thats it alright, that was done in 1976 it said, and my teacher told me about it in 1984. From the article, it sounds like it would have to be huge to generate enough electricity

---

Oil Heater/Foundry/and Stirling  
Staring Johnny Cool Pants

Heating your home/shop, making your own parts, and other places you can use your custom larger Stirling Engines.

Waste Oil Heater & Back Yard Foundry

If you live in the woods like many of us here in the Great Northwest, it is not practical to have a windmill. Going taller than the trees is not easy and cutting them down is not cool. There are many streams and creeks here but not on every property, so water wheels are not always an option and they are already a known science.

It rains alot in the forest and people heat their homes alot. So my focus is on using that heat, or heat recovery and I will get into ideas for using rain some other time on this board.

Pouring your own metal in a back yard foundry is a growing hobby.

You can sand cast your own custom windmill / water wheel parts. Then grind, buff, polish, or leave rough. Now, where to stick that Stirling? I know some of you may reply telling me where to stick it, but that is the beauty of free flow info and opinion, however I remind you this is Q-zone and in here flame wars can get intense enough to run a Stirling.

The Flue part is comical but actually could function as further heat recovery (both Stirling and heat wind blades) if you used your foundry a lot. I don't expect most people would use their foundry often enough,

unless you were building Larger Stirlings to sell, then your foundry would be very busy

This is for the most part assuming you will use it on occasion to build custom parts they don't make, for your other projects. Stirlings are very simple motors, you have to have a blower, might as well make a Stirling to run a mechanical blower, instead of electric, make you look real cool.

So basically focus on the bottom half of that illustration for now. There is a possibility a large Stirling under that intense heat could produce enough electricity to run an electric blower, even steam power possibilities here.

Running an electric blower is in no way, running it's self or providing it's own heat. It is not a claim of overunity.

#### Waste oil heaters

Waste oil heaters offer an excellent way to heat your home or shop for "near free" and also offer good place to put a custom larger Stirling hot air motor/electric generator, running for "near free"

<http://www.ecologixsystems.com>

Sells burners and bunch of waste oil "treatment" machinery for what looks more like commercial use. Not really necessary for most home use, in my opinion. These links can give you ideas though, for size and operation methods.

Reznor oil heater

[http://www.reznoronline.com/mpd/pub/wo/us\\_brochure/features.htm](http://www.reznoronline.com/mpd/pub/wo/us_brochure/features.htm)

Torrid

<http://www.torrid200.com/>

Let's say you have a shop and you want to do your part to help the environment. If you have oodles of money you just buy one of these things, but if you are like a lot of us, you are also trying to save money in the first place. So just make your own waste Oil heater. You don't need that fancy fan in the back either.

If you need a fan at all, that fan can be run free using a stirling powered fan, as well.

Not sure of their prices but these "Smart Ash" portable incinerators can be converted to heaters pretty easy, but this link is more to show you if they can convert an oil drum into an incinerator, you can convert an oil drum into a waste oil heater.

<http://www.elastec.com/smartash2.html>

Here's Mother Earth's Waste Oil Heater with instructions on how to build one for under \$40 though I don't know when that was written, could have been way back, I have many of the original magazines, a gold mine if you move away from Internet access.

[http://journeytoforever.org/biofuel\\_library/ethanol\\_motherearth/me4.html](http://journeytoforever.org/biofuel_library/ethanol_motherearth/me4.html)

You can heat your shop using the vegetable oil you cooked with the week before, you can use old motor oil, etc. If you are worried about smell, these burn much cleaner than you may think for recycling used oil, however you can construct your waste oil heater so it is through the wall, with only the heat box on the inside of your shack, if you don't mind having to go outside to light it. You can screen in that porch, or frame it in if you have bears.

Then you can talk your neighbors, maybe even your local auto service station into giving you used oil. Some fry food restaurants may give you lots too. Heating your home, shop, whatever, can be near free all winter long.

"Links" to some of these pages of mine can be posted elsewhere on the board if desired.

Why do I post here in Quarantine? It's a form of protest, I don't think any science with the desire to improve situations should be Quarantine, even if it is the kookiest idea, there may be one part of it giving someone else an idea. So I crank up a flying circus to get people to at least peak in here, now I find out not much gets sent here since it started, so I pretty much get my own page to go with my own show, tee hee.

PS

Plus some of my stuff was sent here to Q-zone anyway. Casualties of flame war.

This is another good page on back yard foundry

[http://www.artmetal.com/project/TOC/proces/cast/ag\\_cast.html](http://www.artmetal.com/project/TOC/proces/cast/ag_cast.html)

Here is a guy using microwave ovens to melt metal

<http://home.c2i.net/metaphor/mvpage.html>

Note:

If using a Stirling hot air engine with your foundry, depending on what your Stirling is made of, ha, you should have a length of buffer pipe from the foundry to the Stirling engine so you don't melt down your Stirling engine.

Most people will be melting common metals in their foundry so order a piece of pipe that melts at a higher temperature than the stuff you will normally work with.

This is where I get my metal because I can drive there and pick it up, but they have a good selection.

<http://www.onlinemetals.com/>

First Electric Car?

First electric Car circa 1900

Had magnet and coil motor right in each front wheel. Each front wheel (was) the motor, that car, a Porsche.

"In the year 1898 when a new century was ready to begin and nobody had heard about the Y2K effect, Jakob Lohner a coachbuilder who owned the " k.u.k.-Hofwagenfabrik Jakob Lohner & Co ", with manufacturing facilities in Florisdorf, Vienna, decided that it was the right time to build and sell a modern " horseless carriages " to bring such vehicles up to date, offering the latest technical developments to his distinguished customers among them the House of the Hasburgs .

Lohner disliked " the new horseless carriages " powered by explosion engines that were beginning to run around the roads because he considered that they were too rude, dirty and noisy for his aristocratic customers.

In order for the project to come through safely, he hired as chief engineer a 25 years old, engineer, named Ferdinand Porsche, who as a student of the Imperial Technical School of Reichenberg, had learned and experienced with youthful enthusiasm with electricity as a propulsive energy.

The brilliant ideas usually are the simplest and the more beautiful ones, and this was the case of the propulsion system devised by Porsche for the new Lohner electrical vehicle."

Tesla had a car.

In the late 1880's, Dr. Nikola Tesla accidentally discovered an electrostatic "super-charging" effect while trying to verify Hertz' discovery of electromagnetic waves. After hundreds of experiments, he learned how to control and maximize this phenomenon. This led him to the discovery that electricity is made up of different components that can be separated from each other, and that a pure, gaseous, etheric energy can be fractionated away from the flow of electrons in a circuit designed to produce short duration, unidirectional impulses.

When all of the conditions were right, this etheric energy would manifest itself as a spatially distributed voltage that would radiate away from the electrical circuit as a "light-like ray" that could charge other surfaces within the field. Tesla found that this effect was greatly magnified when these impulse currents were produced by the discharge of a capacitor.

This huge explosion of electrostatic energy, that radiates away at right angles from the capacitor discharge pathway, is the primary operating principle of his Magnifying Transmitter. With amazing device, Tesla planned to broadcast energy to the whole world from his facility at Wardencllyffe, New York, for dirt cheap.

After Tesla was prevented from bringing his World Broadcast System into full manifestation, he worked for years to develop a smaller version of the device that harnessed the same principles. By the 1920's he had succeeded. This specialized electronic circuit is what powered his infamous Pierce-Arrow automobile.

He had removed the motor and ran the car using a mysterious little black box. The car ran for three days in the demonstration until people got tired of watching and Tesla's assistants drove it back to the lab.

The Bay Area recently joined Sacramento, Los Angeles, San Diego, and Phoenix and Tucson, Ariz. as the only areas where consumers can lease (not purchase) the first electric car in mass-market production, General Motors' (GM) EV1, which is being distributed by Saturn retailers.

The enduring appeal of electric vehicles stems from their motors: clean, quiet, reliable, low-maintenance, energy-efficient and, in themselves, non-polluting. While dramatic improvements have been made in electric vehicle motors, the battery is still the Achilles' heel. The long sought solution to storing electric energy on board has yet to be realized.

Yeah, I saw that a while back. It is definitely cool to watch. Isn't it computer generated?? The wheels rolling up hill doesn't look quite right to me!!

Too bad it's a Honda commercial..... ;-)

Re: I just think this is soooo cool!!! ([none / 0](#)) ([#2](#))  
by Bach On on Thu Jun 19th, 2003 at 04:40:57 PM MST  
([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

No. It wasn't computer generated. It was done live as a commercial. There were a series of articles written about it. I'd bet they had to do many, many takes before it all worked correctly.

It may be old, but I hadn't seen it before. Somehow, I think Rube Goldberg would approve.

Thu Jun 19th, 2003 at 09:25:17 PM MST  
([User Info](#))

Actually if you look real close, you can see that part of the wheels are weighted, so that's why they could roll up hill for a bit. (The wheels were balanced so that when something would hit them, the weighted end would fall forward, and hit the others)

## Combined Power

By [zork](#), Section [Magnets & Magnetism](#)

Posted on Wed May 21st, 2003 at 09:49:54 PM MST

[Science Fair](#)

I know that if you attach 2 or more magnets together, the power of the field increases.

---

I know that if you attach 2 or more magnets together, the power of the field increases.

My question is, is some of the power lost or is it the exact power of both magnets combined? I would think that they would loose a bit of power, but I'm not sure.

[Combined Power](#) | 10 comments (10 topical, 0 editorial)

Stacking magnets... ([none / 0](#)) ([#1](#))

by [xeroid](#) ([centurion27@lycos.com](mailto:centurion27@lycos.com)) on Thu May 22nd, 2003 at 01:38:56 PM MST

[\(User Info\)](#)

I will need some back up from more qualified colleagues here on the board (Dan B?) but I am pretty sure that stacking magnets only increases the magnetic flux. I don't think there would be any losses, and if there are any, I would think they would be negligible. Stacking magnets is an effective way to force more magnetic flux through your coils. The only thing to consider is the added weight, but with small neos, that's not usually a problem.

Mess around with it. I'm sure you'll find it will give you some more bang for your buck.

Regards,

Xeroid.

Thanks ([none / 0](#)) ([#2](#))

by [zork](#) on Thu May 22nd, 2003 at 07:03:53 PM MST

[\(User Info\)](#)

Thanks, that'll help.

I've considered the weight issue, but you've got to compromise somewhere.

Zork;

Be advised my gauss meter is my hand and is uncalibrated and the scale is not marked.

I kinda fooled around with one neo and then a pair stacked. The how hard is it to pull off the steel door test revealed to me that while 2 is definitely harder to pull off it does not seem to be even near 2X the force to remove 1.

Cheers.

TomW

([User Info](#))

70%?

I'm hearing some conflicting responses...anyone has a definite answer?

[ [Parent](#) ]

Conflicting opinions ([none / 0](#)) (#6)  
by TomW on Fri May 23rd, 2003 at 09:09:46  
AM MST  
([User Info](#))  
<http://oneota.net/~earthsourcepowr/>

Conflicting opinions are pretty normal here.

DanB has a gaussmeter and thats one person we could bug until he gives us some numbers.

But the tests i did on the steel door suggest somewhere in the 125 to 150% increase over 1 magnet when using 2. This suggest to me that dual opposed magnets be better than stacked with all else being equal. I say that because pulling 2 magnets apart is definitely more than 2X what it takes to pull one off steel. Again just observations.

Cheers.

TomW

Distance issue ([none / 0](#)) ([#8](#))  
by Anonymous Hero on Sun May  
25th, 2003 at 12:24:08 AM MST

I don't think it decreases in power, but you have to take into consideration the fact that both of the magnets are not an equal distance from the object.

[ [Parent](#) ]

stacking magnets ([none / 0](#)) ([#9](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sun  
May 25th, 2003 at 07:20:09 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I just did a test using Dan's item #27 magnets and the reading from one alone is around 3000 gauss, adding one more brings it up to 4000 gauss, adding another one it goes to 4600 and a 4th one up to 4700. It appears the most significant gain would be by doubling and the rest is too small to make a cost effective difference. So that's about a 33% increase. It doesn't seem like you're making the magnet stronger I think you're simply expanding the field a bit more so this would increase your output...

Have Fun

Ed;

Thanks for corroborating my hand gauss test with actual numbers. This magnetism stuff is such an odd phenomenon it doesn't always work the way you would expect.

Cheers.

TomW

Hey, I have an idea... Why not get rid of anonymous heroes... That way people can't hide behind anonymity to take cheap pot shots at the board or other people.

... Ever heard of "cut" and "paste"? These two magical commands can save you a lot of re-typing.

If you truly think the new board is "lousy", feel free to not use it.  
Regards, XEROID.

no argument there ([none / 0](#)) ([#2](#))

Subject says it all.

Well when the "old board" goes read only it will be pretty quiet over there.

Not sure why people bitch so much about how a free resource works after its upgraded to 21st century software.

Plus I have confidence that soon this board will look and feel a lot like the old board but actually be useable as an archive of awesome data.

I figure we will lose a few long term members but thats just how it goes.

Cheers.

 I'm sure someone has already thought of this but...

I'm sure someone has already thought of this and one of us has already ran across it on the internet, how about hoisting a small wind genny up where the wind is really blowing with a gyrocopter type kite? Does anybody on the board know how to make the blades for an autogyro? (Remember I'm talking about a Small science fair type of outfit here!) Norm.

Flying Blade ([none / 0](#)) (#2)  
 by [Johnny Cool Pants](#) on Sun May 11th, 2003 at 08:46:33 PM MST  
[\(User Info\)](#)

Flying Blade  
 They can be designed so they land perfectly when the wind dies out and then lift back up again when the wind picks up.

Besides the main line it can have lines on the wings leading backwards behind the kite plane and grounded to reels with low resistance. These would help stablize it and reel it back down level as the winds die.

Wing is always angled upward for instant lift when the wind starts up again. Line the wing with genny props. Give it light weight wire frame shock absorbing mosquito leg landing gear.

I used to fly these really ugly "paper bag" kites that were hexagon shaped and about 5' in diameter.

When you get them up high enough, they can literally fly for days and days since there are various layers to the atmospheric currents.

Anyway, the best way to send your power back down from a flying turbine would be to make it high voltage electrostatic impulses at about 20kv. You only need a single, super-thin wire going up the rope to the turbine. One electrode from the HV output goes to a little cluster of needles that all point straight up into the sky. The other electrode is attached to the wire coming down to you.

Your end of the wire goes to one side of a high voltage capacitor and the other side of the capacitor goes to a metal rod that's stuck in the ground.

Hook up the HV terminal of a car ignition coil to one side of a spark plug and the other side of the spark plug goes to the sky-wire side of the capacitor. The - terminal on the ignition coil goes to the ground rod.

Now just connect your battery between the low voltage terminal on the coil and the ground rod.

Every time the capacitor get's full enough it arcs through the spark plug and into the coil's hv side. This makes the low voltage side put out a high current, low voltage pulse to the batteries.

You'll also be collecting excess electrostatic charge just from the wire being in the air. So, efficiency should be better than normally expected.

Tesla did this in the 1890's. It's in his patents.

#### Solargizer Components

Hello All,  
I've purchased A Solargizer PN i735x150-241.  
I have no manual and Plustechs sit offers nothing.  
Its not what I expected but it may be useful.  
The questin I have is what the moodule between th Solar panel and the battery connection is. The Solar Panel say 12v-24v. and not much on the module. IS this a transformer, regulator??. It seems very small.  
Thanks in advance.  
Steve

Don't know, but it might be a blocking diode.

Re: Solargizer Components ([none / 0](#)) (#2)  
by [sle Cain](#) on Mon Dec 15th, 2003 at 04:26:16 PM MST  
([User Info](#))

To big,  
I'm pretty sure I see a blocking diode on the panel itself.  
Nice guess, and you may actually be correct because I don't know how old it is.  
Steve

Steve the Solargizer you have is for desulphating 6to24 volt batteries .The black box is the electronics for converting the 4.5 volts coming from the panel and pulsing it into the battery at 40 volts. If you connect it to a battery in low light the led should start flashing and in high sunlight should be on continually.You can test it By Placing a radio close to the Battery and tuning it to the frequency of the Solargizer.

George K.

[Interesting solar power use I ran across](#)

By [chuckh](#), Section [Homebrewed Electricity](#)

Posted on Wed Dec 10th, 2003 at 11:41:11 AM MST

[Solar](#)

Thought this was creative solar use.

On a sailing forum I ran across what I thought was a pretty creative idea. Thought people here might be interested.

A fellow has a large trailerable sailboat. Uses solar panels for charging battery bank during boating trips. Plus can use the boat as a camper when trailering to boating area. When the boat is at home, plug it into house system.

Got me to thinking about other possibilities.

Motor home or camping trailer with solar panels and large battery bank for travel. Can stay at cheaper and/or secluded camp sites with no power. Plug it into the house system when at home. Plus have a guest room.

