be united, every particle of coal dust, cinders or scales of oxide must be removed, so as to present two perfectly clean surfaces at the very moment when the union is to be effected.

The piece of metal that would fuse at the lower temperature must be the guide, when bringing the surfaces of conjunction up to the proper heat. If, for example, two pieces of wrought iron are to be welded, the part that will melt at the lower temperature must be brought just to a welding heat, and the surface of the other piece must be heated quite

as hot, or a trifle hotter than the first piece. Then, if the surfaces are clean when the parts are brought together, the union will be satisfactory. The degree of heat aimed at must be, not to produce a fluid, but simply to bring the metal into a condition between the fluid and plastic.

GRINDING TOOLS

All steel is composed of individual fibers running lengthways in the bar and held firmly together by cohesion. In almost all farm implements of the cutting kind the steel portion which forms the edge, if from a section of a bar, is welded to the bar lengthwise, so that it is the side of the bundle of fibers hammered and ground down that forms the edge. So, by holding on the grindstone all edge-tools, as axes, scythes and knives of strawcutters, in such a manner that the action of the stone is at right angles with the edge, or, this is to say, by holding the edge of the tools square across the stone, the direction of the fibers will be changed, so as to present the ends instead of the side as a cutting edge. By grinding in this manner a finer, smoother edge is set, the tool is ground in less time, holds an edge a great deal longer, and is far less liable to nick out and to break.

Plane irons should be ground to a level of about 35 degrees—chisels and gouges to 30. Turning chisels may sometimes run in an angle of 45. Molding tools, such as are used for ivory and for very hard wood, are made at from 50 to 60 degrees. Tools for working iron and steel are beveled at an inclination to the edge of from 60 to 70 degrees, and for cutting gun and similar metal range from 80 to 90.

Pioneer Methods

The "Good Old Days" were those of just recent decades past. In the 1800s and centuries previous the pioneer folk had it unimaginably difficult. People grew soft - and had no idea. City folk could not even begin to do the work of the real farmers who still ran small farms.

A US candidate for president once promised 40 acres and a mule. I always said that the only way I would have possibly made it through the first winter was to eat the mule. The pioneers were survivalists and had survival skills beyond any that we can imagine.

In addition to not having the "toughness", work habits and skills of the early pioneers - we do not have their resources. There are no buffalo herds and there is nowhere near that the deer and antelope play in sufficient number to support most survivors. Those who have taken survival courses that have taught them to go out into the woods and survive will be sorely disappointed. Such animals that have survived the radiation will be in very short supply relative to the survivors that would be in competition for them.

One will not have the horses, wagons or other implements that were necessary to pioneer survival. There will be a far larger population survive than there were pioneers a few centuries ago and there will be far fewer resources of the kind that sustained them. The early settlers of our village were confident in their ability to find in a few minutes enough fish in the stream to make supper. Even in my early days in the village a person could promise the night before that they would go out on the bridge out our back door and get fresh fish for breakfast - and make good their promise. But those days are gone. Fished out and poisoned out by salt on the roads and pesticide run-off from the farmer's fields. At this writing fish no longer come safe even from the farmer's markets without warnings that they are hazardous to expectant mothers.

No, we can't return to the old days - even if we want to. But fortunately we have many, many other advantages. We don't have to cut the forests to gain agricultural ground. We know many things the pioneers did not. Childbirth was a great hazard to pioneer women - simply because people did not know to wash their hands. We have a great advantage in modern knowledge - but we may well need to supplement that, at least for a while, with some of the pioneer knowledge and skills that we have forgotten about. That is the purpose of this page.

This page does not stand by itself, anymore than do any of the others. There may be some duplication on some items that will be found in the pages on simplified machinery and small farming but all that information will probably be just as important to know - if not more so.

The files on this page are all locked until after the nuclear war. Those who have to wisdom to gather the information ahead of time will have to go to other sources but all these pages can be thought of as a

checklist of types of information one may wish to gather together.

Table of Contents:

[SEALED: Making the Best of Basics.](#)

This is a SEALED 188 page .pdf file that won't be opened until after The Great Catastrophe. This 1975 book is by James Talmadge Stevens. It covers sprouting, food drying, game cleaning, recipes for different home products and a variety of similar subjects.

[SEALED: Cloudburst - Handbook of Rural Skills and Technology.](#)

This is a SEALED 126 page .pdf file that won't be opened until after The Great Catastrophe. The book is edited by Vic Marks and is Published in the US by: Cloudburst Press of America, Inc. 2116 Wetern Avenue, Seattle, Washington 98121 and in Canada by: Cloudburst Pres Ltd., Mayne Island British Columbia V0N 2J0 - The book covers a variety of technologies including overshot and undershot waterwheels, juice presses, beehive management, cheese making, a hand operated washing machine, a solar drier, and many other things.

[SEALED: Cloudburst Two.](#)

This is a SEALED 128 page .pdf file that won't be opened until after The Great Catastrophe. This is a second volume of the above book and is also edited by Vic Marks and is Published in the US by: Cloudburst Press of America, Inc. 2116 Wetern Avenue, Seattle, Washington 98121 and in Canada by: Cloudburst Pres Ltd., Mayne Island British Columbia V0N 2J0 - This volume covers a many, many additional technologies including various forms of construction, hand and foot operated machinery, kilns, hydraulic rams, spinning wheels, looms and associated machinery, and many, many other pioneer subjects.

[SEALED: Foxfire One.](#)

This is a SEALED 388 page .pdf file that won't be opened until after The Great Catastrophe. This series of books is edited by Eliot Wigginton and is published by Anchor Press | Doubleday 501 Franklin Avenue - Garden City, NY 11530. Volume One covers many subjects from hog dressing to cabin building.

[SEALED: Foxfire Two.](#)

This is a SEALED 410 page .pdf file that won't be opened until after The Great Catastrophe. This series of books is edited by Eliot Wigginton and is published by Anchor Press | Doubleday 501 Franklin Avenue - Garden City, NY 11530. Volume Two covers many subjects from midwifery to burial.

[SEALED: Foxfire Three.](#)

This is a SEALED 512 page .pdf file that won't be opened until after The Great Catastrophe. This series of books is edited by Eliot Wigginton and is published by Anchor Press | Doubleday 501 Franklin Avenue - Garden City, NY 11530. Volume Three covers many subjects from animal care to hide tanning and making musical instruments.

SEALED: Foxtire Four.

This is a SEALED 480 page .pdf file that won't be opened until after The Great Catastrophe. This series of books is edited by Eliot Wigginton and is published by Anchor Press | Doubleday 501 Franklin Avenue - Garden City, NY 11530. Volume Four covers many subjects from gardening to traps to knife making and horse trading.

SEALED: Foxtire Five.

This is a SEALED 515 page .pdf file that won't be opened until after The Great Catastrophe. This series of books is edited by Eliot Wigginton and is published by Anchor Press | Doubleday 501 Franklin Avenue - Garden City, NY 11530. Volume Five covers many subjects from iron making and blacksmithing to gun making and hunting.

SEALED: Foxtire Six.

This is a SEALED 513 page .pdf file that won't be opened until after The Great Catastrophe. This series of books is edited by Eliot Wigginton and is published by Anchor Press | Doubleday 501 Franklin Avenue - Garden City, NY 11530. Volume Six covers many subjects from shoe making to wooden locks and toy making.

The Renewal of Religion After Nuclear Holocaust

Table of Contents:

[Prolog: Why God would permit a nuclear war.](#)

Here there is given an answer to a question that will concern many. If God is All Powerful and All Good - then why would He permit a nuclear war?

[Essays: Series of Religious Essays - Premises](#)

This is the introduction to the following series of religious essays. It contains the author's premises of religion but the premises are recommended for reading only by those who wish to discuss the subject of religion with him.

[POP: Problems of Prophecy](#)

Here the author describes his own experiences in seeking true prophetic sources.

[Four Souls: The Four Types of Souls](#)

An examination of the concept that there are four types of souls that helps one to determine their own type.

[Four Paths: The Four Paths to Truth](#)

The Four Paths to Truth are the four paths that every seeker of truth must tread.

[MGP: The Most Clear Proof](#)

"The Most Great Proof", is a step by step examination of the largest, most important and most accurate prophecy ever given.

[Seven Churches: From the Book of Revelation](#)

This is essay discusses the The Seven Churches (mentioned in the Book of Revelation) and

presents what many people find as an astounding explanation.

Ocean: The Revealed Word of God available as NEVER before!

The most marvelous source for searching religious writings starting with the Judaic Tradition. It includes the Old Testament, Gospel, Koran, Baha'i Scripture and many, many others. Over 900 books at the time of this writing. I have spent many hundreds of dollars over the years for the best search programs I could find but none have been nearly as good as this one - and it is FREE.

Meditation: and The Path of Prayer

A discussion of prayer and meditation along with some special Baha'i prayers and a rare translation of a Chant by Abdu'l-baha.

Stars: Prophecies in the Stars

Astrological predictions, as regards individual day to day events, are a superstition. Nevertheless, many people feel that there have been notable signs in the heavens, such as that regarding the Bethlehem Star and the birth of Jesus. Here we examine a more recent and even more astounding phenomena, the fulfillment of an ancient tradition in the Millenium Star.

Why God Would Permit a Nuclear War

In times of great stress some people turn naturally to God. Others question how He could exist and permit the tests, trauma, terror, that they are witnessing or experiencing. The Problem of Pain and evil has always been a challenge to every theological thinker. Some see it as the central question of religion and the human experience.

The questioners ask, "How could an Infinite, All Powerful God, that is Good, permit something like a nuclear holocaust?" "Never mind that Armageddon was predicted in centuries old religious prophecy. That is just another problem", they would say, "because if it was foretold and unavoidable, then what does that do for human free will?"

Man's search for Reality and his relationship to God, is the purpose of human life. These then are not just troubling questions, but central questions, in a sense the ultimate questions with which the seeker must wrestle.

It is unlikely that the present writer will answer, satisfactorily for all, that which centuries of religious volumes have failed to communicate unto the majority of mankind. Namely, that God is Good and that His Purpose is being worked out. Still, I will share with you my own thoughts about why the world wide nuclear war was both inevitable and necessary. Because of its inevitableness, some readers will note that at the time of this writing I speak of it as having been a thing that has already occurred.

First one must wrestle with the nature of God and Man. The Creator and the Creature. The Uncreated and the created. The One Being Infinite the other being finite. The One Being beyond time, space, matter, the other involved in the appearance of time, space, matter. However one views it, maya, illusion, duality, it still seems to be a relationship of opposites.

Because of infinite difference in station between the Creator and the created the only way that the latter can come to know The Former is in the manner and to the degree That Former chooses to reveal Itself to the latter. All the Great Divinely Revealed Religions have said that this has been through a Messenger, Prophet, a Chosen One. It is to Them that every reasonable thinker turns for the answers. No reasonable man would think that he could figure out the great ideas of literature, art, mathematics, or science all on his own - and how much less religion, that is to say the proper practice of his relationship to the Nature and Purpose of God and His Creation.

Thus it is that we turn unto Those Infinite Source of Light. Single in Purpose multiple in appearance, Who have come unto man to reveal God's Divine Purpose. Without exception we are told that God loves man and wishes him well. We are told further that God has bestowed many great bounties upon man, to a degree not shared by any other creature. Particularly the bounty of intellect and abstract thought and the bounty of free will. It is this latter that permits man to choose to recognize and serve God - or not.

The two capacities, intellect and will, the ability to know God and to worship (that is serve) Him, are the two defining characteristics of the human soul. They are what make a man a man. If a person loses the ability to think, reason, imagine, believe, then they are no longer in the human state but have entered a vegetative state. Likewise if they no longer have the capacity to desire, wish, feel, love or hate, then they have no more motivation than a rock. But the two capacities together - that which we think and that which we wish - that which we know and that which we will - are what defines each of us individually. That is who we are. Our very existence. When those capacities depart from the body - the body is dead and then decomposes. The Prophets have all told us that the essence - the ability to know and will - continues on separate from the body and that is why the soul is said to be eternal.

If either of these two faculties, either the ability to think / know / reason, or the ability to will are removed or subverted in man - then he ceases to exist as man. For this reason all men have the freedom and choice to believe in God - or not. If the idea, thought, knowledge of God was simply imprinted upon

them as the recognition of its mother is imprinted upon a baby chick - then man too would be a mere creature of instinct having no more free will to accept or reject God than an automaton or computer programmed with certain facts in its data base and memory.

Likewise, should man not have the freedom to sin, that is to say - to not do the Will of God, then again he would be but an automaton, a robot, a creature completely controlled by instinct and patterning. It is this freedom of being able to recognize and know God combined with the degree of choosing whether or not to be obedient to His Will - that defines and separates the saints, sinners, and satans.

Individually, and collectively, man exhibits and implements these two abilities. We are all individually a product of our genes, culture, and free will. The innate capacities between individuals differs greatly. Those innate capacities are then greatly affected by the education which they receive, which is something that is often largely culturally determined. Nurture versus nature is not a choice because it is nurture, nature AND free will that determines the individual accomplishment. The least of men, have the capacity to recognize God and to be obedient to Him, otherwise they are deprived of that which is truly human. The degree that they do recognize and obey God under adverse circumstances such as genetic or social deprivation may well be indicative of hidden spiritual strengths and qualities. God alone can be the Judge of that.

Nations and cultures to a large degree form individuals - but individuals also change and form cultures. Those who most positively affect the direction of a cultural should be duly honored. Unfortunately, cultures can likewise be affected negatively by other individuals. The collective conscience and consciousness is a mighty force to be dealt with. The overall direction and pattern of development, however, has a Divine Destiny. The Creation remains the purview of the Creator.

To return to the question of why evil and disaster occur. In part it is because there is an interplay between humanity and the rest of creation. Spiritual forces do interact and effect the actions of nature. This is a natural interaction, indeed designed by the Creator, and so to say that some of these natural events are "acts of God" is not far wrong - but the degree to which they are precipitated by human action is hidden from most of mankind.

Other events, such as war, depression, conflict, are more obviously the result of the actions of men. Still, we may ask, as to why God permits them to occur. The answer is that to prevent them would be to violate the principle of the Permissive Will of God which is to allow man to have his own free will. To subvert the free will of man would do more harm than good, because it would mean that man was no longer free and no longer man - but simply again as an automaton or rock.

The human race has long endured, and its destiny has long been seen. To say this does not subvert the free will of man. To give an example, most any elementary school teacher can see in her pupils the overall nature of the child, dullness to brilliance, willingness to rebelliousness, and although the teachers are sometimes surprised or disappointed, in later life, seeing the pupil's development - most often they are not. How many an insightful person can look at the habits and behavior of a teenager and predict for

the disobedient sluggard a life of failure and for the industrious performer a life of accomplishment. These are hardly matters of prophecy. The seeds of the future are evident. So has it been with the human race as a whole. The Prophets of old were able to see the rebellious and warlike nature of man and to see that as he gained more scientific knowledge that his wars would increase in intensity and ferocity. Indeed the Infinite Divine Omniscience would see these things far beyond the ken of man.

To foresee something is not to will something. While God Wills the good of man just as parents will the good of their children whom they can see that they must allow to make their own mistakes. One must be careful in attributing to God some anthropomorphic "motivation" but nevertheless it is the nature that has been created in us that gives us what perception we have of the Divine attributes because we do see these in ourselves and in the creation about us.

Mankind collectively followed such a path of rebellion that a major magazine headlined on its cover years ago that God was dead. Materialism and immorality increased after that date, to such a degree, that it would probably have astounded even those editors. Man's greed and lack of concern for his fellowman grew by immense proportions as evidenced through those years of repeated billion dollar scandals in the business community and the ever increasing proportion of all production and wealth that went into weapons and the means of destruction.

Still, all of this was reflective of the free will of man to choose the Path of God or to choose his own unwisdom and ills. While the chosen path led to destruction, to prevent mankind from choosing it would have been to truly destroy mankind because it would have meant subverting the free will of man and man would therefore no longer have been man. But evil contains its own punishment. The results are as sure as the law of gravity. The headache and hangover follow the drunkenness and while the it is fair to characterize the results as Divine Chastisement and Retribution it still remains of man's own doing.

If it were not for the pain which is the punishment for sin and evil, then man would simply always continue in the path of his own destruction which is the turning away from the Purpose of God. Man's collective ills continued to mount until the Day of Destruction, the Day of Holocaust, the Day of the Great Catastrophe, the Day of Armageddon - all as long predicted and prophesized. If it had not been for That Day then nothing would have turned man back around and once again toward God and His Purpose which is the true happiness of mankind. Consequently, the worse thing that could have occurred was for That Day to not have come - for there to have been no nuclear war.

Some will observe that in addition to the shortcomings of man that I have cataloged, that religion itself has been a major cause of suffering and contention. This is quite true. Dogmatic religions of every stripe have increased man's hatred against man. Also the same can be said of rampant nationalism and racism. Those very things that many men have seen as the highest ideals - their love for their religion, country and culture have in their perverted form been the basis for hate. God loves all mankind and in every part of the world provided for his religious guidance but men perverted that love for man to hatred of those who do not share their religion, country or culture.

The ills of religionism, racism, and nationalism became deeply embedded in mankind as a whole and when these were topped with rampant materialism and immorality mankind was already in hell. The direction that mankind was taking was obvious for many centuries, indeed millennium, and the end results were therefore predictable. The solution was also seen and God has always provided mankind with guidance through His Prophets. The Prophet for this Day and Age has revealed to mankind God's Program for the solution of their ills and the establishment of the Kingdom of Heaven on earth - but it is up to mankind to implement the Plan. For God to do it for man would once again deprive man of his free will and thus destroy him as man.

The message for mankind's darkest hour is that God has created for mankind a Destiny that is very Great, if mankind will choose to accept it. For those who would like to discuss with me further this view of the future and this view of religion I welcome their contacting me. I would ask that you first examine [my premises of religion](#) and let me know of any points in which we differ so that we may have a mutual understanding of what we are discussing.

Peace and love,
Bruce

Premises of Religion

**I will be most gratified to correspond
about these ideas
with anyone who is interested in doing so.
If you would like to correspond with me you may
do so at:
DawSayer@webpal.org**

**For anyone who would like to discuss religion with me -
there are some points that I would like to first list -
to determine if we agree.**

**If you do NOT agree about one of the following points -
PLEASE let me know,
and also WHAT your position is.
Otherwise, anything that I might say
would be wrongfully based upon the assumption
that it would be understood in a particular way -
and likewise I would be misunderstanding statements
made by yourself.**

**I first list the points
and then give examples
so that you can hopefully
clearly understand what I mean.**

I call these first points "premises".

Premise One.

**There is but One God (Creator) -
(in the Universe, anywhere, anytime -
in any manner of true concept.
Beyond what we call space or time -
or any other qualification that one might make
to say that there is or could be any but**

the One True God.)

Premise Two.

God is separate from His Creation.
(meaning that God the Creator is something different than the Creation and apart from it. The opposite belief, called "pantheism" being that He is in His Creation and that creation itself is god).

Premise Three.

Both God and His Creation are Infinite (and Eternal) -
(meaning without end - beyond definitions of size, or limitations imposed by concepts of space and time).

Premise Four.

God is Infinite Spiritual REALITY and Truth
(but mortal man is subject to illusions, and delusions, about the appearances of reality and truth.)

Premise Five.

God being Infinite and men being finite -
men cannot comprehend God on their own.
(This means that God has to make Himself known to man).

Premise Six.

God makes Himself known
through His Prophets and Revealed Word.

Premise Seven.

God, and His Creation, being Infinite -
means that there always has been -

**and always will be MORE for man
to learn about God and His Creation.**

As examples of the above (by the same number as the premises) -

- 1. Many people in the past have been polytheists,
and many in the world are still so today -
but few avowed Christians, aside from Mormons,
proclaim themselves to believe in more than one god.
A great many people, indeed most people,
actually have difficulty accepting that there is REALLY
only one God and they make in their minds idols
of other powers separate from God.**
- 2. The concept of God and His Creation being one,
which is defined as pantheism,
is more usually found among what we call
New Age Religion.**
- 3. Most people do not really wrestle with
or try to grasp the meaning of the concepts
Infinite and Eternal.**
- 4. Again, the Mormons see God as a physical being,
and that all is matter. Monality versus duality,
like Infinite and Eternal, is another one of those concepts
that many people have not really wrestled with.**
- 5. Man's relationship to God in that man
is completely subservient to God
offends a great number of people today -
who feel that they can figure out anything
through what they call "science"
and that in reality God is unnecessary to them.**
- 6. Recognition of the Prophets
and the Revealed Word -
is almost anathema to many people today.
Their view is, if Jesus existed,
He was "just" a man -
and that Scriptures are simply
a collection of myths, ancient stories,**

and outdated beliefs from early times.

**7. On the other hand -
many people hold an opposite view
regarding Scriptures.
They feel that they have in THEIR scriptures
ALL knowledge and that there is none other.**

**Thus the Jews hold onto only the Old Testament - saying to Jesus -
"What need have we of You. -
We have Abraham and our Fathers (the Prophets).
And the Christians are not about to accept
Mohammad and the Koran,
because they feel the Bible is the FINAL Word of God,
although Jesus said -
that He could not reveal unto them many things
that they were incapable of understanding at that time.
And the Moslems feel that the Koran is the Final Book -
and that Muhammad was the "Seal of the Prophets" -
so that they persecute Those Who follow Him.**

**In discussion with Christians,
a beginning point often is that I say that
Christians hold too small an idea of Jesus.
In response to their question of how that can be -
I respond:**

**1. Many Christians hold Jesus to be God.
"The Father and I are One".
If this is true,
then with God being Infinite
any comprehension about the nature of Jesus
would then need to be Infinite also -
and equally impossible to encompass
as would it be impossible to encompass
the understanding of God.**

**2. While many Christians will repeat phrases
such as -
"Under no other Name under heaven,
shall man be saved,
except through the Name of
the Lord Jesus Christ" -**

**they do not really look at the immensity
that we see today of the Galaxies -
and comprehend what that means.**

**3. Many Christians in talking about Jesus
place Him at one point in time and space -
2,000 years ago on this single planet.
THAT is a very limited idea.**

**The most difficult concept for most person's to comprehend about Baha'i-
is what is meant by the term "Manifestation of God".
This is most often where we need to begin -
but I am willing to discuss instead any other issue
that correspondents wish to discuss.**

I welcome your emails.

**Peace and love,
Bruce

Essays on the Problems and Power of Prophecy

by Bruce Beach

In these essays I describe some of my own experiences in seeking true prophetic sources. These essays and experiences were a series of an email newsletter and if you wish to get right to point that I was driving at - you can just skip to the last one, or even go on to the next series regarding the Four Paths to Truth.

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at:

DawnSayer@webpal.org

If you wish to enter into a discussion with me regarding religion - I highly welcome that. I have some [religious premises](#) that I would like you to review first, and let me know regarding any about which you disagree to help me better understand any points that you are making.

POP01 - Mother Shipton

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

This POP (Power of Prophecy or Problems of Prophecy) series that I am presenting, shares some of my own experiences in that search.

Those who are not interested in the subject or who feel that they already Know ALL Truth or at least the source for all Truth will find it tedious, and probably will also feel that I am ill-informed. And those who feel that it is impossible to find Prophetic Truths will consider these accounts silly.

I have carefully investigated many claims of prophetic ability, and in the series I will be reporting on some of those investigations. I am beginning this series with my investigation of a famous prophetess by the name of Mother Shipton.

Mother Shipton was born Ursula Sontheil in 1488 in a cave beside the river Nidd in North Yorkshire, England. The location remains today as a popular visitor site, attracting great numbers of visitors annually.

Since 1641 there have been more than 50 different editions of books about her and her prophecies and a great amount of information about her can be found on the Internet.

Many people feel that many of her visions came true within her own lifetime and in subsequent centuries. Mother Shipton is said to have predicted important historical events

**many years ahead of their time -
the Great Fire of London in 1666,
the defeat of the Spanish Armada in 1588 -
as well as the advent of modern technology.**

**She is said to have even forecast her own death in 1561.
She died in 1561.**

Today many find her prophecies are still proving uncannily accurate.

**She wrote her prophecies like poems
and after the following poem**

**I present my own research about her -
prior to the time of the Internet.**

-----A Version of One of Her Poems-----

**And now a word, in uncouth rhyme
Of what shall be in future time
Then upside down the world shall be
And gold found at the root of tree**

**All England's sons that plough the land
Shall oft be seen with Book in hand
The poor shall now great wisdom know**

**Great houses stand in far-flung vale
All covered o'er with snow and hail
A carriage without horse will go
Disaster fill the world with woe.**

**In London, Primrose Hill shall be
In centre hold a Bishop's See**

**Around the world men's thoughts will fly
Quick as the twinkling of an eye.**

**And water shall great wonders do
How strange. And yet it shall come true.**

**Through towering hills proud men shall ride
No horse or ass move by his side.**

**Beneath the water, men shall walk
Shall ride, shall sleep, shall even talk.**

**And in the air men shall be seen
In white and black and even green**

**A great man then, shall come and go
For prophecy declares it so.**

**In water, iron, then shall float
As easy as a wooden boat**

**Gold shall be seen in stream and stone
In land that is yet unknown.**

**And England shall admit a Jew
You think this strange, but it is true
The Jew that once was held in scorn
Shall of a Christian then be born.**

**A house of glass shall come to pass
In England. But Alas, alas
A war will follow with the work
Where dwells the Pagan and the Turk**

**These states will lock in fiercest strife
And seek to take each others life.
When North shall thus divide the south
And Eagle build in Lions mouth**

**Then tax and blood and cruel war
Shall come to every humble door.
Three times shall lovely sunny France
Be led to play a bloody dance**

**Before the people shall be free
Three tyrant rulers shall she see.
Three rulers in succession be
Each springs from different dynasty.**

**Then when the fiercest strife is done
England and France shall be as one.
The British olive shall next then twine
In marriage with a German vine.**

**Men walk beneath and over streams
Fulfilled shall be their wondrous dreams.
For in those wondrous far off days**

**The women shall adopt a craze
To dress like men, and trousers wear
And to cut off their locks of hair
They'll ride astride with brazen brow
As witches do on broomstick now.**

**And roaring monsters with man atop
Does seem to eat the verdant crop
And men shall fly as birds do now
And give away the horse and plough.**

**There'll be a sign for all to see
Be sure that it will certain be.
Then love shall die and marriage cease
And nations wane as babes decrease
And wives shall fondle cats and dogs
And men live much the same as hogs.**

**In nineteen hundred and twenty six
Build houses light of straw and sticks.
For then shall mighty wars be planned
And fire and sword shall sweep the land.**

**Footsteps will be seen in every room,
Left by none other than the man on the moon.
One man's heart shall be given to another,
Blood shall be shared by sister and brother.**

**Voices shall rise in the land of the black,
And the Holy Land shall come under attack.
China will rise as some have foretold,
But the wall that falls will not be so old.**

**When pictures seem alive with movements free
When boats like fishes swim beneath the sea,
When men like birds shall scour the sky
Then half the world, deep drenched in blood shall die.**

**For those who live the century through
In fear and trembling this shall do.
Flee to the mountains and the dens
To bog and forest and wild fens.**

**For storms will rage and oceans roar
When Gabriel stands on sea and shore
And as he blows his wondrous horn
Old worlds die and new be born.**

**A fiery dragon will cross the sky
Six times before this earth shall die
Mankind will tremble and frightened be
for the sixth heralds in this prophecy.**

**For seven days and seven nights
Man will watch this awesome sight.**

**The tides will rise beyond their ken
To bite away the shores and then
The mountains will begin to roar
And earthquakes split the plain to shore.**

**And flooding waters, rushing in
Will flood the lands with such a din
That mankind cowers in muddy fen
And snarls about his fellow men.**

**He bares his teeth and fights and kills
And secrets food in secret hills
And ugly in his fear, he lies
To kill marauders, thieves and spies.**

**Man flees in terror from the floods
And kills, and rapes and lies in blood
And spilling blood by mankind's hands
Will stain and bitter many lands**

**And when the dragon's tail is gone,
Man forgets, and smiles, and carries on
To apply himself - too late, too late
For mankind has earned deserved fate.**

**His masked smile - his false grandeur,
Will serve the Gods their anger stir.
And they will send the Dragon back
To light the sky - his tail will crack**

**Upon the earth and rend the earth
And man shall flee, King, Lord, and serf.
But slowly they are routed out
To seek diminishing water spout**

**And men will die of thirst before
The oceans rise to mount the shore.
And lands will crack and rend anew
You think it strange. It will come true.**

**And in some far off distant land
Some men - oh such a tiny band
Will have to leave their solid mount
And span the earth, those few to count,**

**Who survives this and then
Begin the human race again.
But not on land already there
But on ocean beds, stark, dry and bare**

**Not every soul on Earth will die
As the Dragons tail goes sweeping by.
Not every land on earth will sink
But these will wallow in stench and stink
Of rotting bodies of beast and man
Of vegetation crisped on land.**

**But the land that rises from the sea
Will be dry and clean and soft and free
Of mankind's dirt and therefore be
The source of man's new dynasty.**

**And those that live will ever fear
The dragons tail for many year
But time erases memory**

**You think it strange.
But it will be.
And before the race is built anew
A silver serpent comes to view**

**And spew out men of like unknown
To mingle with the earth now grown
Cold from its heat and these men can
Enlighten the minds of future man.**

**To intermingle and show them how
To live and love and thus endow
The children with the second sight.
A natural thing so that they might
Grow graceful, humble and when they do
The Golden Age will start anew.**

**The dragon's tail is but a sign
For mankind's fall and man's decline.**

**And before this prophecy is done
I shall be burned at the stake, at one
My body singed and my soul set free
You think I utter blasphemy
You're wrong. These things have come to me
This prophecy will come to be.**

**My mother-in-law, who lived to be 90,
during the whole of her adult life,
was a gatherer of newsprint curiosities.
These amounted to many thousands of items
which in her retirement she spent many hours,
days, weeks and months in sorting.**

**I gathered together empty cereal boxes,
covered them in various shades of wall paper,
and lined the walls of a room with shelves
to aid her in her task.
Eventually, I purchased over ten thousand dollars
of microfilming equipment**

**and hired three ladies for a summer
to microfilm all the material she had categorized.
There is sufficient resource in
the material for several books
and I may someday donate it to a library.**

**In reviewing this material on prophecy
I found a number of versions
of the poem by Mother Shipton.
This raised my curiosity
as to which version was correct
and so I made a trip to Chicago and
visited the Central Public Library on Michigan Avenue
where I inspected the listings in the main catalogue.**

**Some references to rare books
led me from one librarian to another
until I reached the chief librarian
who gave me a letter of introduction to the
Rare Books Archives located on the north side of Chicago.**

**Because of the lateness of the hour
I hailed a cab and informed the driver of my hurry,
which in retrospect proved to be an erroneous and incautious act.
I thence braced myself between the seats
and endured with white knuckles and clinched teeth
the most horrifying ride of my life.
This from one who has flown upside down in fighter jets,
ridden with high speed police escorts,
survived several auto crashes, and flown in antiquated aircraft
through the air pockets of arctic storms.**

**Upon arrival the driver turned to me and said,
"I thought you were in a hurry?"
"But not to reach the next Kingdom", I replied.**

**The building before which I was deposited was
an ordinary apartment house of a half dozen stories
and indistinguishable from the dozens of others
that lined the street.
The front entrance was unlocked and the foyer empty
so I passed through them**

**and a second set of doors into a gallery empty
except for a single uniformed policeman who immediately halted me.**

**Upon my presentation of the letter of introduction
he opened an elevator,
pushed a button for another floor and sent me on my way.**

**When the elevator doors opened I found myself in a gallery
similar to the first
and again occupied by a single uniformed policeman.
Once again my credentials were reviewed
and then I was escorted through a set of doors
to a receptionist who still again examined the credentials, interrogated me as to my purposes,
relieved me of my overcoat and briefcase
and finally led me away to a fish bowl sort of room
surrounded on all sides by clear glass paned windows
and in which there was but a single table and a single chair.**

**There shortly appeared another lady
who took in detail my request
and I was then left for another twenty minutes
to examine my fingernails.**

**Upon her return she brought with her a stack
of about a dozen old volumes
and pointed out a button that I was to push
when I was ready to depart.
I was then left alone to examine the treasure.**

**The volumes before me were truly ancient.
I am told that modern printing will not last near so long
because of the sulfur content of the paper.
The ages of the volumes spanned back over several centuries
and the most recent of them leapt frogged back
by many decades the earliest version that, until then,
I had been able to find upon the subject.**

**I first arranged the volumes in the order of their antiquity
and then set about to examine them.
The earliest volumes were of course set in Old English type
with the what appears to us as the f for s symbols,
and the quality of handset type was of course quite different**

**from what we are used to today,
as was also the nature of the prose.
Nevertheless, an hour and a half of study
afforded me numerous insights.**

**To my disappointment I found that in no case
which I could determine were the prophetic references to events
which have occurred
printed prior to the occurring of those events.
In these versions, in the ones that I had examined previously,
and in the many that I have examined subsequently,
there are often references to contemporary events
not found in all the versions.**

**In the version above
the lines starting from:**

**Footsteps will be seen in every room,
to----
But the wall that falls will not be so old.**

are of my own creation.