People with a remote cabin. Mount solar panels and battery bank on a trailer. Take it to the cabin. Plug it into house system when at home.

Anyway, I'd never seen anybody mention this type of thing and thought it worth sharing.

Chuck H.

I met a guy who runs his whole house in downtown toronto on a huge battery bank he keeps in his one ton van. He drives it to work and plugs in. He owns this buisness (rebuilding batterys etc.)and also enjoys 100% tax write off from this power I imagine.

Aparently had a discrepancy with hydro and told them to hit the road.

Marv.

This is what I did this summer with the old Mini Wini. I put the genny up only when camped. It works great. We've got 14 12 volt batteries onboard. No generator.

A 2500 watt inverter to power, small electric heater, tv vcr combo, iron, microwave oven, hair dryer, other electric hair things (wifes stuff), mixer, drill, sawsall and some other things but not all at once. We've been out 5 days at a time with plenty of power. The genny is a tape drive motor and

3 Jerry blades. JK TAS Jerry

And if you ever did run out of power you could always go for a drive. :-) Maybe I'll mount one of my turbines to an old Rx-7 I've got sitting out here so if the wind doesn't blow I can just take it for some spins around the pasture. LOL Hmmmmm, I wonder if some of DanB's tests were really tests. ;-) Seems like a good idea though, if you're off the grid, maybe put the batteries and turbine on a trailer...blah blah blah

Just wondering if anyone has checked out this site and any of it's claims. I've long thought that if solar and roofing were combined it would become a viable alternative. This company seems to be making headway. Unlike many other sites that "claim" to have the answers; i've visited this place and it does exist. I know i'll be keeping a close watch on developments from this company in the near future.

I welcome unavoidable most valuable principles for my system

Hi guys,

I'm a newbe and I love this discussion group. I posted a request for solar cel WB-27 distributor and the discussion went on and ended how PV w/d can be stretched beyond my upmost understanding .Altenergystore introduces this PV as having odd voltage 23.2V. Does this mean off spec? Partonsale claims that they don't sell off spec panels! Ed illustrated that 6.82 amp X 14.6V comes to 95W. Where did the 6.82amps come from as PV are advertised by watt ouput. This illustrates that we must investigate beyond watt rating posted. Chuck illustrated further that his own panels rated at 630W come out to an upmost 500 watts even with a MPPT. I'm baffled. I welcome a few unavoidable principles for purchasing PV and MPPT which would be the most valuable for my system powered by 2 Trace DR2412, 2400 amps battery bank and an Onan diesel generator for a remote cabin under construction. -- Richard

Maybe you already know this, but the discrepancy between ratings and actual measured output comes from the fact that most manufactures rate the output of their cells using a standard amount of sunlight falling on them: 1000 watts per square meter. When the cells' output is measured in the real world many factors come into play that degrade the theoretical rating. The angle of the sun in the sky, the time of day, the angle at which the cells are pointing, atmospheric effects, temperature, the material covering the cells, quality of solder joints, resistance due to wire size (and length), and the fact that some cells just turn out to be 'duds' all affect output. The manufacturer's rating might best be viewed as a theoretical maximum from which you start deducting all the little real-world inefficiencies. For instance, I have a home-built panel with cells rated at 110 watts. I've never gotten more than 85 watts out of it and usually it's more like 70 watts, chiefly due to to the fact that my panel may not be facing the sun squarely.

Your panel that puts out 23.2 volts... How many cells are in it? With 36 cells, typical for a 12v array, you should expect 18-25 volts in sun with no load.

--Tom

converseur;

I believe most manufacturers rate their panels as open volts times short circuit amps in full sunlite with a 90 degree angle of incidence. "Open volts" can vary anywhere from 17 volts to 21 volts but as soon as you connect the panels to a battery the voltage becomes battery voltage which itself is dynamic.

Anyone with any common sense on electricity knows that watts is amps times volts and with a short circuit you have 0 [zero] volts and 0 times anything is still zero.

In my real world experience my 300 watts of solar in dead on full sun into my batteries will put out approximately 18 amps or somewhere around 70% of "rated". If I was charging @ 16.6 volts this would be about right for a true 300 watts but I am charging at anywhere from 11.5 to 14.4 volts depending on battery state of charge.

Frankly, I just write it off as sales hype by the manufacturer much like those ads that make me think if I buy "this car" I will be the envy of all the other men as they see me with the ladies in my car.

To make it even worse different companies use different open voltage numbers which further confuses the rating game 17 to 21 volts is a broad range I have seen quoted.

Your angle of incidence makes a really big difference and a tracker and proper seasonal altitude adjustments can add to your incoming substantially. And I have seen cloud edge effect boost the amps up above 25 for short periods so the panels can achieve or exceed rated output in certain conditions.

Just my real world experience over the past couple years with good quality manufactured panels.

Cheers.

TomW

I only brought that up because you don't get what the advertizers are selling you. I was figuring out the amount of panels I would need to power my office and made a realization during the process. I had calculated I needed about 400 watts to keep things going while the wind was slow in the summer. At the time I was looking at some 100 watt panels. Going through their ratings I realized they listed maximum charging amps and open voltage as the final output. So I took their max amps and combined it with my average battery voltage ( actual charging ) and found they couldn't possibly perform to their rated output.

If I had purchased on 4 of these panels with the expectation of getting 100 watts per panel to meet my 400 watt need I would have been greatly disappointed only getting 340 watts or less. If each panel makes 6 amps charging and your battery bank is running at around 12 volts then the actual watts being put into the batteries is about 72 watts so  $4 \times 72 = 288$  watts not including any line or other losses along the way. So I assume its a buyer beware or catch 22 advertizing scheme. I'm still looking for some panels but with a different perspective... I would need 6 100 watt panels to deliver my 400 watt charging that I want. This makes cost a major determining factor...

Have Fun  
Ed

Ed, Just a thought, you mentioned you have a wind generator, and by the way you talk it sounds like it does the job all winter when the wind is higher, then it would seem to me that maybe another small windmill would be the answer to your summer time problem. Hope that helps.

Home Made Solar

---

I ordered the cells from Plastecs Co. WB-28 cells\*\*\*----100mm round ( 4" round )----single crystal---2.0-2.25A @ 0.57-0.60V-----efficiency 12-12.9%----easily solderable----weighs 0.28 oz. each ( 8 gms )-----\$3.55 each plus S&H. Plastecs treated me very well. I soldered the cells in series using the included foil wire that plastecs included. At first I thought the foil was packing material, then realized it was foil used on the solar cells! I had to use a solder GUN 140 watt to solder these cells. The back of the cells are positive and completely covered in solder. This acts as a heat sink and makes soldering difficult. I advise to pre-tin the foil or wire and then apply heat as short as possible. After attaching each cell please test for cell to be working. Solder, test, solder, test till all 36 cells in series are attached. The housing of the cells were a little crude. This is just the pre-testing stage. I used 2 sheet of lexan, laid out the soldered cells on the lexan, put another sheet over them. Flipped the sheets over to view the back of the cells. Put a dab of silicon on the back positive side of the cells, laid the lexan on the cells. This way the cell won't slide and short each other out. I had some aluminum mirror channel that I used for a frame, U channel. Before sealing the frame I drilled 2 holes for screws to go thru from leads of cell positive and negative foil wrapped around screws. Test again for full panel voltage then ran silicon thick around edge of lexan and squished together and applied U channel frame around lexan, like a picture frame. Had some 4X4 laying around had the kids dig a hole 46 inches in the ground and placed 4X4 in hole. Mounted half inch 45 degree pipe fitting treated to top of post. Mounted a 40"X20" plywood to top of fitting and mounted solar panel to plywood. Drilled out two large holes for the panels power posts, positive and negative. Mounted out door inclosure boxes over the power posts. In the inclosure boxes are the diodes. Then ran water tight electrical pipe to "test box" with battery and small inverter. It worked, took about half of day light to charge the battery that I ran down. Here are some pictures, with cheep cam sorry. Later will run heavy gage wire to garage to battery bank. The panel is using 12 guage wire for now. Full sun 21VDC almost 2 amps were flowing thru meter when first attached to drained battery.

Good job Mike

I have a different panel than you, otherwise I have the same setup as you as you. My panel was surplus from a local electronics store. This panel puts out less than 1 amp. My small fan and 12vdc flourescents pull my systems volts down too much every night in the summer.

I have been looking at those Plastecs Co. WB-28 cells too. .

WB-28 are impressive. But the cold weather is here. My test box outside is cold, yesterday instead of 4 hours of inverter use I got 2 hours. The battery was at full capacity. Tested with a battery load tester. Will the freezing 26F degree effect the time of use on my battery?

Yes, the cold will very much affect battery capacity. Flooded lead acid cells want to be at the same temp you do, about 70F.

Good luck and have fun!

troy

Awesome looking panel! And you're getting great voltage output from it too. How does your current output respond to sun angle? My panel, made with 108 WB-29's and a glass covering, puts out better than 85 watts when it's pointed straight at the midday sun, but drops off to 60 watts or so if it's tipped a few degrees. I wonder if maybe lexan is more tolerant of sun angle than glass. --Tom

Re: Home Made Solar ([none / 0](#)) (#4)  
by Adrian L on Thu Dec 4th, 2003 at 06:38:09 AM MST  
([User Info](#))

I like your battery box/inverter setup, reminds me of an earlier setup of mine.

Just a tip, do yourself a favour and replace the stock leads on that inverter, or at least put proper terminal ends on, they die really quick from the acid eating away at them on the terminals and it looks like the acid are eatings yours up already?

Solar power is really great to setup a nice little functioning self contained remote power supply, and its just so easy and fun I can't see why more people don't do it!

Once you have the RE bug there is no going back, you will keep spending more and more on new equipment, but what a great hobby.

Have Fun,

Adrian L

get off spec solar panel to adequate voltage? ([none / 0](#)) (#1)

by [drdongle](#) on Tue Dec 2nd, 2003 at 07:50:56 PM MST  
([User Info](#))

To get 18 Volts use a "buck" DC to DC converter, though 5 volts isn't a lot to drop. to get 32 Volts you will need a "boost" DC to Dc converter.

Dr.D

Re: how to get off spec solar panel to adequate vo ([none / 0](#)) (#2)

([User Info](#))

If that 23V rating is for open-circuit voltage, it's already just fine for charging a 12v battery.

Looking for solar cells at fair price

[Solar](#)

Hi guys,

I had plans to build solar panels. I checked at plastec. They asked \$177.00 for 50 cells, or \$3.25 each for 1000 cells. I find this price extremely abusive. Anyone would know a better place to buy cells? I can get brand photowatt 155 watts for \$499.00 ( \$3.16 a watt) at partonsale.com or brand sharp 165 watts for \$519.00 (\$3.20 a watt) at Sunelectronic sunelec.com. Sunelectronic has slightly blemished Photowatt 155 at \$400.00 BR-250 50 watts at \$184.00 posted on Ebay.

Anyone needs a sine Wave inverter at a good price Sunelectronic has Trace PS2512 or PS2524 at \$1,200.00 on Ebay

Richard

Hi guys, I made a mistake for the Trace PS2512 or PS2524 for auction on Ebay, they are \$1020.00 and not \$1200.00

Richard

Re: solar cell WB- 27 ([none / 0](#)) (#4)  
by Tom in NH on Mon Dec 1st, 2003 at 09:05:11 PM MST  
([User Info](#))

It has been my experience that you do not build your own panels to save money over commercial units. I build my own panels so I understand more about them, I have more flexibility in designing arrays, and I know what they're made of. I've bought from Plastec and have been very happy with the service compared to several other companies I've tried, and their prices are competitive. Still, you'd think the price for raw cells, no matter where they come from, would be low enough to give you some savings if you elect to go the do-it-yourself route. --Tom

([User Info](#)) <http://www.windstuffnow.com/main>

That really gets me... parts on sale list the Kyrocera 158 watt panels for 499 and state that its only 3.19 per watt. Thats actually not true... They are really about 5.15 per watt, unless your running an 23V system. I don't know of any person charging their 12V batteries to 23Volts. Maximum current is 6.82 amps into a fully charged battery of 14.6V comes out to a 99.5 watt solar panel in my book....

Makes you wonder who set the rule (lie) for solar panel sales....

Just my opinion

Ed

[ [Parent](#) ]

Re: solar cell WB- 27 ([none / 0](#)) (#10)  
by Chuck on Wed Dec 3rd, 2003 at 05:24:47 PM MST  
([User Info](#))  
<http://www.greeleynet.com/~cmorrison>

My guess is that an mppt charger is required to get close to rated output. Even then it doesn't really make it.

I have 630 watts (rated) of panels. Even with a good mppt charger, the most I've seen go into the battery is 18.x amps @28 volts, just over 500 watts (dead of winter at noon). This would make each 105 watt panel actually 83.3 watts. Better than the example you give, but still \$4.81/watt instead of \$3.81/watt.

oh well...

Chuck

### Home Made Solar Questions

I have build a solar panel using 36 solar cells tied together in series. In bright light this panel produces 21 volts DC.

I purchased a 40 watt diode from Radio Shack and hook up to solar cells so not to have the batteries discharge into panel when darkness appears. As a test I took voltage measurements direct off panel with no load, 21 volts DC.

I tested a battery that was low in charge 11.9 VDC. This battery is a boat deep cycle 12 volt battery. When I attached to solar panel to the battery then read the battery it was still 11.9 VDC. I was hoping to see a higher voltage like when you read the battery voltage on a car with the alternator running. Check futher using an AMP meter the battery was sucking almost 2 AMPS. About an hour later the battery voltage rised to 12.4 VDC. So I take it my monster is working?

1. Why when charging the battery off the solar panel I'm not reading the solar panel 21 volts when not connected to battery.
2. Just 2 amps of draw off the panel? Should'nt it be more?
3. By using 40 amp bridge rectifiers from Radio Shack and only using the single diode on the bridge, note I attach a diode to each leg of the panel. Will this cause the panel to be less efficient?
4. The battery I'm using has a led indicator to state the charge condition, green is charged, black is low and red is recharging. Funny it is in the red always when I ran down the battery for the test. With or without the panel attached.

I am doing this project for therpy, keeps mind off of things. The objective is to just make the family room solar powered for starts. I will take pictures later this week and give you an idea of what I made. Any thoughts would be welcome.

Thank You

The solar panels will produce open voltages as you said at or near 21V. But when you connect them to your batteries, the batteries draw more current than the panels can produce and maintain the 21V. So the voltage drops to the level of the batteries, 11.9 low and 12.4 (charging).

If you watch, your batteries will continue to rise in volts until they are charged, at which time the panels will start to dump more voltage into the batteries (but not much more than a volt or so) because the batteries will always let a little current flow through them. You could watch your ammeter and chart the amps being drawn as it is being charged and soon you will see the amps level out. At that time, your batteries will be fully charged. The amps at which they level out will be the 'float' charge your panels will be able to provide. This is OK as long as the 'float' charge is not out of specs for your battery.

Have fun!

Doug

Re: Home Made Solar Questions ([none / 0](#)) (#2)  
by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Mon Dec 1st,  
2003 at 03:24:20 PM MST  
([User Info](#))

Mike-

I'm curious, what solar cells did you use? Where did you get them and how much did they cost? I myself am looking into cheap solar, as my neighbors complain loudly about windmills and the like, and I think your route will be the most cost effective. Diodes won't lessen the efficiency of the panel itself, but do burn some power themselves. Most have a .5 to .7 volt drop. That means that when you are drawing 2 amps through them, you are losing 1 - 1.4 watts of power. You might hook up your solar panel through your ammeter without the diodes, and cover the panel to see if the diode is really needed. Good luck, and have fun. I sure am.

Demetri

([User Info](#))

I ordered the cells from Plastecs Co. WB-28 cells\*\*\*----100mm round ( 4" round )----single crystal----2.0-2.25A @ 0.57-0.60V-----efficiency 12-12.9%----easily solderable----weighs 0.28 oz. each ( 8 gms )-----\$3.55 each plus S&H. Plastecs treated me very well. I soldered the cells in series using the included foil wire that plastecs included. At first I thought the foil was packing material, then realized it was foil used on the solar cells! I had to use a soilder GUN 140 watt to soilder these cells.

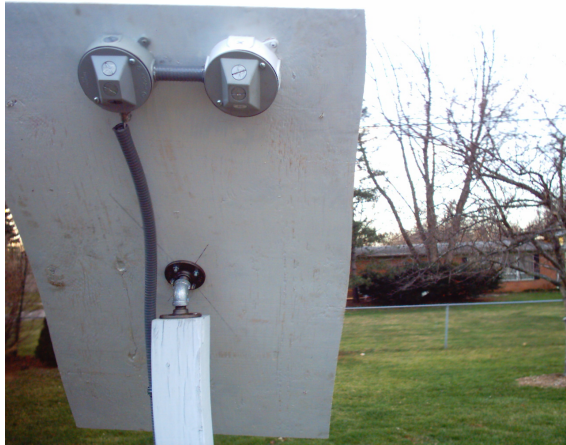

The back of the cells are positive and completely covered in soilder. This acts as a heat sink and makes soildering difficult. I advise to pre-tin the foil or wire and then apply heat as short as possible.

After attaching each cell please test for cell to be working. Soilder, test, soilder,test till all 36 cells in series are attached. The housing of the cells were a little crude. This is just the pre-testing stage. I used 2 sheet of lexan, laid out the soildered cells on the lexan, put another sheet over them. Flipped the sheets over to view the back of the cells. Put a dap of silicon on the back positive side of the cells, laid the lexan on the cells. This way the cell won't slide and short each other out. I had some aluminum mirror channel that I used for a frame, U channel.

Bofore sealing the frame I drilled 2 holes for screws to go thru from leads of cell positive and negative foil wrapped around screws. Test again for full panel voltage then ran silicon thick around edge of lexan and squished together and applied U channel frame around lexan, like a picture frame. Had some 4X4 laying around had the kids dig a hole 46 inches in the ground and placed 4X4 in hole. Mounted half inch 45 degree pipe fitting treated to top of post. Mounted a 40"X20" plywood to top of fitting and mounted solar panel to plywood. Drilled out two large holes for the panels power posts, positive and negative. Mounted out door inclosure boxes over the power posts. In the inclosure boxes are the diodes. Then ran water tight electrical pipe to "test box" with battery and small inverter. It worked, took about half of day light to charge the battery that I ran down. Here are some pictures, with cheep cam sorry. Later will run heavy gage wire to garage to battery bank. The panel is using 12 guage wire for now. Full sun 21VDC almost 2 amps were flowing thru meter when first attached to drained battery.

([User Info](#))

Drawing 2 amps is doing pretty good on a 21 volt panel.  
Remember, watts/volts = amps. I have a 30 watt solar panel that powers the fans in my solar heating panels. I paid around \$90 new for the pvc panel off ebay, and it's worked wonderfully.

Anyway, when I'm operating 12 volt fans, my 30 watt panel only has about 2.5 amps available. 30 watts / by 12 volts = 2.5 amps. Each of my fans draw .45 amps. I probably won't hook a third fan to it, as it kicks out less amps on overcast days.

Of course, most appliances take way more amps. Which means way more solar panels!

Mark

by [pexring](#) on Mon Dec 1st, 2003 at 11:02:03 PM MST  
([User Info](#))

Oops, I gotta quit answering posts at midnight! I only have a 20 watt panel that I paid around \$90 for on ebay. Which means I only get about 1.5 amps to work with on a full sunny day. So I only power the two fans which together draw less than an amp. Works pretty good that way. Gees.

Mark

Solar panel

Well today was the first day I could test my little Solar panel and charge controler out this is what I found . I tested at 12 noon full sun DCV 10.45 DCA .95 ??? then I tested it on ACV and got 21.9 V don't know the amps on ac . All the tests with no load . The panel is a Hoxan HSP 10-6 and I have no info on it ... got it off of E-BAY , What do you guys think ... did I do something wrong ?? Need help

your Solar Panel puts out DC voltage. If you measure that output with an AC voltmeter your reading will incorrect. For solar panels, measure them with the meter set to DC volts.

However, 10.45 vdc is not enough to charge your batteries. A Solar panel should put out more than 15 volts in full Sun

Try disconnecting everything and measuring the volts and amps of just the solar panel. This should only be DC. How big is the panel? How many individual cells does it have?

Tom

The reason you are only getting 10.5 volts is because that particular panel is obviously made to charge a 6 volt battery, thats what the numbers would mean 10-6 = 10 watt 6 volt panel.

Usually a 12 volt panel has 36 solar cells inside it, yours only has 18, what you could do is buy another panel the same and hook it up in series to get 21 volts at 1 amp (21 volts is about what a normal 12 volt panel will output open circuit) and you would have the equivaent of a 20 watt 12 volt panel.

Sorry to break the bad news,

Adrian L

## [Wiring 2 solar panels](#)

By [pexring](#), Section [Homebrewed Electricity](#)

Posted on Wed Nov 19th, 2003 at 11:45:04 PM MST

[Solar](#)

Why doesn't this work?

Hi,

I just finished building my second solar heating panel. Each panel has its own fan that draws .45 amps. The fans are powered by a 20 watt pvc solar panel (1.5 amps). I'd like to hook both fans up to one t-stat.

When I hook both fans directly to the pvc panel, they both run great guns. The problem occurs when I add the t-stat. Fan 2 runs perfect. It turns on when the t-stat reaches the desired temp, and shuts off when the t-stat falls below the set temperature. Fan 1 runs the exact opposite -- it runs when the t-stat is off and stops when the t-stat clicks on.

I'm baffled. It's probably something stupid, but I'm not seeing it. Here's a wiring diagram of how I got things wired. Appreciate any thoughts.

Mark

 (User Info) <http://oneota.net/~earthsourcepowr/>

pexring;

My very first guess is that you actually have the fan that runs at exactly the wrong time wired across the switch rather than in series with it that would explain why it runs with the thermostat [switch] is off. I suggest you wire the fan leads together first then wire that to the thermostat. That way both will be energized at the same time.

Cheers.

TomW

Tom's right, it's got to be wired wrong. Your drawing is correct, tho, as it shows them wired in parallel. I like his solution - it will help keep the wiring straight in future, also. I would normally put both switches on the same line, also. I find it best to be consistent. So I always put switches or anything else in the positive lead. I started out with automobiles where you often have no other choice.....HTH,

Well i agree with everybody else your diagram looks good, but it must be wired wrong. I want to know what did you use for a t-stat, I am trying to due a similar setup to blow heat in the house from the woodstove, but I only want the fans to work when the other rooms need the heat. Thanks and good luck. From Mike

Re: Wiring 2 solar panels ([none / 0](#)) ([#4](#))  
by pexring on Thu Nov 20th, 2003 at 11:23:53 AM MST  
([User Info](#))

I just used a typical Honeywell round heat/cool thermostat.

I put it directly inside the panel and set it to 'cool'. So when the panel heats up to about 72, it comes on, and runs until it cools down to below 72 and shuts off.

I'll start over on the wiring. I was also thinking of putting both switches on one line. I've looked at my wiring a 100 times and it doesn't look wrong to me, but it has to be wrong. There's always 101!

Mark

Re: Wiring 2 solar panels ([none / 0](#)) ([#5](#))  
by Electric Ed on Fri Nov 21st, 2003 at 05:31:12 AM  
MST  
([User Info](#)) <http://www.electric-ed.com>

The heat/cool thermostat has two "sets of contacts" in the mercury switch, in other words, it's a double throw switch. When one closes, the other opens. You likely have one fan controlled by the heat contacts, and one controlled by the cooling contacts.

Keep in mind these thermostats are designed to operate with a relay. The mercury switch contacts won't handle much load.

Electric Ed

Solar panel

Hi all ... I'm a Newbee , I've been a lurker to this site for some time now , so I finally joined . I got some Questions , I bought my first Solar cell and charge controller off of E-bay ... they are small but they got to start somewhere . Well the guy I got it off of doesn't know anything about them , so maybe you guys do . well this is what I got ... The Charge regulator is a TT1B Photovoltaic regulator from Integrated Power corporation and the Solar panel is a Hoxan HSP10-6 it's like 15 1/2 by 13 1/2 inches . Any info on them would be great . Thanks Oh ya by the way I made a little gen out of a lawnmower and a GM Alternator a boat Battery and an a 300 watt inverter .

## [Thermostats for solar heating panels](#)

By [pexring](#), Section [Homebrewed Electricity](#)

Posted on Thu Nov 13th, 2003 at 09:51:41 PM MST

[Solar](#)

Where do I find them?

Does anyone have a source of where I can buy thermostats for my solar heating panels? Right now I'm operating them on a switch, which my wife never seems to remember to turn on. So I turn them on before I leave for work, and they tend to run cold until around 9am when the frost finally melts off the glass. Be nice to just have them turn on automatically. They do need to be 12 volt.

Mark

Re: Thermostats for solar heating panels ([none / 0](#)) (#1)

by Norm on Thu Nov 13th, 2003 at 10:10:34 PM MST ([User Info](#))

almost all thermostats run from low voltage to a relay that turns on a 110 volt blower motor if your fan/blower motor is 12 volt all you need is a 12 volt relay like from a riding mower starter relay. Norm.

Re: Thermostats for solar heating panels ([none / 0](#)) (#2)

by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Thu Nov 13th, 2003 at 10:16:10 PM MST

([User Info](#))

<http://timmythy.home.mindspring.com/timmy.htm>

You will need 2 thermostats  
One inside of the room you are trying to heat  
and  
one inside of the outlet of the heating panel

Wire them in series, so your heater fan will only turn on when the room needs heat AND the panel is warm enough to provide heat.

A couple of years ago a friend built me a device using two thermistors and an Op-Amp to turn off and on my attic fan.

He said he got the circuit from a website that had a solar heat panel that did the same thing. The device needed a temperature differential and a certain temperature to energize and would shut off when these weren't met.

Ron

Maybe You could try this one... ( <http://www.fieldlines.com/story/2003/9/23/92535/4705> ) i have not built it myself. I know there is another circuit (LM35) wich gives a output proportional to °C for those who likes it better than °F.

One other describtion is available on the Homepower download page (in a article about solar hot air).

Lars A

Re: Thermostats for solar heating panels ([none / 0](#)) (#7)  
by jubalearly on Fri Nov 14th, 2003 at 08:17:16 AM MST ([User Info](#))

The easiest thing to do is buy the thermostat for an electric automobile fan. I think Auto Zone has them for less than \$15. They are normally open until the thermocouple gets above the set temperature, which is adjustable. I used one at the cabin to automatically operate the circulation pump for the water heater.

I don't recall the amperage capacity (20a?) of these. You may want to use a relay anyway since it will simplify setting up longer wire runs to the pump. About the only drawback is that the thermocouple is only about 20" from the control, so you have to mount it near the panel (or whatever you put the thermocouple on). HTH, -RussH

Re: Thermostats for solar heating panels ([none / 0](#)) (#9)  
by pexring on Fri Nov 14th, 2003 at 12:08:05 PM MST ([User Info](#))

Great link. I can build, wire and plumb a house without even looking at a book. Yet my knowledge of this type of electronics is minimal. This website should sell this type of thermostat where I could simply run a wire inside the solar panel and adjust the dial on the wall.

Today I had another thought. Why not just buy an ordinary mercury-type thermostat and put it inside the panel. Set the t-stat on a/c so it kicks on when the temp reaches about 80. Then it would never shut off until it got cold again. With my solar panel on the wall, I could reach in through the intake vent and adjust the dial if necessary. Crude, but it may just work!

Otherwise, I'd possibly pay someone to build and send me one that worked.

Mark

Re: Thermostats for solar heating panels ([none / 0](#))  
([#10](#))  
by hydrosun on Fri Nov 14th, 2003 at 07:55:40 PM MST  
([User Info](#))

I've been running my homemade solar heating panel for years with a simple mercury thermostat that I picked up at a used store. I had to mount it backward (I had to take off the spring holding the mercury and mount it inside the heater. I drilled a hole in the side of the panel and push the shaft holding the spring into the hole) to make it turn on at the higher temp instead of off that it would do for a heater. A solar air heater only needs a single thermostat to turn on when the temperature in the heater goes above the preset temp ( maybe 90) I doubt you'd have enough panels to overheat a house. And you can just shut it off in the summer. A solar water heater would need the slightly more complex differential thermostat to allow the unit to start at a lower temp if the water is cold and shut off if the water is too hot.

Re: Thermostats for solar heating panels ([none / 0](#)) ([#11](#))  
by pexring on Fri Nov 14th, 2003 at 08:53:42 PM MST  
([User Info](#))

You're right, overheating the house is not a concern. Today I did pick up a Honeywell round heat/cool thermostat. I think it will work perfect without any modifications. I'll put the thermostat in the panel I'm finishing this weekend and set it to 'cool' when the temp hits 75 degrees. It will operate the fans in both panels. So then the fan starts and doesn't stop until the temp drops below 75. Was a spendy thermostat (\$38), so it'll have to serve both panels.

With the mercury in these t-stats, is there any concern of getting it too hot?

Mark

solar module wire

[Solar](#)

I have 3-75 watt solar modules and going to upgrade to 5-75 watt modules. They are 35 ft. from the shack so I will need 50 ft of wire and I need to stay with 12 volt to run the ham gear. What size wire should I run in from the pannels to the house? I am thinking of ordering a c40 Xantrex controller as my Morningstar will not work with the extra amps. Can someone tell me the size of wire this controller will take. Wish I had the wind in TN. for a wind genny. Thanks Larry

Larry;

I run 4 75 watt panels at 12 volts and 50 feet of wire to the batteries. When I sized that run of wire I decided I needed #1/0 for the 20 amp load i calculated to get an acceptable loss. Well I had #4 on hand so while it calls for #1/0 i used the #4 and lose some I suppose.

Check this chart

<http://oneota.com/~earthsourcepowr/dropchart.html>

You can also parallel more than one cable to share the load if you have it on hand.

Cheers.

TomW

Another option that will work but may be a bit more for the controller is to go with 4 or 6 modules, and an MPPT controller. Then you could run the panels at 24 volts and control it down to 12 volts at the batteries or load. That's what I did when I had to place my solar panels 100 feet from my batteries. I used the Solar boost 50.

Dave

Even though we have wind here in the pass, solar carries the load. So go solar and then wind. Wind powerplants are improving all the time.

I use 1/0 wire and it would carry 100 amps at 12 vdc and this keeps the losses low. But smaller wires can be used. For a long time I used solid #12 wire and it worked ok.

## Solar Heating Panel Update

By [pexring](#), Section [Homebrewed Electricity](#)

Posted on Thu Nov 6th, 2003 at 12:00:33 PM MST

[Solar](#)

Here's an update on the heater I built.

A couple times over the summer I asked questions and posted info on the solar heating panel I was building. I thought you'd all like an update of how it turned out. Now that we've had a couple sunny but cold days of temps not over 30, I can say that this panel does work. This is just a measly 4'x6' panel, and I'm blowing out heat in temperatures of 115-125 degrees farenheit. I live in a 1900 square foot doublewide, and over the last 2 days I haven't had to turn the furnace on during the day. I'm also taking advantage of the sun shining in my south windows and skylight. I wrote an article outlining the details I did to build this panel. The article can be found in my quarterly newsletter, or at this URL:

<http://www.mobilehomerepair.com/article17solar.htm> We also talk a lot about alternative ways to heat mobile homes in the FORUM section of my website, <http://www.mobilehomerepair.com>

Why silver

I thought black was the best absorber of solar and silver/white the least. I think if you went with black backing you would improve your results also another trick is to increase your surface area. This is done by bending (corrugating) the backing so you do not have to increase the size of your box.

Silver? Nothing is silver on my panel. All black. Originally I had tried corrugation, but it took so long to heat-up the corrugated panels, I took them out. Plus, corrugation throws a shadow. I got better results with flat painted-black aluminum.

I'll have to try and find what the CFM's are. I knew it when I bought the fan. The temp in the house holds steady at 67-72 degrees. Of course, the rooms on the north side are on the colder end.

If you put the fan on the bottom inlet, and blow the cold air in, you will get better air flow than sucking the hot air out at the top.

don't know if you need more airflow ?

Cold air is more dense and the fan will work with that better. And you mention that the air is 115-125 degrees fahrenheit, your fan will not be heated up to this point. In the summer your fan will be sitting in 200 degree or more heat. It won't be so high a temperature at the bottom . . .

by Norm on Thu Nov 6th, 2003 at 09:36:00 PM MST  
([User Info](#))

Blowing the air in is good...sucking air into a house is bad...of course a small fan like this probably wouldn't have that much of an effect on your flue for your gas water heater or gas furnace if you have them...still it's better not to take the chance? Seems like there was a link about this somewhere on the board. Norm.

That is HOOOTTT! I like that idea! I have seen it before, but didn't really think about it. I think it's going to be a weekend project comming up! Seems simple enough to build and fast. THANKS! That was a good job you did in explaining it and the Rules of thumb! I alfo figure a small wind turbine to power the fan would be cool!

Re: Solar Heating Panel Update ([none / 0](#)) ([#8](#))  
by pexring on Thu Nov 6th, 2003 at 07:50:46 PM MST  
([User Info](#))

Today I picked up materials to build another solar heating panel. This one I intend to blow heat underneath my mobile home to help keep the floors warmer. Getting free heat is the only way I'd ever heat underneath my home! LOL. Good thought about switching the fans to the inlet.

On a side note . . .

I was able to keep the furnace off for 12 hours today! Temp is 18 degrees outside right now and it never got above 30. Last night I was doing some calculations, and I figured for every hour my natural gas furnace ran, it cost me over \$1/hour at the current rates. So if the furnace runs 6 hours a day, that's \$180 a month. Be more than that in the real cold months tho.