**About the only reference that I found consistent,
was that regarding snow in the streets and on the housetops,
a symbolic reference that does give one pause to think.**

**I do not wish to be totally disparaging about the poem
for I do not feel that it is entirely without merit
but I do feel that it is an excellent example
of the caution with which one
must approach these matters.**

**There is really little of benefit
that can be communicated by prophetic writings
to anyone who does not have a pure spirit of
scientific inquiry and a mature method of historical analysis.**

**Much of what passes for education today,
even from the universities,
is pseudo scientific.
The true spirit of inquiry**

**into the underlying reality of things is most often missing.
The most advanced scientific thinkers
and the most advanced religious and mystical thinkers are of a kin
but their imitators dogmatically fall
into the morasses of materialism and
superstition, respectively.**

**I hope that I have not overly bored you
with this meandering of a raconteur,
and that you may be curious
about some of the other experiences
that I shall recount in this series.**

**Peace and love,
Bruce Beach

POP02 - Ouiji

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

This is a continuation of the POP (Power of Prophecy or Problems of Prophecy) series that I am presenting, in which I am sharing some of my own experiences in that field of search.

I had long researched in this area when my wife and I had occasion to stay overnight with friends on our way to Hollywood where I was to see my book agent.

While our hostess was preparing supper I took down one of a large number of 3 ring binder volumes that were on a shelf above the sofa on which we were sitting. There were numerous typed accounts with dates and names of great numbers of sessions with individuals.

Therein I read a dialog with a particular individual, in which it was foretold that he would die in an airplane accident. Hmmm, said I, to myself. Taking the volume I went out to the kitchen and addressed my hostess.

"What are these?", said I.

"Oh, those are Ouiji Board readings", said she.

"But we don't do them anymore", she continued.

(Knowing that I would know that it was dis-recommended by her current religion.)

"Hmmm", said I, "Would you happen to remember whatever happened to this particular individual?"

"Oh, he was killed in an airplane accident", said she.

I continued ---

**"Really? That is what it says here will happen to him!
I have often heard of Ouiji Boards but I have never seen one.
Do you still have one?"**

"Yes", she replied, "But we don't use it anymore".

"Well, I would like to see how it is done."

"Okay, I can show you after supper, but we won't do it ourselves, because like I said, we don't do it anymore."

(More philosophical discussion about its use and accuracy and then after supper my wife and I sit down with the Board between us, and direction from our host and hostess from across the room.)

"Put you hands on the device. Have your wife put her hands on yours. Say a prayer and call on the name of a Spirit Guide".

(I called upon the name of a well known Spiritual Leader, I might say a prophet (with a small p) that had ascended into the next world.)

"Now, start asking questions".

"Where are we going?"

**(To my surprise the device began to spell out a word).
SALEM.**

(Now that was ridiculous. I knew there was a Salem Massachusetts and a Salem in the Carolinas where they had burned the witches, but we were in Utah and headed West. The OPPOSITE direction. So, how in the world was I going to end up in Salem? I asked.)

"How are we going to get there?"

BY THE NORTHERN ROUTE.

(More ridiculous still. So it thought we were going to Massachusetts, but we were heading for Hollywood by the Southern route. I was now ready to reject this non-sense, so I asked a sarcastic question.

"Does this thing really work?"

YES, BUT YOU DON'T NEED IT.

(And so we had a good laugh about it and put the silly thing away).

**Less than two weeks later,
through a very odd set of events,
we ended up without any choice
in Salem, Oregon
that I didn't even previously know to exist.**

**I took the VERY GOOD ADVICE
(knowing the Source)
and never used such a thing again.**

**In previous years,
I had read books about phrenology,
palm reading,
tea leaf reading,
crystal ball gazing
and so forth,
but this was my only personal experience
or experimentation.**

**The problem with these things
(and other things like drugs and channeling)
is that they work -
in the beginning.
But eventually they lead you down a wrong path
of dependence and ineffectuality.**

**I could go into much more detail about these matters,
along with other subjects such as
Brain Washing**

**Deprogramming
and a variety of other phenomena
but that is not the purpose of this presentation.**

**Common sense will tell you,
if you look upon abusers of these phenomena
(any use is abuse)
that their practitioners benefit no more
than alcoholics do from alcohol.**

**Practicing alcoholics BELIEVE they benefit from alcohol,
as fortune tellers believe they benefit from fortune telling,
but you only need to look at the quality of their lives.
If they could really derive such benefits as they claim,
they would pick the winning lottery tickets,
or at least good investments in the stock market,
and would live a much different lifestyle
from than that in which one usually finds them in.**

**I only report this incident to you
that you may know that I have traveled
all these avenues.**

**Today I know many people, personally,
who are dependent on astrology, channeling and such.
I now have a large accumulation of evidence
that it is not beneficial.**

**It is like trying alcohol or drugs.
If you never take the first drink
you will never become addicted.
But like with smoking,
it may be hard to get started,
but it is a lot harder to stop.
So, just don't do it.**

**Peace and love,
Bruce Beach

POP03 - Plants One

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

This is a continuation of the POP (Power of Prophecy or Problems of Prophecy) series that I am presenting, in which I am sharing some of my own experiences in that field of search.

This time I am going to write about something a little different. A scientific experiment, but at the end I hope you will see the relevance. I actually conducted three series in this area, the last with government funding but at this time I will tell you only about the first two series.

They are with a growth inducer and a growth retardant. I hope that you will carefully read the description of the method and see that it was a carefully controlled experiment. I, and many other hundreds of researchers, have done the same experiment and you are welcome to repeat it yourself.

First came the preparation of the subjects. We bought a dozen brand new aluminum pie pans taking them out of their original plastic wrapping so that we could be sure that none of them had been contaminated.

We then took bags of sterilized soil, purchased from the store, and put the soil in the pans, leveling it off at the top with the blade of a ruler so that we could be sure that every pan had the same amount of soil.

Next we drew a line through the middle of the soil in each pan and took red fingernail polish and painted the edge of the pan one-half way around on one side.

We used the fingernail polish so that it could not be erased or moved, and so that we could always tell which half was which half of the pan.

Next, in each pan, we put from the same seed packages, of non-hybrid seeds, two types of seeds - corn and bean, about two inches apart and two inches from the rim of the pan.

Because the pan was round and we measured the distance between each seed there were two longer rows toward the center with 5 seeds two inches apart then progressing outwards in each direction two other rows with 3 seeds and 2 seeds, for a total of 10 seeds on each side of the pan.

If you have the picture in your mind there were six rows in the pan with a total of 20 seeds and an imaginary line down the middle between the two longest rows. This was done exactly the same with each of the 12 pans.

Now we took a water sprayer and gave each of the pans the same number of squirts of water.

And then we took the fingernail polish and numbered each of the twelve pans. So far as we could tell, everything was now identical.

We then wrote the 12 numbers on separate identical pieces of paper, turned the papers upside down on a table and shuffled them as randomly as we could.

Then we called another person into the room and asked them to randomly select 6 of the pieces of paper, and the numbers of the pans on those pieces of paper we put in the control group.

Next we took two chess pawns, one black and one white, shook them behind and held out two hands, each one containing a pawn and saying which ever one the person selected that is the one that would receive the growth retardant. (They happened to select the dark one and so the red side of the pans with the fingernail polish received the retardant and the other side received the inducer).

The pans were then set on the table in front of the window, and each day they each pan received the same number of squirts of water all from the same water container and each day the pan on one end was removed and taken to the other end and all the pans were moved down one place in the row

so that each would receive approximately the same angle of light throughout the experiment.

The only difference was that twice each day, once in the morning and once in the evening the plants in the experiment received growth inducer on the plain side and growth retardant on the red fingernail polish painted side. The pans in the control group received nothing else than the measured squirts of water.

I hope that you will agree that this was a thoroughly controlled experiment. Now let me tell you the results.

Two weeks later, the 120 plants in the control group (6 pans with 20 plants) were all up one and a half to two inches tall. All healthy green looking - all very nice and even looking like a good farmer's field.

The plants that had received the growth inducer were however very sickly. Only about half had come up at all. Some of these had actually turned down and grown back down into the soil.

The plants that had received the growth retardant were, however, all there. Tall gangly and strange looking. Some over four inches tall - much taller than the control group.

What can we conclude from this experiment? Think about it.

That the growth inducer and the growth retardant had become mixed up?

That each side had received the opposite of what we intended?

This may all seem very off topic, but let me assure you that it isn't.

The reason will be given in my next email.

I just want to give you the time to think about the experiment.

**Remember,
our goal is to find, if we can, a true source of prophecy,
and we have yet, many things to examine.**

**Peace and love,
Bruce Beach
DawnSayer@webpal.org**

POP04 - Plants Two

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

This is a continuation of the POP (Power of Prophecy or Problems of Prophecy) series that I am presenting, in which I am sharing some of my own experiences in that field of search.

Now, to explain what the growth inducer and the growth retardent were (in the previous email). They were prayer.

Yes, that is correct - PRAYER.

The plain side had received nothing else except prayer for its growth and the red side nothing else except prayer that it would not grow.

If you find this latter strange, please do remember that Jesus cursed the fig tree and that it withered.

And that such a prayer could be very effective against cancer, plagues of locusts and such.

But no matter, the experiment did go strangely, (the side receiving the prayer for growth - withering, and the side receiving the opposite - growing astoundingly strange). and later I shall explain to you why.

As I have said, these experiments, of the Power of Prayer on Plants, (there is a book by that name) have been conducted at Red Stone University, and elsewhere (I think perhaps Duke) and I know at the University of Wichita, because I later did them there myself.

The experiments have been thoroughly controlled

and there is no statistical possibility that the results are attributable solely to chance.

POP this time stood for the Power of Prayer on plants, but we shall get around to the relationship between prayer and prophecy.

My interest in prayer had been long standing. I am a class taught student of the Massachusetts Metaphysical College which is the training received by Christian Science Practitioners. I had already served as a volunteer War Time Minister, and although I am no longer a Christian Scientist I still have a deep respect for its teachings and can give many testimonies to its effects.

Thus it was, at that time, I approached the Botany Department at the University of Wichita and asked permission to repeat my experiments there. I was granted use of the entire green house, and with the aid of the Department Chairman undertook the experiments on a much grander scale.

We emptied and scrubbed the green house. New flats were obtained along with wheel barrows of sterilized soil. The Chairman insisted that we use hybrid seeds known for their consistent response and even growth. A planting device was devised to assure that all were planted at the exact same depth. A more accurate watering method was stipulated, and so forth.

I won't go into the details, but the end result was that we had rows and rows and rows of the most evenly grown plants that one might imagine.

To my mind the outcome was the result of the exact same cause that had contributed to the reversed results in the first experiment.

What in Christian Science is called mental malpractice.

**I won't go into all the philosophical details,
but there is good reason that Jesus said,
"That whatsoever ye ask for secretly
will be awarded to you openly."**

**Similar results had been reported in the Redstone experiments.
What I think happened in the first case
was that my former wife,
who was quite distraught with me at the time,
was present with the plants on the table all day long,
and she was quite aggravated with me, them, and the experiment,
and consequently the inverted result,
as with much else in my life at that time.**

**In the University green house,
many people made the trip down to the green house,
having heard about the experiment,
to laugh about it.
Their cumulative mental influence
and trust in the power of hybrid seeds
far exceeded mine.
Probably the world's most even crop ever.**

**Miracles are only miracles
to the person for whom they occur.
If by a miracle we mean the repudiation of natural law,
there is no such thing,
but rather there is application of supranatural (not supernatural) law.**

**Jesus said that if you have the faith of a mustard seed
you can move mountains,
but if one claimed this faith to a non-believer
and they asked you to prove it,
and you pointed at a mountain and prayed
and it jumped into the sea
they would simply say,**

"You were just lucky that an earthquake came along right then."

From years of experience

**I know the power of prayer.
I am no longer a Christian Scientist
but it doesn't make any difference who prays.
The sun shines on all,
and God loves all.**

**Many do not know how to pray effectively.
Myself included.
It has been said that God punishes us in two ways.
Either by not answering our prayers,
or by answering them.
I really don't have the wisdom to know what is good.
Jesus plead to be delivered from the cross,
but in the end He said, "Thy will be done".
And that is where I always end up at,
because I never know that what I wish
is necessarily what God wishes.**

**Even my grandchildren pray with more direct desire
than I do.
And I think that is well.
When I have gone to Christian Science practitioners for help
it has been immediately forthcoming for health problems
and all sorts of other problems.**

**On two occasions I was so broke that I had not eaten for 3 days.
Both times I immediately received more affluence than I had previously had in my life.
On the one occasion the next morning.
A very dramatic story, but I won't tell it
and on the other some the next day
but within two weeks I had in my pocket over fifty million dollars.
Literally.
A cashier's check for \$50 million dollars,
plus a one hundred dollar bill that I took and placed with it,
so that I could say that I had over \$50 million dollars
in my pocket at one time.**

**There are MANY other things that I could tell you about,
but once again miracles are only miracles to those to whom they happen.
And I don't like relying upon Christian Science practitioners.
It is sort of like relying upon the Ouiji Board.
It works.
But we don't need it.**

**We are supposed to walk these journey's on our own.
Not that I am saying it is not good to pray with others,
and to ask others for help with prayer when you need it,
because that is a very good thing to do.
But what I am saying is
that I don't have it anywhere nearly all figured out as yet.**

**More to come.
And it all does tie into the subject of prophecy -
eventually.**

**Peace and love,
Bruce Beach
DawnSayer@webpal.org**

POP05 - Straight Arrow

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**This is a continuation
of the POP series
(Power of Prophecy or Problems of Prophecy)
that I am presenting,
in which I am sharing some of my own experiences
in that field of search.**

**For a number of years
after I left Christian Science
(actually, I was excommunicated,
when my former wife informed them
that I had become a nudist -
in my volley ball and sunshine days),
anyway in those years following -
I became a Buddhist.**

**Attended a Buddhist Church for about a year,
and then got into Zen.
(Traveled to temples in China,
and all that sort of thing).
Was much attracted to the teachings in a book called -
"Zen and the Art of Archery".
(Was also very much into Sufi,
and other teachings -
but I have never been that much of a purist -
about anything).**

**For years, after moving beyond Buddhism,
I continued to practice
"Zen and the Art of Archery".
Also taught my children.
Rented a corner lot cat-a-corner across from the house,
on the main corner of our village,**

**and set up an archery range with 4 target butts,
of various distances, so 3 children and I could shoot
at the same time.**

**Each of their special bows,
sized as to weight, left or right hand, and so forth,
still hang on our wall after years of usage.
We sometimes attracted quite a crowd of onlookers,
but I was never much of an archer.
Wrong type muscles to properly pull a bow,
and not really physically adept or coordinated
at anything**

**But the idea of Zen,
is not so much one of physical adeptness,
as that of mental (actually spiritual) mastery.
The question is -
what guides your arrow?**

**The stories are numerous
such as the old Zen Master,
who sent the acolyte out to the garden
to pin the target on a tree,
and then shot the arrow through
the Japanese papered wall of the house
and the acolyte then goes back to the garden
to find it implanted in the bulls eye.**

**Indeed, what is it that guides our arrow?
After years of practice,
I too felt that I was becoming somewhat adept.
The arrows continuously landed in the bullseye.
Finally I summoned wife to come and watch a demonstration.**

**I placed my arrow in the bow.
Raised it to my chin and let it fly.
It did something that it had never done before.
It flipped out of the bow,
tumbled forward and high into the air
above the hill behind the target and to one side
to come down on our dog who was lying peacefully there.
Of all the places to land.**

**The dog was shocked.
So was I.
Fortunately it was a spent arrow
and the dog wasn't hurt,
but what had guided my arrow?
A lack of humility.**

**There are two great tests for each of us in this life.
Self and passion.
Self is the greater test.
Trying to serve God - without self.**

**"Oh, God, if I do this -
how great I will be in Thy sight."**

The Walter Mitty dreams always plague us,

**"How great I will be".
"How people will be astounded with me".
"What great things I will have accomplished".**

**Getting beyond this is very, very difficult.
We must learn to serve God -**

**Neither in hope of heaven
Nor in fear of hell.**

**How willing are we to serve God?
I have a test that I often give people.
Look at the following choices -**

- a. Would you like to be rich and famous for serving God?**
- b. But what if you were given the choice,
that you could provide some great benefit to humanity,
and that while it would make you rich still,
humanity would not recognize you for the benefit.**
- c. Or that you could provide some great benefit for humanity
but that you would always be in great poverty.**

**d. Or that you would provide some great benefit to humanity
but not only would you be in poverty
and not recognized for the benefit
but that people would revile and despise you
because they did not recognize the benefit or that you were the source.**

**e. Or even that you came to understand
that while what you suffered to do
and for which you were reviled
while it was a benefit to humanity
while it was God's wish that you perform it
that you would still go to hell.**

**At which level would you be willing to provide the benefit to humanity?
If you think the latter case strange,
you must remember that the Book says,
"Even in hell will I set my angels to look over them",
so some angels have to serve in hell.
If that is where God wanted you to serve,
is that where you would be willing,
even want to go,
if it were God's will?
You say,**

"You would want to go to hell?"

**Indeed, I look at some of the hells on this earth,
and there I find angels and saints looking after the inhabitants.
Not my bit, I tell myself.**

**"Oh, Lord", I say,
"deliver me from that!"**

**And probably he finds me unworthy (I hope)
(that old self will)
of that.
But we never know.
We will have to do that which we will have to do.**

**But, what does all this have to do with POP
(the Path of Prophecy)?**

**Oh, my brother,
Oh, my sister,
if thou would's't step upon the Path
thou must first purify thy soul,
so that not the least trace of self or passion remains.**

**And thus it is
that I am but an observer -
and not a prophet.**

**Peace and love,
Bruce Beach
DawnSayer@webpal.org**

POP06 - The Iching

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**Through the decades
I have conducted many classes
on the subject of meditation.
At one time traveling a circuit
on weekends week after week
through small communities
where I had placed newspaper ads
in Northern Ontario.
Never have I charged a dime
(nor taken a donation)
for these courses.**

**At another time I had large classes
in what was the then popular
"free college movement"
at a large university.
There came to these classes
week after week
an individual who repeatedly pleaded with me
to allow him to cast the I-Ching for me.
I declined.**

**But, finally I agreed,
on one condition -
that it be cast in the dark.
If you are not familiar with this method,
it is similar to that related in the Book of Daniel
where the king called in his astrologers and soothsayers
and asked them to interpret his dream
without his telling them what the dream was.**

**My fortune teller,
was equally well astounded at my suggestion**

(you must read Daniel to see the king's fortune tellers' response)

but at last he agreed to proceed.

What we did in this method,

is that I wrote the question on a piece of paper,

folded the paper so the question could not be seen

or changed

and placed it in the middle of the mat

on which we were about to cast the I-Ching.

Assuming the traditional positions,

and offering the traditional prayers,

we began the process.

If you are not aware of how the I-Ching is cast

I shall briefly explain the process.

A die is cast,

and a marker is positioned.

There are something like ten groupings

of five each (as I remember).

The arrangement would look something like this:

10100__11000__00110__01101__11101
11011__01100__01011__00110__10111

The actually arrangment of the ones and zeroes

in the above example

is coincidental.

I just picked them randomly as an example.

The thing to notice here is that there are two rows

The top row represents

HEAVEN

and the bottom row represents

EARTH.

Each of the groupings has an interpretative meaning,

and the interpretations are given according to long tradition

as found in Interpretative Books written about the I-Ching.

The actual position of the ones and zeroes,

is determined in a ritualistically prescribed order

by casting the die.

It takes a while to go through the whole process,

but in the end here was our ACTUAL result.

11111__11111__11111__11111__11111
00000__00000__00000__00000__00000

**The getting of all the ones in a line
and all the zeroes in another
is the equivalent of flipping a coin
and first getting fifty heads,
and then getting fifty tails all in a row.**

**I was teaching statistics in the college
and I can tell you that the probability of this happening
is much, much less than than of picking all seven numbers
in the lottery.**

**Now the real significance of this comes in regards to the question.
Sort of like that quiz show on TV called Jeopardy
where they give you the answer
and you formulate the question.
This was the answer.
What was the question?**

**First to examine the meaning of the answer.
In this answer
all the ones in heaven
means that heaven is ruling
over all the zeroes on earth.
I won't go into all the mystical significances.**

**But now we opened the paper
so my fortune teller friend could see the question -
It was -**

**"Is the Prophet that I am trying to teach you about
the True Prophet?"**

He never returned.

**Peace and love,
Bruce Beach

POP07 - The Seeker

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**This letter in the POP series
is the last one in which I will be talking about
my own experiences.
The next several should be much more interesting
to you,
because they will be talking about YOU.**

**My purpose in talking about my own experiences
has been two fold.
So, that you could know something about me, but,**

**While it is good to know the teacher,
It is better to know thyself.**

**Secondly, I wanted you to know
that I have examined many, many paths to Truth
and while I won't say that there are any false paths
some of them are very, very circuitous.
I am hoping to show to you what I have found to be
The True Path.**

**Many people send me all sorts of information today.
And I am very appreciative to receive it.
Information about all sorts of
dreams
visions
prophets
predictions
and many other interesting things.**

**I have a very Fast Filter
so I can deal with all of these very rapidly.**

**But the problem is
that other people have fast filters also.**

They say to me -

"Beach, do you believe X about _____ ?"

**"And if you don't then you are
wrong, wrong, wrong."**

**You can fill in your own words for the blank,
but just yesterday some them would have been
the Rapture
the NWO
Christ
Resurrection
Reincarnation
and twice about the White Buffalo
and twice about the Environment
and one of the fellows wanted to be removed from the list
because my answer was not the right one about the environment.**

**Many times too,
the blank is about which church
and this can be
Catholic
Mormon (LDS)
or just Christianity itself.
Millions of people out there
have such fast filters
that they would not even be on this list in the first place.**

**The real issue is not
how FAST one's filter is,
but how ACCURATE it is.
Better accurate than fast,
but we get so much information today
that you need to be able to sort out what you are going to examine.**

**Here is a good test.
You have a lot of experience in your life
and have hopefully already sorted out lots of baloney.
As a result you have developed a system of thought,**

perhaps even a philosophy that you trust.

**When someone comes with something new,
then your natural and proper response is,**

**"How does this fit in
with what I already know".**

**If the person has no idea of what you believe,
then they can't explain their belief from your perspective.
It just boils down to:**

"I believe this - you believe that",

about superficial matters with no understanding of why.

**Okay, so they have a great and complicated system,
about physics or whatever,
but they need to be able to put it in terms
that you can understand.**

**It is a long journey to understand a complicated system
but every journey must begin from where you are
and in terms that you understand.
That is the teacher's responsibility
to meet you on the path at the point where you are.
It is then your responsibility
to take the next step on the path
in which the teacher points.**

**If someone shows up at my door in the next few minutes
and says:**

**"Beach, you are full of baloney,
and I can prove it to you."**

I will say,

**"Welcome, welcome in.
I have been waiting for you.
What took you so long to come?"**

**Now, this person, to know that I am wrong,
"full of baloney"
is going to have to know what I believe.
Otherwise, it is as if he says,**

**"Beach I have something WONDERFUL in this box
that you should have."**

and I look in the box and I say -

**"Oh, THAT is wonderful,
but I have something even more WONDERFUL
in my box."**

and he replies,

**"No, no, no, this is the MOST wonderful thing
that there is. There can't be anything more wonderful."**

and I say,

**"Yes, that which you have IS wonderful,
but I have looked in both boxes,
and I know that what is in my box is MORE wonderful."**

still he replies,

**"No, no, no, I have a lot of experience with what is in my box
and there just can't be anything more wonderful."**

At this point, we can't go forward.

If the person is a Christian

I tell them,

**"Yes, Christ is WONDERFUL,
and I would not have you to have Christ any less,
but I want you to have Christ more,
because God is Infinite and there is always more."**

**But, it is often the case that people can only look in their box,
or if they will even glance in another box**

**it is not really to see what is in it
but just so that they can "prove" that what is in their box is better.**

All this will never do.

**One must lay aside their prejudices
no matter what they are
to step forward on the True Path.**

People are born into all sorts of prejudices.

**You are whatever color skin you are -
because your parents were that color skin.**

**You speak whatever language you speak -
because your parents spoke that language.**

**You are probably whatever nationality your parents were,
and a member of whatever religion (Christian, Moslem, Buddhist, Hindu)
that your parents were.**

You are in the box that you were born in.

**Oh, we make small changes,
from one denomination to another.
Learning a "foreign" language,
changing from one political party to another,
but all within the culture of which we are a part.**

**If you were born in America
it is very unlikely that you will end up
as a Buddhist in Japan speaking Japanese
or as a Hindu in India speaking Punjabi.
And why would you want to.
You know that what you have is good.
But it is just that a dramatic change
that I am inviting you to,
because it is to something BETTER.
MUCH BETTER.**

**There is really no need for you to read further
in this particular email.
If you are committed to the journey,
then I have had said enough.
The rest is too much,
because it is again just about my personal experiences.**

Many the tale

**that I would like to share with you -
about a number of mystical experiences in the Arctic,
about my UFO encounters -
(that alone takes over an hour to relate verbally),
but briefly I was a control tower operator
at one of the five experimental Air Force Bases in the U.S.,
and actually sent planes in pursuit.**

**I would like to tell you about my publishing
(for another writer)
lengthy books on Pyramidology
(I was a publisher for some years).**

**I would like to tell you about
many strange astronomical phenomena that I have studied
(I set up a professional observatory at one college)
and you might like to look at my [millenium star](#).**

**I would like to tell you about studies
on the Bible Code
(a way of counting and arranging the letters
in the original Bible Texts
so as to create prophecies).
Or about a study that a friend of mine did
on the Celestine Prophecies,
that really impressed me.**

**I would like to talk further about Bibliomancy,
the various methods of turning randomly
to Scriptures for guidance.
(One method that I am considerably more inclined towards).**

**I could tell you about experiences
in many different Ashrams,
with the Moonies,
and the Hari Krishnas,
with Dianetics and the E-meter
-yep, read the whole book - did the tests.**

**Yes, I took the courses,
received the secrets,
of most every Guru that you can name -**

**from TM (the Beatles favorite)
to the (young at the time) Guru Maharaji
(just checked that he is still around).
All very interesting.**

**Met all sorts of interesting people.
Weekly luncheons with one group
that had several UFO abductees
(so they claimed or believed).
Most of them realized that they were schizophrenic,
having at sometime been hospitalized,
but one may have been one of the few real charlatans
that I have ever met.
He made, and I guess still makes,
a substantial living from his books
which are particularly popular in Japan.
Most of these people are simply self deluded.
Doesn't mean that I don't still like them,
and also that they don't sometimes (mixed in)
have amazing insights -
because they often do.**

**Just like drug and alcohol addicts.
Often amazing insights
about everything except their own problems.
Too often we are quick to call groups cults.
They are just people
who have gotten off the path of reality
more commonly accepted.
Usually the paths have many erroneous elements,
but so then is the path followed
by most "normal" people.
That of knowing all the latest sports scores,
what the popular brand names are for clothing,
knowing who the stars are in the latest movies ,
and all the materialistic hype of modern CULTure,
is another path equally divorced from reality,
as is all the dogmatic conformance to churchianity,
patriotism, or for that matter any other fanaticism
of the current "CULTural revolutions".**

**We should not envy the powerful or rich
(I have been in the same room**

**with a number of U.S. presidents),
nor despise the poor and downtrodden,
for God leads each on their own way.
I have taught volunteer college courses
to lifers in prison,
and have served as a psychiatric social worker,
in several institutions,
and I know that many of these people are
more sincere in their struggle to find reality,
than are masses of people
that freely wander the earth.
I at one time lived a block and a half
from the corner of Haight and Ashbury.
You have to be ooolld
to understand the significance of that.**

**My purpose in reciting all this to you,
is that you may know that
I have examined every avenue,
in the search for Truth.
And as lengthy as is this accounting
it does not begin to exhaust all that I have done.
Strange Rosicrucian experiences.
Serving as Chauffeur and Guard for Ezra Taft Benson,
then Secretary of Agriculture of the United States,
and later Prophet of the Mormon Church
(I put this in for my LDS friends),
and still the list goes on and on.
Who else among you has had your life threatened
in Philadelphia Mississippi
(where three voting workers bodies
were found buried in the dam),
or have lain on the floor with your family
as the gun battles went on in the street
one floor below and a block and a half
from the Black Panther Headquarters.**

**But enough of this.
Too much already,
although I could go on and on.
I receive many emails each day
(all of which I try to answer)
from people with a great variety**

of different belief systems.

**The purpose of the previous emails was to show
the spirit of search
with which one must seek.**

**But, as Jonathan Livingston Seagull once said,
"It is good to be a seeker,
but it is better to be a finder."**

**And in my searching-
I did find.**

**I found not only how to identify the True Prophet,
but I also found the True Prophet.**

The time is now too short to continue with tales.

**The time has come for the Truth to be Told,
and I shall tell you how to find it for yourself.**

But, you must be willing to make the journey yourself.

No one else can make it for you.

**Just as every student of mathematics
must work the mathematics out for themselves,
because no one else can do it for them.**

**Oh' we can show the formula,
go through the exercise,
but in the end each one must think it out for their self.**

**Because we live in a Christian Culture,
the proofs that I am going to present are
Christian proofs.**

If we lived in a

Buddhist,

Moslem,

Hindu,

or other culture,

then I would use proofs from those cultures.

**It makes no difference
if you consider yourself a Christian or not,
because you live in a Christian culture,
you will be able to understand the proofs
from a Christian perspective.**

**Yes, we will look in the Bible,
and if you do not currently believe in the Bible,
then afterwards, if you follow the presentation,**

you will come to a new appreciation of its significance.

**So now, our search for the True Prophet,
and the True Prophecies,
has taken this turn.
Bear with me if you will,
or depart in peace.**

**Peace and love,
Bruce Beach

Millennium  *Star*

Millennium Star

Fulfillment of an Ancient Prophecy

This oft-told ancient prophecy,
with roots back in the Sufi and Illuminati teachings,
is reflected in the Tale of the Ancient Mariner,
with its "star dogged moon"
and in the ancient symbolism on the flags of
many modern Moslem countries.

What the prophecy says is that:
at the Time of the End,
a Star will appear between the Crescent Points of the Moon.

Now, all astronomers KNOW that this is impossible.
Stars are generally very large astronomical phenomena like
our sun.

The closest being our sun,
and the others many light years away.
For one, to appear in the orbit,
between us and the Moon,
would be IMPOSSIBLE, they would say,
and WOULD destroy the earth should it occur.

And yet, this phenomena,
this end of the old - beginning of the new,
millennial event - of a Star appearing between the Crescent

Points of the Moon,
WILL OCCUR this very month.

Let me explain:

To the ancients, there were two types of stars,
fixed stars,
and moving stars,
and they both looked alike to them,
since they did not have a telescope.

The only distinction was that the one small group of stars
moved,
and for this reason they called them planets (travelers),
which to them simply meant moving stars.

Now, today we have a different view of planets,
but nevertheless, it is a planet that will appear
between the Crescent Points of the Moon.

But, whoa, hold up you may say, if a planet
is going to change its orbit
and pass between the earth and moon,
that TOO is certainly going to be a catastrophic event.

Well, actually, still some further explanation is needed.
To any primitive people,
that would happen to be occupying the earth at this time,

if they were out tending their flocks on a clear night,
they would notice that new stars,
new traveling stars (planets),
have appeared in the sky.

We call them satellites.

Now, the fact is,
that a Traveler will appear between the
Crescent Points of the Moon.

And I would like to have a photograph of the event.

When and where will it happen?

Well, probably about every month,
from some advantage point on the earth.

To observe and photograph it,
one needs a cloud free night,
(or to be above the clouds)

and for the satellite to be **AT THE CORRECT ANGLE**
between the observer,
and a Crescent Moon.

POP 07a - My Declaration

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

Baha'i's use the term "declaration" regarding their belief in and commitment to Baha'u'llah. Here I will tell you about the event that led to my declaration.

I had been aware of the Baha'i Faith for many years and had visited the Temple in Chicago a number of times.