So last night a friend of mine mentioned to me about seeing a halogen heater on the internet. They run on less watts and kick out a lot of heat. Except we were having real trouble finding someone who sells them in the United States. But low and behold, I discovered that K-Mart carries them. So I bought their last one today. The halogen heater is also listed on KMart.com.

The halogen heater's maximum setting is 800 watts and it kept my entire living/dining/kitchen-room area comfortable. Heck, a 2500 watt heater can hardly keep one of those rooms comfortable! So now I'm toying with the idea of buying one for each of the three bedrooms. The heater set on 800 watts cost me about 8 cents an hour to run. On the 400 watt setting (which would probably be perfect for the bedrooms), it would be half that. Of course I'd only need the halogen heaters in the evenings and on days the sun didn't shine. So maybe I'm getting close to throwing that expensive gas furnace out on the front lawn! LOL

by pexring on Fri Nov 7th, 2003 at 11:48:54 AM MST  
([User Info](#))

I'd like to know how many BTU's it kicks out too, but I don't see it anywhere.  
May look on the web for more info.

Last night once the sun went down, I pulled my thermo curtains to hold the heat in the house. Then turned on this halogen heater to keep things from cooling down too fast. We made it until about 8:15pm before having to kick the furnace on. Basically I went 12 hours without running the furnace. Normally my heat bill is \$200-\$300 a month. If I can get it down to under \$100/month, I'll be one happy camper.

Hey Guys! I just did some simulations for airflow moving through the solar collector, I love sims... Anyway I was playing with this ripple tank and putting Baffles in the ripples (viewing the ripples as "air flow"), I noticed that by shaping these baffles, that I got localized regions of hot spots. And it also slows down the airflow. Which makes the air hotter I believe, well that's the way I interpreted it. Any way here is the simulation and the link to go play with.. Tell me what you think.. Is placing baffles that are a specific shape going to increase the heat and slow down the flow?? (Resistance creates heat too, would this?)  
Opinions????

Hi pexring,  
Nice project. I've got a question for you. If you added a 4'x 6' window where your 4'x 6' solar collector is would it give as much heat as the collector? Seems like it would to me but... I've been wanting to do something like the solar collector thing, but if a window would do the same I'd have a much easier time convincing the wife to add a window instead of the collector. :-)  
Btw, I put in some big windows in my garage and work shop, all face the sun in the winter, but no full sun in the summer. On a sunny winter day my very uninsulated garage (you can feel the wind blow at times) and work shop will be around 8 degrees warmer than outside.  
Kevin

Re: Solar Heating Panel Update ([none / 0](#)) (#17)  
by pexring on Fri Nov 7th, 2003 at 11:40:27 AM MST  
([User Info](#))

Hi,

Cold sunny day #3 without the furnace running. 20 degrees outside. At noon my solar heater is blowing temps of 112 degrees. That along with the sun from the south windows does a good job of keeping the house comfortable without using the furnace. I do need to set up some fans to have move the heat better tho. The solar panel is right next to my sliding glass doors in the dining room, and that room really gets warm, so need to move that air further into the home.

As far as converting a window into a solar heating panel, a friend and I are also experimenting with that. On one of my windows I do have an insulated aluminum box up against the window with a hole in the bottom left corner, and another in the upper right. I have a round solar-powered marine fan in the bottom hole that pulls air in and pushes it out the hole at the top. The air does not go through any pathways. I'm finding that I'd probably be able to heat the room just as well without the box over the window. But maybe this weekend, I'll pull off the box and add pathways and hopefully that'll get me more heat. If I do, I'll post pictures then.

Mark

Re: Solar Heating Panel Update ([none / 0](#)) (#19)  
by kww on Fri Nov 7th, 2003 at 04:58:20 PM MST  
([User Info](#))

I got to thinking about what I'd said and realized your collector thing will work better than a window because it doesn't suffer the loses a window does, which is a lot, especially at night. You need some foam insulation window covers for night time. ;-)  
Thanks for showing your work.  
Kevin

Re: Solar Heating Panel Update ([none / 0](#)) (#20)  
by kww on Fri Nov 7th, 2003 at 05:14:52 PM MST  
([User Info](#))

One other thing I was going to tell you about, something I've learned through the experience of heating my house with only a wood stove insert at one end for 12 years. Put a box fan on the floor about half way between the coldest and hottest room and blow (low speed should work fine) the cold air into hot room, works much better than trying to blow the hot into the cold, someone explained it above. Basically the cold air has more momentum and the fan can "throw" it farther.  
Kevin

Re: Solar Heating Panel Update ([none / 0](#)) (#21)  
by monte350c on Fri Nov 7th, 2003 at 10:12:44 PM MST  
([User Info](#))

Hi All,

I'm trying a really low-buck experiment that was inspired by the last round of solar heating panel stuff I read on the board.

We have several windows that get really good afternoon sun. I went to Home Depot and bought an aluminum slat mini-blind. They were nice enough to trim it to fit the window for free! I also bought a can of flat black paint.

Once I got home I deposited the contents of the flat black paint all over the mini-blind. Next the blind went into the window, adjusted so the lower part of each slat faces the window, and the upper part faces the room. I figure it would set up a convective flow this way.

So far (it's only been a week or so) I've noticed the blind heats up to about 120 - 130 F in the sun. I blew out a match, and held the smoking end near the blind. There's a definite upwards flow off the slats. Plus just by putting your hand near it you can feel heat from about 6" away or so.

If this continues to look good, I'll replace the blinds or curtains on all the windows that get sun in the house. It probably will make a difference, and it's pretty easy and cheap to do too.

Ted.

Re: Solar Heating Panel Update ([none / 0](#)) (#22)  
by pexring on Fri Nov 7th, 2003 at 11:45:10 PM MST  
([User Info](#))

Ted,

Last year I had bought a solar window heater based on the concept you described, but it sure didn't give out the kind of heat you describe. You've definitely peaked my interest.

The trick is to figure out if the heat gain you are getting is more than thge sun simply shining unblocked and heating a larger area. If you had 2 rooms about the same size facing south, the experiment could be done -- 1 room with the black blinds, the other with just a naked window. Then watch the room temp over several hours. Be interesting to know.

Do keep us informed.

Mark

[ [Parent](#) ]

Re: Solar Heating Panel Update ([none / 0](#)) (#24)  
by monte350c on Sat Nov 8th, 2003 at 07:48:12 AM MST  
([User Info](#))

Hi Mark,

When I was hanging this converted (painted) blind, I used a fairly unscientific method to position it. It seems that all windows even good double glazed pass quite a bit of cold through them. I held my hand near the window and noticed the first 1 - 2" were noticeably colder than the room temp. So I hung the blind about 2.5" away from the glass.

I'll try the comparison between the blinded window in one room and open windows for another for a week or so and post the results.

You'd have to think every bit helps!

Ted.

Re: Solar Heating Panel Update ([none / 0](#)) (#26)  
by pexring on Sat Nov 8th, 2003 at 07:59:06 AM MST  
([User Info](#))

Ted,

Thanks for doing the experiment. Even just doing the experiment on one sunny day should be able to tell us. I'd do the experiment myself, but all my even-sized bedrooms are on the north side of my home.

Well, this morning its cloudy. Could be an expensive day running that furnace. I went 11 hours yesterday without running it. Wish I could put up a big ole wind jenny, but that's not possible here. Too bad, its always blowing.

Mark

Re: Solar Heating Panel Update ([none / 0](#)) (#23)  
by kww on Sat Nov 8th, 2003 at 06:14:20 AM MST  
([User Info](#))

You really shouldn't be getting any more heat than if you'd just left the window unblocked and let the floor, etc. in the room absorb the heat. However, when comparing two windows, both with closed blinds, the one with the black facing the window will certainly do more for heating the room as it won't reflect as much UV out the window. I do sort of the opposite during the summer, I keep all the white blinds closed during the day which keeps the house several degrees cooler.

Kevin

Re: Solar Heating Panel Update ([none / 0](#)) (#25)  
by Reno on Sat Nov 8th, 2003 at 07:50:14 AM MST  
([User Info](#))

When covering a window in the winter you should always remember about condensation which can lead to water damage and worse mold. Good air flow over glass should always be maintained.

Chris,

Solar Panel are not affordable in Canada. They cost about 3 times of what it cost in the USA. There is no renewable energy market in Canada. I'm looking for solar panel also. They are some on Ebay. Some are used, other are off spec, and other are perfect. I have found a few webbsite. Altenergystore.com, they do business in the Atlantic. They have several discussion panels, articles and forums very good prices. There is also Partonsale.com in California. They have competitive prices. They have live 1-800 technical support. I found a new website Sunelec.com located in Miami. They sell refurbished inverters, off spec solar panels (auction on Ebay), their website seems like a hay wire business.

Beat regards, richard

[connecting solar panels without solder](#)

By [Peterthinks](#), Section [Homebrewed Electricity](#)

Posted on Fri Oct 31st, 2003 at 08:57:11 PM MST

[Solar](#)

thought you'd like to know....

I had to connect a solar cell to some wires and didn't want to solder it.

it was a small cell from a calculator.

The lcd display from the calculator had a small strip of rubber with black lines in it used to conduct to different parts of the display from the circuit board.

So I cut two pieces off the strip and pushed them against the cell with the ends of the wires

A blob of epoxy on them to secure them and a few hours later two solderless connections were done.

Another coat of epoxy on the back of the cell secured them even better.

I don't know what you call that strip or where you can get it (other than in calculators) but it's something to think about.

Peter

I think those strips are a rubber based carbon impregnated material. They often oxidize and create resistances. Even though you sealed it I wonder if you will still have problems in time. The displays they drive are very low current in the order of microamps not amps.

Just my two cents.

RobD

actually I just dug the cell out of a drawer...I put the thing together around 5 years ago for a beam robot.

still gives out loads of power....sorry no measurements on resistance from 5 years ago to compare to today.

SORT OF RELATED, I had to repair a broken connection on the glass on the rear window defogger on my van and got some electrically conductive glue from NAPA. Seems to work fine. I would think it should work to connect to solar cells as well.

### Building a Solar Panel

Hello everone,

I have purchases 38 WB-28 solar cells from [www.plastecs.com](#). These cells are 100mm round 4 inches. Single crystal 2.0-2.25A @ 0.57-0.60V efficiency 12-12.9%. I am looking for suggestions on wiring, housing for out doors or any other comments for this project. The primary reason for this 37W panel is well, charging a 12V battery bank. This bank of quantity 10 batteries in parallel, Dynasty VRLA valve regulated lead acid freebe 12V batteries, would they run a inverter 400W for starts and supply power for one room in my house to start? In addition this would be a back up for those days of no power, eg: blackout 2003, weather, coronal mass ejections, ect. So I am looking for great housing ideas, cheep of course, weather resistant. Wiring, wire guages, inner solar cell wiring ways, web sites. I have follow this web page for some time. I needed to have a winter project so this is it. I live in Michigan. So gang what you say?

Michael

Re: Building a Solar Panel ([none / 0](#)) ([#1](#))  
by Tom in NH on Fri Oct 24th, 2003 at 09:04:08 PM MST  
([User Info](#))

I recently assembled a panel of 108 cells from Plastec. 32 x 42 inches. Low wattage soldering irons don't work well. Make sure the cells in your array are spaced so they don't touch each other and short out. You won't burn anything up, but output will be reduced. Also, check the output of each cell after you solder the tabs on. If you put a "dud" in the array, it will affect your output. I mounted mine on 1/4 inch clear luan plywood. Ran screw-type connectors out the back side and I can wire groups of 36 cells either in parallel or series. Used double strength glass, with spacers, to cover the cells without placing excessive pressure on them. I used 1 x 1 x 1/16 aluminum channel stock formed the frame.

On my next panel which I'll be starting soon, I'm thinking of putting a dab of silicone caulk on the back of each cell to hold them in place on the plywood before soldering the top faces. I'll use a closed cell foam tape as a gasket and spacer between the glass and plywood.

This was my first panel and I have a lot to learn. One big lesson was order a few extra cells to cover for breakage. Also, the ratings used in the cell descriptions are the theoretical maximums. They're the max from which you deduct power due to everything: a glass covering, two cells

touching each other, the panel not being aimed perfectly at the sun, etc. My 100 watt panel was actually running around 87 watts at in the midday sun in September. It's probably less now that the sun is a little lower in the sky.

My goal is to use the electricity to produce hydrogen, which works well even on cloudy days. Keep us posted on your progress.

hi,

I'm quite excited to read about your project. I dream to built my own renewable power system. I have 2 refurbished Trace 5548 and I have another 2 coming. I have a 2400 amps battery bank. I'm to the point to investgate renewable charging system. Solar energy is quite interesting, but it is totally unknown in Canada. I know that solar panel can be built. Can I aks you how long did it take to built you panel? Can I ask you how much cost the solar cells.

Best regards,

Richard

Re: Building a Solar Panel ([none / 0](#)) (#2)  
by ChrisW on Wed Oct 29th, 2003 at 10:55:21 AM MST  
([User Info](#))

The picture of the blue solar panels built with WB-28s on the plastecs web site is mine! I built four panels using those cells and I must say the output is pretty impressive, especially when you get the panels aimed DIRECTLY at the sun. I've seen 13 amps with all four panels hooked up on a bright, sunny day.

I have a few thoughts and suggestions:

1. Use a FAT wire for interconnecting the cells. I discovered that using the recommended "foil tape" with cells of such a high current capacity severely limited their output. When I switched over to 10 AWG bare copper, I was amazed at how much more current I was able to get out of them. Be sure to use an equally beefy wire from the panel to the charge controller.
2. CRITICAL: Be EXTREMELY careful about soldering -- \*DO NOT\* keep the soldering iron on the cell any longer than absolutely necessary; if you leave it on there for too long, the cell will short-circuit itself internally and die. Result: wasted money and disappointment.
3. If you don't have a DVM (digital volt meter), GET

ONE that's capable of reading 10 amps or more, then before you start wiring the cells together, test each one in full, bright sunlight. Check both the voltage and the current; each cell should put out upwards of 0.5 volts at 1.8 amps or more. After you solder a pair of cells together, check them again, both individually and in series. The current should be approximately the same and the voltage should be roughly doubled, i.e., 1.0 to 1.6 (or more) volts. Once you have a string of cells wired together, test the whole string. The point of all this is to ensure you don't end up with a dead cell due to overheating with the soldering iron. No matter how careful you are, there's always a chance that you'll blow a cell or two along the way.

4. I built four wooden frames and used tempered glass to cover them. I used ordinary window glazing compound to seal the glass against the frame; if you ever need to get to the cells in the future, the glazing compound will release the glass without too much effort. Be sure to provide a couple of holes in the back so the whole thing can "breathe", otherwise you'll be surprised how quickly condensation will form on the glass.
5. Speaking of condensation, I'd love to hear some comments on this phenomenon. I had one my panels positioned near a guard rail on my deck which cast a shadow over several cells. After 20 minutes or so, I noticed condensation building up on the glass, directly over the shadowed cells! I could only assume that those particular cells were heating up and sinking more current than they were putting out, though I didn't notice any appreciable decline in the panel's output. Strange! I now avoid shadows like the plague and my panels seem to be happy about it.
6. The WB-28 cells are VERY delicate so handle them carefully, and once they're mounted in a frame, be careful with them outdoors particularly on windy days. I had one panel perched rather precariously on the deck when a gust of wind came along and knocked it down. I cringed and said several prayers for its survival, but the sound of broken glass rang clear as I picked up the panel. The tempered glass survived the fall, but most of the cells shattered into a million pieces. Having lost a quarter of my power generation capability, I decided to build a wind turbine rather than replace the panel.

Hope that helps!  
ChrisW

by converseur on Mon Nov 24th, 2003 at 07:02:59  
PM MST  
([User Info](#))

hello Chris,

I have an excellent power system of 4 Trace SW5548 that I have rebuilt and I raised my battery bank to 2400 amps. I would like to run it wholly from renewable energy. Solar energy represents the best choice but it is totally unknown here in Canada. I have thought building my own solar panels. If possible I do not want to begin from scratch. I saw on sunelectronics website ``sunelec.com that they have off spec multicontact connector 75 watts panel 23V at 1.53D/W or \$115.00 that need to be framed. Could you confirm that at 23v there is nothing can done? And what about the price, that's only half price? too expensive? Any suggestions for plan over 20 panels?

## [Carrizo super gold spec sheet and wiring information](#)

By [ADMIN](#), Section [Homebrewed Electricity](#) [Solar](#)

Posted on Fri Oct 24th, 2003 at 10:37:22 AM MST

We had an email requesting information on old Carrizo panels, and I was able to dig the info up out of my files.

These panels were removed from service at the Carrizo power plant in California about 10 years ago, so as such they had no manual with them. I was actually able to dig up the original literature that came from the surplus distributor; I still run a pair of 4-panel Carrizo sets.

The biggest thing to be alert for---most of these panels were low voltage, and made to be used in "quadlams" or "trilams"---sets of 4 or 3 panels wired in series to get 12v. So if you have only one panel, your first step is to take a voltmeter and measure the output voltage in full sun. If the panel is intended to stand on its own for 12vdc, you should see 17-22v from it--this would be one of the carrizo 12v conversion panels, which were uncommon and more expensive. If you see 4-6v, then it's intended to be part of a multi-panel set....probably 4 panels.

Since I thought this info might be useful to others too, I put the scans of the literature I got with my Carrizos years ago up on our website...hope it helps. Also, my panels came with no frame; I acutally had to build a wooden frame to hold the glass laminate sheets.

One of the scans is pretty marginal, but the durn thing was printed on gold-colored paper!

Spec sheet:  
<http://otherpower.com/images/supergold.jpg>

Wiring / installation info:  
<http://otherpower.com/images/carrizo.jpg>

Cheers -- thought this might be useful to folks out there.

DANF

### [Mixing solar panel types](#)

By [Quigs](#), Section [Homebrewed Electricity](#)

Posted on Fri Oct 24th, 2003 at 12:08:39 AM MST

[Solar](#)

I currently have an array of six BP Solar 75 watt panels.

Now I have the opportunity to obtain several 60 watt panels of another type, not free but very cheap. Is there any inherent difficulty in mixing the array? The new panels claim a similar open voltage, but they are of a different crystalline type, judging from their appearance. Any comments appreciated.

Quigs

by [wpowokal](#) on Fri Oct 24th, 2003 at 04:22:23 AM MST  
([User Info](#))

Quigs, from one who does it, mix and match till your hearts content.

If you are putting panels in series then keep the same wattage in each series (or the lowest rating will prevail), but beyond that go for it.

regards Allan

Re: Mixing solar panel types ([none / 0](#)) ([#2](#))  
by [TomW](#) on Fri Oct 24th, 2003 at 06:18:25 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

I agree 100% with Allan on this. You should have no problems whatsoever. If you mix wattage units in a series string you will only get the current out equal to the lowest rated panel and even that would do no harm just lose output amps.

Hope you get a great deal because solar is so reliable here I would glom onto all I could find cheap. Retail is just so expensive on panels.

Well, off to get some more of that "free" firewood thats my real AE / RE here.

Always feel better when there are a few billion BTUs in the woodshed awaiting the combustor. And, as anyone who burns wood for heat know, its free. Of course thats after you own the saw, the woodstove and retrieval equipment.

Cheers.

Quest For The Solar Garage!

Quest For The Solar Garage!

Starting to love the RE stuff. I have been doing a ton of reading, a ton of playing, and a ton of smiling while my wife rolls her eyes at me when I start a new project. I have been playing around with the wind turbines, but San Jose Ca. just isn't the greatest place. Especially when you live in the middle of suburbia. So I wanted to do something to produce electricity.....

Timing being everything, it was my birthday a couple of weeks ago. I hinted for Radio Shack gift certificates, and little links for what I may need. I got a 15 watt 1 amp solar panel with 7 amp charger. Radio Shack is probably not the best place to buy a solar panel, but it's easy for friends to get gift certificates there:). Anyhow, my total cost: \$0.

Battery...I own my own business. I sell safety products, and one of my customers sells RV batteries. A little barter, and I walked out with a 175 amp battery. Just a little more than I expected...nice guy. Price: Not what it would usually cost.

Inverter...Walgreens special, 400 watt continuous, 800 watt max...\$39.95. It uses .6 amps while it on. Is that good?...bad? I don't know.

Anyhow, I simply connected my garage lights to the inverter, making the switch on the inverter as the light switch. I have two 37 watt flourescents and one 15 watt. I also have my computer monitor hooked up to it as well. A while back I hooked up an old computer in my garage networking it. It turns out to be one of the greatest things. I got tired of running back and forth from my office in the house to the garage all of the time looking up directions on how to build something.

In the future I plan on adding another panel but something with a lot more bang for the buck. I want to have my whole garage powered. I would love to have the garage door, the water softner, and sprinklers all running off RE.

Having fun with Renewable Energy, and Love OtherPower.com.

Mr. Rob

camp185,

nice little write up there, priceless. It feels good to make your own power and give's you a sense self of security. I survived Hurricane Andrew, even though my erges to produce AE started before then. currently I am managing a 3000-watt 12v input 120vac output inverter. We had to run our refrigerators with gasoline powered AC generators, following the moring after, the entire grid system was destroy'd, it took a full three full months for the local utility to get power back to our house. from hind-sight, it would have been nice to be as hurricane prepared as the family is today.

-JW

Re: Solar Garage! ([none / 0](#)) (#2)  
by TomW on Tue Oct 21st, 2003 at 08:51:57 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Mr. Rob;

Hey, you stole my idea! [just kidding].

I don't live in hurricane country but I do live in tornado and ice storm country. Equally as devastating at times to the power distribution infrastructure.

I have converted about 80% of my office / shop area to solar. It does not run freezers, refrigerators, etc. It does, however, run most of my personal entertainment, tools, communications and computer gear. Far from off grid in this all electric home we have but a step in the right direction, I believe. It makes you feel you are a part of the solution rather than a part of the problem. My link below has info on my system if you are interested. It includes 5kw of inverters, 1300 Amp Hours of battery storage and 300 watts of solar.

I think converting one "area" at a time is a fine way to get started without a lot of cash.

One point I would like to raise is that it is a whole lot easier to conserve a kilowatt hour of power than it is to produce it. By eliminating those incandescent light bulbs that should actually be marketed as heaters that produce a bit of light you have saved lots of energy that goes up in heat you usually don't need.

I simply wired certain circuits of my office / shop area to plugs which I plug into either my inverter[s] or the grid connected socket near the inverters depending on battery state of charge, etc. This makes it very easy to run certain parts of my area on either RE or grid power without expensive systems and devices. So far so good.

Another point i must make:

Beware! This stuff is highly addictive and as far as I know there is no intervention system in place for the RE addicted.

Cheers.

TomW

Tom W,

LOL, That's AE. This reminds me of that movie MR. MOM, especially the part where the guys wife's boss visits the house, and says to the husband oh I see your doing some rewiring here on this wall. And the husband replie's as he pulls up his pants. ya, doing some home improvement here between this room and that one there, the wife's boss chimes in, oh, ya, gonna re-wire with 220, and the husband reply's YAaaa, 220 221 "whatever it takes"

AE , RE blaa bla blaa...

> two 37 watt flourescents and one 15 watt. I also have  
> my computer monitor hooked up to it as well.

Sounds like about 120watts of stuff running off of the inverter. that would be more than 12 amps draw off of your battery (all on same time), with only a 1 amp solar panel charging the battery for 7 hours in a day.

Nice battery but it would be wise to add more solar panels. I have exactly the same setup here with a 12vdc 7watt flourescent and a 7 watt 12 vdc fan as the only loads (1.2 amps all on same time), and I run outta power frequently.

I would love more power...I would also love more money. The way I have it set up right now actually seems to work out. I don't work in the shop every night so it looks like it's going to balance out ok the way I have it set up. Maybe for Christmas I'll put in a request for a 75-100 watt panel. It's the gift that keeps on giving!. I would love to open that garage door opener with solar.

 I've got solar panels but no junction boxes

Has anyone got plans for junction boxes and frames for solar panels? I thought I remember reading about using heavy duty speaker terminals reclaimed from higher end stereo components and dismantling and resizing aluminum storm window frames. The panels are approx 51x13inch Seimens 50 watters that I plan use for power. They have 2 tin strips apiece on either end and I would like to possibly set the junction boxes up so as I add panels the junction boxes parallel together. While ultimately the panels will remain outside, initially they will be removable for use in remote locations. Thanks in advance for any help. I have learned a lot since I found this site.

[\(User Info\)](#)

I used those metal studs they use in home construction and I glued the panels to them with some liquid nails like glue. They've been together for about 6 months which isn't that long for a solar panel so not to sure how they'll do in the long run.

Joseph

jtb, I would simply look on the panal manufacturers web sites. Surely some of the solar panel manufacturer's have a drawing of the JB's they are using. Also, Homepower magazine undoubtedly has pictures of a number of these. I would simply use a waterproof box the size of a receptacle box with whatever terminals are convenient in it. Two screw terminals are all you really need.

Making solar cell and inverter

<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&category=3240&item=2351985714>

Anyone try this ? Any comments ?

I have not connection to the seller.

Thanks, Rob

Hi Rob,  
My opinion to this is:  
Don't give a Damn to it.  
Because I've tried to find Inverter Info (DIY...a.s.o.) in the net but found most such things like...aaroncake... not really a solution. I've want to have really good solutions. 'Bout the solarpanels it is the same. All sh.. !  
Greez Thomas

I don't know much about inverters, and less about that CD on ebay, but have you seen the inverter plans that appear at:

<http://www.theverylastpageoftheinternet.com/forsale/plans/inverter/inverter.htm>

Often you see reports of make-your-own solar cells that are based on the copper oxide method where you basically heat a piece of copper until it starts to oxidize. I haven't actually tried making these kinds of cells, but I understand their low efficiency would pose problems for people who want to power their house with them. You would need acres of them to do it.

-Tom

Re: Making solar cell and inverter ([none / 0](#)) ([#3](#))  
by Budgreen on Sat Oct 11th, 2003 at 09:33:25 PM MST  
([User Info](#))

those linked plans (theverylastpageoftheinternet) should work fairly well for diy power  
only drawback is the lack of efficiency and output waveform. I currently have a project going and using bits of the final output section schematic to make a sinewave inverter

[ [Parent](#) ]

Re: Making solar cell and inverter ([none / 0](#)) ([#6](#))  
by RobD on Sun Oct 12th, 2003 at 08:56:27 AM MST  
([User Info](#))

Quickly looking at these plans I see some problems.  
Because of the low frequency the transformers will get very hot due to saturation and secondly the transformers would be expensive. More expensive then buying a cheapo 700 watt inverter for \$75.00 that would work better.

by ThomasK on Sun Oct 12th, 2003 at 12:44:03 PM MST  
([User Info](#))

Hello Tom in NH,  
Thank you for the link with the inverter.  
This seems a bit underdesigned for 1000 VA but it is an Idea to follow on.  
I´m in a Project for myself which is about to compare some Designs and put  
the best together for a Inverter.  
I hope by the end of the Year i´m come to some results.  
By the way, does anybody of you know some DIY plans for a sinewaveinverter?  
Greez Thomas

Re: Making solar cell and inverter ([none / 0](#)) (#8)  
by LowTechWreck on Mon Oct 13th, 2003 at 07:03:14 AM MST  
([User Info](#))

I built this one.

[http://zephyrgennys.tripod.com/tony\\_van\\_roon\\_inverter.doc](http://zephyrgennys.tripod.com/tony_van_roon_inverter.doc)

It doesn't work.  
Hardly any way to screw it up.  
\*\*\*\*\*

I have ordered the parts for this one:

<http://www.uoguelph.ca/~antoon/circ/555dcac.html>

Looks more promising.

by Norm on Sun Oct 12th, 2003 at 07:32:13 AM MST  
([User Info](#))

My opinion, based on what I've read here on the board is to buy a bunch of solar cells fairly cheap and stick em in an oven with solder and connect them all together. Seems like someone posted about this about a month or so ago with larrge pics...seemed like he was quite sucessful with it. Maybe the author can step right in and clue us in again? (:>) Norm.

[Solar](#)

First Panel Up!!! Homemade!!!

HI!!!

10 watts doesn't seem like much, but when one builds it from a chunk of aluminum, some fiberglass and a handful of solar cells, it really means a lot!!!

Those Silicon Solar cells I posted about a while ago finally got put to use! After a day's worth of machining, etching copperclad fiberglass, and a whole lot of soldering, the panel is complete. It is sitting in the sun right now, charging my batteries, and running a small portable tv.

I used the technique I explained a couple of posts back about copperclad pcb solar panels. It turned out to work very well! I made little 1 volt 2 cell boards, and then epoxyed them on the the machined aluminum, and soldered them all together without putting any stress at all on the cells. Not one cracked, and all are performing flawlessly! I will have pictures shortly.

Hopefully more of these to come!!!

Already have over \$400 in the solar panel budget. By this time next year, my whole house will be off grid!

-Andrew

([User Info](#))

Wooo hooo, go Andrew!

I don't care if they're commercial or homebrew, electricity from the sun is just fundamentally better than electricity from dinosaurs.

I have two 110 watt panels now and plan to add six more next year.

Best regards,

troy

Well, after almost a day worth of charging, I decided I need two more cells to get in the peak power range... The panel voltage is just a shy low, so I am not getting full current. I was having fun lighting up small halogens, and florescents. It was kinda weird running the inverter directly off the solar panel, as it would just shut off if the current was to high, because the panel went under voltage. Luckily it was a nice sunny day, so I got a lot of use already.

When I find the usb cord to my digital camera, I'll upload the pictures.

You should look at the fiberglass mounting idea... It really works out great!

-Andrew

<http://homepage.ntlworld.com/s.amesbury/homepage.htm>

Hey 10 watts is 10 watts!!! And im only using a 15w panel but when the suns out its a superb battery charger. Where did you get your cells from? And how much cheaper did it work out building it yourself? And how big is the panel? Sorry for all the questions but im into solar if it can be made cheap enough. Well done though andrew and getting off the grid is something i just dream off but im so limited with space and solar is so expensive in the uk i just keep dreaming.....one day it may come true.....sean

Re: 10 watts of Joy ([none / 0](#)) (#4)  
by Tom in NH on Mon Oct 6th, 2003 at 10:58:03 PM MST  
([User Info](#))

Way to go! I'm eager to see the photos. What do you think one might draw from your technique that would be applicable to larger installations of hundreds or thousands of watts?

I'm looking for ways to streamline building of 100 watt panels which actually are only 87 watts in full sun, less if they're not aimed right, but you probably already know how that goes.

Tom

Re: 10 watts of Joy ([none / 0](#)) (#5)  
by johnjach on Tue Oct 7th, 2003 at 07:54:16 AM MST  
([User Info](#))

I appreciate the photos of your fine work. Are you or anyone else out there familiar with a website called [www.knowledgepublications.com](http://www.knowledgepublications.com) ? This author claims there are many sources for getting used solar cells for free. He said some of these sources would include local governmental agencies such as public works departments, county and state highway departments and the like. Any truth to all of his claims?  
I would buy his book if I knew his claims were true.

Re: 10 watts of Joy ([none / 0](#)) (#6)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Tue Oct 7th, 2003 at 10:01:01 AM MST  
([User Info](#))

Well, I left my usb cable in wisconsin somewhere, so I am heading to the computer store to get another one... Photos will be posted today.

As for getting solar cells and panels for free, I doubt it. You can get old highway sign panels for cheap, but not free. Gov. auctions rarely have that stuff here. (Mostly old cars, and furniture)

Also, I just bought 36 cells from silicon solar. I think they are 0.5v @4.5A peak power  
5A short circuit. It was pricy, but the total for a 120 watt panel with shipping, and materials is only \$220. Thats about %40 less than the cheapest panel I could find. (Astropower 120, at \$410)

The link for the cells is: <http://www.siliconsolar.com>

Now to answer the other questions...

For mounting the cells on fiberglass, I did have much success. It seemed quick, and less stress on the cell the bare soldering. (I use the analogy of soldering to a potato chip) I would etch the boards, apply solder paste, and lay the cells on. Cook in a (toaster over :) ) and let the solder paste flow. This would pull all the cells in alignment because of the surface tension, and it didn't require any manual handling of the cells. Once the cells were mounted on the fiberglass, I would then solder to the surface contacts, since they are now a lot more rigid. You can see this on the pictures.

As for trying to mass produce this, I haven't tried big cells yet, but it seems that everytime I use bigger cells with this method, it gets harder to lay them correctly, etc. You could give it a try, as I had nothing but success so far.

If that doesn't work, I know solar companys use this method sometimes: Lay the cells on a sheet of teflon, solder all top contacts, lay teflon sheet on top, and flip, solder all bottom contacts, flip again, cover entire set with epoxy, (like a mold) and then mount in aluminum case, and add more epoxy.

-Andrew

\$0.20 a Watt?

<http://www.st.com/stonline/press/news/year2003/t1355h.htm>

STMicroelectronics, Europe's largest semiconductor maker, said that, by the end of next year, it expected to have made the first stable prototypes of the new cells, which could then be put into production.

~~~~~

Following that, ST and others would need to develop production technologies to make solar cells and panels in large quantities to achieve the \$0.20 per watt target, he said.

"Our target is fixed at \$0.20," said Coffa, who expects no major technological difficulties in going from prototypes to mass-produced commercial products.

~~~~~

Let the fun begin....