Then, back in my native Kansas I saw an ad in the Sunday paper with a picture of the Temple and called out of curiosity that there were Baha'i's there.

At the local Baha'i's insistence I visited with the group that morning but told them I had no time to read a book. Their reply was:

"God will give you time."

During next week a major Evangelical Crusade was planned for the City of Wichita. Everywhere one looked one saw banners that proclaimed -

"Hear Haggai"

the evangelist.

**The banners were in store windows,
on car bumpers,
on telephone poles,
and on two big banners
strung across the main street
at both ends.**

"Hear Haggai"

**On the radio,
in the newspapers,
everywhere one looked
or heard - it was:**

"Hear Haggai"

**The newspapers reported
the week long event.
Many thousands in attendance -
the gigantic choir -
the moving sermons.**

**Each evening a Baptist friend
would come and ask me to go
but I was too busy.**

**The final evening he came
and insisted and insisted
telling me that the night before
over a hundred and fifty people
and gone forward to be baptized,
and that this was my last chance to -**

"Hear Haggai"

**In consideration for my friend -
I finally went with him.
The coliseum was packed.**

**The main floor
which was the city basket ball court
was filled with chairs.**

**At one end of the court was a stage
with 150 robed members of the choir
comprised of the joint choirs of
a number of the cities churches.**

**Three of the four balconies surrounding
three sides of the basket ball court
were also filled with only some vacant seats
in the fourth balcony.
Thousands in attendance.**

**It looked something like a political convention
with lettered signs held up on tall poles
showing the seating location
of each of the city's many churches.**

**East Side Baptist,
Rosedale Alliance,
Central Bible Church,
Broadway Church of God,
"Hear Haggai"**

**The church with the largest percentage attendance
was being given new hymnals for the church.
The winning church
had 300% in attendance.
It was a large meeting.**

**The choir and congregation concluded a hymn
and all sat down
and Haggai rose to speak.
Indeed a powerful sermon.**

**I still remember from the sermon
how he pointed out
the number of beneficial institutions of mankind
that have been started
because of the teaching of Christ.**

**There are hospitals,
and schools,
orphanages
and relief organizations of all sorts.
The list goes on into the tens -
as he gave it,
and the numbers of each
in the tens of thousands or more.**

**What man,
he asked,
has ever done more to benefit mankind?
One can look at all sorts
of political organizations
and political philosophies.
Personal organizations,
and personal philosophies
but what has done more
than the teaching of Christ
to benefit mankind?**

**Then he pointed out.
One is either for
or against
this movement that has so benefited mankind.
One cannot say
that they are neutral or indifferent -
because they are either part of the solution
or part of the problem.
Many were the points
that Haggai made of this sort.**

**I concluded that
well it doesn't really do any harm
in supporting Christ -
and better this source of good
than none.**

**When the altar call was given -
no one went up
although over a hundred and fifty
had gone the night before.**

**Even more were expected this night -
but I guess the crowd had thought
to beat the rush.**

**Several times Haggai paused the choir -
and urged sinners to come forward.
One time he gave an exhortation
that those there would be standing
on one side of the Pearly Gates
and that husband, brother, sister, friend
next to them would not be
because they had not turned to them
and offered to go forward with them.**

**My friend stood next to me
like a statue of rock,
but I must have dropped a shoulder
or something
because an usher came up from behind
and asked if I would like to go forward.**

"Well, yes."

**At the front I found myself
and one other fellow who eventually came forward
standing there looking up at the choir.
Haggai finally stopped the music
and looking down at this poor catch said -**

"Well, the Lord is looking for quality - not quantity".

**He assigned to each of us
two deacons (or guards as I called them)
and told them to take us to an upper room
where he would come shortly.**

**And so we marched out -
I and my two guards leading,
and the other fellow and his two guards trailing.**

**Up the broad cement and steel stairways
behind the auditorium**

and into a team dressing room.

**Red brick walls and wooden floors
with windows two feet above one's head.
Fold-down windows with opaque
chicken wire-embedded glass.
Hanging from the 15 ft ceiling
down the middle of the 50 ft room
five single light fixtures on stranded cord
with green shades and 150 watt bulbs.**

**Except for one table -
the otherwise unfurnished room
had lining down the walls on each side
a half dozen 7 ft benches
with patches of white showing through peeling green paint
worn out from a generation of showered athletes
having been sitting upon them.**

**Being first through the door -
my guards and I proceeded forward
several benches and sat down
with one guard on each side.**

**With a couple of benches in between
my companion captive was also similarly seated.
And thus we sat -
in total silence
none of our guards
having every spoken a single word
to either of us.**

**Through the thick walls of the fortress
and away in the distance
we could dimly hear the voices of thousands
raised in praise to the Lord of the Ages.**

**And then -
total silence
as there must have been being offered upon them
a final blessing.**

**And suddenly -
a loud clamor and commotion
as thousands rose from their seats
and moved towards the exit.**

**Bit by bit,
the clamor died away
until again there was total silence.**

Wait.

Wait.

**And then from the distance -
thump, thump, thump
growing louder -
thuMP, tHUMP, THUMP,
and the door burst open
and in marched Haggai with
twenty or more ministers behind him.**

**He stopped in front of the other prisoner,
whose guards IMMEDIATELY
split away from him and departed
as the ministers formed a semi-circle
around behind Haggai, who said -**

"Have you made your decision for Christ?"

*"Well, I was b..b..b.. baptized before -
but it d..d..didn't take."*

"Having you been attending church?"

**At this point one of the ministers said
that the conversant had been attending his
and stepped forward and put his hand on his shoulder
and then with a glance over towards me -
seeing that he did not know me,
led the petitioner from the room.**

**Haggai then turned towards me.
THUMP, THUMP, THUMP,
and the semi-circle formed behind him.
SUDDENLY my guards were GONE!**

"Have you made your decision for Christ?"

*"Well, I have one question that concerns me.
May I ask it?"*

"Yes?"

*"Well, you see I have been attending this
Buddhist Church in Chicago -
and what I want to know is -
'Are my Buddhist friends ALL
really going to go to hell?'"*

**At this point
Haggai glances back over his shoulder
and about a fourth of the ministers**

are standing there shaking there heads up and down -

and about a fourth of the ministers

are standing there shaking there heads side to side-

and about a fourth of the ministers

are standing there sort of shrugging-

and about a fourth of the ministers

are standing there with blank expressions on their faces.

And Haggai says,

"I tell you what I want you to do -"
**and he tells one of ministers to hand him
from the table in the corner
a copy of a pamphlet
of the Gospel of St. John -
(which I have to this day - over forty years afterwards,)
and he says to me -**

"I want you to take this home,

*and each night
and each morning
read a chapter of it
and get down on your knees
and pray to God to show you His Will."*

And then he says,
*"And I want you to call me tomorrow
at my motel
and I will meet with you."*

**So, I did as he said.
And the next morning,
I called at his motel,
and the operator said he had gone for breakfast -
and when I called again -
a little later she said that he had left -
and so I never got to talk to him.**

**But, I did exactly as he said,
and I want to testify to the efficacy of Christian prayer.
Each evening and morning
I read a chapter of the Gospel of St. John
and each morning and evening
I got down on my knees
and I prayed to God to show me His Will.**

**A few nights later -
I was asleep in my room -
when a figure appeared through
the darkened doorway.**

*"Arise -
and dress!"*

*"Wha, wha, what?
Who is that??"*

*"Never mind!
Arise and dress!"*

I fumbled over and turned on the night stand lamp.

**There in the room stood another friend -
from the Christian Science Church.**

*"Uh, what's up doc? -
It is after midnight!"*

"Get up and get dressed."

"Why?"

"Never mind - do it."

"What should I wear?"

*"Those pants, that jersey,
and a warm jacket."*

**Thus it was that I descended the stairs -
in my good suit pants and non-matching garb,
to find his new motorbike parked at the curb.**

"Come on -we'll go for a ride."

*"Neat. But no thanks,
I have been on a motorcycle before
and we had an accident."*

**(Same happened with my father,
and one of my sons was nearly killed on one,
and a friend's son is paralyzed -
I do not care for them.)**

But my friend insisted.

*"Okay, but just around
to the all night restaurant
on the other side of the block."*

"Well, okay."

**We didn't make it.
We were on a one way street.**

**Putt, putt, putt,
slowly up to the stop-light at the corner,
waiting for it to turn green,
which it does
and a car on the four lane road ahead
pulls up on the center lane and stops
to wait at their now red light
and we speed up to go across in front of it and turn -
when a car load of drunks comes through
on the curb lane and hits us.**

I sail completely across the street -

"Take this one first,"

**someone is saying to the ambulance driver.
A phrase which is repeated at the hospital.**

**I ask that a call be placed to my Christian Science Teacher,
(I am what they call a class taught student)
as they take me down to X-ray,
for 14 breaks where the car had hit me -**

*"Wrap it up -
and I will take it home with me."*

**I tell the attendant.
(The other fellow only had a broken shoulder bone.)**

**And so I ended back at my office -
when my father shows up from our home
30 miles south -
having heard about it on the radio.
He arrived at the same time
as one of the Baha'i's I had met.**

**My father and the Baha'i insisted
that I accompany my father home,
where my father summoned a local physician.
Although there were three hospitals in the
town the physician decided
I should be sent back by ambulance to the city,**

**where I was confined to a bed
although I still declined surgery.**

The next day the Baha'i came with a book.

*"See, I told you God would give you
time to read."*

**I had never felt pain
from the moment my CS Teacher was called,
and all the bones set themselves
and healed without surgery,
although I was released a week later
with a leg cast
but the fellow in the next bed was REALLY sick -
and there I was
reading the Baha'i Book
and in exaltation -**

*"I Found It!"
"At Last I Have Found IT!"*

That alone could have killed him.

**My favorite song became,
Jeanette McDonald and Nelson Eddy singing -**

*"Ah, Sweet Mystery of Life -
at last I have found you!"*

I played it over and over and over.

**Each person's experience in their religion
is a mystery.
Each person finds the mystery of life and love
in their own experiences.
For some my experience
may seem more story teller than story -
but we all seek the mystery of life.**

**There are always deeper Truths
and we can always grow deeper to God.**

**Many are the paths
and some may wonder how one can say
that one path is better than another.**

**One never has the FINAL answer
and all that one can do is compare what they have
with what they are given the opportunity to examine.
You have a box --
and I have a box.
You KNOW that what is in your box is beautiful and wonderful.
You just can't imagine
that there can be anything better.**

You say to me -

"Look in my beautiful box."

And I LOOK and say,

*"Yes, that is WONDERFUL! -
but what I have in my box,
is more wonderful."*

**Unless you look in my box -
you will never know.
God is Infinite
and His Creation is Infinite.
If you live 10 million years -
(and you will and many times that more)
you will never begin to exhaust
what you can learn about God and His Creation.**

**But, those who are haughty before God -
and refuse to look in another box,
will never know.
They can progress but only within their box
and as wonderful as that may be
it is still confining
and that is all that they will have
from Eternity unto Eternity -
while there is Infinitely more to God
and His Creation.**

**What we are meant to gain and set in this life
is our attitude of openness to the Holy Spirit -
and not some limited amount of finite knowledge
or dogma.**

**If there is good in all religions,
one may ask -
then what difference does it make
which religion one chooses.
The difference is that one must choose
to do the Will of God -
and they must always be open
to making comparisons and choices
as He leads us on the path.**

**Many a Christian,
many a Mormon,
has borne me their testimony.
Because I lived in Provo, Utah
and would always welcome the practicing Mormon Missionaries
I am sure that I have had more Mormon Testimonies
borne unto me
than any other single individual on earth.**

*"Before I leave -
I want to bear you my testimony."*

*"Oh, no, no -
not that again -
please!"*

"Nope, I am going to do it."

"No, really, you don't have to do it."

"Yes, I do."

*"Well, okay, I suppose so,
if you have to."*

And I am glad that they -

**and the many hundreds of other
truly devout Christians that I have met -
have a Testimony.**

**But I do wish -
that they could also look into my box,
and see then which they think
it is the Will of God that they should choose.**

**Peace and love,
Bruce Beach

Essays on the **Four Types of Souls** by Bruce Beach

This is a continuation of the POP series which were originally an email series of essays.

The intent of the series was to lead the reader through such subjects as the nature of the soul and how it recognizes God through the Four Paths to Truth, and then on to presenting The Most Great Proof.

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at:

DawnSayer@webpal.org

If you wish to enter into a discussion with me regarding religion - I highly welcome that. I have some [religious premises](#) that I would like you to review first, and let me know regarding any about which you disagree to help me better understand any points that you are making.

POP08 - The Four Types of Souls

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

Good morning Seekers of the True One,

**Now that you have stepped upon
the Path of Search
for the True Prophet
it is important to know first the Seeker.**

Who are YOU?

**Well I can tell you that
you are a soul,
but as a teacher and traveler
we need to know what kind of soul.**

**There are only four kinds of souls.
I know that this may surprise you.
Some people think that there may be
only one kind of soul.
Others think that every soul is different
and that there are therefore infinite kinds of souls.
But no, there are only four kinds.**

**Recognition of this fact
is to be found in Aristotle, Shakespeare,
and many other classical thinkers
down through the ages.
It was acknowledged in the work of
William James, Americas greatest psychologist
and intimated in that of Pavlov,
which was Russia's. Many thinkers and teachers,
of the East were also aware and today
there is a large body of study on the subject.
But still it is not common knowledge
and most people are not aware that there are only**

four types of souls.

**My source for this information is of course
the True Prophet,
but I have mentioned the above because
Truth is Universal and can be universally found.
2+2=4 in both Russia and the US
or anywhere else one may go
no matter by what name the numbers are called.
So it is with other Truth such as religious truth.**

**Types of things come in limited numbers.
Water can be seen as a**

- **Liquid**
- **Vapor (clouds, fog, steam)**
- **Solid (sleet, hail, ice, snow)**

**and while every snow flake may be unique
it is still one of the three states of water.**

**Each person has blood of some particular type.
You may know yours.
While there are variations within the types,
we still say that there are only so many types.**

**As one last example -
Suppose that we said that there were only
four kinds of animals.**

- **Insects**
- **Birds**
- **Fish**
- **Mammals**

Among the insects there would still be great variety -

**from the tiniest ants to the giant beetles,
and from scorpions to the butterflies.**

And among the birds

**from the humming birds
to the ostriches and the eagle to the parrot.**

In the fish

**from the gold fish
to the Great Blue Marlin,**

and among animals

**from the tiny shrew
to the elephant.**

**With great, great numbers of varieties among all the species,
but still for our convenience we listed them as four categories.**

And no matter how great the variety,

**and the fact that every individual specimen is unique
just as each snow flake is unique**

there remain a limited number of categories.

**And so it is with the soul -
there are but four types.**

**Not to say that there is not great variety in the types,
or that you are not individual and unique,
because both of those things are true.
But it is still true that you have one of the four types
of soul.**

**It is important to know the type of soul.
Otherwise we will end up
putting the canary in the aquarium
and the goldfish in the bird cage.
Yet the world as a whole remains blind to this fact.**

**When you take your child to the kindergarten,
to enroll them in their first day of school
they may ask you a hundred questions
regarding**

- **sex**
- **age**
- **height**
- **weight**
- **even blood type**
- **and IQ**

**but never on the form will you find
the most important of all questions for a teacher -**

what kind of soul will I be teaching?

**In my next four letters
I will be discussing the four types of souls.
It is important to identify and understand
your own type of soul,
but it is also useful to know and understand
the other types.**

It will much help you

- **in teaching your children -**
- **understanding your spouse**
- **getting along with co-workers,**

**and the dozens of other situations
that you meet in life.
It is well to understand others,
even if they do not understand themselves.**

**For a teacher it is essential
to understand the kind of soul
that they are attempting to teach.
And in this I have a problem,
because I cannot know each of you individually.**

**I have taught before through email
on a one to one basis
but I have never tried to do mass teaching
through email
and I know of no other teacher
who has tried to do it either.**

**So perhaps it can't be done.
But perhaps it can.
So it appears that you are a part of an experiment.**

**Somethings can be learned out of a book.
But for other things a teacher appears to be necessary.
Probably no great musician or mathematician
has ever been self taught.**

**In the past I have seen attempts
to teach mathematics by computer.
In fact I was VERY enthused about the idea
and was involved in some very substantial programs
to do so.
Didn't work out.**

**Turns out that you can give printed example
after printed example with a computer
but successful teaching requires interaction
between a pupil and the teacher.**

**The teacher stands at the blackboard and explains
but needs to watch the eyes of the students,
and when they start to glaze over,
the teacher must slow down and wait for them
to catch up.**

**At some point the pupils may just not get it
and the teacher will stand at the blackboard
and tap with the chalk
at some particular point in the formula.
And then the gleam of recognition
will appear in the pupil's eyes
and the teacher can proceed on.**

**Readiness to read,
readiness to learn,
readiness to comprehend,**

**is something comprehended among all primary teachers,
consciously or unconsciously.**

**Many are the stories of the Zen Teaching Masters,
or of the Abbots in the Catholic Monasteries,
who suddenly performed some action
like reaching over and tweaking the pupil's nose,
grasping their ear and not letting go,
or thumping them on the head,
at the moment that they called satorie,
and that the pupil suddenly saw the light.**

**Yes, every student is unique,
and every step along the path is unique,
and every student must make every step for their self.
And therein is the problem,
because I must address a general need,
speaking at one moment to one type of soul
and at another moment to another.
Addressing some with a particular level
of concern or comprehension at one moment,
and those with another at the next.
We shall have to see if this will work.**

**In all communication there are three elements.
There is**

**the SOURCE
the MEDIUM
the RECEIVER.**

**It makes little difference what we are talking about.
It could be light.**

**The source (a bulb, the sun, or a fire)
The medium (light waves - I won't get into the subject of aether.)
The receiver (a mirror or any matter).**

It could be sound.

**The source (a drum or other instrument)
The medium (a gas or liquid such as air or water)
The receiver (an ear or transducer).**

It could be radio.

**The source (a transmitter or star)
The medium (radio waves)
The receiver (a walkman or a radio telescope)**

The principle remains the same.

In this case we have:

**The source (the teacher)
The medium (email)
The receiver (the pupil)**

In each case there is also the MESSAGE.

**The MESSAGE is quite separate from the signal or datum.
The Message should contain Information.
Otherwise, as in writing it is just empty marks, scribbling on paper.
Many people can see the signal
but not get the Message.**

**They can see the notes written on the musical score,
but not hear the Music.**

**They can even hear the sounds of the orchestra
but not hear the Music.**

**The Message and the Music
are something separate from the Signal.**

**The Message and the Music
are something heard in the soul,
not in the ear or in the instrument.**

**For this reason some can pick up the Bible or Koran
or other Book of Revelation
and just have the words sing off the pages to them
while someone else will just see the smudges of words on paper.**

**The problem of lack of communication
rests in either**

**the Transmitter
the Medium
or the Receiver**

**In this case
the MESSAGE
comes from a perfect source.
If you do not GET IT
then the problem rests in**

**the Transmitter (the teacher)
the Medium (email)
or the Receiver (the pupil - YOU).**

**I shall do my best to communicate it to you,
but I assure you
the problem is not in the Message.**

**Peace and love,
Bruce Beach
DawnSayer@webpal.org**

POP09 - The Soul of Self

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**The first of the four types of souls
that I shall discuss
is the type that there are the most of..**

**This is the Soul of Self.
This type of Soul well loves God,
and is well beloved of God.**

**The possessors of this type of soul
are the very backbone and foundation
of society.**

**As with all types of souls
their strengths can become their weaknesses
if they are misused.**

**As with all types of souls
they have their preference as to type of religion,
type of employment,
type of enjoyment and association.**

**These souls delight in order,
and when properly trained and educated
are highly respectful of authority.**

**Every religion whether Christian, Moslem, Jewish,
or any other,
has branches (sects) that provides a haven for these souls,
just as they have branches
that provide havens for other types.**

Some may consider the Catholic church

**to be a monolithic sect
but it is not
and that is why there are many different Orders
within it
so as to provide havens for the different types of souls.**

**The same is true of every religious system
and since things are never black and white
but rather a continuum and spectrum
from the brightness of the noon day sun
to the darkness of night -
a spectrum that includes dawn and dusk,
sunrise and sunset,
there is naught that one can speak on
but that some will eagerly point out the exceptions.**

Birds fly,

but then so does the bat which is a mammal.

Fish swim, and live in the water

but then so does the whale which is a mammal.

**Those who would be argumentative
can always find some evidence to bolster their position.
Nothing is pure in this world.
All is relative.**

**All men contain some feminine characteristics,
and all women some masculine characteristics.
The brightest among us will have some intellectual blind spots,
the dullest will occasionally have a brilliant insight
whether they will recognize it or not.**

**Still we can distinguish noon from midnight,
and the cold of winter
from the heat of summer.
And in like manner
we can make the distinction between the types of souls.**

Although many organizations

attract several types of souls

**Within those organizations that attract a single type
there is often a division of activities
that still further singles out those with some degree
of the qualities found predominately in the other types.**

**By this latter, I mean, that in organizations
that serve those of the Soul of Self,
there will be some individuals who will still fill
administrative or creative functions
although these are not primary qualities of this type of soul,
but those individuals will have those qualities (in a mixed degree)
more than others in the organization.**

**In discussing this first type of soul,
I am also discussing some generalities that apply to all types.
One thing that should be noted
is that soul characteristics do not appear to be inherited,
like blood type or skin color.
Any couple may have offspring
of any soul type.
(Among my half dozen children and dozen grandchildren,
I have had every type that there is).**

**Thus comes the danger
of trying to force children into your own paths.
Though you may be musically inclined
a child may not be at all,
or vice versa - very inclined in that way
where you are not at all.**

**The examples that I could give in this regard
are so numerous, but also so obvious,
that I will not even begin to list them.
Nevertheless, so very, very often,
children are directed into paths that do not really suit them,
and consequently they neither find the joy in life that they might,
nor do they begin to fulfill the potential that they might
in another field.**

**The nature of a child
needs to be recognized at a very young age,**

**because the training to gain full potential
needs to begun very early.
Once the child has been forced into a path
unnatural to its proclivity
it has no choice but to mature in that path
the best that it can
because a full turn around
cannot be accomplished.
But that is the nature of our present world.**

**So much for generalities.
Back to the soul of self.
This soul, in its search for order,
seeks that order in its family,
its government,
its schools and education,
and its employment.**

**These souls can become skilled technicians.
Learning, knowing, applying
in great depth
the rules, regulations, formulas and details
of their disciplines and professions.**

**They also can find fulfillment
as craftsmen, merchants, tradesmen.
Our society, and all societies,
are very dependent upon their contributions.
Their employment is often as electricians,
and plumbers, carpenters, and mechanics.
Farmers and soldiers.
Indeed they are the backbone of the military,
filling the ranks
and the roles of the non-commissioned officers.**

**Unfortunately, souls of other types
can also be found in those positions.
They often do a satisfactory job,
but they themselves are never truly satisfied,
because the positions do not match and fulfill their needs.**

Community service clubs, and veteran's organizations

**have great numbers of members of souls of this type.
They most often have a very similar social and political outlook.
They would prefer to see more order in society,
and are often distressed (and angry) at the disorder that they see,
at the lack of obedience to established rules,
and the lack of conformity to the standards that they admire
and appreciate.**

**As I have stated before,
each soul can turn its capacities for good
in the opposite direction
and thus it is that we also find
the major occupants of our prisons
to be souls of this type.**

**In their misdirected pursuits
they often fill the lower types of bars
involve themselves as participants or observers
in the more violent sports.
Indeed their interests in every activity
from work, to entertainment, to sex, to diet,
can become oriented towards the most base and physical.
They make up the class of petty criminals,
and are the main statistic behind violent crime.**

Every type of soul likes

- **music**
- **food**
- **sex**

and participates in

- **family**
- **work**
- **employment**
- **religion**

and becomes a part of

- **society,**
- **government,**

- **war**

but the distinction can be seen in the varieties and types of responses between the various types of souls.

For each type of soul, there are types of music, food, entertainment, participation in government, religion, work and family, that are beneficial and specific to that type of soul, and there also other types of music, food, entertainment and so forth that are not beneficial.

In future discussion of other types of souls, I shall make some comparative references to the nature of this soul in regards to its search for Truth and also to some of the requirements for the spiritual training of this type of soul.

But, enough for now.

Next time on to the second type of soul.

**Peace and love,
Bruce Beach
DawnSayer@webpal.org**

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Four Souls Directory](#)

POP10 - The Soul of Love

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**The second type of the four types of souls
that I shall discuss
is the Soul of Love**

**This type of Soul loves God well,
and God well receives that love.**

**The possessors of this type of soul
breath the very spirit of life into society.**

**As with all types of souls
their strengths can become their weaknesses
if they are misused.**

**As with all types of souls
they have their preference as to type of religion,
type of employment,
type of enjoyment and association.**

**These souls delight in beauty,
and when properly trained and educated
help direct society in the path of compassion,
mercy, and justice.**

**These souls need to be trained
with particular tenderness and sensitivity.
As they mature they must be guided
in experiences that give them appreciation
of the qualities of the other types of souls.**

**These souls can become musicians,
poets and artists.**

**They are also a proper source for healers,
teachers, social workers,
and a wide variety of other occupations.**

**In misdirected pursuits
they create decadent music and art,
associate themselves with others
of weak moral discipline,
and misdirect society as strongly
as they might have morally directed it.**

**In future discussion of other types of souls,
I shall make some comparative references
to the nature of this soul in regards to its search for Truth
and also to some further requirements for the
spiritual training of this type of soul.
But, enough for now.
Next time on to the third type of soul.**

**Peace and love,
Bruce Beach
DawnSayer@webpal.org**

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Four Souls Directory](#)

POP11 - The Soul of Reason

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**The third type of the four types of souls
that I shall discuss
is the Soul of Reason.**

**This type of Soul seeks God through Reason,
and God showers great bounties upon it.**

**All men of course possess a rational soul,
as well as a soul with the capacity
for love and obedience.**

**What determines the type of one's soul
is the predominance of one quality.**

**Society as a whole possesses a collective soul.
I don't want to make a major philosophical point of this,
because I don't have a major philosophical point,
but we do appear to have a collective consciousness,
and a collective conscience.**

**Society as a whole goes through stages and cycles.
Maturing or retrograding spiritually.
Most people recognize that we are at the perigee
or low ebb in our present cycle.**

**But the stage of the maturation of
present day society as a whole
is approximately that of adolescence.**

**It is interesting to observe how
ontogeny recapitulates phylogeny
(that is to say how the individuals history
recapitulates that of the human race).**

**Yes, there is evolution,
but it is also true that man is a special and unique creation.
The purpose here
is not to get into the theological battles
that so greatly stir the emotions of some souls
but rather to make some observations.**

**Man (yes man - not some other creature)
began as a single cell in the sea,
and progressed through stages
of multiple cell division.**

**So also does each individual in his ontogeny
that recapitulates that phylogeny.
First as a single cell then as a multiple cell,
in a private sea,
that has the same saline content as the oceans.
And so shall we continue to ever find it
in our blood and our sweat and our tears.**

**Through progressive stages in the womb,
having states similar to that of the tadpole,
salamander, and other creatures,
the embryo travels the path of nature,
to obtain the human form.
At one time having this appendage,
and at another time that,
but growing on to what we are today.**

**In some percentage of births today,
the child is still born with a tail,
but the obstetrician simply separates it from the tailbone,
before sending the infant home.
But, what the physician sends home is a human child,
and such it was from the moment of its conception.
It was never going to grow into a rose or a tiger,
but always into that which it was conceived to be.
Thus it is that the argument between
the Creationists and the Evolutionists is irrelevant,
because while we evolve
we always are, always were, and always will be
what we were created to be.**

**And the race has continued to progress outside of the womb.
Color blindness has decreased
but centuries ago it was quite common
and in the time of the early Greeks almost universal.
We can tell this from their poetry
that under the bluest skies of the Mediterranean
that in their poetry they took no notice
of the azure blue of the skies
in distinction to the green verdure of the fields.**

**We know also that the knights of old were relatively short
to the warriors of the present day.
This is visible in the small suits of armor
still displayed in the castles of Europe.**

**Indeed, induction statistics, from the First World War,
to the Second and later conflicts,
tell us the same, about both these examples.
The race has been, and is, changing (evolving) physically.
But these are not the matters of import to us.
What we are examining here is the spiritual evolution of man.**

**The race as a whole,
and each individual also,
(through the rules of ontogeny recapitulating phylogeny)
follows certain paths of development.**

**And so it that an individual child,
first develops the qualities of the Soul of Self.
Seeks gratification in the physical senses,
and the obedience to authority,
the first word it probably making real use of
being the word "No".**

**The child soon becomes sensitive to emotions,
music and love.
How sensitive a child can be!
And then there begins to develop reason,
the prime facet of this third type of soul.
Psychologists have observed and mapped
the development of the reasoning faculty.
The degrees or relationship and abstractness,**

**that will be apparent in the child
at mental progressive ages of development
and in what order and stages.**

**Such is the development of every soul,
from the point of conception and its coming into existence,
on through to its maturity at around the age of fifteen.
Once mature, the soul continues to spiritually develop, or not,
through Seven Stages - through the choice of its will,
and the guidance of its teachers.**

**These seven stages of spiritual development,
recognized or unrecognized,
take place regardless of the religion to which one belongs
or the church of which one is a member.
But the Seven Stages are another subject,
and one that I shall not cover in this series,
for our purpose here is simply to discover the True Path
and the Source of the True Prophet
so that each one can unravel and discover the Mysteries of Life
for their self.**

**In this particular letter
it has been my purpose to describe
the third type of soul.
The possessors of this type of soul
provide guidance and reason to society.
While they are not so much its conscience
as those of the second type
they nevertheless are the providers of order
for all.**

**But as with all types of souls
their strengths can become their weaknesses
if they are misused.**

**And as with all types of souls
they have their preference as to type of religion,
type of employment,
type of enjoyment and association.**

These souls delight in reason and logic,

**and when properly trained and educated
help direct society in the paths of science,
and discipline.**

**These souls can become engineers,
lawyers, philosophers and theologians.
They are also a proper source for doctors,
teachers, lawyers, scientists of every sort,
both in the social and physical fields.**

**In misdirected pursuits
they lead humanity into materialism,
and greed and inharmony.
They can be the source of great benefit
or great evil, for they bear
the authority of control in society.**

**In the next and final discussion of the four types of souls,
I shall describe the fourth type of soul
and then go on in later letters to some matters about
the nature of the soul itself
and how it finds Truth.**

**Peace and love,
Bruce Beach
DawnSayer@webpal.org**

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Four Souls Directory](#)

POP12 - The Soul of Spirit

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

The fourth of the four types of souls may be called the Mystical Soul or the Soul of Spirit.

Those of the Mystical Soul, walk the Path of Intuition, and are potentially of the highest and most enlightened type. This type of Soul seeks God through Intuition, and God informs it of its relationship to God.

But the danger of this soul is that it can also most readily fall most deeply into the abyss of vain imaginings.

Substantial numbers of them used to inhabit our mental institutions, until the recent open door policy, and now they often wander the streets.

Among some I have as personal friends, is one who claims to be Jesus, another Sarah the Wife of Abraham. One believes that he is from Venus, (how many Venetians do you count among your friends?), and numerous ones have been UFO abductees and so forth.

The Mystical Soul is a Beautiful Gift, but oftentimes,

**I feel not one to be envied.
Nevertheless, among strange,
and even the irrational ones
they often have insights
that have often astounded me.
For this reason alone,
I count them as dear friends.**

**As a percentage of present day society,
about 60% are souls of self,
20% souls of love,
and 20% souls of reason.
I recognize that adds up to 100%,
and it is the "abouts" that make the difference,
because they leave some small percentage
that are the souls of spirit.**

**I myself am a soul of reason.
It makes no difference.
Each of us are what we are.
In a sense we are all born equal
- just different.
It does no good for one who is a male
to wish that they were female,
or vice versa.
Nor one who is of one race
to wish that they were of another.
We are what we are,
but all loved by God.
None of us will rise
to the full potential and opportunity
that God has provided for us
no matter what state that we are in.**

**The soul of spirit,
must travel the same paths to Truth,
as anyone else.
Those Paths are also Four,
and I shall describe them
in the following four emails.**

**The souls of spirit
have their particular gifts**

**and their particular hazards
like every other type of soul.**

**This is a particularly difficult
and dangerous time for them,
if they are living in the present day
because the darkness of the age
can easily mislead them.**

**They should properly be
the light unto the world,
but when they themselves are dark
then it is darkness upon darkness.**

**In their occupations,
they are often poets,
and some of the more successful,
(although they do not seem to often be successful,
by the world's monetary definitions),
have been in occupations like psychologists.**

**But, for the most part,
in the terms of this world,
they appear to be among the alienated.
Most of the alienated,
come from other types,
particularly the first type,
but nevertheless I have most usually,
found the Mystical Souls among them
as bag ladies, mental patients, hobos and transients,
sometimes living as hermits,
other times in communes, monasteries, and ashrams.**

**Likewise,
Be assured that most of the individuals,
in those situations and locales
are not among the Enlightened,
or even of this type of soul,
but we must be careful not to judge them
by the eyes of the world,
because God says that He leads them on their way,
and sees them with different eyes than we do.**

**There is of course much more that I could say
about these souls, and
there are many other things
that I might discuss with you
about the different types of souls
and about the nature of soul itself.
Many questions that people have
about the purpose of life
and life after death.
Indeed the questions would become endless.**

**However, as I have stated many times,
the purpose of this series is none of that,
but rather its purpose is to show you the Path
to the True Prophet
so that you may discover all those things
for yourself.**

**Until my next letter,
when we shall step forth,
on the first of
the Four Paths to Truth.**

**Peace and love,
Bruce Beach

Essays on the The Four Paths To Truth

by Bruce Beach

These essays are a continuation in the POP series which which were originally sent out in an email newsletter.

The intent of the series was is to lead the reader through such subjects as the nature of the soul and how it recognizes God through the Four Paths to Truth, and then on to presenting The Most Great Proof.

The essays presented here deal with nature of the search for Truth on the The Four Paths to Truth.

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at:

DawnSayer@webpal.org

If you wish to enter into a discussion with me regarding religion - I highly welcome that. I have some [religious premises](#) that I would like you to review first, and let me know regarding any about which you disagree to help me better understand any points that you are making.

POP13 - Authority

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**In this next four letters,
of the POP Series,
I am discussing
the Four Paths to Truth.**

**There are ONLY four possible paths.
Each and every type of soul,
must travel each and everyone of the paths,
if they are to find the True One.**

**The most used,
the most useful,
Path is
Authority.**

**This path
is the most beloved path,
of the Self Type of Soul,
and yet it must too travel
the other paths also.**

**And all the other types of soul,
must most certainly travel this path.
All souls learn over 90%,
way over 90% of what they learn,
through this path of authority.**

**If we were isolated in a closed room,
or were on an island by ourselves,
and had no teachers,
from the present or the past,
we would unlikely never even learn**

**how to turn the door knob or means
of getting out of the room or off the island.
So we are taught by authorities.**

**First it is our parents,
then our teachers,
and ministers and Sunday School teachers.
We learn from books,
and magazines,
and newspapers,
and the TV, and movies,
and many other places
that we hear people say things.**

**For the most part,
we do not have time to check it all out,
for ourselves,
so we most often separate conflicting opinions,
by asking the source,
and accepting the source we respect.**

**Who said that?
The doctor, the lawyer, the minister,
the teacher, our parents.
Ahh then, that must be right,
because they are our authority.**

**We can do no otherwise.
Even the doctor and pharmacist,
must rely upon the Pharmaceutical Book,
because they do not have time to go check out
the effect of every drug personally.**

**The Engineer must rely upon the Engineering manual,
because he cannot test the strength of everything himself.
EVERY profession relies upon its authorities,
whether medical, scientific, or religious,
because no one has time to check it all out,
for themselves.**

**I could go on at much greater length about
how AUTHORITY is so important as our source of Knowledge,**

**BUT, on the other hand,
AUTHORITY is the main block and obstacle,
to any new advances in knowledge.**

**EVERY new idea,
scientific invention,
discovery of a law of science,
is the repudiation of Authority,
which previously had said,
that it was not THAT way,
or otherwise the new idea is nothing new,
but simply the application of old existing principles.**

**So, there we have the First, and Foremost,
Path to Truth.
Authority.**

**Tomorrow,
the Second Path.**

**Peace and love,
Bruce**

POP14 - The Senses

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**Here now in the POP series
I am presenting
the Second Path to Truth.**

**Each of the Paths are preferred
by one of the Four Types of Soul.
But each type of soul
must travel each of The Four Paths.**

**The four paths develop in the individual,
somewhat in the progressive order
that I have named the four types of souls.**

**The second path is the path of the senses,
and is the one preferred by the Loving Soul.
It is expressed in their art and music,
in their love for nature and life
and yes in the expression of love called sex.**

**The senses are generally listed as five.
Sight, Sound, Taste, Odor and Touch.
If it were not for the senses,
we would be senseless.**

**Some are so convinced of this
that they think that when the body
ceases to sense,
we cease to exist,
or that we then become so nebulous,
as to be practically non-existent.**

But, that is another matter.

**In this world,
we test everything by the senses.
For the physical scientist
if it cannot be seen, or heard,
touched or tasted or smelled,
it does not exist.**

**Sometimes, oftentimes,
the scientist uses instruments
to extend his senses,
and there is no sense possessed
by humans
but that some kind of animal
possesses it 10 fold.**

**But no matter how refined the sense
or instrument
the senses can always deceive.
Examples can be given for each of the senses,
but I shall let one suffice here.
We look at the dawn or sunset,
and the sun appears to move,
but most people today believe
that it is the earth that is moving
and that the sun is standing relatively still.**

**Illusions, mirages, and their like are numerous.
No astronomer can see what is.
The observed pattern in the sky
is made up of light from the stars.
Some from stars at one distance,
and other from stars where the light left there
thousands of times earlier than from the first star,
but all the light arrives to the astronomer at the same time.
Not showing where it is,
relative to the other stars at this moment,
not even showing where it was,
in actual physical relation to the other stars,
of for that matter whether it even still exists,
but rather showing an illusion
of what could never have collectively been.**

This line of thought extends

**into the work of the physicist.
The psychologist knows that all we know
is perception in the mind.
So, while the senses are necessary to that perception,
we know that they are fallible,
and can never be considered
an infallible path to the Truth.**

**The world of sense
is what the Hindu religion calls Maya,
that is to say
the world of illusion.
In western philosophy and metaphysics
such as that of Immanuel Kant
it is recognized not to be the "ding ang sich",
"the thing in itself".**

**Advanced thinkers,
physicists,
philosophers,
all who strive to reach beyond illusion
from matter unto mind,
recognize the limitations of the senses
and the human mind.**

**While we could discuss this subject for hours,
and it is a very popular subject today,
our purpose here has been only to recognize
that the Path of the Senses,
is a fallible path
and that while we must travel it
we must still seek Truth elsewhere.**

**And thus,
tomorrow,
on to the Third Path.**

**Peace and love,
Bruce
DawnSayer@webpal.org**

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Four Paths Directory](#)

POP15 - Reason

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**In this POP Series,
I have so far discussed
Authority and the Senses.
What else is there?**

**Reason.
The beloved path of the third type of souls.
The Reasoning Souls.
One can figure out the truth by REASON.
REASON is God's GREATEST gift to man.
It is what most distinguishes man from the animals.
His ability to hold and manipulate abstract thoughts.**

**But, reason is only logic.
Like found in a computer.
Give a particular set of premises,
it can prove anything that follows from those premises.**

**However, human reasoning is not even as good as machine reasoning.
It is often faulty.
Given the few rules of a chessboard,
which is limited to 64 squares,
look at how often humans make mistakes,
in playing chess.**

**Life is MANY, MANY, MANY times
more complicated than a chessboard.
There are a great number MORE parameters,
so when we go to reason about economics,
politics, religion, or any thing else of this world,
we are much more likely to make a mistake.**

**And we make mistakes all the time.
Look at a computer program.
Very few rules as compared to life.
Yet how often is a computer program
of any length written with out bugs?
Just bugs regarding the computer rules,
so that it will not run at all.**

**And then there are very often bugs
regarding the purpose of the program itself.
Reasoning is often very inaccurate.**

**But the real problem is that
even if it is accurate,
it depends upon the premises with which it begins.**

**So, Reason Alone, is not a sure guide to the Truth.
Indeed, while it is God's greatest gift to man,
it is VERY fallible.
Thus we are left with the
Fourth Path.**

**And that tomorrow.
Peace and love,
Bruce
DawnSayer@webpal.org**

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Four Paths Directory](#)

POP16 - Intuition

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

Now in the POP Series
we come to The Fourth Path to Truth.
It is the chosen path of the
of the Fourth Type of Souls.

We can call it by many names -
Testimony of the Holy Spirit,

- Conscience
- Inspiration
- Intuition
- Enlightenment

or any one of its many other attributes.

It is the BRIGHTEST Path to Truth.

Without this Divine Spark,
no discovery,
religious or
scientific
can be made.

Without it,
the processing of reason
and the human brain
would be as dead
and unimaginative
and uncreative
as a computer or
any other machine.

**Every scientific discovery,
every advance in human thinking,
comes from In-sight,
sight from with-in.
Sight from beyond,
beyond the boundaries,
that existed before.**

**That Divine Spark
rests within each of us,
so long as we breath,
and have life.**

**Every student of mathematics,
draws upon it to initially comprehend
that $2+2=4$, or any higher concept.
For every learner,
each and every concept,
comes as a new insight,
a new manifestation of the intuitive.**

**This power of the mind,
soul,
like all others
is developed through practice.
The power of reasoning,
using the brain,
like any other muscle,
must be developed through exercise.
The storing up of knowledge,
from authority
does not come in a minute.
All the skills of the senses,
being able to sing
like an opera star,
or observe
like a diagnostic physician,
or to listen, or feel,
require a degree of training
that most never master
or even realize exists.
Most particularly is this true
of man's highest mental capacity,**

intuition.

**Concentration,
Contemplation,
Meditation,
are skills still largely undeveloped,
in the majority of mankind.
Yet, these are the disciplines needed
to develop intuition.**

**It seems to come
unheralded and unbidden,
but be assured
never to the unprepared.**

**Intuition is the brightest,
most joyful,
most beautiful path to Truth.**

**And yet,
intuition is the DARKEST,
most misleading,
path of stupid superstition
and vain imaginings.
In this path,
as many are led astray,
with the possible exception of
authority,
as in all the others combined.**

**As great a barrier
as may be the senses,
with its false sense of reality,
and its inducements of idle pleasures,
As faulty as man's reasoning
may ever be,
intuition alone can sweep the soul
into the paths of error
with a degree of confusion
from which only by the
Grace of God
will one ever be recovered.**

**For it is intuition
that whispers into the ear
of every convinced believer,
ONLY my truth is real,
all the others are false.
Only you are safe and saved,
all others have gone astray.
But reason stays its claim,
because how can there be
so many different claims
to be the one and only truth?**

**And so,
we have examined the
Four Paths to Truth,
and have found none
to be infallible.
Some would say there is
a fifth path.
The eclectic path
of combining all four.
But while this is the proper thing to do,
and the SUREST path,
it too still remains fallible.**

**And so,
in the human condition,
we remain BELIEVERS,
NOT KNOWERS
of ABSOLUTE CERTAINTY.**

**And so,
some become discouraged,
and say,
since I can know nothing
of a certainty,
I will believe nothing.
I will be a skeptic
and a scoffer.
Let others be subject
to their idle fancies
and vain imaginations,**

**I will remain steadfast
in my knowledge
that they can know NOTHING.**

**But, my dear friend,
THAT is the path to DEATH,
UNBELIEF,
Dissolution,
and Chaos.
Nothing becoming nothing,
yielding nothing,
attaining nothing.
Nothing.**

**Every Vibrant Soul,
must grasp reality,
as it is presented to us.
It must travel each
of the Four Paths
to the best of its ability,
and remain always open to change,
in recognition of the fact that it
is fallible.**

**For this is the Path of Power
of both Science and Religion.
Building upon the Four Paths,
and discovering reality,
TESTING it,
USING it,
Re-examining it,
Improving upon our comprehension of
IT.**

**For while our feet remain anchored
in the mud and morass of DOUBT,
our spirits soar upon the
Paths of Truth.
Building bridges and skyscrapers,
traveling to stars,
observing the Macrocosm
and the Microcosm,
evidencing the Power of**

Accomplishment.

**And then,
we have it upon the Best of
Authority,
from those Divine Prophets,
that if that soul asks,
it Will receive,
if that soul knocks,
it Will be opened unto it,
and THAT seeker
will be guided from shoals
of insecurity and Unbelief,
to the secure safety of the bay
of Belief in God,
and that which He has Revealed.**

**Thus have I concluded
my explanation of
the Four Types of Souls
and
the Four Paths to Truth.
In my next letter
I shall proceed onto what is called
The Most Clear Proof
in our journey to discover
the Source of Truth
and
The True Prophet.**

**Peace and love,
Bruce
DawnSayer@webpal.org**

Essays on the The Most Clear Proof

by Bruce Beach

"The Most Clear Proof" as presented here in a continuation of the POP Series which was originally a series of email essays whose intent was to lead the reader through such subjects as the nature of the soul and how it recognizes God through the Four Paths to Truth, and then on to presenting The Most Great Proof about who Jesus really was.

In these essays we examine some tests for reality and sanity. And a different paradigm regarding location and time than you were taught in school - plus the definition of "Manifestation", which is key and most difficult concept to comprehend.

The concepts presented here completely changed my world view and the world view of many others who took the time to master them. I hope that you will take the time to carefully study through these 14 essays. Some are just a matter of reading them. Others among them take careful thought and calculation. You need take out pencil and paper and "do the numbers" for yourself.

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at:

DawnSayer@webpal.org

If you wish to enter into a discussion with me regarding religion - I highly welcome that. I have some [religious premises](#) that I would like you to review first, and let me know regarding any about which you disagree to help me better understand any points that you are making.

POP17 - Most Clear Proof - Introduction

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

Intro to the MCP

**This is an introduction to the Most Clear Proof.
I am going to pause here a moment
and recap where we have been
and to map out where we are going.**

**First I described the Four Types of Souls
and invited you to introspectively determine your type.
This is important so as to understand
how and why you will make the responses that you do
on the journey to Truth.**

**Secondly, we described the Four Paths of Truth,
and saw that while each of them are fallible,
that we must use each of them
on the journey to Truth.**

**What I am going to do now will be a shock
to many of my non-Christian readers.
If you subscribe to a New Age Religion
or No Religion,
please follow, nevertheless, what we are going to do.**

**Almost all my readers were raised in a
"nominally" Christian culture
and therefore you will have no problem
in following the presentation
if you will just make the effort.**

**What I am going to present is a
mathematical proof**

**that Jesus was (is) the Christ
and that the Bible is a reliable source of prophecy.**

**This is not going to hurt you in any way.
Do not be afraid -
I am not trying to turn you into
a flaming Fundamentalist.
Believe me, I get flamed many times a day.**

**As traumatic as you may feel
that such a change in viewpoint
might be for you,
you may rest assured
that the things to follow
will be even more of a challenge
for our Christian Friends.**

**The growth in Truth is
always a challenge
for all of us.
Myself included.**

**After the mathematical proof
about Jesus
we will take a small pause
and look at the
Three Spheres of Reality
used by psychiatrists
to determine whether one is sane or not.**

**From there we will pass on to the
New Paradigm
that will undoubtedly completely change your life
if you comprehend it and accept it.**

**It is on the basis of that paradigm
that I have my own expectations
about the future.
At that point you will understand
why it would have done no good
to explain to you the source of my expectations
without your having understood the paradigm.**

**To begin the journey,
I am going to ask you to read two chapters
in the Bible.
This is not a terribly arduous thing to do.
If you don't have a Bible,
they aren't hard to come by in our society.
It really makes no difference which version you use.
I was raised on the old King James Version -
but whatever you have or get will be fine.**

**The two chapters that I wish you to read are:
Matthew 24
and
Daniel 9**

**We will start into this next time.
Not verse by verse,
but on a mathematical thread.**

**If you follow it through
I can promise you that it will be an experience
that you will remember the whole of your life.**

**How many things can you remember from the past,
that were truly significant to your life
and that you will never forget.
On the other hand,
how many TV shows, Movies, Books,
conversations, events and so forth
have you forgotten.**

**Then take the time,
to do something that will be so significant in your life
that you will never forget it.**

**Till tomorrow,
peace and love,
Bruce
DawnSayer@webpal.org**

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Most Clear Proof - Dir](#)

POP18 - Most Clear Proof - Numbers

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

In the POP series we are now going to examine the math used in the Bible.

Matthew 24 is possibly the single most read chapter of the Gospels among Christian's today, possibly surpassing the Sermon on the Mount and the Christmas and Resurrection stories.

The reason for this is that it is the chapter in which Jesus prophesizes His return.

In the opening verses the Disciples come to Him and ask Him

"What will be the signs of His Return".

And He answers them, and among those answers is the directive to read and understand The Book of Daniel. (Matthew 24:15)

This was what brought us to the Book of Daniel.

A remarkable Book in itself, and containing many interesting prophecies, particularly about "the Time of the End".

However, our purpose here, is not to examine such prophecies, but rather to show mathematical proof that Jesus was (is) the Christ, and that the Bible is an accurate source of prophecy.

Later we shall use the same mathematical techniques in a much more remarkable way

**and to a much more remarkable degree
to look at other prophecies in the Bible.**

**The reason that we are using the Bible
is because it is the cultural underpinning
of most of you readers
whether you consider yourself Christians,
or even religious, or not.**

**If we were in another culture
such as Hindu, Moslem, or Buddhist,
then we would use the Scriptures of THAT culture,
because the TRUTH that we are examining is universal.
But we are in THIS culture
so we will use THIS cultures Scriptures
to restore an appreciation of the Spiritual Foundation
that underlay this culture but which has become
temporarily weakened.**

**The basis of time translation in interpreting Bible prophecy is
well established. The basis of using a day as a year comes from
Num. 14:34 and Ezek 4:6 and that a week is seven days is of
course based upon the Creation account. The fact that an average
month is thirty days is found in the account of the flood.**

**If you wish to confirm to yourself such a detail you can look at:
Genesis 7:11 and you will find mentioned there
the Second Month and the Seventeenth Day of the month
and later in
Genesis 8:3 there is mentioned 150 days
and immediately after in
Genesis 8:4
the Seventh Month and the seventeenth day of the month.**

**Consequently the above covered a period that was EXACTLY 5 months to the day, (7 months
minus 2 months equals 5 months)
which divided into the 150 days gives us an AVERAGE of 30 days per month.
(5 divided into 150 = 30).**

**The point of all this is NOT to convince you to believe in the story of Noah and the account of The
Flood,
but just to show you the NUMERIC Integrity of the Bible and the system that we are using.**

The math that we will be using is no more difficult than this, but with the following I will conclude today's presentation to allow you to absorb the math up to this point.

It is important that we do this in a step by step fashion.

Leave out a step

and the end result will be questionable.

Comprehend them all and it will be unquestionable.

Okay, our formulas are as follows:

- **a. 1 day = 1 year**
- **b. 1 week = 7 days = 7 years**
- **c. 1 month = 30 days = 30 years**
- **d. 1 year = 12 months = 360 days = 360 years**
- **e. dividing of time - 1/2 time**

a. comes from Numbers 14:34 and Ezekiel 4:6 as mentioned above and is referred to as "prophetic time". Some people refer to references that a 1000 years is as a day for the Lord. This latter does have a scriptural and spiritual meaning but when used in the formulas gives lengths of time so long as to be meaningless to our human experience. Consequently, we use the calculation that a Prophetic Day is a year.

b. comes from the Creation account of the 7 days of creation, and that on the 7th day the Lord rested. Without getting into any arguments about whether that was Saturday or Sunday it is still the source of the week having 7 days in our culture.

c. the calculation to determine that an average month, or a Bible Prophetic Month has 30 days has been given above in the account about Noah and the Flood with the appropriate Scriptural References.

d. The determination of "d" derives from "a" and b and "c" above. That a Prophetic year is 360 Calendar years is simply an extension of the above math. If one Prophetic day = one year and a month is 30 days a Prophetic month is therefore 30 calendar years and the 12 months in a year are therefore 12 times 30 or 360, which is to say that there are 360 Prophetic Days or 360 calendar years in a Prophetic year.

e. this is an equivalency example which we will examine in its proper place.

**To repeat,
the purpose here,**

**has not been to convince anyone of any of the Bible Stories,
but rather to simply show the integrity and consistency of Bible Math.**

**Tomorrow -
an application of these principles
to begin to demonstrate by this math
that Jesus was the Christ.**

**Peace and love,
Bruce
DawnSayer@webpal.org**

POP19 - Jesus

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

One of the most amazing things about Bible Prophecy is the prediction of the re-establishment of Israel. Futurists today have difficulty making predictions 50 years into the future.

Look at these:

"Computers in the future may weigh no more than 1.5 tons."
- Popular Mechanics,
forecasting the relentless march of science,
1949

"I think there is a world market for maybe five computers."
- Thomas Watson, chairman of IBM,
1943

"I have traveled the length and breadth of this country and talked with the best people, and I can assure you that data processing is a fad that won't last out the year."
- Editor in charge of business books for Prentice Hall,
1957

"But what... is it good for?"
- Engineer at the Advanced Computing Systems Division of IBM,
1968, (commenting on the microchip).

"There is no reason anyone would want

a computer in their home."

**- Ken Olson, president, chairman
and founder of Digital Equipment Corp.,
1977**

**"This 'telephone' has too many shortcomings
to be seriously considered
as a means of communication.
The device is inherently of no value to us."
- Western Union internal memo,
1876**

**The prophecies in the Bible,
that many people are concerned about
being fulfilled today,
were made MANY CENTURIES ago.
Is it possible
that there can actually be this kind
of accurate prophecy?**

**And yet, there in the Bible
was the Prophecy and Promise for the Jews
that they would return to Israel and
it came true CENTURIES later.**

**I am going to tell you now about another prophecy
that was made to the Jews
centuries before it came true.**

**Prophecy and the Prophetic Times associated with it
are difficult for many people to see,
and therefore
many people do not recognize its fulfillment
even when it has occurred.**

**Such was the case with Jesus.
He claimed to be the Messiah promised to the Jews.
In fact that was the BASIS of His claim to fame.
If He was not that ONE then,
so far as they were concerned,
it made no difference who he was.**

But, for TWO THOUSAND years the Christians were not able to prove to the Jews who Jesus was while the mathematical PROOF lay RIGHT THERE in the Jews' own Book of Daniel.

This is the reason that we are examining the 4 verses in

The Book of Daniel 9:24-27.

It is surely not too much to take and comprehend

four Bible verses.

(Read them for yourself - as Jesus commanded).

**Verse 24 mentions 70 weeks
comprised of in
Verse 25**

**7 weeks
3 score weeks and
2 weeks and**

Verse 27

**1 week
-----**

**Everyone should know,
from the Abraham Lincoln's Gettysburg Address -
"Four score years ... ago
our fathers brought forth on this continent....."**

**that a score is 20
so 3 score is 60.**

What we have therefore is:

**7 weeks
60 weeks
2 weeks
1 week**

70 weeks total as stated in Verse 24.

**"Seventy weeks to seal up the vision and prophecy
and to anoint the Most Holy"**

70 weeks

x7 days is of course

490 days in Prophetic Terms,

(or as we discussed last time)

490 calendar Years

**To measure a time, one must know from where to begin
and verse 9:25 tells us that this time begins from:**

**"the going forth of the commandment
to restore and build Jerusalem".**

**That historical date you can obtain
from a number of different sources.
Some encyclopedias
(especially Bible encyclopedias)
or the marginal notes of some Bibles,
or other similar references.
(I have looked it up in many places.)**

**The event is referenced is in Ezra 7:13
and most scholars (Christian, Jewish and otherwise)
agree that it occurred in 457 BC.**

**The prophetic date of 70 weeks is broken up into blocks.
Basically, if we look at 69 weeks
plus the one last week
we can see the dates that interest us.**

69 weeks

x7 days is

483 Prophetic days or 483 calendar years.

483 calendar years minus

457 BC takes us to:

26 AD (or 27 AD depending on how you count in the zero year).

**Again a Bible Reference will tell you
that this is when Jesus began His ministry.
(He was born in 4 BC and 26 plus 4 makes Him 30 years old -
when He began it,
which is the age, under Rabbinical Law
that a man could become a Rabbi or Teacher).**

**Again look in a reference and you will find
that Jesus was crucified 7 years later in 33 AD
Seven years is the same as one Prophetic Week
and this means that He fulfilled the Covenant (The Promise)
to the Jews for one week
and just EXACTLY at the TIME
as the Scriptures had prophesized.
(Do read the whole 4 verses in Daniel -
the tell about the Messiah being cut off -
but not for Himself -
because He was a sacrifice for the whole of mankind).**

**But down through the centuries,
the Christians were never able to show this prophecy,
to the Jews,
because as The Book of Daniel says,
it was a SEALED BOOK
and the MEANING was not opened
until the Time of the End.**

**That too is an interesting story -
but for next time.**

**There are many details about this prophecy
that I could talk about for hours.
In fact I used to conduct courses on it that took weeks.
But we are not going into details here.
The following is a chart that I have made up to give you
an overall view.**

Ezra 7:13

457 BC

Dan 9:25 | 7 weeks 408 BC completion of rebuilding

| (49 years)

Dan :25 | 7 weeks & 62 weeks = 69 weeks 26 AD John

| (49 years) & (434 years)= (483 years) the Baptist

Dan 9:27 | 69 weeks & 1 week = 70 weeks

| (483 years) 7 years=490 years

Dan 9:24 | 70 weeks 33 AD

| (490 years) Christ

The Prophecy of the Time of Christ

Peace and love,

Bruce

POP20 - 2300 years

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**So, there was mathematical proof for the Jews,
all along,
that Jesus was the Christ.
But they never saw it,
and they never accepted Jesus for other reasons.**

**The reasons are listed in the New Testament,
and they are many, many.
Basicly, He did not fulfill their expectations.
They had THEIR tests
and He did not meet them.**

**Of course they said that their tests
were from Scripture
and that since He did not fulfill them
that He was a false prophet.**

**Just as the Jews expected their Messiah
to come and Establish an Earthly Kingdom
so too today
do the Christians expect Him to come and set up a throne
where every knee shall bend and every tongue shall confess,
in some similar earthly fashion.**

**Just as the Jews expected a time of Milk and Honey,
so do many Christians today
expect a Millenium of a Thousand Years of Peace
with Lions literally lying down with Lambs.**

**Some then and now expected phenomena
similar to what is called the Ressurrection,
or Rapture,**

or other Marvelous Miracles.

**They had then,
and Christians have now
quick little tests -
Is the person claiming to be The Return**

living or dead

**- some Christians require
that He comes down from heaven
with nail prints in His hands,
and that He not be buried anywhere.**

**The Jews had believed that Elijah,
(who the Bible said had never died but had been translated),
would come first.**

**"Where is Elijah, (who was to come back down from heaven),
they asked."**

"John the Baptist", said Jesus.

"Can't be - he was born of a woman", they replied.

Where did you come from, they asked Jesus.

Nazareth.

**"The Book says no good will come out of Nazareth',
said they, quoting their Scripture.**

What happened to Jesus, they asked for centuries later.

Crucified.

**"Only those accursed of God are crucified", said they,
again quoting their Scripture.**

**And for century after century,
the Rabbis pointed out,
that the promise of the Messiah, their saviour,
was that:**

**He would gather the Jews together,
"as a mother hen gathers her chicks"**

as promised in Isaiah.

**But the very opposite happened.
At the time Jesus came,
the Jews WERE together in Israel
although under Roman prosecution
and then they were banned from the country
and never allowed to return again
until the Edict of Toleration was given
in 1844.**

**So what other proof would a young Jew need
from his rabbi,
that Jesus was not his Messiah,
not the saviour of the Jews.
But the rabbi could and did present him
with much more proof and evidence.**

**And now this story takes a strange, strange twist.
Because in the last century their grew up
among the Christians and Moslems
what was called
The GREAT Expectation
about the Return of Christ.**

**These numbers that I am telling you about
became WIDELY known.
There is evidence that they were first developed by one
whom many even today recognize as the greatest scientist
the world has ever known. - Isaac Newton.
His literary assistant, Edmund Halley,
discoverer of the periodicity of comets
and after whom Halley's Comet was named
contributed much to the authenticating of calendars.**

**As a result of these numbers,
many, many people began to expect the return of Christ,
in a particular year.
That year was 1844.
They arrived at that number because if one takes the verse -**

Daniel 8:14

**And he said unto me,
Until two thousand and three hundred days;
then shall the sanctuary be cleansed.**

**[We are not dealing here with how these verses
have been interpreted
or might be interpreted
but as before are only interested in
the mathematics and the dates.]**

**This date, and using the same starting point as we used before,
yields -**

**2300 Dan 8:14
-457 B.C.

1843 A.D.**

**1844, rather than 1843,
is taken as the year of the GREAT EXPECTATION
and the Great Disappointment
for the return of Christ.
There are several reasons for this.
One is that there is no year zero.
The other reasons are the differences between lunar
and solar calendars so that 1843 actually ends in 1844.
And still other explanations are given
as to which month in the year actually begins the year.**

**[It used to be that New Year's Day was in March.
A quick proof can be given.
The fifth and sixth months
were changed to the names July and August
after the Roman Emperors Julius and Augustus Caesar.
Sept means seven and hence September.
Octo means eight and hence October.
Like in octave, octogon or octopus,
an eight legged sea creature.
Novem means nine and hence November.
Deca means ten and hence December.
Like in decade, decalog and even decimal.
January was the eleventh month**

**but was renamed in honor of the Roman God Janus.
February was the last month and this is why
we always put any extra days of a year,
like in a leap year, or leap century,
at the end of February.
So the new year begins in March.
Actually on March 21st, at the Spring Equinox.]**

**Prior to 1844 there were many millennialist groups.
With the possible exception of the year 1000
there had never been such intense expectation
in Christendom at one single time.
But the really phenomenal matter is
that similar expectations were
equally intense at that time in some Moslem sects.
Today, the Seventh Day Adventists,
the Latter Day Saints
(hence these two groups' names)
and some fundamentalist groups
still maintain that interest.
The interest was not by any means confined
to either Protestant Christianity
or the United States.
Both the Christian Templars from Germany
and the Carmelite nuns went to Israel
prior to 1844
in expectation that Christ would appear there in 1844.**

**The single largest and most active group
in the United States,
with the possible exception of the Latter Day Saints,
was the Millerites,
the predecessor of the Russelites, Bible Students,
Millennial Dawn, and Watchtower,
all synonyms for the Jehovah's Witnesses
which took the latter name in 1931.
Their disappointment
in the original 1844 expectations
led them to formulate a new date of 1914,
about which their literature still
concedes "wrongful expectations".**

**The thesis here is that
Christiandom's original interpretation (expectations)
of the dates were absolutely correct,
just as were the Jewish interpretations (expectations)
for the first quarter A.D..
What was wrong was the nature of their expectations.
1844 was again a repeat of what happened
in the first century of the Christian Era.**

**But enough for one letter.
Perhaps too much.
God willing, we shall continue again tomorrow.**

**Peace and love,
Bruce

POP21 - Year 1844

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

Yesterday's presentation was so paradigm shaking that many undoubtedly could not believe what was said.

That the 1844 GREAT EXPECTATION of the Christians was fulfilled and that Christ returned.

However, the Christians failed to recognize The Return just in the same way and practically for the same reasons as the Jews failed to recognize Jesus at the beginning of the first century.

Many Christians would say, "Well, if it didn't make any more difference than that - if my expectations about rapture, the graves opening, and the Kingdom of Heaven on Earth, were not any more fulfilled than that it doesn't make any difference to me."

Just as many Jews said, "Well if that is the way it turned out for God's Chosen people and we ended up being booted out of Israel and going through the Holocaust at the hands of a nation that called itself Christian - then who needed Him?"

To answer some quick questions:

"Where did Christ return?"

In Persia.

"When?"

1844

"What was His Name?"

The Bab, Meaning the Gate

or Forerunner,

declared Himself on May 22, 1844.

"Where is he now?"

He and His Successor,

Baha'u'llah are buried near each other

at Mt. Carmel in Haifa, Israel.

"How many people know this?"