Ron

This will be interesting to follow. I heard, but don't know if it's true, that there is only one manufacturer in the country (AstroPower) that is not owned by oil companies. Thinking about this plus the high price for photovoltaics, it kinda makes you wonder doesn't it. 20 cents a watt, if it comes to pass, will certainly shake things up. --Tom

Re: New and cheaper Solar Cells ([none / 0](#)) ([#6](#))  
by Bach On on Fri Oct 3rd, 2003 at 05:32:28 PM MST  
([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

Remember gas wars? The oil/gas companies hated those. Think what will happen when/IF a manufacturer finally breaks through the price barrier with a low cost panel. We might have watt war. That would do my heart good!

Bach On

there was a very good article in new scientist magazine sometime this summer about the technology used to make solar cells. cant find it a the moment but the jist of it was to try and reduce the cost of heating the silicon which is far and away the most expensive part of the process. if anyone is really intersted you can subscribe to thier archive for a week and look it up.

bob

Re: New and cheaper Solar Cells ([none / 0](#)) (#8)  
by troy on Sat Oct 4th, 2003 at 04:16:20 PM MST  
([User Info](#))

Yes, I did some reading on Evergreen (the continuous draw process, not ingots) and tracked down prices. At the time they cost more than the premium Shell solar panel. Maybe someday cheaper, maybe not. If you look back over the literature, there have been many promises of drastic price drops as the technology advances.

Unfortunately, there haven't been any dramatic breakthroughs yet. But I am still hopeful, as humans are endelessly inventive.

On the bright side, panels in large quantity have stayed around \$4.00 a watt for almost a decade, while modest inflation has made those dollars cheaper, effectively reducing the cost per watt by a third in one decade. So I'll take progress at whatever speed I can get it, incremental or breakthrough.

Best regards,

troy

Hi All,

There was also an article in Homepower magazine about some company using a new technique to continuously draw out the silicone so that production was several orders of magnitude quicker. I don't remember which issue, but I'll look into it and see if I can find it.

RogerAS

([User Info](#))

I heard, but don't know if it's true, that there is only one manufacturer in the country (AstroPower) that is not owned by oil companies

Evergreen solar is independent (they're the ones with the continuous process), but it seems like they are more interested in licensing their technology than producing panels. Kyocera and Sharp make panels and they aren't controlled by oil interests.

I really don't think that Shell and BP are interested in holding their own prices higher or stifling the industry, anyway. I saw a BP executive on tv a while back. He said the days of oil were limited and BP is transitioning into an energy company. Solar panels, hydrogen, biodiesel, whatever, they'd sell whatever can make a profit.

Re: New and cheaper Solar Cells ([none / 0](#)) (#7)  
by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Fri Oct 3rd, 2003  
at 10:06:40 PM MST

## Solar Panel

By [Frank Lussier](#), Section [Remote Living](#)

Posted on Mon Sep 29th, 2003 at 11:30:52 AM MST

None

[Solar](#)

Hi

I just finished building a warm air solar panel for my house.

I used 2x6 treated lumber for the box with 2- 2" holes on the bottom and the top, 1/4" plywood for the back, 2" Styrofoam insulation, 230 pop cans cut off the top and the bottom, 4'x7' thermal glass (patio door), I have 11 of them in my barn and a computer fan 5 inch square.

My first test was on a cloudy day, the temperature outside was 66°F and the temperature of the panel was 158°F not bad, this afternoon the temperature outside is 68°F and sunny and the temperature of the panel is 254°F. The panel is so hot the insulation is melting.

What can I put on the isolation to prevent melting?

Here are some pix

Just wondering, the cans ends are removed and lined up to be a tube?  
yes

-The cans are mounted how?  
the cans are mounted in place with 1 inch shingle nails - pushed by hand-it's quite easy

The bottom and top of the unit have a gap a can length this is where the in out holes are?

-approx 1 1/2 can length and yes that is where the inlet and outlet are.

The fan is sucking out or pressurizing in?  
-it is pressurizing in

Please more details on construction.

first i made a 3 sided rectangular box out of 2 x 6 lumber. i added a 1/4 plywood as the backing. i then added two inch styrofoam insulation on the top, bottom and two sides ( i nailed them in place)

I caulked all joints

I then added my cans - 260 of them! lol

for the gap i added a piece of aluminium to cover the insulation.

i then painted everything black with high temperature matt paint.

then i added my thermal window - which was already in an aluminium frame. I screwed it on top of the 2 x 6

I drilled two holes of 2" side by side on the top and bottom (next time i will cut out one rectangular hole instead)

This is my first test panel.  
Thanks  
Frank

yes I just installed a 300 cfm fan and it brought down the temperature to 100 °F  
but now i have to replace all the styrofoam because it's all melted lol!  
boohoo. I was expecting a moderate to good temperature not 254 °F i got..i could bake a cake in it.

Thanks for your suggestion - it works

Re: Solar Panel ([none / 0](#)) (#4)  
by troy on Mon Sep 29th, 2003 at 12:57:41 PM MST  
([User Info](#))

Styrofoam can't take the heat, as you know first hand. There is another kind of foam that is widely available and can stand heat in the 250+ range. One brand is Thermax. You can recognize it at the lumber yard because it is a dirty brown or yellow foam with a much finer "grain" than beaded styrofoam. It also typically has some kind of foil on both faces. I want to say it is isocyanurate foam, but I'm not totally sure on that.

I used it on a solar oven that routinely hits 300F no problem and the foam's still fine.

Don't depend on high air flow alone to solve the foam problem, because invariably, the fan will get unplugged or you'll have a brief power outage at just the wrong time and poof, melted foam.

Good luck and have fun!

troy

([User Info](#))

Why any kind of plastic foam at all? why not crumbled up newspapers? Thats what I've seen them use on solar cookers that boil water, funny isn't it we're so used to associating boiling water with fire or red hot heating elements and that the paper would catch on fire. Norm.

[ [Parent](#) ]

Re: Solar Panel ([none / 0](#)) (#14)  
by troy on Mon Sep 29th, 2003 at 09:40:05 PM MST  
([User Info](#))

I would be cautious about the use of paper as an insulator that is used in a solar collector hooked to your house. As paper is exposed to routine high temperatures, a process of pyrolysis changes the structure of the paper so that the spontaneous ignition temperature drops to 200-300 degrees F.

We do want to make heat, but not by burning the collector, or worse still, the house. Some claim that even wood can develop dangerously low ignition temperatures upon prolonged exposure to solar collector heat. I think that is why you never see a commercial collector made from wood. I did see a recommendation to bake a sample of your wood at 300 for a week and see if there are any significant changes, smells, color, etc just to be safe.

Food for thought anyway.

Best regards,

troy

([User Info](#))

Hey Troy: Thanks for the information I never realized something like that could possibly happen...once again I went typin' away and forgot to fully engage my brain...but even so someone might have tried it...now they'll know better, but I guess newspaper does work okay in an outdoor solar cooker. Sure do learn a lot from this board....don't we! Do you happen to have any good links about solar heating in this regard? Might be beneficial to all of us. (:>) Norm.

Re: Solar Panel ([none / 0](#)) (#20)  
by troy on Tue Sep 30th, 2003 at 05:58:03 PM MST  
([User Info](#))

Hey Norm!

I built a flat plate aluminum collector with pretty good results. My dad built one that used recycled aluminum beer cans with just the top cut off, with the opening facing the sun. His idea was more surface area = more heat. I was not overly impressed with Dad's design. And I ran across this design, which is intriguing because it uses furnace filter for the absorber:

<http://ww2.green-trust.org:8383/2000/solar/Homebuilt%20Collector%20Instructions.pdf>

"The collector design was tested using the ASHRAE 93-77 procedure, at Western Michigan University's Energy Learning Center (no longer operating). The result: greater than 72% maximum efficiency. This was the highest efficiency air collector they ever tested. It bettered all liquid collectors but one, which it virtually equaled. I know of no non-concentrating air collector, Conserval's SolarWall included, with higher efficiency."

Best regards,

troy

Re: Solar Panel ([none / 0](#)) (#26)  
by Gordy on Sat Oct 4th, 2003 at 07:44:39 AM MST  
([User Info](#))

For a good article on the furnace filter idea click on "more diaries" and go back to #52 Black paint on solar hot air experiment.

Speaking of filters don't forget to use one on the inlet side of your collector. Otherwise dust will start collecting on the black paint and start blocking the sun from your collector.

by [pexring](#) on Mon Sep 29th, 2003 at 07:58:55 PM MST  
([User Info](#))

Frank,

I too have made a solar panel this summer, although not as big as yours. Mine is 4'x5'. I'm getting temps in the mid to lower 100's on 50 degree days. Instead of aluminum cans, I simply lined the back of the panel with aluminum sheeting and painted it black with the high-heat paint. A couple questions for you:

I assume the air simply blows over the cans? Or can it blow through them too? I then assume the air comes in contact with the glass? Did you use a single or double glass?

At first I built mine with single glass, then made it double. Got much better results with double glass. Plus I would think double glass would be crucial to help shield against the cold in the winter. I'm about ready to make another panel or two as I know where I can get some big double-glass doors.

I'm basically wondering if tin cans are really better than aluminum sheets? Except for when the sun is straight on, you'd throw a lot of shadows too, which I avoided with the flat aluminum sheeting. Maybe I should try pressurizing mine and see if I can also get the temps to build-up. That would prove whether or not cans are worth all the work.

Thanks for posting. Always great to hear other ideas.

Can I suggest bending the sheet in a zig zag pattern  
45 degrees at the bends. This will dramatically increase  
the surface area of the collector face while not increasing  
the size of the apparatus.

Re: Solar Panel ([none / 0](#)) ([#17](#))  
by pexring on Tue Sep 30th, 2003 at 07:43:32 AM MST  
([User Info](#))

In my original design I tried a corrugated sheet of metal. The shadows became a problem, and it seemed to take forever to heat-up. Once it heated, it worked OK. I'm trying to create a solar heating panel that starts heating with the first morning sun! So far the flat black aluminum seems to work best for that.

Re: Solar Panel ([none / 0](#)) (#21)  
by John D on Tue Sep 30th, 2003 at 09:54:03 PM MST  
([User Info](#))

You mentioned you were using treated 2x6. I think if you do some checking you will find there are extremely deadly chemicals used in the preservation process. When the wood is heated these chemicals can easily vaporize, mix with the air and I won't go there. Just some food for thought.

Re: Solar Panel ([none / 0](#)) (#22)  
by Frank Lussier on Wed Oct 1st, 2003 at 03:36:47 PM MST  
([User Info](#)) <http://www.fludan.com>

Hi guys

I just bought some 2x6 channels for steel stud framing and the only insulation I found was from ROXUL - it is made from nonflammable material, the max temperature is 1200°F.

I am putting the new solar panel together today, when I'm finished I will post the new pictures. They are announcing rain for the next few days. I can't wait to see how high a temperature I will get with this new panel. As soon as I get the data, I will post it.

([User Info](#))

I have 4 of these that heat a 700 square foot building, they work well but i well give you a few pointers on better constuction. First of all I found that 2 inch copper tubes instead of cans works better, I also made my frame out of aluunim. The computer case fans work well, I have a 8 inch by 2 in slot in the bottome and top of mine, with four fans in it, this way if one fails it still has three to run on. Another thing I did which works good was a set the exterior of the top at a 70degree angle and mounted a VW solar panel wired to the fans, this way the brighter the sun, and the hotter the heater gets the more speed the fans turn on. This setup took me from 5 cords of wood 2 years ago to heat my building down to little over a cord of wood last winter. Hope this helps youout and everybody else out there who is trying to use the natural resources.

Looks like 1 1/4inch PVC Pipe, the 90degree fittings for that pipe are a lot like squares and present a lot of resistance to liquids. If you used 1 1/2inch fittings the 90degree fittings are a lot more like circles and will give you a lot less head pressure to the pump. How are you getting any flow through that many tight 90degree corners?

Plus if this was a picture test, you should size your pictures to an internet friendly size of less than 640pixels in any direction.

by bretco on Thu Sep 11th, 2003 at 08:32:21 PM MST  
([User Info](#))

Sorry about the pic size. Hope to climb the learning curve on pic posting enough before the next one.  
I actually used a small 110vac "utility" pump and a 5 gallon pail and got about 3 gallons/minute of flow. Basically didn't think a high flow rate would be necessary, but I imagine the elbows do give a lot of flow drag. I just wanted to fabricate a quick and cheap test unit using a sliding glass door (free in the newspaper) as the glazing, 2x6 sides, and a plywood back with insulation. I got approx a 2-3 temp rise across this thing (high noon in Vermont, June), which I think is around 3000 btu's/hr. Just curious what a "baseline" output has been seen on other units. Just starting to really research homebrew collectors, so any advice would be welcome.

U know.. sliding galss doors are meant to block heat transfers????

Better to use that plastic celifane insulation for windows i bet....  
the stuff with double sidded tape and u use a hair dryr to make it  
shrink to a flat/non-rippled surface....

Re: First time on new board, test PIC ([none / 0](#)) ([#7](#))  
by bretco on Sat Sep 13th, 2003 at 10:20:32 AM MST  
([User Info](#))

Hi,

The insulation I used was Celotex, which is that foil backed styrofoam type of stuff, not the heat shrink plastic film you're thinking of. Hopefully sliding glass door glass does block heat, but not light, which is what I want to hit the pipes. Do you think a single pane of plain glass would work better? I just tried this glass 'cause it was free.

Take care

Personaly Lexan stands up the best.

Dr.D

Re: Panel Design Question ([none / 0](#)) ([#2](#))  
by [troy](#) on Wed Sep 3rd, 2003 at 09:49:40 AM MST  
([User Info](#))

Most plastics, including Lexan, will eventually degrade in the sun. Glass is heavier and far more brittle, but no long term degradation in the sun. It will still be working fine in 30 years, which the lexan will not. Depends on how long you want it to last.

Transmission characteristics also play a role here. As an example, polycarbonate is a very good UV absorber. Some PV cells utilize some UV photons to make electricity, so polycarb may actually reduce output. Normal window glass uses some iron as an additive (glass looks green on the edge), which costs you 6-8% light transmission. Commercial PV panels use special low iron glass for improved transmission, but it costs more.

They will all work reasonably well, so use what you want, some materials just work slightly better than others, or last better.

Good luck and have fun!

troy

by Tom in NH on Thu Sep 4th, 2003 at 08:43:20 PM MST  
([User Info](#))

Thanks for your comments, drdongle and troy. I thought I had decided on tempered low iron glass... until I got the price quote from my local glass place. I'm looking at a glass price of \$100 per 32" x 42" panel! And Lexan is even more. Now, plain old window glass is looking better and better. Do you know of a reasonably priced source of these materials?

Tom

Re: Panel Design Question ([none / 0](#)) (#4)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Sun Sep 7th, 2003 at 12:20:57 AM MST  
([User Info](#))

That's a lot!!!!  
Wow!

I would suggest looking it up on google or calling a local glass blower. They usually will have something you might need. Also, they can order direct from factory, so it saves you a lot.

-Andrew

6 to 8 percent isn't bad considering the epoxy the companies encapsulate them drops about 15-20 percent light transmission.

## [Solar Heating Panel Question](#)

By [pexring](#), Section [Homebrewed Electricity](#)

Posted on Sat Aug 23rd, 2003 at 10:26:28 AM MST

[Solar](#)

Question about the absorption plate

I just finished building a solar heating panel. I followed the instructions to a tee with this website being one of my main sources:

<http://ww2.green-trust.org:8383/2000/solar/solair.htm>

My question is how far should the glass (glazing) be from the absorption plate? Mine is about 2" because my neighbor thought maybe if the absorption plate was too close to the glass, it would cool off. I originally had about a half inch gap between the glass and absorption plate.

Also, would double glazing be a whole lot better than single glazing?

For an absorption plate, I just painted corrugated metal flat black. Right now the panel is warming 80 degree air to 95 or so -- and that's during the summer!

Mark

by [Bach On](#) on Sat Aug 23rd, 2003 at 09:04:59 PM MST  
([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

I take it that this uses solar energy to heat air, not some form of liquid collector.

I'm not sure of your location or the placement of your unit, but reaching an internal temperature of only 80 degrees in Summer seems a bit low to me. Was this facing the sun directly, or was the corrugated collector at an angle to the Sun? The Sun will appear lower in the Winter. Do you have a means of mounting the box so the Sun rays are nearly perpendicular to the black collector? That will provide a much higher gain.

Did you insulate and seal the interior walls and the surface beneath the collector? I'd think that any leaks here would negate the solar gain.

Two panes of glass should provide better insulation provided there is an air-tight gap between them. Without two panes, the glass will serve as a radiator to cool the interior. Air changes temperatures pretty quickly, as compared to a liquid.

I saw projects like this back during the energy crisis in the late 70's. One guy had mounted these on his windows. They blew air through a gap created by raising the window.

Still, it's an interesting project. Please keep us posted.