**There are now over 10 million Baha'i's
world wide.**

**There is much more
that can be said about Them.
Particularly regarding Their prophecies
for the present and future.**

**But I realize that this paradigm
is so shaking
I shall pause here for my next 3 POP emails
while many go screaming for the exits
quoting the same kinds of quotes
as were quoted about
Jesus' appearance at the first century.**

**So a pause or intermission to allow a mass departure,
and during which we will examine
the Three Tests of Reality
used by psychiatrists to determine if a person is sane.**

**Because I am sure that many will wonder how
a sane person can believe that Christ has returned.
But you must remember that this proof started out
for those who did not particularly believe
in Christ and the Bible
in the first place
although they had been raised in a Christian culture.
Our purpose was to raise their confidence in the Bible**

**as a source of Prophecy
through this mathematical proof that
Jesus was the Christ.**

**After the following 3 letter intermission,
we will return to SIMPLER but even more astounding,
indeed,
MUCH MORE ASTOUNDING mathematical prophecies
from the Bible
that have gone TOTALLY unrecognized by the Christians.**

**Eventually, I will explain and summarize
the paradigm upon which all this has been based.
Those who can comprehend and accept that paradigm
will then be able to comprehend
the nature of the prophecies
that I have mentioned before
but have not been able to present
because people knew nothing of
the paradigm upon which they are based.**

**Peace and love,
Bruce
DawnSayer@webpal.org**

POP22 - Responses

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

A slight detour.

I have decided to share with all of you four responses that I have received and my answer to two of them.

I have selected these as being typical of quite a number.

I also very much appreciate the affirmative responses I have received. They mean a lot to me.

From D.

It has been interesting to know your views over the past 2 years. As you expected, many will leave your list after your last mailing. I choose to be one.

I feel that you have been deceived with one of many false messiahs that the Bible prophesied would be appearing during these last days. I hope and pray that your eyes will be opened to the fact that JESUS will appear again just as he said and will take his church to be with him. I believe it will be very soon. Trust in Him only for the forgiveness of your sins and then I can look to meeting you in heaven.

From K.

To save me from deciphering anymore of you paradigms let me cut straight to the point....do you believe that Jesus was/is the Son of God...and am I to understand that you believe Jesus returned in 1844 and is now dead and buried at Mt. Carmel.

My Answer to K.

**The questions that you ask K,
are impossible to answer to you meaningfully.**

**That is the point of a paradigm.
It is a view of the world.**

**Someone who lived in a very hot country
and who had never heard of or seen ice
would find miraculous
the story of someone walking across a river.
The explanation that it had frozen
would be incomprehensible to them.**

**Likewise would be the explanation
to someone who had never seen or heard of a microscope
that the small little bugs that were harming them
were not really invisible
or some type of evil spirits.**

**Your statements
that you want to understand the answers
but not understand the paradigm
would mean that the answers would seem
impossible
ridiculous
illogical
or otherwise out of touch with reality.**

**Whereas, as in the above examples,
a new paradigm gives one a higher sense of reality
and permits them to understand things
that they have not understood before.**

**A new and higher paradigm
explains all that was believed before
and explains WHY it was believed in that way before.**

**As regards Christ Jesus,
the problem with the Christian view
is that Christians have too small a view of Him.
You may think this a strange statement
when you think that you put Him at the center of everything,**

**Preceding everything, the Purpose of everything.
But the statement remains true - too small a view.
But you cannot know what I mean -
without a paradigm shift.**

**Paradigm shifts are as necessary in Religion as they are in Science.
In Science, the Einstein Theory of Relativity was a Paradigm Shift.
The very idea that two parallel lines could meet,
or that a clock traveling in space at a high rate of speed
would reflect that Time had slowed down,
or that light could bend when passing a large gravitational lens or sink,
such as our sun,
or a variety of other such phenomena (he had five proofs)
was a paradigm shift that many still do not understand.
It has not penetrated the consciousness of the man on the street.
Still, for those scientists who have grasped it,
it has permitted the development of atomic and nuclear energy,
new methods of constructing materials used in electronics and computers,
calculations for space travel and explanations for phenomena of astronomy,
and other control over our physical world
that did not exist before.**

**The Einsteinian Paradigm did not destroy the Newtonian Paradigm.
It merely provided a HIGHER explanation and showed the latter
to be a SPECIAL case.
Many of my readers believe that Science deals with relative knowledge
but that religion deals with absolute knowledge.
However, they are wrong.
God's REALITY is ONE.
Science and Religion are the TWO wings of the One Bird,
seeking to explain the ONE REALITY.
That Reality is Absolute,
but because God is Infinite
our understanding is always relative and can always become greater
through REPEATED Paradigm shifts,
so one may as well get used to it
or they will stop growing through eternity.**

**Do you know what the one unforgivable sin is?
It is blasphemy against the Holy Spirit.
This does not mean taking the Name of the Holy Spirit in vain
like we hear many people use the word God or Jesus,
but they don't use Holy Spirit in that way**

(although some Batman followers would try in saying - Holy Smoke).

**No, this means failure to listen to the Holy Spirit.
That is to say
failure to listen to the small calm voice of Truth.
But rather to remain dogmatic and argumentative.
With that attitude then one cannot ever understand the Truth.
Although one may be in error
so long as they are willing to examine with an open spirit
something new that is presented to them
then they can eventually learn to better know the Truth,
but if they close their mind
and won't listen and examine
then they will never find the Truth
and that is why Jesus said blasphemy against the Holy Spirit
is the one unforgivable sin.**

**It is time for you to examine
and to try to comprehend.
When you understand the paradigm
well enough that you can explain it to someone else
then you can say that you understand it.
Until then you are criticizing that which you do not understand
and you have no basis for comparison.**

**I have looked in both the boxes.
I know that what is in both of them is very good.
But having seen in BOTH of them I can make a comparison.**

You need to be able to do the same.

**These communications from P
who was apparently forwarded the Four Paths
but I am not certain that they were read.**

The First Path

There is Only ONE PATH and that is Jesus Christ, and his One holy and apostolic Church. Outside the Church there is no salvation. Today the Church

is hard to find so one may say the only ark available is Mary His Mother who does know the way to His Church. P.

The Second Path

All of this is outside the teaching of the one holy and apostolic Church. Outside the Church there is no salvation. The easiest way to the Church today is through Mary and the Rosary. None else is needed. P.

The Third Path

Reason is subject to Grace. Grace of God not reason is the greatest gift God has given to men. Without grace, reason is what made Eve and thence Adam take of the forbidden KNOWLEDGE tree. P.

The Fourth Path

All of this ... comes from the tree of knowledge that was forbidden to Adam and Eve. It begets PRIDE THE ULTIMATE SIN.

Reason must be subject to Grace, or faith in Jesus Christ and His Church.. NOTHING ELSE IS NEEDED FOR SALVATION. OTHER THAN TO REMAIN A LOYAL AND FAITHFUL SUBJECT OF JESUS AND HIS CHURCH.

The most foolish or unintelligent man, the most unreasoning and humble being, the man of simple faith, THE CHILD is the most assured of heaven. P.

My Answer to P.

Dear P.

Your responses show that you believe that there is really only ONE PATH to Truth, that which has been identified in these four essays as The Fourth Path which you would call the Path of Grace, or others might call the Path of the Holy Spirit, or they might call it by some of the other many names besides those that were listed in the essay.

**Still, the fact abides,
that you have gotten most of your knowledge,
and that upon which you base your beliefs
comes from AUTHORITY
in this case much from the Bible
and what you call the
One holy and apostolic Church.**

**Your type of thinking is what I refer to as Fundamentalist thinking.
It is often reflected in what I have, in discussion with others,
identified as "black and white" thinking.
Very often it is referred to as Dogmatic Thinking.
Dogma simply means the Teaching of some Authority.
In your case what you call the One holy and apostolic Church.
This type of thinking is not, however, restricted to any one sect,
or even any one religion
(it could equally well be Christian, Moslem, Hindu, Buddhist or other)
and most definitely does not need to even be restricted to religious belief,
as demonstrated in my following response to the following correspondent.**

**The following correspondence is from F.
Who has only heard about our discussions
and has never received copies of the Four Paths.**

*Why am I not at all surprised that another proponent of prophecy
"fulfillment" refuses to defend his positions in an open public forum? You
are all alike. You preach to the choir and hide from having your absurd
claims answered by an informed opposition.*

*I have a point to contribute that you may want to consider now. Neither you
nor anyone else can prove a single, verifiable case of prophecy fulfillment.
If you ever find the courage to put your faith where your mouth is, please
contact me. I have an internet forum where the debate can be published.*

My answer to F.

**Can you not see that you are bitter and angry,
and not open to calm and reasonable discussion.**

When you make prejudiced and judgmental decisions like -

"You are all alike."

**When you have never even examined this paradigm,
and have no idea what it is like.**

Or that I am even alike in that I

"preach to the choir"

**because the audience that is being addressed
has absolutely no knowledge of the paradigm either.
Most of them will be resolutely opposed also
because it does not come from a Fundamentalist background
or other paradigm with which they are familiar.**

"and hide from having your absurd claims"

**You have absolutely no knowledge of the claims of this paradigm
because you know nothing about the paradigm itself
and therefore you have no way of knowing whether there are absurdities or not.**

"answered by an informed opposition."

**How could you possibly be informed -
when you know nothing about the paradigm?**

**And why are you in opposition to something that you know nothing about?
That is an entirely biased, bigoted, and closed minded attitude.
If another synonym came to my mind I would use it.**

"Neither you nor anyone else"

**It is against this type of close mindedness that I am presenting the paradigm -
the very idea that one can judge the unknowable -
because neither I nor anyone else can know in advance -
the capabilities of everyone, or anyone else.
I realize that in that statement that I also have invoked
the "paradox of the absolute skeptic".**

"can prove a single,"

**In our previous correspondence,
I explained the limitations of proof,
and the distinctions between "belief" and "knowledge"
based upon evidence.
Did you miss the point?
If you didn't miss the point,
then your now stating this,
is evidence that you are not open to calm rational inquiry.
If you did miss the point,
then that demonstrates that you are not capable of such inquiry.
In either case, then,
what would be the benefit of trying to pursue such inquiry with you?**

"verifiable case of prophecy fulfillment"

**Once again, I have previously pointed out to you
the nature of evidence and verification.
It is a matter that was examined at some depth in the Four Paths to Truth.
Since you have not availed yourself of that presentation
you do not even know what criteria has been established there
in this POP series which I call the "Power or Problems of Prophecy".
The first P stands for Power or Problem -
one is free to make their own choice between the two.**

I have an internet forum where the debate can be published.

**Debate is useless,
when it is conducted with people who are NOT informed
and who are NOT of good will.**

**The good will that is necessary is that one must be willing
and desiring
of seeking the Truth
in an unbiased way.**

**I plan to go on to the 3 spheres of reality -
tomorrow.**

Peace and love,

Bruce Beach
DawnSayer@webpal.org

POP23 - Where

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**Psychiatrists have a quick test
which they determine
whether a person is sane or not.
They determine whether a person is oriented
to the three spheres of reality.**

Do they know -

- **Who they are?**
- **When they are?**
- **Where they are?**

**"Who are you?"
The psychiatrist asked.**

**"Jesus Christ,"
was the reply.**

**"Who told you that?"
asked the psychiatrist.**

**"God",
was the reply.**

**"No, I didn't",
came the voice
from the next cell.**

**We all have our reality tests.
We do it in accordance with our paradigms -
that is to say our world views.**

**In these next three emails I am going to present
a new paradigm about**

- **who,**
- **when and**
- **where we are.**

**The idea here is NOT for you to believe the paradigm.
It is for you to understand it.
Proofs will be presented later.**

**First we will begin with
"where" you are in-**

1. A paradigm of the origin of this world.

The people asked Moses,

"when did the world begin?",

**and He wrote the story of Creation,
in the Book of Genesis.**

**What He gave them
was a paradigm
(a view of the world)
that was comprehensible to them.**

**He did NOT tell them that there were
other planets in the solar system,
other galaxies,
about the immensity that the Hubble shows to us.**

**Ever since the development
of the telescope
Astronomers have thought
with just a bit more powerful telescope
(the general plea today is for one 15% more powerful)
they would be able to see to the edge of the universe,
(or the origins of The Great Bang,
as they put it.)**

They have just never mastered the concept of INFINITE.

**What is to make them think,
that just as if one gets beyond this solar system,
that there are other solar systems, in this galaxy,
and if one gets beyond this galaxy,
there are other galaxies,
and that if one got beyond this "island universe"
there wouldn't be "other" island universes?**

INFINITE is something Different from BIG or MORE.

**Even then, the astronomers deal
with only the PHYSICAL (visible) universe.
The SPIRITUAL REALITY,
of which the physical reality is only a shadow,
is INFINITELY (that word again) more immense.**

**And so where are YOU,
in all this IMMENSITY?**

Short answer:

**Planet Earth.
Physical Shadow.**

**Locating one's self
is sort of like the school child problem
of sending a return address to God.**

**Name,
street,
city,
province,
country,
planet,
solar system,
galactic arm,
galaxy,
galactic cluster,
island universe,**

island cluster,

where does it end?

Doesn't.

The problem is that one is dealing with an illusion.

The illusion of space.

The illusion is that it is reality,

but the REALITY is much more IMMENSE than the illusion.

In fact, the concept of Immensity is inadequate,

so long as it denotes size.

Even Einstein and the advanced thinker physicists,

say that no matter how real it seems

we must remember that Time, Space and Matter,

are illusions in our minds.

NOT that there isn't a REALITY.

A MUCH DEEPER REALITY.

But, for the man on the street,

these ideas have been incomprehensible.

Of course they have been discussed by all philosophers,

down through time, way back to the Greeks,

and Plato and Socrates.

They have been dealt with more in Eastern Religions,

and in a few Western Religions, such as

Christian Science, and to some degree by Swedenborg.

But, for the most part, the man in the street,

while he hears about these ideas,

he really has just not caught on.

The idea still abounds,

that the earth is the center of the universe.

The center of creation.

That all of creation revolves around the descendants of Adam.

Physically created in seven days.

That it is going to end,

and everything with it.

That the center of it all

is the advent about 2,000 years ago

of one particular individual (Jesus),

on this one particular rock,

whirling about this one particular star.

**When infants first become aware,
their Universe centers around their momma,
and their bassinet.**

Later to their nursery and members of their family.

Eventually to their community and school.

Gradually to their citizenship in their country.

**Most people, today, have not yet grasped the idea
of their citizenship in The World.**

**Their relationship to a Universe and Cosmos beyond that -
completely eludes them.**

**Children, in their infancy, naturally have infant concepts,
of creation and the world about them.**

This applies to mankind as a whole.

**An infant race, like the human race
(we only have a few thousand years of recorded history)
has infant concepts.**

**Young people and teens,
often think they have all the answers and understand everything.**

**That is the way many people are,
with their pat answers, "The Bible says".**

For a child, everything revolves around them.

For a childish race, everything revolves around it.

In its mind,

God created everything for It.

The purpose of everything is It.

**The question is,
where are YOU in the universe.**

**To answer that
you have also to answer the question of
when
and
who.**

**Next time -
when.**

**Peace and love,
Bruce**

DawnSayer@webpal.org

POP24 - When

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

We are examining a new paradigm of who, when and where we are. We have already looked at where, we are now going to examine *when*.

2. An examination of the History and Purpose of Mankind.

Again, in the Bible we see a History set down. The first five books of the Bible, are attributed to Moses.

Just as He wrote an understanding, suitable to the people of the time of how the world was created. So, did he also write an understanding, suitable to the people of the time, of when the world was created.

Some people reject The Bible, because they feel they have a longer view of history. (Others still insist on taking The Bible literally, - creation a few thousand years ago). Both positions are in error.

The Bible is SPIRITUALLY correct. Any seemingly literal statements are RELATIVE. They MUST of necessity be, because they are attempting to describe the INFINITE. To suppose that we are CAPABLE (or indeed may have today ABSOLUTE answers from say science) is at just as infantile a mental stage,

**as believing that the Bible should be believed literally.
Understanding of the ABSOLUTE,
always has been,
and always will be,
RELATIVE.**

**So, what I am about to present,
is a new RELATIVE paradigm,
suitable to mankind's present stage of growth.
It is simply a HIGHER
more INCLUSIVE understanding.
Don't belabor the literalness of it.**

**If you prefer a different paradigm
about which I have not heard
that is fine.
Share it with me.
I am always on the lookout for enhanced paradigms.**

**Anyway, in this paradigm,
we first posit the existence of cycles.
We see them about us everywhere.
Day and night,
the seasons,
life and death,
generation upon generation.
Astronomers even pose them for sunspots,
and the wheeling of the galaxies.
(The latter being too slow - taking billions of years,
for us to have actually observed one).**

**Over billions of years,
stars too are born and die.
But since man has only observed them
with telescopes for a few hundred years
and in recorded history for a few thousand years,
we have never seen the event,
from beginning to end.
Oh, we have seen supernovas,
and with the Hubble
some think we have seen star nurseries,
but we have been around too short a time
to observe a billions-of-years-long process**

**from beginning to end.
We can only Hypothesize
or have Revealed to us the overall process.**

**We do hypothesize that stars go through cycles.
From white dwarf to red giant.
For that matter, for all that we have seen,
because the cycle would be beyond the duration
of the human race,
they might repeat their cycles, repeatedly.**

**The earth is in relationship to the sun,
in its cycle.
Were the earth 10% further from the sun,
it would be so cold
that all its water would freeze,
at its poles,
like Mars.
And if the earth were 10% closer to the sun,
it would be so hot
that all its water would evaporate
and cover it in thick clouds,
like Venus.**

**If the sun were to shrivel further
towards becoming a white dwarf,
Venus would cool,
and its clouds would fall to the surface,
creating seas.
Earth would then become like Mars.**

**Indeed, this is the destiny of the earth,
(why I believe these things
is the subject of another essay).
But even during the time of its fruition
there come and go upon the planet
numerous races of men.
Much like a tree,
passing through its seasons,
blossoming in the spring,
bearing fruit,
and becoming dormant in the winter,
to eventually after many seasons**

wither and die.

There have been past races upon this planet.

There shall be future races.

Although it is possible

for a race to destroy the planet.

(Observe the missing planet in our solar system,

in what we call the asteroid belt,

as possible evidence of this).

It is the destiny and purpose of every star,

to have planets,

and of every planet,

to have its races of men.

Just as it is the destiny (fulfilled or not)

for every tree to be fruitful.

There are multitudes of questions

that one can ask about the appearance of the race.

The old arguments

between the Creationists and the Evolutionists.

Both error in fundamental premises.

One as to their materialist

and mechanistic concepts of cause and effect,

and the other as to their dogmatic

literal interpretation

of the Spiritual Analogy

related in the Bible plus their misconceptions

regarding the realities of Time, Space and Matter.

It is a curiosity that man has the same saline ratio

in his blood, sweat and tears,

as does the sea.

And one does well to contemplate

the philosophical concept that

Ontogeny Recapitulates Phlyogeny.

That the individual starts off as a single cell,

becoming at conception multiple cell in a saline sea, (the womb)

and proceeds through various stages,

having a tail and other appendages,

that atrophy before being born.

**Nevertheless, this is not a proof of devolution,
(descent from other creatures),
because man has always been man,
whatever his form,
individually or collectively.**

**But as far as evolution is concerned,
the evolving of the species,
as I have stated before,
there is evidence for any observer to see,
by simply looking at the armor of the knights of old,
or the statistics for military induction,
between WWI and WWII.
Whatever.**

**If the paradigm presented here,
is more meaningful to you
than one of creation a few thousand years ago,
and you can bear the idea,
that when you are is -
within this diminishing cycle
of the star that we call the Sun,
in this particular revolution of the galaxy,
that we call the Milky Way,
in this particular expansion
of what we see as our island universe,
etc.
then you have a very different idea of when you are
than someone who feels that all the purpose of ALL life,
revolves around a SINGULAR event,
that happened upon this one rock,
circling this one star,
approximately 2,000 years ago.**

**Next time -
as to who you are.**

**Peace and love,
Bruce
DawnSayer@webpal.org**

POP25 - Manifestation

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**And now
to my final explanation of the paradigm.
Next time on to the proofs,
but remember the only goal now
is to comprehend -
not to necessarily believe.**

**I have covered where and when we are,
and now on to who we are.**

This is:

3. An analogy of "Manifestation"

**This deals in part,
with who we are,
as a race.**

**And who we are
ties into when we are.
To clarify the Biblical Paradigm.**

**Adam was the first man.
In actuality, there were a Thousand Adams.
Simply lost to history.
In fact, all the Adams,
were pre-historic.**

**The question is what is an Adam.
Or for that matter what is a man.
To be a first man.
To be distinguished from the animals.**

Man has certain unique characteristics.

Language.

Humor.

Abstract thought.

**These are all facets of man's unique intellect,
that distinguishes him from the animal.**

No animal could have explained to it,

that the sun stands relatively still,

and the earth circles about it,

nor even that 2+2 equals four.

**(Yes, I have seen the trick
of counting horses and dogs.)**

The GREATEST of all abstract thoughts,

is the comprehension of God.

This is what truly distinguishes man

from the animals.

Therefore, the first to Recognize God,

is who we call the First Man.

Because God is Infinite, and Man finite,

it is God that must Reveal Himself to Man.

Man is incapable of discovering his Creator on his own.

The pot can never comprehend the potter.

Thus it is, in the scheme of things,

that God chooses One to reveal Himself through.

This One we call a Manifestation of God.

To give an analogy.

Consider Betelgeuse.

The largest known star.

A red giant.

**If someone were to point into a telescope mirror,
and say:**

"There is Betelgeuse",

someone else of a literal mind might reply.

"That cannot be,

**because Betelgeuse is a red giant,
larger than that glass,
larger than this whole planet,
even many times larger than our sun.
It is NOT possible THAT could be Betelgeuse."**

**And then if the first one were to break the mirror,
and on a subsequent night
pick up a different mirror
and say to the skeptic:**

**"Look again,
there is Betelgeuse."**

The skeptic could reply,

**"Even if I were to concede
that what you showed me before,
had been Betelgeuse,
this could not be it,
because that glass has now been broken.
Moreover
if you are going to give me some abstract argument,
about it having been the rays of light
within the glass,
that too is not possible,
for those rays are no longer here.
They have long passed."**

**Many analogies of this type could be given.
The image that you see on this TV or on another.
The light that appears in this lamp,
or another.
All being the same energy.
All having come from the same source.**

**To say that is Bob Hope on this TV,
and Bob Hope on that TV is understandable.
To say that it is Betelgeuse in this mirror,
and Betelgeuse in that mirror is understandable.
To say that the light in this lamp,
and the light in that lamp,**

are both from the same source is understandable.

And so it is with the Manifestation of God.

There is but one God

(as there is but one Betelgeuse)

and whether He selects one Mirror,

or another,

in which to appear,

He remains the One God.

God is Infinite.

(There is no comparison between God and Betelgeuse).

There is no way that Betelgeuse

could be contained in a mirror,

and no way that God

could be contained in a Mirror.

Yet, all we know of Betelgeuse or other stars,

is what we see in the mirror.

And all that we know of God

is what we see in the Mirror

(the Manifestation).

To look at the mirror and say,

"There is Betelgeuse,

is not illogical.

To look at the Mirror (the Manifestation)

and say,

"There is God",

is not illogical.

But to think that Betelgeuse

can be "contained" in the mirror,

is illogical.

And to think that God can be "contained"

in the Mirror (Manifestation)

is illogical.

But, nevertheless,

this is what those who believe in Incarnation, believe.

**Those who believe that Jesus, was God incarnate.
But, what Jesus, was,
was the MANIFESTATION of God.
Not God incarnate.
If the distinction is not important to you
then not to worry about it.
None of us comprehend the nature of God
nor our relationship to Him,
and certainly not the Manifestation's relationship
to Him.**

**But any way, according to this paradigm,
God MANIFESTS Himself,
(Makes Himself known unto men)
through some individual that He selects.
The distinction here,
between Christian Theology is that God can
Manifest Himself as often as He likes.**

**The Manifestations have told us that
God selects only one individual at a time
(on any given planet)
and usually about once every thousand years.
Since God makes Himself known
to all His Creatures,
given the billions of planets throughout the Universe,
it is possible, even probable,
that many Manifestations,
must be occurring simultaneously.**

**The key to all this is,
that the ONLY thing that we can know about God,
is what He tells us about Himself,
through His Manifestations.**

**But, the key also is,
that we must RECOGNIZE the Manifestation.
Individuals recognize the Manifestation,
and because of His influence on their lives,
whole civilizations
come to pay at least lip service to His Station.**

**Those who do not Truly see the Light,
confuse the Light with the Lamp.
They begin to worship the Messenger,
instead of the Message.**

**If the Light appears in a different Lamp,
the Blind will not see it,
but may continue to do obeisance to the Lamp,
that has now been extinguished.**

**Each of the Manifestations
have bestowed upon Them Innate knowledge.
They know ALL the answers.
But Their hearers are not capable of hearing them.
The teacher of First Grade students,
may know just as much
as the teacher of Sixth Grade students,
but the students are just not ready to understand.**

**Each of the Manifestations,
bring two sets of Teachings.**

- **Eternal Spiritual Teachings and**
- **social teachings**

suitable for the people and the Time.

Thus it is that Adam taught that there was a God.

**The first teaching of the Manifestations.
Why we call Him the first man.**

He also gave social teachings regarding

**the establishment of the family
(The story of Adam and Eve),
the command to labor for one's livelihood
(The story of being cast from the Garden),
the command against murder
(The story of Cain and Abel)
and so forth.**

**Later, there came another Manifestation of God.
He reinforced and ENLARGED upon
the Spiritual Teachings of Adam.
He said, Yes, there is God,
but God must be worshipped as a Spirit,
not as the idols that you make with your own hands.**

**There is an interesting story regarding this in the Koran.
Abraham's father's profession was as an idol maker.
One day when the father returned he found that Abraham
had destroyed all the idols, except the largest one.**

**"Abraham! Why did you do this?",
he said with great anger.**

**"It wasn't I father,
it was the Big One, ask him".**

**"You know that he can't speak
and couldn't have done this".**

**"Then, father,
why do you worship that which is dumb
and has no power?"**

**We call that form of worship
practiced by the followers of Abraham - animism.
Like with the North American Indians,
the Spirit is in the Trees, the Wind,
the Water, and so forth.**

**There are many interesting things
that I could write about Abraham,
but I suspect my essays are too long already.**

**The Bible tells how he had three wives.
And each was promised
to become the mother of nations.
The Bible tells about
the descendants of one wife, Sarah.
But other nations
track their lineage to the other wives.**

**Abraham established a new social order.
He sent his brother in one direction
with His brother's sons and their wives and flocks,
and He Himself went the other with His.
This was the beginning of Nomadic Tribes.
A much advanced social order
over that of the Adamic period,
with one male and many wives.
When an organization of the new social order
with many males,
met an organization of the old social order
with one male.
it was a wipe out for the old social order.**

**Later came Moses.
The people had returned to idol worship.
(The story of the Golden Calf).**

**He taught a new Spiritual Teaching.
Yes, there is a God, as Adam taught.
Yes, God is to be worshipped as a Spirit
as Abraham taught.
But the Jews were to have Only ONE God.
(Not that other people didn't worship
other gods.)
"The Lord God of Israel is One".**

**Moses also taught a larger social order.
Rather than just nomadic family tribes,
the Children of Israel were organized into 12 Tribes.
There were thousands in each Tribe.
When an organization of the new social order
with thousands of males,
met an organization of the old social order
with a few males,
it was a wipe out for the old social order.**

**Moses also gave many other social teachings,
both in the Ten Commandments,
and Books of the Law.
But I will pass over these.**

**In due time,
there came as promised by Moses,
the next Manifestation.**

Jesus.

**For Who was He,
if not the one Promised to the Jews?
And He taught a new Spiritual Teaching,
that God is a God of Love.
And he taught a new social teaching,
upon which there were built city states.
(Render unto Caesar that which belongs unto Caesar,
and unto God that which belongs unto God).
Leading unto a much stronger social order,
that allowed for the organization of people
who were not even related to each other,
as were the 12 Tribes of Israel.
And He, Jesus, promised unto them another,
the Paraclete,
as understood by those who recognized Mohammed.**

**And Mohammed brought a new
and Higher Spiritual Teaching.**

**That yes, as Adam taught,
there is God.
And yes, as Abraham taught,
He is Spirit.
And yes, as Moses taught,
we are to worship One God.
And yes, as Jesus taught,
He is a God of Compassion.
And yes, something new.**

**That there is No God but God
(Allah - The Only - the meaning of Allah).**

**Monotheism.
Philosophically comprehended
by the Christians and Jews of Europe,
as a result of the Crusades,
and then spread to Judaism
and most of Christianity
(The Mormons are still not monotheistic).**

**Mohammed also brought new social teachings.
The establishment of Nations.
Even secular historians recognize Him for this.
The law that we call Blackstone Law,
or the Common Law of Europe
is not to be found in the Bible,
but rather is in the Koran.**

**When organizations of the new social order,
met organizations of the old social order,
it was of course a wipe out
for the old social orders.**

**I could write volumes
on all these matters.
But have probably written too much already.**

- **Each of the Manifestations promises a successor**
- **Each brings new Spiritual Teachings**
- **Each brings new Social Teachings**
- **Each reveals a Book**
- **Each starts a new calendar**
- **Each revitalizes the Religion of God**
- **Each revitalizes Society**

**The latest of the Manifestations to come,
are the Twin Manifestations
(One immediately after the Other)
of the Bab and Baha'u'llah.**

They have brought a new Spiritual Teaching,

**that there is but One Religion,
The Religion of God,
and that all Religions,
(that is to say that All the Manifestations)
have always come to renew THAT religion.**

They have also brought new social teachings.

That there is but One race,

**the human race.
That there is but One nation, the World,
and Mankind is its Citizens.**

**There is so much more that I could write,
about Other Manifestations.
Buddha, Krishna, Zoroaster.
There is so much more that I could write,
about the New Teachings,
and the Destiny of the Human Race.**

**But the time has come for
you to think about this new paradigm.
About who we are.**

**A race of people,
receiving Progressive Revelation from God,
through His Manifestations,
as we now make the transition
from Spiritual Childhood,
through Adolescence,
into Spiritual Maturity.**

**A view quite different from the Christian view.
This is a view in which we are at The Beginning,
rather than at the Ending.**

**A view in which
we are having our relationship to God,
being Progressively taught to us
by the Manifestations of God,
rather than a view
in which all truth has already been revealed.
A view in which we are at the beginning of maturity,
rather than at the end.**

**A view in which,
once again the Manifestation of God,
has come to Mankind,
and it is the responsibility of every individual
to recognize Him and serve Him.
This is the ONLY salvation for us.**

**Individually or collectively.
Because, whether we desire it or not,
who we ALL are is
the servants of God.
(Obedient or disobedient, and that is who we are).**

**This is the paradigm
that I have asked you to comprehend.
The matter of acceptance and belief
comes next.
For that there needs to be proof.
And for that I shall continue next -
with the Most Clear Proof.**

**Peace and Love,
Bruce
DawnSayer@webpal.org**

POP26 - Revelation

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

**There are as many paradigms
as there are people.
We all view the world differently.**

**Some people view the world
as having been created a few thousand years ago -
others think that it may have been
millions or billions of years ago.**

**Whatever one imagines
it is too little
because we are dealing with
the Infinite and Eternal
and that is a different concept.
A different paradigm.
A different way of looking
at the world and Reality.**

**Some people see Creation in a "magical" way.
Others feel that they have a "scientific" appreciation of Creation.
But no matter what our concepts
the best that we can know today is that
they are limited and relative to the Absolute Reality.**

**There are many speculations held by people
about the nature of reality,
the nature of creation,
the source and purpose of our being.**

**I hear a great variety,
about reptilian evolution,**

**seeding from the stars,
special creation from the dust,
and many others that I won't delve into.**

**The two extremes which I challenge are
scientific materialism
that says man has all the answers in his intellect
with no need for revealed religion
and its opposite pole
dogmatic orthodoxy
which says all Truth has been already revealed
and no further Truth can be revealed.**

**It has been to the followers of scientific materialism
that I have made the attempt
to prove mathematically
that Jesus was the Christ
and that the Bible was a reliable source of prophecy.**

**While the mathematical proof that Jesus was the Christ
was a difficult emotional challenge to the atheist and agnostic
the next mathematical proofs from the Bible
will be an equally difficult emotional challenge
to any of a dogmatic orthodox religious inclination
who have managed to hold on to this point.**

**Because whereas before
we used mathematical proofs
to show from the Jewish Old Testament Scriptures
that those Scriptures contained prophecies about the Christian Religion
we are now going to use the Christian Gospel
to show with **EVEN GREATER MATHEMATICAL SURETY**
that the New Testament contains prophecies about other religions
such as the Moslem and the Baha'i.**

**There are many marvelous prophecies in the Book of Revelation,
but they are mostly concealed from Christians
who give fantastic superstitious interpretations about them.
The Book of Revelation contains prophecies
about things both past and future.
It is through understanding its prophecies about things past
that we can have confidence about its prophecies of things future.**

In my next email

**I shall get into the mathematical proofs
and while I shall not spend a lot of time
dealing with the prophecies themselves
other than showing the mathematical key to them
my dear saintly wife has asked that I at least share with you
a typical interpretation of one of those Scriptures.**

**Many a Christian has opened the Book of Revelation
to find Marvelous Prophecies and Exhortations
directed to several small and insignificant congregations
in the vicinity of Israel.**

The Churches Addressed

**were not those actual specific congregations,
but the church names were used in the Prophecies
as type designators or markers
for whom to the Messages were actually addressed.
Each of these tiny little congregations were but symbols
for the Religions of the World.
Each one being used as a Symbol for one of the
World's Major Religions.**

**This is why they were so Important as to be addressed
in this Summary Book of Christian Revelation.
What was actually being addressed was
each of the World's Major Religions.**

The Seven Religions were:

- 1. Sabaenism:**
Southwest Arabia and later Ethiopia-
Revelator unknown. 4000 - 5000 B.C.
- 2. Hinduism:**
India -
Krishna. 2000 - 3000 B.C.
- 3. Judaism:**
Egypt -
Moses. 1250 B.C.
- 4. Zoroastrianism:**
Persia -
Zoroaster. 900 - 1000 B.C.

5. Buddhism:

**India -
Buddha - 500 - 530 B.C.**

6. Christianity:

**Palestine -
Christ. 26 A.D.**

7. Moslem:

**Arabia -
Mohammed. 622 A.D.**

While a study of each of the ancient religions would be interesting and I might be able to make it interesting to some of you since I have a degree in Comparative Religions it is far beyond the limits of this presentation.

Nevertheless, it was not beyond the view of the Bible. And it was to each of these Religions that the Book of Revelation was addressed.

Rev: 1:4

" John to the seven churches which are in Asia ----"

The messages are not addressed to the Churches (Religions) in the order (above) of their appearance, but one who has studied the religions can determine which Church is which by the nature of the Message delivered unto it.

The references to things like Seven Stars being in the Hand (or Crown) of the Messenger or the Seven Golden Candle Sticks are symbolic and again refer to the Seven Religions being in the Hand and Kingdom of the Lord, and that He walks among them. One might note also that it is the Angel of Each Church that is addressed.

Rev. 2:1 Ephesus

Rev. 2:8 Smyrna

Rev. 2:12 Pergamos

Rev. 2:18 Thyatira
Rev. 3:1 Sardis
Rev. 3:7 Philadelphia
Rev. 3:8 Laodiceans

**Each Church (Religion) is generally praised
for some aspect of its behavior
and chastised for some other aspect.
And thus it is with any open minded student
of comparative religion
that usually we can find some
strong beneficial point in each religion
along with some characteristic weakness in its followers.**

**I am not as much a student of the Book of Revelation
as my dear wife.**

**(She does not like for me to refer to her as saintly,
but I tell her that since everyone else does also,
how can I deny it. But let me tell you also,
it is not always easy living with a saint.)**

**My wife has deeply studied the book,
has taken courses with numbers of churches,
maintains 3 ring binders on the subject,
and a library of reference books.**

**She would have me tell you much more,
than this little bit,
but that is not my intention here,
and it is only in deference to her
that I have told you so much as I have.**

**Next time, now, I can return
to the mathematical proofs.**

**Peace and love,
Bruce Beach
DawnSayer@webpal.org**

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Most Clear Proof - Dir](#)

POP27 - First Step

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

In the previous emails
I have presented a paradigm
that states that ALL the Revealed Religions
(Major Religions with a culture, etc.)
have come from God.

We now turn to mathematical proof
in the Bible
regarding one of them.
Specifically the Moslem Faith.

First we need to gather the numbers.
So far as I am aware
after many years of study on the subject -
the following are the only locations in the Bible
that have the following numbers.

"Scriptures"

DAN	8:14	1844 A.D. from our previous proof regarding Christ)
	7:25	time, times, and div. of time
	9:27	midst of week
	12:7	time, times, & half
Luke	4:25	three years and six months
REV	11:2	42 months
	:3	1260 days
	:9	3 1/2 days

:11	3 1/2 days
12:6	1260 days
:14	time, times, & half
13:5	42 months

**The First Step is to
bring the numbers
to a common denominator**

- **time, times, & div. of time and**
- **time, times, and a half, and**
- **the midst of the week (one half of seven days)**

are all equal to

3 and 1/2

Let us consider the first of these :

time is

1

times is plural and therefore in this case

2

dividing of time, or dividing of one is

1/2

therefore -----

3 and 1/2 total

likewise:

time = 1

times = 2

a half= 1/2

3 and 1/2 total

"Scriptures"

DAN 8:14 1844 A.D. from our previous proof regarding Christ)

7:25 3 1/2

9:27 3 1/2

12:7 3 1/2

Luke 4:25 three years and six months

REV 11:2 42 months

:3 1260 days

:9 3 1/2 days

:11 3 1/2 days

12:6 1260 days

:14 3 1/2

13:5 42 months

I will pause here so that you can look at this and see if you see how the rest come to the common denominator.

**The answer -
next email.**

**Peace and love,
Bruce
DawnSayer@webpal.org**

MENU: [HOME](#) » [Reconstruction](#) » [Recovery](#) » [Renewal](#) » [Most Clear Proof - Dir](#)

POP28 - Next Steps

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

Continuing with our mathematical proof from the Bible that the Book of Revelation talks about religions other than the Christian.

We had thus far brought the following scriptures to this much of a common denominator.

"Scriptures"

DAN	8:14	1844 A.D. from our previous proof regarding Christ)
	7:25	3 1/2
	9:27	3 1/2
	12:7	3 1/2
Luke	4:25	three years and six months
REV	11:2	42 months
	:3	1260 days
	:9	3 1/2 days
	:11	3 1/2 days
	12:6	1260 days
	:14	3 1/2
	13:5	42 months

Second Step
bringing the numbers
to a common denominator

(3 1/2) prophetic times or years
are equal to 42 months
that is to say:

3 years of 12 months = 36 months
plus a half year of 6 months
brings the total to ----->42 months

Making the substitution in our above table
we get the following:

"Scriptures"

DAN	8:14	1844 A.D. from our previous proof regarding Christ)
	7:25	42 months
	9:27	42 months
	12:7	42 months
Luke	4:25	42 months
REV	11:2	42 months
	:3	1260 days
	:9	42 months
	:11	42 months
	12:6	1260 days
	:14	42 months
	13:5	42 months

Third Step
bringing the numbers
to a common denominator

**42 months is equal to 1260 days (years)
because a biblical month
(as per an earlier proof)
contains 30 days and**

**42 months multiplied by
30 times**

1260 days (years).

**Now making the substitutions
we arrive at:**

"Scriptures"

DAN	8:14	1844 A.D. from our previous proof regarding Christ)
	7:25	1260 days (years)
	9:27	1260 days (years)
	12:7	1260 days (years)
Luke	4:25	1260 days (years)
REV	11:2	1260 days (years)
	:3	1260 days (years)
	:9	1260 days (years)
	:11	1260 days (years)
	12:6	1260 days (years)
	:14	1260 days (years)
	13:5	1260 days (years)

**This in itself, was pretty astounding to me
when I first saw it.**

**To think that all these scriptures
were saying the same thing!**

**That all these reduce to 1844
will be the subject of the next email.**

Peace and love,
Bruce
DawnSayer@webpal.org

POP29 - Final Step

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

In the previous email e
we arrived at:

"Scriptures"

DAN	8:14	1844 A.D. from our previous proof regarding Christ)
	7:25	1260 days (years)
	9:27	1260 days (years)
	12:7	1260 days (years)
Luke	4:25	1260 days (years)
REV	11:2	1260 days (years)
	:3	1260 days (years)
	:9	1260 days (years)
	:11	1260 days (years)
	12:6	1260 days (years)
	:14	1260 days (years)
	13:5	1260 days (years)

The explanation of how to convert these all to 1844 is found at the start of Revelation Chapter Eleven which is the start of most of the series.

Rev. 11:1-2

*"And there was given me a reed like unto a rod:
and the angel stood, saying,
Rise and measure the temple of God,
and the altar,
and them that worship therein.*

*But the court which is without the temple
leave out,
and measure it not;
for it is given unto the Gentiles:
and the holy city shall they tread under foot
forty and two months.*

**Now the question is
who were the Gentiles that occupied
the area outside the Temple.**

**Answer:
They were the Moslems.**

**So we are not to use the Christian measure
in measuring this forty and two months
but rather the Moslem measure.**

**We have seen how 42 months
(and ALL the other scriptures)
reduce to 1260.**

**Previously, I have given you the following general rule
for finding a date of commencement any Mohammedan year.
This has a maximum error of a day;**

**multiply 970,224 by the Mohammedan year,
point off six decimal places
and add 621.5774.**

**The whole number will be the year A.D.,
and the decimal multiplied by 365
will give the day of the year.**

**Here is the math.
Be SURE to check it through for yourself.**

**It will then be meaningful to you.
If you are not sufficiently interested
to check the math
then you are not sufficiently interested
in the answer for it to make any difference.**

970224

1260

58213440

1940448

970224

1222.482240

621.5774

1844.059640

!!! 1844 !!!

And what happened in 1844?

Two things of significance.

1. There was the Edict of Toleration.

**The above Scripture pointed out -
the holy city shall they tread under foot
forty and two months.**

**After Jesus came as the Messiah of the Jews,
the Jews were scattered and
not permitted to enter the Holy Land.**

**This bothered the Jews greatly
because their scripture in Isaiah had said
that He would gather them
"as a mother hen gathers her chicks".**

**But He said,
"I would have gathered -
but ye would not gather".**

**So they were dispersed,
and not allowed to return,**

but now in 1844 there was given the Edict of Toleration.

Here is some historical evidence that came to me just this week, from another researcher.

"During the 1970's I was researching parts of the Baha'i Faith and, out of curiosity, wrote about the Edict of Toleration to the PUBLIC RECORD OFFICE in London. The following is the reply I received.

"A translation of the edict, an acknowledgement from Stratford Canning to the Sublime Porte, and an accompanying letter from Canning, dated 23 March 1844, is in Foreign Office, Turkey, FO78/555/No.49. there are several other letters from Canning in the same volume on the question of the religious intolerance of the Turks. The draft of a letter from the Foreign Office, dated 16 January 1844, which made plain the attitude of the British Government and which provided the direct impetus for the negotiations leading eventually to the issue of the edict, is in FO78/552/No.4."

-you can obtain copies of the English language documents that refer to it from the Public Record Office in London.

H.G.Guinness, in his book, "Light for the Last Days" (probably published around the turn of the century) wrote "the decree [Edict of Toleration] was published in the 1260th year of the [Muslim] calendar. It is dated March 21st 1844. This date is the first of Nisan in the Jewish year, and is exactly 23 centuries [2300 years] from the 1st Nisan, BC457, the day on which Ezra states that he left Babylon in compliance with the decree given in the seventh year of the reign of Artaxerxes."

So there we have it ----->

"Scriptures"

DAN	8:14	1844 A.D. from our previous proof regarding Christ

POP30 - The Final Analysis

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

This is a summary discussion of the POP Series.

We set off with the idea to discover whether or not prophecy was truly possible, and we examined a number of prophetic claims.

Next we investigated the nature of proof, saying that there are ONLY Four Paths to Truth, and that each is fallible.

We then applied the Four Paths in a Mathematical Proof of Bible Prophecy showing that Jesus was the Christ.

On the same basis we then began to examine the following 12 Scriptures

"Scriptures"

DAN	8:14	1844 A.D. from our previous proof regarding Christ)
	7:25	time, times, and div. of time
	9:27	midst of week
	12:7	time, times, & half
Luke	4:25	three years and six months
REV	11:2	42 months
	:3	1260 days

:9	3 1/2 days
:11	3 1/2 days
12:6	1260 days
:14	time, times, & half
13:5	42 months

And reduced them all down to the following:

"Scriptures"

DAN	8:14	1844 A.D. from our previous proof regarding Christ
	7:25	1844 A.D.
	9:27	1844 A.D.
	12:7	1844 A.D.
Luke	4:25	1844 A.D.
REV	11:2	1844 A.D.
	:3	1844 A.D.
	:9	1844 A.D.
	:11	1844 A.D.
	12:6	1844 A.D.
	:14	1844 A.D.
	13:5	1844 A.D.

The calendar that we used to make this reduction was the Moslem Calendar and was a part of the evidence for our hypothesis that the Bible contains prophecies about other religions.

We then asked what significant thing happened in 1844

and our answer was - two things:

- 1. The edict of toleration
that in fulfillment of Jewish Prophecy
permitted the return of the Jews to Israel.
and**
- 2. The Return of Christ
as prophesized and expected
in the Great Expectation of 1844.**

**(Others, such as the Mormons, would add to this list
things like the martyrdom of Joseph Smith.)**

**In regard to the return of Christ I explained that
over 10 million people world-wide
(mostly from their Scriptures - other than Christian)
now recognize Baha'u'llah as the Return of Christ,
and have accepted a new paradigm about
themselves and this planet in relationship
to the Universe, Space, Time, and to what is called
a Manifestation of God.**

**The following is a chart that I have made
of Prophecies and dates
from the Bible.**

**While I have listed the key
Scriptures, prophecies and dates
I will not be going on to discuss them.**

**To actually understand the references
(in the Book of Revelation)
to the Moslem dates
one has to be acquainted with the Moslem Religion
and Moslem history.**

**Suffice to say,
the references both
in the Book of Revelation
and SURPRISINGLY found with the SAME DATE
in the Koran
both refer to the Return of Christ.
(It surprises many Christians to learn
that the Moslems are looking for
and expecting the Return of Christ.)
However, just as the Jews failed to recognize Jesus,
and the Christians failed to recognize Mohammed,
so have the Moslems failed to recognize**

the Bab and Baha'u'llah.

**If you had been a Jew 2,000 years ago
and had been shown then
(which the Christians were NOT able to do -
but which can be shown now -
because the Books have been opened)
the mathematical proofs from the Old Testament
about Jesus
then you should have been willing to examine
the Gospel of Jesus
and to find out what Jesus had said.**

**Today, you have been shown from the Bible
the mathematical proofs about Baha'u'llah
and you should now be willing to seek out and study
the Teachings of Baha'u'llah.**

**The claim is that
He is the Manifestation to this Day and Age.
That He has brought the solution
to mankind's problems
and has told us in prophecy the nature of our destiny.**

**But all this
you will only discover by studying His own Writings.
To try to dispute about Him
based upon one's present understanding about the Bible,
would be the same as a Jew
refusing to read the Gospel of Christ
and continuing to dispute about Him
on the basis of the Old Testament.**

**To accept all this
(even to the point of being willing to examine His Writings)
of course requires a MAJOR, MAJOR paradigm shift
on the part of a Fundamentalist Christian.**

**I know that it is hard.
Here is just a partial list of the ideas
that a Fundamentalist will think are FANTASTIC
and completely UNBELIEVABLE.**

**1. That the world -
contrary to the Creationist point of view
wasn't created just a few thousand years ago.**

**I realize that the evidence wasn't there
for almost 1500 years - three quarters of the duration
of the development of Christian Theology.**

**Even as recently as when Columbus discovered America,
the sailors that were with him were concerned
that the world was flat
and believed that the sun went around the earth.
It has only been in the last couple of centuries
(a mere ten percent of the time of Christian Theology)
that we have had telescopes to show us
anything approaching the concepts of galaxies
such as we have formed using telescopes
like those on Palomar and Hubble.**

**Archaeology and the study of paleontology
along with discovery and acceptance
by most people of the existence of dinosaurs
just had not occurred.
That the Universe is NOT
SPACE CENTERED
or TIME CENTERED
about the earth and man
was just totally inconceivable
to a Bible Believing Christian on the Street
during most of the time of Christianity.**

**HOWEVER, THE POINT HAS BEEN
THAT THE BIBLE WAS NOT WRONG
about Creation
but simply that it must be understood
in a GREATER MORE INCLUSIVE SPIRITUAL SENSE
and that the explanations given in it
were those suitable for the people
to whom it was revealed -
at their level of understanding at that time.**

2. As shocking a paradigm shift

**as I have asked the Fundamentalist Christian
to make about the non-centeredness of his world
in Space and Time**

**I have asked him to make a MUCH MORE DIFFICULT
paradigm shift about the non-centeredness
of HIS RELIGION
in relationship to the CREATOR
of this IMMENSE Universe we have described.**

**In regards to just this one planet -
we have examined that there have been
GREAT Numbers of People
and cultures on this one little planet that have had
religious guidance other than the Christian one.
Moreover, we have looked at evidence,
that just as the Bible when not taken Literally
but when taken in a Spiritual Sense
is correct in its Creation Accounts
so also does it contain evidence about OTHER Religions.
That the Old Testament had promised
that ALL the nations of the earth
would be blessed by the seed of Abraham's THREE wives
but the Old Testament only tells
the history of the descendant's of one (Sarah).**

**We saw that the Old Testament
gives with MATHEMATICAL ACCURACY
prophecy of the both the first coming of Jesus
and of His Return in 1844.**

**The Jews of course did not accept Jesus,
although His followers, the Christians,
accepted all the Prophets of the Old Testament
(but not the laws of religious practice -
sacrifice, circumcision, Sabbath day, kosher foods, etc.)
of the Jews.**

**However, neither did the Christians accept Mohammed
although there are in the Bible
TEN TIMES
the number of MATHEMATICAL PROOFS (the 1260 dates)
about HIM
and the return of Christ in 1844**

**based on the Moslem Calendar.
Even though the Moslems accepted all the Old Testament,
and the New Testament
(although again not the religious laws
such as baptism and others such as we mentioned above)
and all the Prophets AND Jesus
as explained in the Koran.**

**And once again, the Moslems had the 1844 prophecies,
(in their dates on their calendar)
in the Koran
and were well expecting the Return of Christ
but they also failed to accept Him
at His Return in 1844,
and they persecuted the Bab and Baha'u'llah.**

**3. As difficult as are the first two paradigm shifts
for a Fundamentalist Christian
the THIRD about the NATURE of the MANIFESTATION -
about the VERY CONCEPT of what is meant by a
MANIFESTATION of God
is often just totally incomprehensible to them.
In their eyes it destroys Jesus.
For them He was the Center of Creation -
a one time event
on this one planet
2,000 years ago
around which the whole Universe revolves.**

**That this could be TRUE,
not in the small literal sense that they say,
but in a MUCH GREATER SPIRITUAL SENSE
is to them - just non-meaningful.
But just as Jesus did not come to destroy the Law,
but to fulfill it,
neither did Baha'u'llah come to destroy Jesus,
but rather to fulfill His prophecies.
To unite the world and the religions.
To bring Peace and the Kingdom of Heaven on Earth.**

**4. A FOURTH paradigm shift
is necessary for the Fundamentalist.
It is central to being able to understand those above.**

**This regards the very nature of Truth itself.
This regards about how to understand the Bible -
not in an absolute literal sense -
but in a higher spiritual sense.**

**I have suggested that the CREATOR has to be
so much more EVEN MORE IMMENSE
(I am avoiding the word Infinite
which is more completely incomprehensible)
and to have existed so much LONGER than this earth
(again I am avoiding the term ETERNAL
for the same reasons)
that He is simply unknowable to us
in an ABSOLUTE sense.
For this reason, as Scientists today understand,
our knowledge of just the Creation
leave alone the Creator
is RELATIVE and limited to us
by what I have described as the
Fallible Four Paths to Truth.**

**It is in this sense -
that as we come to know more about
the Creator's Creation
that we gain an EVER EXPANDING sense
of how IMMENSE it is
(billions of galaxies
in the visible universe of the astronomer
and beyond that through the black holes
to we don't know where and on from that
to Infinity
of which we have no concept of the meaning
and the Spiritual World which is the basis of it all.)**

**It is in this sense -
that as we come to know more about
the Creator's Creation
that we gain an EVER EXPANDING sense
of how old it is
(billions of years long -
again into the black holes
where light, and space and time cease to exist,
and the concepts become unmeaningful**

**as we gaze at the thought of Eternity
about which we can have no concept).**

**It is in this sense -
that as we come to know more about
the Creator's Creation
that we gain an EVER EXPANDING sense
of the purpose of it all
that has been increasingly explained to us
in OUR SHORT HISTORY OF TIME
by the Manifestations of God
as they have raised us to increasing social consciousness
and social organizations of
the family, the extended family, the tribe,
the city state, the nation
and now on towards one unified world
with a world government,
so that there can be an ever progressing
peaceful and advancing civilization
to support individuals in their journey
towards spiritual enlightenment.**

**There is so much more that I long to share -
about the nature of the soul,
the nature of life after death,
the purpose of life on this planet,
the future of mankind on this planet,
and many many other issues
but all those things are to be found
in the Writings by the Prophet to this Day and Age -
Baha'u'llah.**

**My poor and inadequate words
do not have the power
to reach and penetrate the soul
with the Spirit of Truth
as does His.**

**My purpose has simply been to point
towards that source
so that you can discover the Truth
from the Source of Truth
for yourself.**

**Those who cannot make the 4 paradigm shifts
will continue to say
that they believe in**

Rapture

(their ascending up into the clouds)

Resurrection

(the graves opening and the dead coming forth)

Return of Christ

**(from the clouds above
with nail prints in his hands)**

Creation

in the last few thousand years.

Centeredness

of this planet in the Universe.

Vicarious redemption of sins

by the suffering of another

**and dozens of other things
because they have FAITH,
and that since I don't believe what they believe
(in the way they believe it -
because I do believe in the accuracy of the Scriptures)
that I have been deceived by a false prophet
and that I am doomed.**

**The fundamentalist ideas have been around for centuries.
They are deeply ingrained in the culture
and are passed on from generation.**

**One has almost gotten them
along with the air that they breath.
But paradigm shifts do occur,
and the ones that I am describing
are occurring.
How long it will take,
decades or centuries, I don't know,
for them to become universal.
But because they are NEARER the Absolute Truth,
these paradigms, and others more advanced,
will eventually replace the present ones
in the collective consciousness of mankind.**

**If you are willing to examine them
with an open heart
and can look at their Source
and the Spiritual Source of Truth
for this Day and Age -
the Writings of Baha'u'llah -
you will be one of the lights of the age,
helping to lead mankind out of the present
relative morass of vain imaginations and superstition
towards greater enlightenment.**

**I hope that you will be a contributor
to the effort.**

**Peace and love,
Bruce

The Seven Churches

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

Prolog:

For most readers -
this will be a very, very strange explanation -
about some verses from the beginning of the
The Book of Revelation.

The idea that Book of Revelation is about
Religions other than Christianity-
will just not be acceptable to many Christians.
Yet - that is the explanation presented here.

The Book of Revelation
is addressed to Seven Churches.
The churches named are what we call archtypes.
That is to say -
it is not really to the seven
historically insignificant locations named
but rather those names are stand-ins for the real subjects.

Oftentimes, the true significance of Scripture
is far beyond the expectations
of the members of the religion who claim ownership
of that Scripture.

Thus it is -
that the Messiah expected and promised
in the Jewish Scripture
was the Messiah and Lord
for what was far beyond
what was then probably less than 2 million persons

who considered themselves "The Chosen People".

Likewise, the Message and Meaning behind the Book of Revelation is much greater than that attributed to it by Christians in general.

This is an introduction to that expanded concept.

Introduction

The Book of Revelation, in the Bible, was a spiritual message revealed by Jesus Christ through St. John the Divine in about 96 AD, sixty three years after Jesus' ascension. John was on the island of Patmos and is believed to have been nearly 90 years old at the time.

The Book of Revelation is a deeply mystical writing and in order to comprehend the dramatic concepts within it, one must be willing to examine it with spiritual eyes and an openness to inquire if there is a deeper meaning than the literal meaning of the words that one sees on the surface.

The prophetic message in the Book of Revelation is about the destiny of seven churches. These are referred to as seven candlesticks and each one has the name of a town that was in John's teaching circuit and which still exists in what is now west Turkey and is somewhat north of what we now call Palestine and Israel.

Revelation -verses 1:10-17 (Introductory Verses)

1:10 I was in the Spirit on the Lord's day, and heard behind me a great voice, as of a trumpet,

1:11 Saying, I am Alpha and Omega, the first and the last: and, What thou seest, write in a book, and send it unto the seven churches which are in Asia; unto Ephesus, and unto Smyrna, and unto Pergamos, and unto Thyatira, and unto Sardis, and unto Philadelphia, and unto Laodicea.

1:12 And I turned to see the voice that spake with me. And being turned, I saw seven golden candlesticks;

1:13 And in the midst of the seven candlesticks one like unto the Son of man, clothed with a garment down to the foot, and girt about the paps with a golden girdle.

1:14 His head and his hairs were white like wool, as white as snow; and his eyes were as a flame of fire;

1:15 And his feet like unto fine brass, as if they burned in a furnace; and his voice as the sound of many waters.

1:16 And he had in his right hand seven stars: and out of his mouth went a sharp twoedged sword: and his countenance was as the sun shineth in his strength.

1:17 And when I saw him, I fell at his feet as dead. And he laid his right hand upon me, saying unto me, Fear not; I am the first and the last:

The central concept being presented here is that the towns and their names represented spiritual "archetypes" of what the prophecy was really about - which is the churches, or rather, major religions of the world.

The little towns themselves, while historical and geographic realities, have fallen into obscurity, but the Prophetic Message about the state of the Seven Churches, The Seven Golden Candlesticks, that is to say the Seven World Religions, in the "Last Days" has come to have GREAT significance.

The first of the seven churches was the Sabean - here called the Church of Ephesus.

2:1 Unto the angel of the church of Ephesus write; These things saith he that holdeth the seven stars in his right hand, who walketh in the midst of the seven golden candlesticks;

2:2 I know thy works, and thy labour, and thy patience, and how thou canst not bear them which are evil: and thou hast tried them which say they are apostles, and are not, and hast found them liars:

This is the most ancient of the churches. It is religion as found in the remmanents of Ancient Tribes of the Earth. Hence the commendation of its Patience.

This church is so ancient (4000-5000 BC) that we don't really know the name of its Revelator, but symbolicaly we contribute it to Adam. Baha'u'llah says there were a "thousand Adams", but much of what is written here is symbolism and we won't dwell upon it.

2:3 And hast borne, and hast patience, and for my name's sake hast laboured, and hast not fainted.

**Each of the Churches receives a COMMENDATION
and a CONDEMNATION.**

This was the commendation of this church.

2:4 Nevertheless I have somewhat against thee, because thou hast left thy first love.

And here is the condemnation.

2:5 Remember therefore from whence thou art fallen, and repent, and do the first works; or else I will come unto thee quickly, and will remove thy candlestick out of his place, except thou repent.

**Which may be why
we really know so little
about this church.**

2:6 But this thou hast, that thou hatest the deeds of the Nicolaitanes, which I also hate.

**The Nicolaitanes were a group
that had risen against religion.
It is to be noted that God hates the deeds
of the Nicolaitanes -
and NOT the people.**

2:7 He that hath an ear, let him hear what the Spirit saith unto the churches; To him that overcometh will I give to eat of the tree of life, which is in the midst of the paradise of God.

**Each of the churches
will receive such a call to enlightenment.**

**The Tree of Life
in the midst of the Paradise of God -
is called the Divine Lote Tree.**

It is said to be the point beyond which there is no passing.

Symbolically it is the Manifestation of God.

**Meaning that one can go no further in Paradise
or know more of God -**

than what is revealed by the Manifestation.

The blessing here

**is that those who are open and receptive -
to what the Holy Spirit says to ALL the churches
will recognize the next Manifestation of God.**

I realize that I am going a bit far

**in delving into such mystical meanings -
so I will restrain myself on such points from here out.**

**The second of the seven churches
was the Hindu -
here called the Church in Ephesus.
The Revelator of this church was Krishna (2000-3000 B.C.)**

2:8 And unto the angel of the church in Smyrna write; These things saith the first and the last, which was dead, and is alive;

**The First and the Last.
The Alpha and Omega.
He which was and ever shall be.**

**In the concept of Progressive Revelation -
all the Revelators are the one and the same.
Jesus said -
"Before Abraham - I am."
The Jews of course disputed with Him about that.**

Here is a similar quote from Baha'u'llah.

XLVII. O Jews! If ye be intent on crucifying once again Jesus, the Spirit of God, put Me to death, for He hath once more, in My person, been made manifest unto you. Deal with Me as ye wish, for I have vowed to lay down My life in the path of God. I will fear no one, though the powers of earth and heaven be leagued against Me. Followers of the Gospel! If ye cherish the desire to slay Muhammad, the Apostle of God, seize Me and put an end to My life, for I am He, and My Self is His Self. Do unto Me as ye like, for the deepest longing of Mine heart is to attain the presence of My Best-Beloved in His Kingdom of Glory. Such is the Divine decree, if ye know it. Followers of Muhammad! If it be your wish to riddle with your shafts the breast of Him Who hath caused His Book the Bayan to be sent down unto you, lay hands on Me and persecute Me, for I am His Well-Beloved, the revelation of His own Self, though My name be not His name. I have come in the shadows of the clouds of glory, and am invested by God with invincible sovereignty. He, verily, is the Truth, the Knower of things unseen. I, verily, anticipate from you the treatment ye have accorded unto Him that came before Me. To this all things, verily, witness, if ye be of those who hearken. O people of the Bayan! If ye have resolved to shed the blood of Him Whose coming the Bab hath proclaimed, Whose advent Muhammad hath prophesied, and Whose Revelation Jesus Christ Himself hath announced, behold Me standing, ready and defenseless, before you. Deal with Me after your own desires.

(Baha'u'llah, Gleanings from the Writings of Baha'u'llah, p. 101)

**This one quote from the Baha'i Writings
pretty much sums up what this is all about -
that each of the Revelators of the Seven Churches
are all the One and the Same.**

**In reality not only they -
but the Manifestations
wherever they appear
throughout the Universe and All time.
That is the reason that there is none other Name (identity - not vocal sound)
under heaven by which men are saved.
It is by the Manifestation - God made Manifest -
who appears through all eternity and all infinity.
Again - I may almost be going too far.**

2:9 I know thy works, and tribulation, and poverty, (but thou art rich) and I know the blasphemy of them which say they are Jews, and are not, but are the synagogue of Satan.

**One must remember that while this is about the Hindus,
at the time it was written
it was to the Christians
and thus recognizes their dealing with the Jews at the time.**

2:10 Fear none of those things which thou shalt suffer: behold, the devil shall cast some of you into prison, that ye may be tried; and ye shall have tribulation ten days: be thou faithful unto death, and I will give thee a crown of life.

**I could make commentary on each verse -
but you will probably think already
what I will be writing to be overly long -
so I will restrain myself.**

2:11 He that hath an ear, let him hear what the Spirit saith unto the churches; He that overcometh shall not be hurt of the second death.

The message to each of the Churches ends with a similar promise. I will not mention this again.

**The third of the seven churches
was the Jewish -**

here called the Church in Pergamos.
Coincidentally, each of these Greek names
has a spiritually significant meaning -
but I will not go into such detail.
The Revelator of this church was Moses (1250 B.C.)

2:12 And to the angel of the church in Pergamos write; These things saith he which hath the sharp sword with two edges;

2:13 I know thy works, and where thou dwellest, even where Satan's seat is: and thou holdest fast my name, and hast not denied my faith, even in those days wherein Antipas was my faithful martyr, who was slain among you, where Satan dwelleth.

2:14 But I have a few things against thee, because thou hast there them that hold the doctrine of Balaam, who taught Balac to cast a stumblingblock before the children of Israel, to eat things sacrificed unto idols, and to commit fornication.

You can see here
that this is addressed
directly to the Jews -
"the children of Israel".

2:15 So hast thou also them that hold the doctrine of the Nicolaitanes, which thing I hate.

Amazingly, today even in Israel -
the far larger majority of the Jews
say in public opinion polls -
that they are "not religious".

2:16 Repent; or else I will come unto thee quickly, and will fight against them with the sword of my mouth.

2:17 He that hath an ear, let him hear what the Spirit saith unto the churches; To him that overcometh will I give to eat of the hidden manna, and will give him a white stone, and in the stone a new name written, which no man knoweth saving he that receiveth it.

The "new name" is of course the name of the New Manifestation -
which of course no one recognizeth
except those who do "receive it".
All these things have spiritual significance -
such as the "hidden manna".
Just too much to go into.

**The fourth of the seven churches
was the Parsee/Zoroastrian -
here called the Church in Thyatira.**

The Revelator of this church was Zoroaster (900-1000 B.C.)