([User Info](#))

Hi,

Thanks so much for the response. I was thinking maybe nobody had built one of these. Yep, the panel was in full direct sun for much of the day. It is designed to heat air. During the hottest part of the day, it did get to 115 or so. But that's a far cry from the 140+ that others are getting. Today the outdoor temp got to 110, so that heater should have been easily kicking out temps of over 200.

Yep, everything is insulated. Someone had suggested to me to paint everything black underneath the absorption plate. The absorption plate is black, but nothing underneath is. So maybe tomorrow I'll do that and see about adding a second sheet of glass or plastic. With what I've done so far, I've gone overboard to see that everything is good and sealed.

My absorption plate is corrugated metal. Maybe I should change it to aluminum. I can't find corrugated aluminum, but can get flat aluminum. Would then have to put something in the pathways to create turbulence so the air mixes and heats.

I welcome any other thoughts. Thanks for your response. Will keep in touch.

([User Info](#))

Try cutting Aluminum soda, beer cans in half.  
Then cut them with a scissors lengthways (make 3/8 slices) downwards, fold them over.  
(you are making little stars out of them), use sheet metal screws to mount them to the front. paint them with stove paint. (Aluminum dissipates heat much better than steel.  
If you want to get fancy, run a 4 inch air duct from the bottom and one up top.  
Run a puter fan from the bottom with a cheezy solar panel to push air through.  
(use a furnace filter so as to keep the dust off your glass!)

GOOD LUCK

Having prob's with my cam or i would send pix.

I am using soda cans (uncut) 1/2 holes drilled through the bottom and top mounted on top of each other (using

caulking), a peice of 1/2 copper tube to cualk and hold them together till it dries. (in the process myself)

The STARS WILL WORK! I have made panels that kicked out the heat.

try [www.canssolair.com](http://www.canssolair.com)

(could be a bad link)but from memory. (a weak one at that!)

([User Info](#))

I would make the frames from 2x6. Cut rigid 2" blue insulation board for the back. Silicon the inserted board both sides for an air seal. Cover insulation board with aluminum foil shiny side up. Use silicon glue to hold in place until corrugated collector sheet installed over top. Use double glazed sealed window units and mount flush to top edge of 2x6. You can make these units any length say 8 feet attach to a south facing shop wall. If you cut 2 or 3 holes in the bottom and top you will get natural convection flow. The cold air near the floor is sucked out into the collector, heated and forced back into the shop. A down draft fan inside will keep the hot air from pooling at the ceiling. This works quite well north of the 50th where winter temps frequently hit -40 C.

John;

Good idea but may I add a point?

If you do it this way at nite air will flow in reverse robbing you of that precious heat as air in the heater cools, falls out the bottom all nite.

The one I built long long ago to assist in heating a mobile home I lived in had a "trap" to let cold air settle into and stop the reverse circulation at nite. Very much like a "P" trap in A waste water line. Same principle anyway.

Cheers.

TomW

Steven Baer worte a book called "Sunspots", I think, a few years back. It went through a lot of solar heating projects and such - GOOD information. I would see if I could find a copy to look through.

Just for kicks, I moved my glass closer to the black corrugated absorption plate. Instead of the glass being 2.5" from the absorption plate, it is now 1 inch. It made very little difference in heat. Someone suggested maybe my corrugated metal absorption plate is too hard to heat. So next I'll either try a different absorption panel, or replace it with a second glass and heat the aluminum inside the panel.

My neighbor once made a solar panel shaped like a triangle. Holes in the bottom let air in, and he had a fan at the top which pulled it out. He claimed he got heat of 140-160F. I can't get above 115 on a 100 degree day!

I like the p-trap idea, although a bit to late for the design of this panel. So instead I may use a trap door.

Thanks for the input. Keep it coming. Fuel prices will be extra high this year, so need alternative ways to heat.

Mark

Hmmmmmm... I think i will have to make some measurements of air flow through my collector and add a measurement of outdoor temperature (my collector gets its air from the outdoors and a fan transports it into my house..... I will give You some figures in m3/h and °C as soon as i have them..... Nice with people making use of sunshine like this..

The cheapest supplier of solar cells i have found around here is about 6700\$ for a installed effect of 1kW.... I think it is too much when grid electricity cost me about 0,1\$.. How are Your prices..??

Good evening Lars A

I've been tinkering with a very similar project recently. I've used aluminum cans, glued end on end, with holes drilled between them... so they make something of a pipe. But wonder if this is any better than one big flat collector plate of aluminum, or perhaps corrugated aluminum.

Anyone have thoughts/experience?

I built mine like a flat box in a glass covered box, it takes outdoor air through the inner box and into my basement. The inner box is made of a frame from 2"\*1" wood covered on the back side (except for air transport holes) with "masonite" and on the sun facing side with thin aluminium sheet metal (painted black). Inside the inner box is one "inner wall that makes the air pass like a up side down "U" and the inner side of the alu sheet has "fins" on it to increase the heat transfer area. I works quite well and was built with a minimum effort.....

I used 2inch copper pipes in my solar heaters, works good, and was cheap from the local scrap dealer. Just a thought, considering everbodys can idea.

Neo, PMA and Stirling info

I found this while looking up information about Stirling engines (still trying to figure those out):

<http://gltrs.grc.nasa.gov/reports/2001/CR-2001-210952.pdf>

It's about the degradation of Neo magnets under high temperatures and with a de-magnetizing field being exerted on them. Not sure it's strictly applicable to Neo magnets in terrestrial applications, but it might be useful to someone.

There's a similar discussion of Samarium-Cobalt magnets here:

<http://gltrs.grc.nasa.gov/citations/all/e-7144.html>

VERY interesting looking reports abstracted here:

<http://gltrs.grc.nasa.gov/citations/all/e-7929.html>

<http://gltrs.grc.nasa.gov/citations/all/e-7017.html>

but they want spending cabbage for the whole reports.

This one, describing a linear alternator (really the demagnetization occurring within a linear alternator) is pretty interesting, too. Be careful trying to open this. It locked my Adobe reader up for some reason (may just need to reboot), but I managed to download the file and then open it up okay.

<http://gltrs.grc.nasa.gov/reports/2001/TM-2001-211084.pdf>

Unfortunately this one is not available in .pdf:

<http://gltrs.grc.nasa.gov/cgi-bin/GLTRS/browse.pl?2001/TM-2001-211084.html>

#### ABSTRACT:

Permanent magnet excited linear alternators rated tens of kW and coupled to free-piston Stirling engines are presently viewed as promising candidates for long term generation of electric power in both space and terrestrial applications. Series capacitive cancellation of the internal inductive reactance of such alternators has been considered a viable way to both increase power extraction and to suppress unstable modes of the thermodynamic oscillation. Idealized toroidal and cylindrical alternator geometries are used here for a comparative study of the issues of specific mass and capacitive tuning, subject to stability criteria. The analysis shows that the stator mass of an alternator designed to be capacitively tuned is always greater than the minimum achievable stator mass of an alternator designed with no capacitors, assuming equal utilization of materials ratings and the same frequency and power to a resistive load. This conclusion is not substantially altered when the usually lesser masses of the magnets and of any capacitors are added. Within the reported stability requirements and under circumstances of normal materials ratings, this study finds no clear advantage to capacitive tuning. Comparative plots of the various constituent masses are presented versus the internal power factor taken as a design degree of freedom. The explicit formulas developed for stator core, coil, capacitor and magnet masses and for the degree of magnet utilization provide useful estimates of scaling effects.

Lots of interesting stuff on the NASA Technical Reports Server:

Anybody seen this site

Anybody seen this site. They appear to be trying to sell the technology they theoretically have developed, Servel referigeration that can be used with waste or solar heat. Should be doable, I'm thinking, but since I don't have a degree in thermal dynamics or HVAC, I'm posting here. I'm new to this group but have been interested in alt-energy for many years and have a degree in electronics with 20+ yrs expetience with UPS, 3 phase, ect.  
TIA,  
mel

## [Passive Solar Windows, Multi-pane low-e right?](#)

By [joe4324](#), Section [Remote Living](#) [Solar Thermal](#)

Posted on Fri Nov 28th, 2003 at 12:21:54 AM MST

Cant figure out wich ones I need!

Ok, I'll make this quick. I'm working on a floor plan and materials list for my earth bermed passive solar home I will be building hopefully next year. I know this is a dumb question but I want to verify before I assume I know what I'm looking for the type of windows best suited for my purpose.

I live in indiana, and I'm on a mission, I dont EVER want to pay another utility bill again, I'm going to attempt to construct a home that will require NO heating or cooling, at least not conventional expensive methods.

So basically, I want the suns energy to come INTO my thermal envelope. Wich windows am I looking for. I want the best available. I'm currently trying to settle on an exact square footage so I can work on my formula for the 'amount' of glazing I need. soon as thats ready its time to call window manufactures to price them. Am I looking for better then double-pane Low-E? or is there something better?

[Passive Solar Windows, Multi-pane low-e right?](#) | 5 comments (5 topical, 0 editorial)

More information? ([none / 0](#)) ([#1](#))  
by [wdyasq](#) on Fri Nov 28th, 2003 at 07:55:09 AM MST  
([User Info](#))

Joe,

First I recommend a book, Sunspots: An Exploration of Solar Energy Through Fact and Fiction by: Steve Baer. He has a lot of thoughts and experiments about solar energy that actually make sense. And, he built and lived in solar homes over 20 years ago.

By now you realize windows work two ways - they let energy in and, in a home, they are usually the largest energy leaking device in a well-built home. In Indiana, you are probably worried about heat loss and want to maximize heat gain. For those in warmer climates, there may be different concerns.

I am attaching a rendering I did trying to explain some features I will put in any dwelling I plan on owning and living in. Here are some of the simple explanations. There is a Sunroom/greenhouse on the south end. A reflective bi-fold panel is on the south face and a reflective panel covers the roof. Both are insulated. In the daytime, the panels can be opened to let the sun shine in. At night, they may be closed to conserve heat. Pipes collect the heat and distribute it under the house. small fans circulate the air. In warmer climates, one might reverse the procedure to rid themselves of heat when needed.

The dwelling itself is near a cube. The reason is to get as much volume as possible with the smallest wall and roof area. The flat roofs are for "drawing purposes only". I don't think any building deserves flat roof problems and will avoid them whenever possible.

Not shown is the "batch style" water heater, the small generator, and the heating system that, by thermosyphon, heats the home and domestic hot water when needed.

There will also be solar stills to assure water used for drinking, cooking and making coffee. A catchment system will provide rain water for clothes washing and solar cells will provide for "priority" devices such as a freezer.

So no, I'm not going to answer if you want single, double or triple pane glass and specify the iron content and surface treatment. But then again, I don't know if these windows are to be vertical or at an angle, shaded or in full sun, how much window area you plan. AND, there is a saying where I come from - Go ahead, it's your cow.

Here is a home built in Iowa a few years back:

[http://www.public.iastate.edu/~envr\\_stu\\_324/house.htm](http://www.public.iastate.edu/~envr_stu_324/house.htm)

Ron

Diplomacy is the art of saying 'Nice doggie' until you can find a rock. - Will Rogers

Re: Passive Solar Windows, ([none / 0](#)) ([#2](#))  
by troy on Fri Nov 28th, 2003 at 10:07:53 AM MST  
([User Info](#))

I built a passive solar superinsulated house in Ontario that was very successful. As you have discovered, windows get complicated in a hurry. Here's my short answer: Double pane low-E, be cautious about over glazing (too many windows). Don't put any windows on the north, unless it's strictly for view--they lose energy period. Limited glass on the east and west, most glass on the south.

The medium answer: If you're willing to insulate your windows at night, you'll have much better results Nov-Feb.

Indiana doesn't get a lot of hours of sunlight in those months, and quad glazing with low-emmissivity coatings won't fix that. That makes even super duper windows net energy losers every day for those four months, except the rare cloudless day. Even triple glazed low-E windows have poor R-values compared to any decent wall.

So you can stick with modest glazing that will help some in the spring and fall, but not hurt you too much in the dark winter months. Or you can devise a scheme for insulating the windows at night and on cloudy days and make a go of it with a little more window area. This may cause some overheating on bright days unless you try something more complex than just passively heating the cement floor of the house for storage.

If you're interested, I'll send you a longer analysis with some easy heat loss math. It outlines a hybrid active/passive method that should work in Indiana, is low tech using readily available materials, and is affordable.

Best regards,

troy

by joe4324 on Sun Nov 30th, 2003 at 12:05:11 AM  
MST  
([User Info](#)) [www.ecoforums.com](http://www.ecoforums.com)

I would love to recieve more info!

You could either send it to my email  
joe4324@hotmail.com

Or even better post it on my website  
www.ecoforums.com

the site isnt nearly complete, but there is a working forum there and in the future I plan on using this site to gather information and share all my latest exploits and adventures AND disasters with he world :) My home will be one of them.

One thing I want to impress on everyone is that I'm after the least expensive way POSSIBLE to get this done otherwise it 'wont' be happening, I'm only 23 years of age and I dont make much money, I view every day I pay rent and every utility bill as money lost for my home AND my savings account. I live very basically now and there isnt many more corners I can cut.

Providing I can aquire the land I want for \$20k, I will be wanting the home itelf to be 'liveable' when I hit the \$20k mark on building it. (not including well/septic, wich I have to have to get a mortgage..grrr) SO thats 20k for JUST the house. I know thats hardly anything!

But what I want is very, VERY simple. 20ft deep, 50ft wide. Earth-bermed on east/west/north, Only exposed side will be facing south, All glazing vertical. Southernwall will be conventionally built and 'SUPER' insulated. All concret will be Super insulated as well (including footer)

No trim-work or anything fancy on the inside, I want bare concrete walls (I can always hang things or paint them later!) so I'm going to save a big wad of cash there. The floors will be bare as well untill I asses what areas would be nice to have some padding.

I'm looking at a Steel roof (not sure if it will be angled south OR north, I need to pick out a peice of land first) SO all and all doing the majority of the work myself or will friends/family I believe there will be virtually nothing that needs contracted out. So I've done some 'test' calculations and it just might be possible to bring a structure in for 20k... I'm damn sure going to try :)

So if anyone has any input for ANY stage of this type of project please let me know!

Soon as I have more time I should be updating www.ecoforums.com with more detailed outlines of my plans and intentions. and hopefully I'll be able to generate some really good feedback.

Re: Passive Solar Windows, ([none / 0](#)) ([#3](#))  
by JW on Fri Nov 28th, 2003 at 12:09:59 PM MST  
([User Info](#))

joe4324,

Hmmm, passive solar windows. Double pane Low-E. Uknow I did some digging on this one, considering your designing your own floor plan, this may or not be of help to you... "Ecolodge" this company was featured in popular science "best of whats new 10th annual" for december 1997.

Also the design ecolodge uses appears in a book published by ARCO in 1978. in the small artical I found(in the book) there are some very interesting concepts disscussed about this topic. Im going to quote from the artical perhaps this will help.

//the average thermal efficiency- the ratio of heat falling on them to useful heat extracted- of these collectors is generally in the region of 45 to 65%. the main heat losses occur from the front surface of the collector itself, provided

all other parts of the system are well lagged. The glass cover assists in minimizing these losses, since glass is transparent to visible radiation but opaque to infra-red. Thus, solar radiation passes through it but the long wave thermal radiation from the warm collector plate cannot pass out-ward through the glass. the system can be made more efficient by means of a vacuum between the glass and the metal plate and by using suitable spectrally selective surfaces on the metal. These are surfaces with properties opposite those of the glass. they absorb visible radiation efficiently, so they are black to sunlight, but they do not appreciably absorb longer wavelength infra-red radiation. Consequently they do not emit the latter wavelengths either and so cannot radiate heat, and therefore a spectrally selective superblack body reaches a higher temperature in sunlight than does a normal uniformly black body. Solar water heaters incorporating an absorbing surface of super-black anodized galvanized steel are commercially available. They absorb 93% of visible light but emit only 10% of there infra-red, and this produces an improvement in average performance of several percent.--

Also intersting-

/Solar radiation(both direct and diffuse) passes through the glass cover plate and warms the metal surface, which in turn warms water frowing through the pipes. The water is circulated from the hot water storage tank,either by convection or by a small pump. With appropriate thermostat control to switch the system off when the insolation is to weak to make a useful contribution, solar water heaters can readily provide a reliable supply of domestic supply of hot water in consistently sunny areas of the world. A conventional booster heater is, however, generally fitted in the tank to provide heat during cloudy spells. -

Summary-

It appears that solar heaters, mounted on the roof may also be used in a simular fashion as a heat pump, allowing excess heat to be released at night. But the heaters built into an interior wall facing said glass windows cannot be seen through because the heaters themselves are opaque.

Have fun!  
-JW

## Solar Chimney

By [Dameion](#), Section [Homebrewed Electricity](#)  
 Posted on Sun Nov 23rd, 2003 at 01:53:31 PM MST

[Solar Thermal](#)

hello ... this is my first time posting to this very interesting group. I've been following many different ways to make electricity in the last couple of years and one of the more interesting that i've come across is the idea of a solar chimney. Just wondering if anyone has tried this on a smaller scale.