**This church is not very well known about
among most Christians**

**(who in fact know very little about any of the others
except to usually express their prejudices about them.)**

**This religion does appear in the Bible -
when the Magji came following the star
and looking for the Christ child.**

**Those wise men from the East were Zoroastrians
who as told in the Bible had in their religion the prophecies
about the coming Manifestation (Jesus).**

2:18 And unto the angel of the church in Thyatira write; These things saith the Son of God, who hath his eyes like unto a flame of fire, and his feet are like fine brass;

**The emphasis is on fire here
because they are sometimes considered to be
"fire worshippers".**

2:19 I know thy works, and charity, and service, and faith, and thy patience, and thy works; and the last to be more than the first.

The commendation.

2:20 Notwithstanding I have a few things against thee, because thou sufferest that woman Jezebel, which calleth herself a prophetess, to teach and to seduce my servants to commit fornication, and to eat things sacrificed unto idols.

The condemnation.

2:21 And I gave her space to repent of her fornication; and she repented not.

2:22 Behold, I will cast her into a bed, and them that commit adultery with her into great tribulation, except they repent of their deeds.

2:23 And I will kill her children with death; and all the churches shall know that I am he which

searcheth the reins and hearts: and I will give unto every one of you according to your works.

**One has to get into historical matters
to explain many of the verses.**

2:24 But unto you I say, and unto the rest in Thyatira, as many as have not this doctrine, and which have not known the depths of Satan, as they speak; I will put upon you none other burden.

2:25 But that which ye have already hold fast till I come.

2:26 And he that overcometh, and keepeth my works unto the end, to him will I give power over the nations:

2:27 And he shall rule them with a rod of iron; as the vessels of a potter shall they be broken to shivers: even as I received of my Father.

2:28 And I will give him the morning star.

**The study of stars,
and astrology
had great significance
among the Zoroastrians.**

**The allusion to the Morning Star -
and the reference to the search of the Wise Men in the Gospel -
has a connection.**

2:29 He that hath an ear, let him hear what the Spirit saith unto the churches.

**The fifth of the seven churches
was/is the Buddhist -
here called the Church in Sardis.
The Revelator of this church was Gotama Buddha (500 B.C.)**

3:1 And unto the angel of the church in Sardis write; These things saith he that hath the seven Spirits of God, and the seven stars; I know thy works, that thou hast a name that thou livest, and art dead.

**Saying again -
that He has ALL the Seven Spirits of God -
or all the Seven Churches.
The verses altogether**

are a theme about Progressive Revelation.

One of the amazing things about these Scriptures is that they describe the order in which these religions appeared on the earth - as well as the nature of each one of them.

This is of course astounding to those who have an inclination to see - but to those who are fixed in their dogmas they will simply close their eyes and ears and see nothing of this in it.

3:2 Be watchful, and strengthen the things which remain, that are ready to die: for I have not found thy works perfect before God.

3:3 Remember therefore how thou hast received and heard, and hold fast, and repent. If therefore thou shalt not watch, I will come on thee as a thief, and thou shalt not know what hour I will come upon thee.

3:4 Thou hast a few names even in Sardis which have not defiled their garments; and they shall walk with me in white: for they are worthy.

3:5 He that overcometh, the same shall be clothed in white raiment; and I will not blot out his name out of the book of life, but I will confess his name before my Father, and before his angels.

3:6 He that hath an ear, let him hear what the Spirit saith unto the churches.

The sixth of the seven churches was/is the Christian - here called the Church in Philadelphia.

The Revelator of this church was of course Jesus Christ (26 A.D.)

I will make mention of the significance of the Greek name for this one name since it is known to Christians.

It means brotherly -

and it is common for Christian to refer to their Christian brothers and sisters.

Also the city of Philadelphia in the US has the title the City of Brotherly Love.

3:7 And to the angel of the church in Philadelphia write; These things saith he that is holy, he that is true, he that hath the key of David, he that openeth, and no man shutteth; and shutteth, and no man openeth;

Christians will of course see many references to Christ in this verse.

3:8 I know thy works: behold, I have set before thee an open door, and no man can shut it: for thou hast a little strength, and hast kept my word, and hast not denied my name.

3:9 Behold, I will make them of the synagogue of Satan, which say they are Jews, and are not, but do lie; behold, I will make them to come and worship before thy feet, and to know that I have loved thee.

3:10 Because thou hast kept the word of my patience, I also will keep thee from the hour of temptation, which shall come upon all the world, to try them that dwell upon the earth.

3:11 Behold, I come quickly: hold that fast which thou hast, that no man take thy crown.

3:12 Him that overcometh will I make a pillar in the temple of my God, and he shall go no more out: and I will write upon him the name of my God, and the name of the city of my God, which is new Jerusalem, which cometh down out of heaven from my God: and I will write upon him my new name.

**The new name, as before,
is of course the name of the new religion.**

**There are many promises and symbolisms here -
but our purpose has been only to show the general theme -
that these Scriptures are about Seven Major Religions of the World -
which have all come from God.**

3:13 He that hath an ear, let him hear what the Spirit saith unto the churches.

**To say more -
would be to start preaching. :)**

**The seventh of the seven churches
was/is the Moslem/Islam -
here called the Church of the Ladicieans.
The Revelator of this church was Muhammad (622 A.D.)**

It is amazing to the Christians

**(and of course rejected by them)
that the Bible holds prophecies about Muhammad.
The Moslems see MANY, MANY prophecies in the Bible
about Muhammad.
But this is nothing new.
The Christians see many, many prophecies
in the Old Testament -
about Jesus -
which the Jews of course do not see.**

**And of course -
there are many prophecies
in ALL the Religions and Books of God -
including the Koran -
about the End Times
(The Beginning of the Age of Fulfillment)
and the coming of the Messiah to the whole of the world
which the followers of those religions do not see
except as the Return of their own Prophet.**

3:14 And unto the angel of the church of the Laodiceans write; These things saith the Amen, the faithful and true witness, the beginning of the creation of God;

3:15 I know thy works, that thou art neither cold nor hot: I would thou wert cold or hot.

3:16 So then because thou art lukewarm, and neither cold nor hot, I will spue thee out of my mouth.

3:17 Because thou sayest, I am rich, and increased with goods, and have need of nothing; and knowest not that thou art wretched, and miserable, and poor, and blind, and naked:

3:18 I counsel thee to buy of me gold tried in the fire, that thou mayest be rich; and white raiment, that thou mayest be clothed, and that the shame of thy nakedness do not appear; and anoint thine eyes with eyesalve, that thou mayest see.

3:19 As many as I love, I rebuke and chasten: be zealous therefore, and repent.

3:20 Behold, I stand at the door, and knock: if any man hear my voice, and open the door, I will come in to him, and will sup with him, and he with me.

3:21 To him that overcometh will I grant to sit with me in my throne, even as I also overcame, and am set down with my Father in his throne.

3:22 He that hath an ear, let him hear what the Spirit saith unto the churches.

**I have not gone into the meaning
of many of the verses.
But enough -
indeed probably too much.**

**The theme is the Progressive Revelation of God
and it all points towards
the Manifestation of this Day and Age.**

**They that have eye to see
and an ear to hear -
will be joyed to see the bounty
that God has revealed in the Books of Old -
and will be eager to receive
the Message unto the New Age.**

**But many will not see or hear the Message.
Indeed many people look at the Bible
and see only the carbon black of ink
pressed upon the celulose of paper -
and say that they see NOTHING of the Spirit
in it.**

**How joyful to write to those
who are attuned to the Spirit,
and I delight in their writing to me at:**

**Bruce
DawnSayer@webpal.org**

Progressive Revelation - Nine Divinely Revealed Religions

Number	Date	Religion	Prophet	Book	Rev. Verses Church Name
---------------	-------------	-----------------	----------------	-------------	------------------------------------

1	5000 B.C.	Sabean	"Adams"	Oral	Rev. 2:1-7 Sabean
2	3000 B.C.	Hindu	Krishna	Vedas	Rev. 2:8-11 Ephesus
3	1250 B.C.	Jewish	Moses	Torah	Rev. 2:12-17 Pergamos
4	1000 B.C.	Parsee/Zoroastrian	Zoroaster	Ivesta	Rev. 2:18-29 Thyatira
5	500 B.C.	Buddhist	Gotama	Tripitaka	Rev. 3:1-6 Sardis
6	26 A.D.	Christian	Jesus	Gospel	Rev. 3:7-13 Philadelphia
7	622 A.D.	Islam/Moslem	Muhammad	Koran	Rev. 3:14-22 Ladicieans
8	1844 A.D.	Babi	Bab	Bayan	Other Chapters
9	1863 A.D.	Baha'i	Baha'u'llah	Aqdas	Other Chapters

Each Prophet/Manifestation/Revelator

Starts a new Calendar

Brings a new Book

Teaches His followers to love God

Teaches His followers to love his fellow man

Reinforces the former spiritual teachings

Brings new spiritual teachings

Brings social teachings suitable for that Day and Age

Tells His followers to watch for the NEXT Prophet - that is - His Return

The Ocean of Scriptures

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

Prolog:

**This essay assumes
that you have downloaded -**

[Ocean.](#)

**If not -
then you need to pause here and do so -
because that is what this essay discusses.**

**Ocean is an electronic library
that is completely FREE
and while over the last 15 years
I have used over a half dozen electronic libraries
costing many hundreds of dollars
this one GREATLY surpasses all the others in performance.**

**Every few weeks or every couple of months -
WHILE ON LINE
you want to go to the "Resources" pull down window
on the bar on the top of your Ocean screen
and make sure that you have
(1) the latest program version
and
(2) the updates to the bookshelf.**

**I just (May 2002) did this -
and note that I now have 963 books on the bookshelf.
It is always growing,
but it takes up surprisingly little space**

**on your hard disk
for something so Momentous and POWERFUL.**

**You will undoubtedly have much fun with Ocean in
searching the Bible and other Christian books
as well as the Islam works.
However, I have written this essay
for the purpose
of introducing one to The Baha'i Writings.**

Using the System:

**While one may search the entire library
for a reference
it takes a bit longer
and often gives one way too much to look through.**

**As you start using the system
as you may well already have -
it gives you a tutorial on how to use it.
VERY simple.
Just put search words in - in any order
or put in quotes
exact combinations and phrases that you want.**

**Usually it takes very few words to find what you want -
but sometimes you need to add additional words
to reduce the quantity of quotes it brings up.
This is particularly true as one becomes familiar
with Baha'i quotes -
and wishes to locate the source of a particular quote.**

Authoritative versus Commentary:

**Note particularly -
that the Baha'i Library
is divided into TWO categories -
AUTHORITATIVE Baha'i and
Baha'i Studies (or what I have called "*commentary*").**

**You may find it interesting to delve right into
the *AUTHORITATIVE* Baha'i**

**and I will try to explain what is there -
but, if you are new to Baha'i,
I am going to recommend that you first
gain some information from some sources
located in the Baha'i Studies section of the library.**

**Let me, however, tell you -
as marvelous as all this is,
it is by no means the only source on Baha'i
and in due time I hope you will find other sources -
some of which you may find equally astonishing.**

**There are published almost daily
from a variety of Baha'i National Publishing Trusts
and numerous independent Baha'i Publishers
new books about Baha'i.
Years ago - I used to read every new book that came out -
but now I can't even keep up with the titles.**

**There are also many web pages -
web discussion groups,
sites by various Baha'i Communities
and the Official momentous Baha'i sites.
But, not to worry about any of that for the moment.**

The Authoritative Works:

**First, you need to get a structure
to comprehend what it is that you have downloaded.
To do that we need to briefly outline
the history of the Baha'i Faith.
In doing this you will see that the Books
under AUTHORITATIVE Baha'i
follow that outline.**

**You will quickly become acquainted -
with just who the AUTHORITATIVE Sources are -
but at the moment we will more or less just list them,
and hopefully later you will on your own
fill in the details.**

The Authoritative CENTRAL FIGURES:

**The Baha'i Faith began in 1844
with the Declaration of**

The Bab

the First Central Figure of the Baha'i Faith.

**The most authentic and extensive source for that history
is in "The Dawn Breakers"
a massive tome
which I do not recommend that you start with.**

**(A much simplified "readers digest version"
is in Baha'i Studies under the title -
"Release the Sun".**

**Perhaps an early book - but not necessarily
the first book to read.**

**After the martyrdom of the Bab
the second CENTRAL Figure of the Baha'i Faith was**

Baha'u'llah.

**Baha'u'llah is said to have written over 100 Books.
The Persian word for book is "Kitabi" so we get books like
Kitabi-Aqdas (His "Book of Laws") -
Kitabi-Igan (The "Book of Certitude") -
etc.**

**Many of His Writings are also called "Tablets" -
for example -
"The Tablet of Ahmad" (actually a prayer in this case).**

**His last and summary work is called -
"The Epistle to the Son of the Wolf",
and His most mystical Writing
is the "Seven Valleys"
and
"The Four Valleys".**

**I had been a Baha'i about seven years before I read these latter -
and at that time I said -
"I have understood/liked/appreciated everything that I have read
until now -
but I get absolutely nothing out of these."
Years later I would come to say -**

"If there was nothing else but these in the Baha'i Faith - it would be enough." :)

You might enjoy reading the first and second of the Seven Valleys - which are the Valley of Search and the Valley of Love. But not necessarily the first thing that you do.

There are a number of compendiums of Baha'i Writings such as the book called - "Gleanings" - and Baha'u'llah often quotes from Himself - and all the subsequent writers quote from Him - so you will often find the same quote in many, many places.

The Third (and last) Central Figure of the Baha'i Faith is

Abdu'l-baha

the son of Baha'u'llah who was called by Baha'u'llah "The Mystery of God" and named by Baha'u'llah as the Center of His Covenant - The Perfect Exemplar of His Faith, the ONLY Interpreter of His Word. Abdul means "servant" - so Abdu'l-baha means the Servant of Baha'u'llah.

Abdu'l-baha, like the Bab and Baha'u'llah, wrote many Tablets. Early on - one of the most interesting things to do - is to read down through the Table of Contents of "Some Answered Questions" where He deals with many, many different issues.

Abdu'l-baha appointed His grandson-

Shoggi Effendi

to succeed Him - with the title of Guardian of the Faith. Effendi means "sir" - so in effect his title is "Sir Shoggi".

**Shoggi Effendi was educated at Oxford -
and writes, in a very scholarly Oxfordian style,
momentous works explaining about the future of the Faith.**

Additonal AUTHORITATIVE Sources:

**After Shoggi Effendi (an AUTHORATIVE source although not a Central Figure)
there was the Trusteeship of the Custodians -
until the**

Universal House of Justice

**(also Authoritative sources)
was established in 1963.
Writings of some of the Hands
will be found in Baha'i Studies
but these, while highly respected,
are not AUTHORITATIVE Sources.**

**The UHJ (Universal House of Justice), however,
as just stated, is an authoritative source -
and so its publications are under that category of search.
For example - they write an annual "**Ridvan Message**".
Ridvan is a particular time on the Baha'i Calendar -
but not to worry about such details for the moment.**

**I will mention one particular book
under AUTHORITATIVE compilations
(there are many) -
but if you go to the Authoritative list -
look under compilations -
and then look under "**Lights of Guidance**"
and then read the Table of Contents of that Book
you will again find a long list of Information
on many Baha'i subjects.
This is just a note for the future -
because of course -
you cannot do everything at once.**

The Commentary Works:

**Now turning to the Baha'i Studies -
Numbers of the Hands are listed there**

(along with other names)
- some of whom write VERY scholarly works -
but there are three Hands -
whose attention that I will direct you to first.

First there is Ruhiyyih Khanum -
or known as Amatu'l-baha
who was the wife of Shoggi Effendi.
She wrote a wonderful book
about the Guardian called
"The Priceless Pearl" -
and later re-wrote it
and called it **"The Guardian"**.
But this book would be a ways down your reading list.

Hand of the Cause William (Bill) Sears -
was a great favorite among Baha'i's
for his humour and writing style.
His **"Thief in the Night"** -
is an entertaining explanation
of what Abdu'l-baha called **"The Most Clear Proof"** -
but there are many much more scholarly works
on this subject
that are not on the electronic bookshelf.
Bill Sears also wrote **"Release the Sun"** -
the history of the Babi era that I mentioned before.

And finally -
there is J.E. Esslemont -
who wrote
"The New Era"
and while this is an "old" book about the Faith
it is where I would suggest that you begin -
because it gives such a COMPLETE overview.
It is almost like a college text book
(and indeed has been used as such)
but it is not difficult to read.

Of course, you may just wish to search out
answers to questions
using Ocean.

**If you wish to query me about what you are reading -
all you have to do is give me the search words
that you used -
and I can duplicate here
what it is that you are looking at.**

**It is very easy with Ocean
to mail a quote.
All you have to do
is highlight the text
copy it -
and paste it into your email.**

**So, now you should have a source
for any question that you may ask.
Please ask for any clarification,
or help that I can give you -
and let me know what you are finding in the Ocean.**

**It is a joy to me
to respond to you on anything you ask.**

**Bruce
DawnSayer@webpal.org**

The Writings Currently in Ocean

Authoritative Baha'i			
Date	Writer	Station	Sample Books
1844-1850 A.D.	The Bab	Prophet/Manifestation Central Figure	(The Bayan) in Selections from Writings of the Bab
1852-1892 A.D.	Baha'u'llah	Prophet/Manifestation Central Figure	Aqdas Gleanings Igan Epistle to to the Son of the Wolf

1892-1921	Abdu'l-baha	Centre of Covenant Central Figure	Some Answered Questions
1921-1957	Shoggi Effendi	Guardian	God Passes By
1957-1963		Custodians	
1963-forward	Universal House of Justice	UHJ	Messages

Baha'i Studies (Commentary)

Writer	Sample Title	About this work
William Sears	Thief in the Night	An entertaining story that covers "The Most Great Proof" of why Baha'u'llah is the Return of Christ
Dr. J.E. Esslemont	Baha'u'llah and the New Era	A thorough explanation about the Baha'i Faith, historically, it beliefs and customs and so forth.
William Sears	Release the Sun	An entertaining presentation of the early beginnings of the Baha'i Faith
Ruhiyyih Khanum	The Priceless Pearl	The story of her life with the Guardian by the wife of the Guardian.
George Townsend	The Heart of the Gospel	A book about the Baha'i Faith by a Christian Minister
George Townsend	Christ and Baha'u'llah	A book about Baha'u'llah by a Christian Minister
Howard Colby Ives	Portals to Freedom	A book about his Baha'i experience
Lady Blomfield	The Chosen Highway	The experience of an early believer.

The above are just some of the books in the Ocean bookshelf that I would recommend to read first. Some of the other books in the bookshelf are perhaps more scholarly, if not more inspirational. There are also many, many other books that one might find to their particular interest through a Baha'i Publishing House, or at a Baha'i bookstore. For example, I have on my bookshelf a half dozen books dealing with Baha'i economics because that is a particular subject that interests me. Someone else may have many books dealing with a subject like life after death or explanations of scripture.

Prayer

Table of Contents:

[Prolog: Some Thoughts on Prayer and Meditation](#)

The author's personal experience about prayer.

[Ahmad: A Special Tablet.](#)

Shoggi Effendi said: "...the Tablet of Ahmad, have been invested by Baha'u'llah with a special potency and significance, and should therefore be accepted as such and be recited by the believers with unquestioning faith and confidence, that through them they may enter into a much closer communion with God, and identify themselves more fully with His laws and precepts." (Compilations, Baha'i Prayers, p. 208)

[Perspicuous Verses: of Baha'u'llah](#)

Baha'u'llah says in the verses:

"Blessed art thou,
who hast fixed thy gaze upon Me,
for this Tablet which hath been sent down for thee -
a Tablet which causeth the souls of men to soar.

Commit it to memory,
and recite it.
By My Life!
It is a door to the mercy of thy Lord.
Well is it with him that reciteth it
at even tide and at dawn.

[Chant: of Abdu'l-baha](#)

*I had heard the recording a number of decades ago-
and then again at the Baha'i World Congress in New York City in 1992
where I became acquainted with Harjot Sidu and Vido Ighani*

*who provided me with the translation that I first published here,
my not being aware of any other.*

*I have now received from Bob Haugen a translation that appeared in The Baha'i World, 1936-1938,
Volume 7, page 421. The above now largely follows that translation.*

Some Thoughts on Prayer and Meditation

These are simply some random thoughts on the subject of prayer and meditation. There are numbers of Baha'i books on the subject and it is not my intention to recap anything printed there.

There are few Baha'i books on the "method" of meditation and although I have taught the subject for several decades I am not prepared to formally make a presentation at this time. There are numerous methods, and Baha'is are free to choose such as is suitable to them, but they are REQUIRED by Baha'u'llah to meditate.

For many years I have had in abeyance a project to correlate the ancient Aphorisms of Pantanjali (one of the best known guides in Hindu literature on the subject of meditation) to statements on the subject in the Baha'i Teachings. In this regards there is a surprising wealth of material, in the Baha'i Writings, as how to sit, focus one's mind, and other such disciplines. To this end, I have made notes of comparison with several versions of Pantanjali translations, including a literal one, (since I do not read Sanskrit) but with Shoghi Effendi's proscription of teaching meditation in Summer Schools, I have not given a high priority to the project.

There is considerable confusion in the minds of many people about the distinctions between prayer and meditation. Recitation, Intonation and Chanting are important and will undoubtedly play a much more prominent role in Baha'i culture in the future. All of us pray, or should pray, but in the Western world - few of us chant. Chanting is to prayer like singing is to talking. Even someone, such as myself, whom everyone announces to be tone (or at least tune) deaf, can but wonder at the capacity of a trained opera singer to overwhelm the combined efforts of an entire church congregation. I have heard beautiful chanting of Baha'i prayers in English, but it is a rarity. A mere cultural quirk because there is nothing specific about the Persian or Arabic languages that makes chanting only possible in those languages.

Also in the Western world, few people meditate. It is more difficult to describe the relationship of meditation to prayer. It is a capability of the human spirit on up the ladder from concentration and contemplation. It passes beyond the murmuring of sound and symbol although we can be led into the ecstasy of it by revealed meditations. As an analogy, let me say that while we all use math and numbers to some extent we can but vaguely guess at the capacities of theoretical mathematicians. There are many other examples of the distinctions between the accomplishments of the trained versus the untrained in areas such as acrobatics, ice skating, dance, sports and other fields of endeavor. What then would lead one to think that all people can pray or meditate equally well without training when few have even stopped to ponder the distinctions between concentration, contemplation and meditation.

Undeniably, quality of prayer is affected by, among other things, purity of heart. But this is a chicken and egg matter. One leads to the other. No matter how inadequate one feels - they must begin to pray. Indeed, prayer may well (and most surely will) reveal to them even much greater inadequacies than they ever imagined. Still it remains the only path to salvation, no matter the type of one's soul, and whatever paths of Truth they trod (matters which I deal with in the POP series).

Many in the Western World are in non-praying societies and the practice and habit of prayer will be very strange to them. Some new Baha'i's find the requirement of even a daily obligatory prayer requiring a discipline that they are not used to. The further discovery that Baha'i's are supposed to also pray both in the morning and evening and to repeat 95 times the Greatest Name (a step towards meditation) is best left to their progressive spiritual development.

Some like myself, (and I share this with you, only so that you may know the variety of Baha'i life) after decades fall into a pattern of almost perpetual prayer. Indeed, I would say that the goal is to have one's every thought focused on Baha'u'llah. To have one's every motivation to be the motivation of Baha'u'llah. Prayer is the path.

Oftentimes in life, tests and difficulties are the motivation to pray. A prayer often learned early on by new Baha'i's and Baha'i children is the Bab's Remover of Difficulties. That too, some come to a convention or practice of repeating nine, nineteen or ninety-five times, in times of exceptional challenge. A personal choice of mine was to repeat the Tablet of Ahmad nineteen times daily. Indeed, for many years, in addition to the Fast prayers, I would say it nineteen times each day for the nineteen days of the Fast. Each one must find their own discipline and it is well to remember that Baha'u'llah CAUTIONS about being given to long prayers.

It is amazing, in a lifetime, how the prayers will add up. How easy and joyful it becomes. That indeed, the most joyful hours of the day become those spent in prayer and meditation. As one progresses along the path of prayer they come to learn that Baha'u'llah has recommended a number for special situations and occasions. I won't go into those now, but one will eventually come to the Perspicuous Verses, which Baha'u'llah recommends (does not require) that one say every "eventide" and "morn". Add to these Abdu'l-baha's Daily Regional Prayers for teaching, and suggested daily prayers for one's loved ones, and one can have a very full prayer schedule. However, to say daily the short noonday prayer sometime

between noon and sunset, along with the 95 repetitions of The Greatest Name (for this some use a rosary) and to say with absolute sincerity The Greatest Name in the morn and evening, fulfills the requirement of God. God does not need our prayers. We pray to benefit ourselves, not God.

A simple repetition of the Greatest Name ninety-five times a day, will add up in a half century of devotion to the Faith, of one having said it over fifteen million times. In actuality, one who is that devoted will find themselves saying it many more times a day than that, and the lifetime multiple will be much greater. A simple saying of the Tablet of Ahmad, *at least* once a day for the last 30 years of their life will result in their having said it over ten thousand times. Those who recite it that regularly ("withhold not thyself therefrom") will again find that they have actually recited it much more often, and consequently many more times than that.

Yes, over the years, the prayers add up, and as Baha'u'llah says - think not that they do not have effect. We are more blessed by our own, and other's prayers, than we can imagine. Today, we live in a non-praying world, and this presentation will seem very strange to many people, but in the future when Baha'i's gather daily in their communities for prayers and the meaning of meditation becomes better understood, then it will become more meaningful and, indeed, commonplace.

TABLET OF AHMAD

He is the King, the All-Knowing, the Wise!

Lo, the Nightingale of Paradise singeth upon the twigs of the Tree of Eternity, with holy and sweet melodies, proclaiming to the sincere ones the glad tidings of the nearness of God, calling the believers in the Divine Unity to the court of the Presence of the Generous One, informing the severed ones of the message which hath been revealed by God, the King, the Glorious, the Peerless, guiding the lovers to the seat of sanctity and to this resplendent Beauty.

Verily this is that Most Great Beauty, foretold in the Books of the Messengers, through Whom truth shall be distinguished from error and the wisdom of every command shall be tested. Verily He is the Tree of Life that bringeth forth the fruits of God, the Exalted, the Powerful, the Great.

O Ahmad! Bear thou witness that verily He is God and there is no God but Him, the King, the Protector, the Incomparable, the Omnipotent. And that the One Whom He hath sent forth by the name of Ali was the true One from God, to Whose commands we are all conforming.

Say: O people be obedient to the ordinances of God, which have been enjoined in the Bayan by the Glorious, the Wise One. Verily He is the King of the Messengers and His Book is the Mother Book did ye but know.

Thus doth the Nightingale utter His call unto you from this prison. He hath but to deliver this clear message. Whosoever desireth, let him turn aside from this counsel and whosoever desireth let him choose the path to his Lord.

O people, if ye deny these verses, by what proof have ye believed in God? Produce it, O assemblage of false ones.

Nay, by the One in Whose hand is my soul, they are not, and never shall be able to do this, even should they combine to assist one another.

O Ahmad! Forget not My bounties while I am absent. Remember My days during thy days, and My distress and banishment in this remote prison. And be thou so steadfast in My love that thy heart shall not waver, even if the swords of the enemies rain blows upon thee and all the heavens and the earth arise against thee.

Be thou as a flame of fire to My enemies and a river of life eternal to My loved ones, and be not of those who doubt.

And if thou art overtaken by affliction in My path, or degradation for My sake, be not thou troubled thereby.

Rely upon God, thy God and the Lord of thy fathers. For the people are wandering in the paths of delusion, bereft of discernment to see God with their own eyes, or hear His Melody with their own ears. Thus have We found them, as thou also dost witness.

Thus have their superstitions become veils between them and their own hearts and kept them from the path of God, the Exalted, the Great.

Be thou assured in thyself that verily, he who turns away from this Beauty hath also turned away from the Messengers of the past and showeth pride towards God from all eternity to all eternity.

Learn well this Tablet, O Ahmad. Chant it during thy days and withhold not thyself therefrom. For verily, God hath ordained for the one who chants it, the reward of a hundred martyrs and a service in both worlds. These favors have We bestowed upon thee as a bounty on Our part and a mercy from Our presence, that thou mayest be of those who are grateful.

By God! Should one who is in affliction or grief read this Tablet with absolute sincerity, God will dispel his sadness, solve his difficulties and remove his afflictions. Verily, He is the Merciful, the Compassionate.

Praise be to God, the Lord of all the worlds.

- Baha'u'llah

The Perspicuous Verses

Among others, these perspicuous verses have,
in answer to certain individuals,
been sent down from the Kingdom of Divine knowledge:

'O thou who hast set thy face towards the splendors of My Countenance!

Vague fancies have encompassed the dwellers of the earth
and debarred them from turning towards the Horizon of Certitude,
and its brightness, and its manifestations, and its lights.

Vain imaginings have withheld them from Him Who is the Self-Subsisting.
They speak as prompted by their own caprices, and understand not.

Among them are those who have said:

"Have the verses been sent down?"

Say:

"Yea, by Him Who is the Lord of the heavens!"

"Hath the Hour come?"

"Nay, more;

it hath passed,

by Him Who is the Revealer of clear tokens!

**Verily, the Inevitable is come,
and He the True One,
hath appeared with proof and testimony.**

**The Plain is disclosed,
and mankind is sore vexed and fearful.**

**Earthquakes have broken loose,
and the tribes have lamented, for fear of God,**

the Lord of Strength, the All-Compelling."

Say:

**"The stunning trumpet-blast hath been loudly raised,
and the Day is God's, the One, the Unconstrained."**

"Hath the Catastrophe come to pass?"

Say:

"Yea by the Lord of Lords!"

"Is the Resurrection come?"

"Nay, more;

**He Who is the Self-Subsisting hath appeared
with the Kingdom of His signs."**

"Seest thou men laid low?"

"Yea by my Lord, the Exalted the Most High!"

"Have the tree stumps been uprooted?"

"Yea, more;

**the mountains have been scattered in dust;
by Him the Lord of attributes!**

They say:

"Where is Paradise, and where is Hell?"

Say:

**"The one is reunion with Me;
the other thine own self,
O thou who dost associate a partner with God and doubttest."**

They say:

"We see not the Balance."

Say:

**"Surely, by my Lord, the God of Mercy!
None can see it except such as are endued with insight."**

"Have the stars fallen?"

Say:

**"Yea, when He Who is the Self-Subsisting
dwelt in the Land of Mystery.
Take heed, ye who are endued with discernment!"**

**All the signs appeared when We drew forth the Hand of Power
from the bosom of majesty and might.
Verily, the Crier hath cried out,
when the promised time came,
and they that have recognized the splendors of Sinai
have swooned away in the wilderness of hesitation,
before the awful majesty of the Lord,
the Lord of creation.**

The trumpet asketh:

"Hath the Bugle been sounded?"

Say:

**"Yea, by the King of Revelation!
when He mounted the throne of His Name,
the All-Merciful."**

**Darkness hath been chased away
by the dawning-light of the mercy of thy Lord,
the Source of all light.**

**The breeze of the All-Merciful hath wafted,
and the souls have been quickened
in the tombs of their bodies.**

**Thus hath the decree been fulfilled by God,
the Mighty, the Beneficent.**

They that have gone astray have said:

"When were the heavens cleft asunder?"

Say:

"While ye lay in the graves of waywardness and error."

**Among the heedless is he who rubbeth his eyes,
and looketh to right and to the left.**

Say:

**"Blinded art thou.
No refuge hast thou to flee to."**

And among them is he who saith:

"Have men been gathered together?"

Say:

**"Yea, by My Lord!
whilst thou didst lie in the cradle of idle fancies."**

And among them is he who saith:

*"Hath the Book been sent down
through the power of the true Faith?"*

Say:

**"The true Faith itself is astounded.
Fear ye, O ye men of understanding heart!"**

And among them is he who saith:

"Have I been assembled with others, blind?"

Say:

"Yea, by Him that rideth upon the clouds!"

**Paradise is decked with mystic roses,
and hell hath been made to blaze with the fire of the impious.**

Say:

**"The light hath shone forth from the horizon of Revelation,
and the whole earth hath been illumined
at the coming of Him Who is the Lord of the Day of the Covenant!"**

**The doubters have perished,
whilst he that turned,
guided by the light of assurance,
unto the Dayspring of Certitude hath prospered.**

**Blessed art thou,
who hast fixed thy gaze upon Me,
for this Tablet which hath been sent down for thee -
a Tablet which causeth the souls of men to soar.**

**Commit it to memory,
and recite it.
By My Life!
It is a door to the mercy of thy Lord.
Well is it with him that reciteth it
at even tide and at dawn.**

**We, verily, hear thy praise of this Cause,
through which the mountain of knowledge was crushed,
and men's feet have slipped.**

**My glory be upon thee
and upon whosoever hath turned unto the Almighty,
the All-Bounteous.**

**The Tablet is ended, but the theme is unexhausted.
Be patient, for thy Lord is Patient.**

- Baha'u'llah

Translation of Voice Recording of Chant by 'Abdu'l-Bahá

Praise be to God that we are present in this radiant meeting and turning toward the Kingdom of Abha. That which we behold is due to the Grace and Bounty of the Blessed Perfection.

We are atoms and He is the Sun of Reality.

We are drops and He is The Greatest Ocean.

Though we are poor, yet the Treasury of the Kingdom is full of overflowings.

Though we are weak yet the confirmation of the Supreme Concourse is abundant.

Though we are helpless yet our refuge and shelter is (in) His Holiness Baha'u'llah.

Praise be to God!

His traces are evident!

Praise be to God!

His lights are radiating!

Praise be to God!

His ocean is full of waves!

Praise be to God!

His radiance is intense!

Praise be to God!

His bestowals are abundant!

Praise be to God!

His favours are manifest!

Glad-tidings! glad-tidings!

The Morn of Guidance hath dawned!

Glad-tidings! glad-tidings!

The Sun of Reality hath shone forth!

Glad-tidings! glad-tidings!

The Breeze of Favour hath wafted!

Glad-tidings! glad-tidings!

The rain drops of the Cloud of Bounty have showered!

Glad-tidings! glad-tidings!

The hearts are all in the utmost purity!

Glad-tidings! glad-tidings!

**The Sun of the Supreme Horizon hath radiated to all the world with boundless
effulgence!**

Glad-tidings! glad-tidings!

It is the Splendor of His Highness Baha'u'llah!

Glad-tidings! glad-tidings!

Zion is dancing!

Glad-tidings! glad-tidings!

The Kingdom of God is full of exhilaration and commotion.

Stars

Star Thoughts

We all look up at the heavens in astonishment

and wonder what our relationship is to them.

Some feel the stars affect our daily lives -
and indeed the phases of the moon
appear to effect not only the tides
but other affairs of human lives -
such as the number of births
in large city hospitals.

Certainly other heavenly effects
such as sun cycles
and their effect upon weather
and radio transmissions are apparant.

In the aggregate
there does seem to be a correlation
between personalities and sun signs
and the Chinese cycles of birth years
appears to have some substance.

But the speculations of astrologers
are simply superstition
that have no more significance
(and no less)
than that of reading tea leaves,
or entrails,
or consulting a Ouiji Board.

I say no less,
because astrological prediction
is not something that can be left
to the mathematical calculation of computers.
It depends upon "psychic" interpretation
and like all psychic phenomena
has an explanation within human reality
(more often human unreality)
that it is detrimental to deal with.

Prophetic Stars of Heaven

"And I will shew wonders in heaven above"

(King James Bible, Acts 2:19)

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

The Sesquicentenary (150th Year Anniversary) of the Revelation of Baha'u'llah

Prolog:

**In 1852
(150 years ago this year - 2002)
there sat in Siyah-Chal the Black Dungeon of Tihran
Baha'u'llah
with His feet in stocks
and about his neck an enormous chain
of unbearable weight.
He was imprisoned there from August 1852 to December 1852
before being exiled to the Most Great Prison in Acca.**

The Story:

**The Black Dungeon was really little more
than an unlit sewer
in which were chained together thieves, robbers and highwaymen,
awaiting their execution.
It was without bathing or toilet facilities
creating a horrible stench
that repulsed those sent to remove anyone from there.**

*Remember My days during thy days,
and My distress and banishment in this remote prison.
(Baha'u'llah, Compilations, Baha'i Prayers, p. 210)*

**The Bab too
had been a prisoner.**

*Praise be unto Him
Who at this very moment
perceiveth in this remote prison
the goal of My desire.*

*He is the One Who beareth witness unto Me at all times and beholdeth Me ere the inception of 'after
Hin'. [1]*

**[1 The numerical value of the letters of the word Hin is 68.
The year 1268 A.H. (1851-1852 A.D.)
is the year preceding the birth of the Baha'i Revelation.]
(Above selection from: The Bab, Selections from the Writings of the Bab, p. 18)**

**And so it was
that in the YEAR NINE -
which Moslem Year began in October 1852 A.D.
(1269 A.H. the year 'after Hin')
that Baha'u'llah while in the Black Dungeon
sometime between October and December 1852 A.D.
received:**

The Revelation:

*"I was asleep on My couch:
the breaths of My Lord the Merciful passed over Me
and awakened Me from sleep:
to this bear witness the denizens [of the realms]
of His Power and His Kingdom,
and the dwellers in the cities of His Glory,
and Himself, the True.*

*I am not impatient of calamities in His way,
nor of afflictions for His love
and at His good pleasure.*

*God hath made affliction as a morning shower
to this green pasture,
and as a match for His lamp
whereby earth and heaven are illumined.*

(quoted by Abdu'l-Baha, A Traveller's Narrative, p. 77)

"The Couch" is thought of as a symbolic reference to what Baha'u'llah refers to elsewhere as "the tomb of the body". Far was he from having the comfort and luxury of a sofa. These were terrible times of martyrdom and suffering for the Faith.

The same month that year that saw the imprisonment of Baha'u'llah also saw the martyrdom of Tahirih (Qurratu'l-Ayn) "at the height of her beauty and power" (William Sears, Release the Sun, p. 120)

The Dispensation of the Bab ended when Baha'u'llah experienced the intimation of His mission in the Siyah-Chal, the subterranean dungeon in Tihiran in which He was imprisoned between August and December 1852.

(The Universal House of Justice, Messages 1963 to 1986, p. 739)

The intimation of His Revelation to Baha'u'llah in the Siyah-Chal of Tihiran, in October 1852, marks the birth of His Prophetic Mission and hence the commencement of the one thousand years or more that must elapse before the appearance of the next Manifestation of God.

(The Kitab-i-Aqdas, p. 196)

Signs in the Heavens:

Such momentous happenings were symbolized by happenings in the very heavens above.

*"...I see a strange, a unique conjunction in the stars.
It has never occurred before.*

It proves that a momentous event is about to take place..."
(quoted by Abdu'l-Baha, Memorials of the Faithful, p. 110)

Biela's comet disappeared in 1846. It returned in August, 1852.

**This was the very month and year in which Baha'u'llah was cast into an underground prison in Teheran. It was the beginning of the forty years of his Mission which ended in Israel in 1892 with his death; the forty years foretold by Micah during which God would show to the Messiah 'wonderful things'.
(William Sears, Thief in the Night)**

**The Americana record of this astronomical event states:
"Late in August, 1852, the larger portion again came into view; and three weeks later the smaller one, now much fainter than its former companion was seen about 1,500,000 miles in the lead." Sir James Jeans confirms this: "Six years later [1852], when the comet's orbit again brought it near to the sun, two pieces were observed to be one and a half million miles apart." ...Following this twin-appearance, Sir James Jeans states, "neither of them has been seen in cometary form, but the place where they ought to be is occupied by a swarm of millions of meteors, known as the Andromedid meteors. Occasionally these meet the earth in its orbit, and make a grand meteoric display." The two comets were no longer separate comets, but were mingled in one great shower of light, just as the Faith of the Bab and Baha'u'llah are not separate but one in the light which they shed upon the earth.
(William Sears, Release the Sun, p. 218)**

***'Have the stars fallen?'*
Say: 'Yea, when He Who is the Self-Subsisting
dwelt in the Land of Mystery (Adrianople).
Take heed, ye who are endued with discernment!'
All the signs appeared
when We drew forth the Hand of Power
from the bosom of majesty and might.
(Baha'u'llah, Epistle to the Son of the Wolf, p. 132)**

It is said in Scripture and Tradition that at the time of the birth or announcement of every Messenger of God, a star or a sign appears in the heavens. Nimrod was warned of the star that told of the coming of Abraham. The soothsayers warned Pharaoh of the star in the heavens that foretold the coming of Moses. The Magi informed Herod of the new star that guided them to the throne of the "spiritual king," Jesus. The same legend is told of Buddha, Zoroaster, Muhammad and Krishna. What were the signs in the heavens during the appearance of the Bab and Baha'u'llah? The holy Scriptures of all faiths had spoken of

Twin-Revelations that would appear at the "time of the end." Now that the Bab and Baha'u'llah had appeared, fulfilling these prophecies, what were the signs in the heavens? Signs, not for one, but for two Messengers of God, Who would appear almost simultaneously? Some of us know the story of the great comet of 1843 which foreshadowed the coming of the Bab. Sir James Jeans, late British astronomer and mathematician, stated in his book *Through Space and Time*, "oddly enough, many of the most conspicuous appearances of comets seem to have coincided with, or perhaps just anticipated, important events in history. (William Sears, *Release the Sun*, p. 217)

*With regard to the spiritual influence of stars,
though this influence of stars in the human world may appear strange,
still, if you reflect deeply upon this subject,
you will not be so much surprised at it.*

(Abdu'l-Baha, *Some Answered Questions*, p. 245)

Heavenly Events in 2002:

In this Sesquicentenary Year of the Revelation of Baha'u'llah marvelous events are once again happening in the heavens.

Five planets, Jupiter, Mars, Saturn, Mercury and Venus assembled in a rare alignment during Ridvan this year. Such an astounding display won't be repeated for a century. It was an amazing thing for us to observe as we returned home from the Convention Report on eve of the 5th Day of Ridvan.

The five-planet array is a "standout" of the 21st Century, says Robert C. Victor, an astronomer who volunteers at the Abrams Planetarium of Michigan State University and has specialized in predicting and observing unusual configurations of the planets for nearly four decades.

Victor said there will be only three other chances in the coming 100 years to see five planets so tightly grouped, in September 2040, July 2060, and November 2100.

"BUT the groupings of 2040 and 2100 will have some of the planets barely above the horizon as darkness is falling, so viewers will likely have to resort to using binoculars," Victor said. "None of these three groupings will be as accessible to casual skywatchers as (was) the ... spectacular gathering in late April and early May."

And there shall be signs in the sun,

**and in the moon, and in the stars;
and upon the earth distress of nations,
with perplexity; the sea and the waves roaring;**

**Men's hearts failing them for fear,
and for looking after those things which are coming on the earth:
for the powers of heaven shall be shaken.**

(King James Bible, Luke 21:25-26)

**While momentous events may be heralded in the heavens
let no one confuse this recognition,
of the relationship of all things -
and the appreciation of the mysteries
that exist in the heavens and nature,
with the superstitions of Astrology.**

**"Concerning your question
as to the influence of the stars and planets
on the life of a believer;
such ideas should be entirely dissociated from the Teachings.
(Compilations, Lights of Guidance)**

***O handmaid of God!
The stars in the sky do not exert any spiritual influence on this world of dust;
but all the members and parts of the universe
are very strongly linked together in that limitless space,
and this connection produceth a reciprocity of material effects.
(Abdu'l-Baha, Selections from the Writings of Abdu'l-Baha, p. 160)***

"Astronomy is a science, astrology does not come under the same category, but we should be patient with people who believe in it, and gradually wean them away from reliance on such things."

**(Compilations, Lights of Guidance, p. 516)
(From a letter written on behalf of Shoghi Effendi,
dated December 24, 1941, to an individual believer, Ibid., p. 10)**

"We should attach no importance to astrology or horoscopes. No exact science is involved, though sometimes some truth seems involved, but the percentage is small."

**(Compilations, Lights of Guidance, p. 516)
(From a letter written on behalf of Shoghi Effendi,
dated January 15, 1951 to an individual believer, Ibid., p. 18)**

**"...it is absolutely essential that the teachings should not be confused with the obscure ideas related to numerology and astrology and the like. Individuals interested in them are free to believe in and credit such ideas and to make any inferences and deductions they desire from them, but under no circumstances are they expected to identify them with the principles and teachings of the Cause. We must at this stage preserve the purity and sanctity of the Baha'i teachings.
(Compilations, Lights of Guidance, p. 516)**

and then there is

[The Millennium Star](#)

**And in the Future
the Sign of the Southern Cross
but that is a story for a future time.**

My UFO Experience

by Bruce Beach

If you have some suggestions or comments you would like to pass on to me about these pages you may do so at: DawnSayer@webpal.org

I was a USAF control tower operator in the 1950's at Dobbins Air Force Base near Atlanta Georgia.

This air base was one of five in the US that was an authorized stop for top secret aircraft and as such one had to have special security clearance to work at the base.

Many strange aircraft such as Flying Wings, the Black Bird, and others, visited our base. They were usually parked under special guard - some distance away on the tarmac.

We also had so many UFO sightings that the tower was equipped with a special 3-D camera (something very unusual in those days) to take pictures of them - and there was a special form maintained in the tower that all operators on duty had to fill out - when a sighting took place.

I will tell you about my own sighting experiences at that tower and later at another one,

but first I wish to make mention of four other prior acquaintances that I had with the subject.

I have told these following stories in lectures to a number of astronomical societies (usually with accompanying slides) and have presented them to a number of UFO investigators.

In those days - UFO sightings were a very hot subject, and my native Kansas was a particularly active location, perhaps fittingly, because Wichita is called the Air Capitol of the World, with its many aircraft design and manufacturing plants.

My first experience was when at age fifteen I attended a lecture by a UFO abductee (I have known a great many - and will also tell you about some of them). He attributed the UFOs to five apertures in the earth and reported unusual capabilities of their operators such as the ability to levitate.

About that time a Kansan reported that he had been traveling down one of our empty Kansas highways when he spotted some aliens on one side of the road and a spacecraft on the other.

The aliens scurried back across the road to the spacecraft and he tried to stop

but hit and killed one of them.

He took the body to the University of Kansas where it was autopsied and found to have human-like blood.

The body was about three feet tall

and appeared to be that of wizened old male with pink skin.

It was dressed in a silk like garment.

The autopsy is well documented at the university.

Another report of the same time came from a very reliable source.

This from a retired pharmacist and his wife who were flying overseas

and he shot the pictures out the airliner's window.

There is no way that such a substantial and reliable citizen would have faked the pictures or had the technology to do so.

The film was developed at the Kodak laboratory and it was then that the UFO was seen.

The pharmacist had not noticed it when taking the footage.

The film was shown to have been absolutely untampered with.

Finally, during my air traffic control training

I had to take training in radar.

There the instructors explained about an incidence that had occurred with the same type of equipment in the pacific.

These specialists have as much confidence in their equipment as I do in my own eyes.

UFOs would appear on their screens when there were no aircraft in the area.

These would sometimes stand stationary and at other times move along courses at speeds that were not possible for any known aircraft.

They would also make course changes at an angle - and altitude changes that were impossible for any known aircraft.

A great amount of effort was made investigating the phenomena with numbers of top experts flown in from the states.

None of the above experiences were my own but you can imagine my eagerness and interest about the subject especially with so many items appearing almost daily in the press and given the hushed and excited talk among my fellow operators in the tower when they would come off duty having had to have filled out a sighting form - although they were forbidden to share the sighting details.

I bemoaned my deprivation - and at that early age of eighteen was already quite inclined to be given to speculation about both scientific and mystical matters. I had completed a couple of years of college and was in my third year - my Air Force duties being arranged so that I could attend the University of Georgia full-time.

During one of my many metaphysical discourses in the Base Operations the chief dispatcher spoke up and said -

"Well, if you really want to see a UFO there will be some here Saturday night."

"What? How can you know that? They are totally unpredictable. I don't believe it."

"Oh, yes - they will be here."

"How? Why? How? Why?", I insisted.

Finally, he said,

**"Well, if you must know,
I am a Rosicrucian and I meditated -
and that is the message that I got."**

**Now - I was doubly doubtful,
but I agreed to come.**

**He was going to be on duty that night -
and we were to arrive before sunset.**

**Numbers of others heard about my discussion with him
and about 20 of us gathered on the lawn
between the control tower and the Base Operations Building.
Some came equipped with telescope and binoculars.**

**We also brought watermelon
and much discussion between myself and the Rosicrucian.
(I suspect that you can imagine myself in such discussion -
now over 50 years ago.**

**One person later told me later that he hadn't even known
that it was possible to think thoughts like that.)**

**Dusk came and the mosquitoes came out.
I suggested that we take the discussion inside.
About an hour after total darkness
the squawk box from the tower blared -**

"We have UFO's out here."

"Are there any planes in the area?"

"Yes, two JUGs (fighter trainers)

from the Naval Air Station."

"Well, send them after them!"

**(Established SOP (Standard Operating Procedure)
at this tower.)**

**From the first bleep of the squawk box
the screen door of the operations shack had flown open
and a crush of airmen had poured out onto the lawn.**

"Where?"

"There!"

"I see them."

**Through the open doors and windows
we could hear over the squawk box
the discussions taking place between the tower
and the pursuit planes.**

"Yes, tower, I see them - will pursue".

**There was a battle going on to access the telescope.
A voice from the tower -**

**"Turn on the GCA -
(the Ground Controlled Approach radar).**

"It will take 30 minutes to warm it up".

"Go look at the weather radar".

**I was too low in the pecking order
to have any hope of looking through the telescope
or one of the sets of binoculars -
but from the tower to the Base Operations Office**

there was a wire stretching down (for the squawk box).
This I lined up on the largest of the three UFOs
and could see that it was starting to move.

There were three in view.
One larger and the other two smaller or further away.
They had the appearance of a bright orange light -
about the same as one sees on oil well flares -
if you are familiar with those.
One the diameter of a quarter - the other a nickel and a dime.

Their presence had been there for three or four minutes,
but now they began to fade
and from the pursuit plane we could hear -

"Tower- they have disappeared."

"R-roger. We don't see them any longer, either.
Return to your pattern."

I, and my audience, :)
returned to the operations building
and the dispatcher and I continued our discussion
for another hour or so.
End of this event -
but they get more exciting.

Now, for a daytime sighting.
(These stories are usually accompanied by photos -
and I guess I could scan and put them here -
well, maybe someday -
but I feel guilty about taking so much time
to write this - as it is.)

This next event happened on an exceptionally beautiful Saturday.

Usually, I worked the mid-night shift so that I could attend school - but I was also required to pull weekend day shifts.

The ANG (Air National Guard) pilots had to get in so many flying hours each month in order to maintain their ratings.

The weather being exceptionally beautiful - this is the day they all decided to fly. The field had never been so busy.

Three control tower operators on duty already - and I was a spare - with no position available at the console.

Sort of there on punishment for not pulling regular shifts.

So I had to sit perched on the slanted ladder (that went up to the roof) behind the radio receivers.

Excellent view - but borrrring. No duty except to watch.

Down on the tarmac every old C-45 in the place was cranking its engines.

(If I hadn't had to work -

I would have flown with one of them.

I have all sorts of stories about flights in different kinds of planes, crashes and other exciting events,

but I can always tell more than people can bear to hear. That comes from being a raconteur.)

**The old C-45s were OLD.
And their radios didn't work very well.**

**"Tawr ths 4#%euc"
"Say again aircraft."
"#%^ tAWR thiz AF 47.^**"
"Aircraft you are garbled -
wiggle your flaps and we will use the light gun."
"@#\$@%%"**

**While all this was taking place the three controllers
would all move over by the speaker
and sort of bend their ears down to it to try to understand it.
And I would sit on my perch -
sometimes giving an advisory -**

**"Plane at base" (the last turn before final)
"Plane entering on downwind"**

**A couple of miles from the field
and running parallel to it
was a large power line
running through a swath cut in the trees.
About once a week a small plane would fly down the power line
to check it.**

**As I was watching I could see the plane
which was at too great a distance for me to make mention
but then it did something unusual -
it turned back away from the tower
and then back toward the power line
and I thought -**

"Aha! the pilot has spotted something that he is going to double check."

**But then -
instead of turning and following down the power line
the plane continued on towards the field.**

"Small plane entering on the downwind", I said.

**A wave from the A controller, who did not even look up -
from trying to understand the speaker with the other controllers.**

**Somehow, the plane was looking strange to me.
In varying light and at varying angles
one has to somehow to sometimes tilt their head
to identify the aircraft silhouette
and the type of aircraft they are observing.
I couldn't see any wings.**

**I leaned forward
and picked the binoculars off the radio console.
Put them to my eyes -
took them away -
put them to my eyes again -
and stood up on one rung of the ladder
leaning out by holding onto another rung
and pointing with the binoculars said,**

**"Get the camera -
(which was sitting on the window sill
beside the B operator position)
we have a UFO out here."**

Again - a wave from the operators.

"Look - its a UFO!"

At this point the UFO had come up and parked right in front of the tower window.

Traditional form saucer shape - bubble on top that appeared solid also without windows. Possible power ports at both ends.

The operators now turned and looked at me - rather than out the window.

"Where?"

"There!", pointing with the binoculars.

But as they turned - it left - at the speed of light to my right. They never saw it.

I had better luck the next time. It was a midnight shift and the shift chief was S/Sgt. Kelly. There were only ever two people on the night shift - myself and a shift chief.

Usually, I was the only one awake. They all loved to work with me because I would sit at the console doing my studies all night long - and they could sleep.

Kelly slept on the floor with his feet towards me - so that I could tap them if I heard the OD (Officer of the Day)

coming up the stairs.

Then he would just kind of sit up on the floor like he was adjusting the radios in the console that was between us and the stairway.

This night we had only one aircraft in the pattern - a PBY (Patrol Boat Navy - they can land on both land and water) over from the Atlanta Naval Air Station that was getting in a required number of TOL (Take Offs and Landings) (you want them to come out to an even matching number). They say the PBY takes off at 75 mph - flies at 75 mph - and lands at 75 mph. Not too terribly exciting but we did have one pilot that had flown with Doolittle - and we were always coaxing him to do a JATO - (Jet Assisted Take Off) in which the plane would fairly jump into the air.

Our base commander had made a ruling much to the pilots' chagrin that the planes had to fly the full length of our ten thousand foot runway before turning out. It made for a long time consuming flight for a PBY. Another thing about the PBYs was that the tower was supposed to visually check that their gear was down - because some of the Navy pilots would forget that we were a land base. Over on the land runway at the Naval Air Station they had a great big bill board that said - "WHEELS" -

but we didn't.

**The PBY had lumbered into the air
and was flapping down the runway
and I was taking one last look around
before I returned to my studies -
when I noticed a light far off the end of the runway.**

Hmmm. Strange.

**Maybe the red light on the end of the Lockheed plant.
Nope. Over to my right the Lockheed light is still there.
Maybe something on the mountain.**

Binoculars -

and scan down to the skyline.

Nope - it is above the skyline.

Big light - maybe Venus -

though that is not usually red -

**and we are past midnight - way too late for Venus
and wrong direction and not early enough
for when it becomes the Morning Star.**

Hmmm. Better study this.

Aircraft maybe.

Steady watch.

No motion.

No change in size - not approaching or retreating.

Possibly a helicopter standing steady -

but no aircraft advisories and highly unlikely.

Theodolite - but way too distance -

and again holding steady.

Besides no notification from weather that they were launching.

The PBY has now long turned out -

and is on downwind.

**"Uh, Kelly,
we have something strange here -**

I think you had better look at it."

"What is it?"

**"I don't know -
I want you to look at it."**

"Why?"

"Well, I think it may be a UFO."

"Knock it off, Beach"

**"Kelly, take a look at this,"
tapping his shoe with my boot.**

"Grrrf. Knock it off, Beach"

**"Kelly, look at this -"
accompanied with a really solid kick!!**

"Growllf -" and Kelly has sprung up.

"Beach, I am going to -"

**"Look -" I say pointing with one hand -
with the other still holding the binoculars
to my eyes.
I have never taken them off the UFO
the whole time that I have been talking to Kelly.**

"What is that?"

"I don't know. A UFO."

"Where is the PBY?"

**"On the downwind.
Let me send it after it."**

**"No.
What is that?"
Kelly now has another set of binoculars
trained on it.**

**"A UFO -
lets send the PBY after it."**

**"We can't do that.
What do you think that is?"**

"A UFO."

At this point the PBY speaks up -

**"Tower, this is PBY on downwind -
gear down and locked,
request permission to land."**

"Negative PBY, check at base."

**A long silence. The pilot is looking around -
wondering what in the world? Finally, he says -
hesitantly -**

"R-roger tower, will check base."

**"Kelly, let me send him after it -
he will be glad to go
and he doesn't have anything else to do.
We are authorized to send pursuit planes."**

"What do you think it is?"

**"It is a UFO Kelly.
C'mon Kelly - lets check it out."**

**All this time both Kelly and I have our binoculars
on the UFO. I only take mine down to speak to the PBY.**

**"Tower, this is PBY at base -
gear down and locked
request permission to land."**

"Come on Kelly -"

**"Tower, this is PBY at base -
gear down and locked
REQUEST permission to land."**

**"Negative, PBY.
Check at final."**

A REALLY long silence.

"Roger tower."

**"Come on Kelly -
when he turns final
he is going to be lined right up with it.**

**He can just go right ahead after it.
Let me send him after it Kelly."**

Silence from Kelly.

**"Tower this is PBY.
Turning on final -
Gear down and locked.
AM I cleared to land?"**

**"TOWER! This IS PBY.
On final - AM I cleared to land?"**

"Roger, PBY, your are cleared to land."

"THANK YOU, tower." (Pure ice in the voice).

Kelly finally speaks.

"Okay, you can ask him if he wants to go check it out".

**"Alright!"
I grab the mike.**

**"But you can't speak to him on final."
(This was SOP)**

"Arrrrgh."

**Wait, wait, wait.
Watch UFO through the glasses.**

(Kelly never takes his off it).

**Glance back at the PBY.
Wait, wait, wait.
Watch UFO through the glasses.
Glance back at the PBY.
This one must have figured out how to fly at 30 mph.**

Finally, the PBY touches down.

**"PBX - continue landing roll for immediate take off.
There is a UFO off the end of the runway -
we would like for you to take a look at it."**

**"Roger Tower - PBX continuing landing roll
for immediate take off."**

**"Tower - this is PBX
we are airborne -
where is the UFO."**

"Directly ahead of you PBX."

Silence.

**"Tower, this is PBX -
we still do not see the UFO."**

"It is directly ahead of you PBX."

Silence.

**And then as Kelly and I watched
the UFO faded away.**

**"Tower, this is PBX -
we still do not see the UFO."**

**"Roger, PBX.
It has disappeared.
Check gear on downwind."**

"Roger, Tower."

You can see why shift chiefs

**don't like to send planes after UFOs -
but it was nice to have SOMEONE seeing
what I was seeing.**

**The next episode also occurred at night -
but this time it was in perpetual 24 hour night
in the Arctic.**

**Again, I was the only operator awake in the tower.
Suddenly, there would be a light flash
out of the corner of my eye.**

**I would jerk my head up from my studies,
or turn around if I was standing up.**

Gone - nothing.

**We had no light beacons in the subdued lighting
of this SAC base.**

Sudden alerts would occur.

**Doors at both ends of the hanger would roll up
the fighter would fire up in the hanger -
and be gone -**

**straight down the runway -
afterburner blazing as it hurled into the sky.**

But usually nothing.

**Just darkness and subdued lights about the base -
except -**

except --

I know I saw a light.

Ask others -

do they ever see it.

Nope.

Almost a pattern, I decide.

Hours to sit in the darkened tower.

**Trying to stare out into the darkness
with out blinking.**

There it was.

Darkness.

And again.

Now I know the direction to look.

There.

Now.

Again.

And again, and again, again.

But then long periods in between.

Some strange phenomena.

But not the Northern Lights - we are too far north.

Days of study.

Finally, I know.

**It is the water trucks,
turning first one curve and then another
up in the mountains
below the skyline
but their headlights faintly catch
many miles away
the snow cliffs on another mountain.**

**Light is phenomenal -
and there are natural explanations
for much of what we see.**

**The early autopsy at the University of Kansas
had a natural explanation.**

**The creature had human like blood
because it was a Rhesus monkey.**

That is from where we get the term RH factor for blood.

The hoaxer had amputated its tail,

**let it heal, shaved it,
dressed it in silk,
and killed it -
before going to the university with his story.**

**The retired pharmacist
was not a hoaxer.
He actually shot the amateur movies.
They weren't doctored.
It took many hours of flying an identical aircraft -
at different angles to the sun
while shooting an identical camera
from the seat in which he had been sitting -
to get the light reflections from off the tail
to again create a UFO on the film.**

**The military radar men
were straight arrow also.
They saw what they saw.
But what they saw,
it was shown after months of investigation -
was a radio signal set off by a special code
aircraft id-transmitter
sent at a very high frequency
by planes that were over the horizon
and completely out of range of their radar.
The signals somehow bounced off the ionosphere.**

**My Rosicrucian friend may also have been a jokester.
In any case, I learned to duplicate what we saw that night.
And have done it.
An aluminum pie pan like you get with a bakery pie.
Punch 20 one inch slits in the bottom of it with a sharp knife.
Take a dozen or so short birthday cake candles.**

**Light them and stick them about the pan.
Put the open end of a light plastic garment bag
from the dry cleaners
over the pie pan
and scotch tape it to the pan
so the pan sits evenly below the bag
and air can be drawn in through the slots in the bottom of the pan.
The bag will fill with the hot air.
Release into a dark moonless night
(in an area where it will not cause a fire when it descends -
I have had them come down on people's house tops -
THAT adds to the excitement!)**

**Now stand and point at the UFO.
You can't tell if its hundreds of yards away -
or miles away -
as it glows eerily in the night sky.**

**Took me years to understand my daytime observation.
Asked psychiatrists -
(I became a psychiatric social worker
and took graduate courses in psychoanalytic theory) -
if we could review the event through hypnosis,
but that is not possible -
because just as with reviewing past lives under hypnosis -
hypnosis IS suggestion -
one will "see" whatever it is that they are "supposed" to see.**

**Finally, I decided it was a delusion.
Not even an illusion -
because with illusions -
such as mirages or my lights in the Arctic,
there is some physical base to the phenomena.
However, I came to the conclusion**

**that if there had been something there -
with all those hundreds of people at the airstrip that day -
someone else would have seen something.
Sometimes you really cannot believe your own eyes.**

**Most of my space abductee friends
are also deluded.**

Although, I have met two charlatans.

**The fellow giving the lectures when I was about fifteen,
knew that he was lying.**

**Another charlatan of my acquaintance
may have been deluded at one time.**

Met with him weekly at a space group luncheon.

His books sold many multiples of thousands.

Especially in Japan.

**He would announce that he was going off
on another space trip -**

**and we wouldn't see him for a few weeks,
but then he would reappear with another book.**

**My Venusian friend is as honest
as the day is long.**

Very deep insights into many things.

How many of you have Venusian friends?

**You may not believe that he is from Venus -
and I may not -
but he does.**

And he travels there quite regularly on occasion.

Lots of traffic to Venus.

I have a number of friends who have gone there.

**They are completely schizophrenic
but it does not make the trip any less real for them.**

Reality is often hard to determine.

**In TRUTH - Reality is ALWAYS hard to determine.
It is nice to have someone share the experience with you -
as many did with myself and my Rosicrucian friend -
or as Kelly and I did that night in the tower -
(I still have no idea what THAT was about).
But, shared mass delusion is not as uncommon
as one might think.
In fact, I would go so far as to say -
that it is very common in almost all cultures.**

**I believe in flying saucers.
Just not sure that I have ever seen one.
I have seen the Roswell autopsy movie -
(Boy, THAT was good!)
but the evidence to me seems pretty certain
that it was a fake.**

**There are many mysteries that I have seen
in the pyramids and various places
that I have traveled about the earth -
that do seem to me to be significant evidence,
but I feel far too many of my friends
accept UFO ideas,
Chemtrail ideas,
Crop Circle ideas,
NEO asteroid and planet ideas,
and all sorts of CONSPIRACY ideas -
without really sufficient evidence.**

**Some cultural ideas
about resurrection, rapture, return -
are so embedded that you do not dare challenge them
with many individuals.**

**But I can tell you -
that in the fifty years since my UFO experiences
I have discovered
that there are MUCH GREATER MYSTERIES
and phenomena that YOU can come to understand
if you are willing to go beyond the
vague fancies and vain imaginings of most men.**

**Those are the TRUTHS that I seek to lead men into -
and it is for that reason alone -
that I take the time to write these long explanations.**

**Those that have already made up their minds
about these many subjects that I have mentioned -
will often just be angry that I appear to challenge
their beliefs.**

**But, I can always hope
that there will be some
who truly seek the Truth
and that will respond -**

**"Beach, if you can really point out the Path -
then I want to hear about it."**

**It is for they -
that I always wait and listen.**

**Peace and love,
Bruce