[http://www.globalwarmingsolutions.co.uk/the\\_solar\\_chimney.htm](http://www.globalwarmingsolutions.co.uk/the_solar_chimney.htm)

any and all comments would be appreciated

Dameion

Re: Solar Chimney ([none / 0](#)) (#1)  
 by [pexring](#) on Tue Nov 25th, 2003 at 12:32:20 AM MST  
[\(User Info\)](#)

Interesting idea for sure. But I wonder just how big it has to be to produce any useful energy from the turbine. Building one on a small scale may not be enough to turn a turbine. Still might be worth tinkering with tho.

Mark

Re: Solar Chimney ([none / 0](#)) (#2)  
 by [troy](#) on Wed Nov 26th, 2003 at 12:27:06 PM MST  
[\(User Info\)](#)

I don't recall the link right off hand, but Australia is contemplating an enormous thermally driven chimney with a wind turbine at the top. Acres of glass collector on the ground, etc. If I remember correctly, the power generated was related to the overall height as the square or cube of the height, so their conclusion was that anything shorter than hundreds of meters was a waste of time.

Good luck and have fun!

troy

Re: Added new topic: Solar Thermal ([none / 0](#)) (#1) by [windracer](#) on Sat Oct 25th, 2003 at 08:03:49 PM MST ([User Info](#))

Thanks guys for this new topic. This type of energy production can be as easy as painting the back of your building with flat black paint. Since heating is the largest user of energy, there should be a lot of neat ideas out there.

Windracer

heating is the largest user of energy? ([none / 0](#)) (#2) by [wdyasq](#) on Sun Oct 26th, 2003 at 06:11:27 AM MST ([User Info](#))

It is obvious you haven't lived in the tropics - or Texas.

I will agree it is stupid to generate electricity to heat water, use electricity in refrigeration cycles and throw that heat out with one's air-conditioner and have a refrigerator throwing heat out and buy more electricity for the air-conditioner to get rid of THAT heat - with your "Energy Star", government approved devices.

Ron

Save the oil well! It will be easier to grow a tree than finding a dinosaur egg to hatch.

When will there be a solar panel that is cooled by water for higher efficiency and the hot water used also?

### Something odd

By [Demetri](#), Section [Weird Science](#)

Posted on Sun Jun 29th, 2003 at 06:56:24 PM [Superconductors](#)  
MST

Led flashed without any apparent power source.

Anyone ever drop a single led onto the floor and have it flash? I knocked a bright red one off a table onto the floor in a dark room and it blinked on for just a fraction of a second, illuminating the far wall. Only thing I can figure is static. Linoleum floor, wearing thick rubber soled steel toed work boots, hot and kinda humid outside. Led worked fine afterwards. The table it was knocked off of has my stereo on it, lots of power and EM radiation floating around there, I'm sure. Any ideas?

Demetri

Interesting,sounds like the led had a static charge on it and it discharged when the led came in contact with the floor.  
Rayw

That dose sound odd... phizoelectric effect or static or mabey it got an induced volage in it by passing a magnitic field (were the ends touching eachother?) is only things i can think of also.. would be real hard to measure it and im sure its insignificant

personaly i think it sounds neet but dont think it would develop into a powersource :(

Nasher

Heh, I'm envisioning a waterfall arrangement with led's lighting up as they hit the bottom of a basin, and a bunch of buckets on a belt to lift them up and dump them out again. No, the leads weren't touching. This is probably a once in a lifetime thing. I'm sure such charges build up and discharge all the time, but the chances of it happening across the leads of an led, at a voltage useable by the led, and at the correct polarity, are astronomical.

Demetri

## Moisture and Humidity problem?

By [halfcrazy](#), Section [Remote Living](#)

Posted on Sun Dec 14th, 2003 at 05:35:21 PM MST

[Survival](#)

I am building a small home in Maine.

Not sure what category this should be in but here it is. I am building a small home in Maine it is 32 by 24 on a slab with conventional insulation. I am currently heating it during construction with a unvented propane heater. and it is all sheetrocked and painted. The problem i am having is that if i shut the windows the humidity level runs right up to like 65-70% and the windows and doors get soaking wet as well as most of the outlets on the outside wall. I have radiant heat in the slab i just havent got it up and running yet. I have been told the unvented propane heater is the cause of all the humidity? does this sound right or do i need to do something different?

[Moisture and Humidity problem?](#) | 4 comments (4 topical, 0 editorial)

by-products ([none / 0](#)) ([#1](#))

by [wdyasq](#) on Sun Dec 14th, 2003 at 06:58:46 PM MST  
([User Info](#))

The by-products of combustion of hydrocarbons is CO2 and H2O. If insufficient oxygen is present you can get CO - Carbon Monoxide - but you won't need to worry about that after it has killed you.

If you care about the beneficiaries of your insurance policies more than you care about yourself or your life, keep running the propane heater in an enclosed space. If you would like to enjoy the house you are building..... well, make some changes.

Ron

For fuels such as kerosene, white gas, and oil, each unit of fuel burned releases roughly an equivalent unit of water into the atmosphere. If that atmosphere is a tightly sealed home humidity will be a serious problem if much fuel is burned. You are loading the interior atmosphere of the home with a lot of water vapor, and it is condensing on the parts of the home that are below the dewpoint of the interior atmosphere. Check those outside wall outlets...the condensation says that they are a source of cold coming into the home (heat leaving, actually.)

I don't know if it would be worthwhile, but you could try to make a heat exchanger for the heater. It might just be a fire hazard. If you are using one of those jet engine looking heaters, you could have it exhaust the heated air into a long section of metal chimney flue that ran across the house and exited at a window. There would be some sacrifice of efficiency, but some of the heat would radiate through the metal chimney flue into the house, while the rest would blow out the window.

You do have to watch out for carbon monoxide poisoning with any kind of device that consumes oxygen from an enclosed space. You can probably get a cheap CO monitor at the hardware store. They work like smoke alarms.

Better to be out a few \$\$ than be found lying on the concrete all stiff and blue.

There are times when a person can afford to procrastinate, but this isn't one of those times. Please get those co detectors and install them now! Even after you have them installed and as long as you are running this heater be overly cautious and open some windows. Better to be a little cold than....

Hi folks new to this board and need a bit of help

Hi Folks. I am new to the board. I used to drop by the old board once and awhile and have found a wealth of info on it. I live here in St. Catharines Ontario Canada. I have farmed for a good portion of my life and the latter part owned and operated my own woodworking business and landscaping business. We currently have our home up for sale and are moving back north to the country. Hoping our home sells fast so we can get things back to basic. We have tried to do this for years but something always seems to come up. But this time we are going to do it. The reason I am telling you all this is so you know where I am coming from. We have been looking at a piece of property that has 35 acres of land mostly bush. The home is real niceley set up insulated. Septic and a drilled well. The only thing there isn't any hydro. What I was wondering was what a fellow would have to do or buy to set his self up with solar and wind or??? This is all new to me and not to sure if or what to do. I don't have a great deal of money to spend on solar maybe \$5000 or so to start and not sure if this would be enough to get us up and running with things in the house. I suppose the other thing would be for us to buy a place with hydro and start from there. Any help would be appreciated. Taker easy. George

([User Info](#))

Kurt has it right but since you are not yet there, no don't know those numbers.

Try to get hold of the kWh numbers from the previous owner and that should give you some idea of the amount of power that you may need. I say 'may need' because you should also look at the conservation side of things. Does the new place have all incandescent lighting - converting to flourescent will save power. If they were running an old refridgerator, a newer one will save power.

Martin.

Hi Folks Thanks for the replys. The home I am looking at is in Mattawa Ontario. Actually there is two. All depends on if they will still be available when my house sells. We got an offer in on ours yesterday so we are hoping. The other home is in West Nippising. We are going up to go through them both this coming Thursday. I might be an old feller but I am still getting kind of excited. Well thanks again. I will let you folks know exactly what I am getting hopefully by next weekend. George

Re: Country Living ([none / 0](#)) (#6)  
by troy on Mon Oct 13th, 2003 at 11:41:12  
AM MST  
([User Info](#))

Just to get a little feel for the scale of things, if you have anything like "normal" electrical consumption, a US \$40,000 setup might not be enough. If you're careful with conservation and you get rid of all electric heat devices (stove, furnace, water heater, incandescent light bulbs, blow dryers) then you stand a chance of getting a workable system for \$5-10,000. Many sources note that every dollar spent on efficient appliances (eg fridge) will save you 4-5 dollars of solar/wind/battery expenses. Wind and solar often complement each other, as you won't get much sun dec/jan/feb, but the wind often blows then. I used to live just east of Cobourg five miles north of the lake.

Good luck and keep us posted,

troy

### Disappointment

I just got back from the Idaho state fair and you know what? Not one lousy exhibit on renewable energy. If you wanted your palm read, or your back realigned or your chrome polished, or a new spa you came to the right place!!!

[Renewable energy](#) | 3 comments (3 topical, 0 editorial)

Re: Renewable energy ([none / 0](#)) (#1)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Thu Aug 21st, 2003 at 03:13:48 AM MST  
([User Info](#))

Talk about disappointing, Colorado is like number 2 out of the 50 states for the most renewable energy resources. Lots of hydro, wind, and most of all, solar. But hey, were like number 49 when it comes to using them. It's kinda unnerving to be talking about renewable energy when my view of pikes peak becomes every more cloudier with smog. I see the big old coal fire spewing out smoke downtown. It takes two trainloads of coal a day to power Colorado Springs (150-200 cars). Pop. 400,000

Even more disgusting! I live in a neighborhood with "covenances". They won't let me put up a wind genny because it's unsightly. But worst of all, they absolutely refuse to let me put up any solar on my roof! ARRRGH!!!! Don't you think they have gone too far when you have to sneak up little panels at a time on your roof? And hide them from the neighbors. (and do it at night so noone sees you.)

It's sad really.

In my adventures in Holland, I gained a new respect for the rest of the world and their action to switch over to renewable resources. Makes us American's look selfish. I hope we gain a perspective of thinking outside the small borders of our country, and deal with issues that effect the world and not just us. Let's just hope we don't learn the hard way, and get caught with our pants down.

-Andrew

I agree that is absolutely discusting!!! And as far as what you do on your own property shouldn't be governed by what other's think! They would think quite differently when you were the only one with power and all others were sitting in the dark during an outage... you would find you have a bunch of new friends. Sometimes it takes a good shake to get people to see things differently ( or correctly).

Have Fun  
Ed

Re: Renewable energy ([none / 0](#)) (#3)

I wish it was that simple. They claim they can take "legal action" and force me to take down any "unsightly objects". Get this, I said if it was ok to put up a darrius or savinous turbine, but they claimed it would make "too much noise"! Yet they let the neighbor keep their noisy as hell rat dog out night barking until the sun comes up!  
Frankly if I controlled the covenances, I would encourage people to put up any renewable energy they could. It might lower the property values in the short term, but when the oil gets expensive, the solar powered neighborhood will look mighty lucrative.  
Sigh.

### Black Out 2003

Cought with my pants down. I live in north suburbs of Detroit. Black out of 2003 occured, no power, cell phone eventully died, beepers soon died, Detroit water supply stop pumping, after 20 hours no central office no dial tone on the phone. Were we ready? Did we have cash? No ATM machines, no gas stations pumping. Did we have a full tank? Was the generator full? Did we have gas cans full? Did we store water? Was any stores open? NO NO NO NO. Are you ready? I will keep more in touch with this web site. I have a goal to be ready the next time.

Simple things like your car is in a paking lot chained in and the electric gates will not open. Yes I now carry bolt cutters in my car. Yes I will always have a full tank. Yes I will always have cash on hand. I realized my generators vary between 90-130v ac under load conditions. Freezers and fridges run at about 80% under generators. The big hall way fan never spins up to full RPM. Lights and TV was fine, keep in mind to have a antenna for broadcast reception when the cable goes out. Many radio stations were off the air. Batteries in flash lights go fast after 48 hours of no power. A good collection of glow sticks should be at hand. It was a comfort feeling having HAM radio as a source of communication for 911 emergencies with no dial tone anywhere. This was a perfect test how we depend on power and how we were not prepared. I just had to wite this note, make your power so you have power.

we all got caught with our pants down!! WE run a small variety store/gas station and gave away a morning-delivered order of \$600 worth of icecream novelties that night..

it helped stave off a near panic buying spree...we closed the doors, when it became too dangerous to navigate the aisles in the store in the dark...

Oh yeah, us too. We like to have candles around for nice romantic movie-night-in dates when we can't find a sitter for the baby. It's a good thing, because we needed them that night!

One thing that did help us - I heard about a trick to make your deep freezer run a little more efficiently - fill bags with water and freeze them in the deep freeze when you don't have much in it. When they freeze, they help to keep the temperature down in there. I had a few large zip lock bags full of water in there, so I took one out and put it in a plastic bowl in our fridge to help keep the temperature down in there too.

The power for us wasn't out too long (about 12 or 14 hours) compared to some, but I think the freezey bag thing helped. Just a thought.  
Regards, XEROID.

Xeroid;

Been doing that for years and it does seem to work.

In a pinch you can line a cardboard box with a plastic garbage bag or sheeting and fill it. I think it helps the fridge run less overall and definitely keep frozen longer should there be a power failure.

Too much wasted effort on the big things when the little things are what count.

Cheers.

TomW

Hey, good tip about the box, Tom. That way the frozen block will have a more definite shape. The bags I used were just zip locked shut with the water inside and took on random shape depending on what they leaned against in the freezer. A nice rectangular block would be easier to work with, geometrically speaking.  
Regards, XEROID.

About freezing blocks of ice to keep the fridge cold...We used to do that back in the 40's a guy we called the iceman delivered ice we put a card in the window that said 50 on one side and 100 on the other 20 cents for 100 pounds (sometimes you gave him a quarter and told him to keep the change and he thanked you for the tip! and not a trace of sarcasm! Whatever happened to Serval gas refrigerators? or solid state camper 12volt reffridgerators? Norm.

The message that is shockingly clear, in yours, is that we are captives to our technology, without which, the majority would be devastated. The general concensus is that it will always be there. The reality of a blackout says: What If?, the consequences horrific. Those of us who are prepared know, it had better be anonymous.

Sorry about the gloom people, it was just a thought running through my..

Hi,

Yep that black out for the northeast was a royal pain. Try living in the mid south(Arkansas Ozarks). Every winter we have ice storms. Not only does the power go away but the roads are almost, if not, impassable even with chains.

My wife and I have lived over 3 years off-grid, and every winter we are the only lights visable for miles. We had a game warden come down our prvate road 'cause he thought "something" was up. After an hour of education he left, saying he was going to have to set up his home for just this sortta thing.

More power lines, more generation stations, more more more. We Americans never seem to learn. SAD aint it?

Well i know out here in hawaii alot of people bought stuff in case of powerfailures also.. one of the big things were those shake flashlights that sharper immage sells... you shake it and it runs for 20-30 min and then every now and then you shake it for 30 or so more seconds to keep it going.. nice alternative energy solution for a flashlight... no more worrying about are there fresh batteries in the car's flashlight...

Woa!

Man, I was on a ship headed for Boston when this happened. I had no idea, on the ship there was only a dinky sattelite tv that didn't work half the time. When we docked in Boston, everybody was pissed/worried, but I was ignorant as usual. When I flew to denver to pick up my car (oh yea, the president of the US was in the same hotel I was parked at, and the jerk towed it! apparently there wasn't enuff room for his 5 limos.)

Drove home to find more pissed/worried people, and just learned about the blackouts from a previous post here on this board. Maybe I was caught with my pants down, but I was too ignorant to realize.

I saw a Nuclear plant near the detroit area when flying home, did that kick the bucket too?

-Andrew

Wonder if my 50 watt solar, and 100ah battery will save my ass next time?

nuclear plants are well... designed to run at 80+ % load... when load drops to less than 10% they are really hard to keep running ... also when the load goes away 80% to zero... well the plant has safety equipment that will probably shut it down...

course the Nuclear plant needs some power (to run its pumps and such) to start it up.. so once it dropped off line it could easily take hrs just to safely restart it

There Is Water in the Air

---

Some weeks ago 'Rexresearch' has published a new version of their article 'Air Wells, Dew Ponds & Fog Fences'.

There is really a lot of water above us, even there, where under our feet the desert is dry.

Anybody has seen any of these systems in use?

<http://www.rexresearch.com/airwells/airwells.htm>

A Stirling will run off of cold air just like it will off of warm air.

Hook up my kinfolk's friction heater (one cylinder inside another with about an 1/8 inch space in between them, having oil or water in that space, so the one cylinder will slide real easy and you have something float on a little.

One cylinder turns and the other is stationary.)

Then have the wheel of the 3 foot Stirling just barley rubbing the cylinder so it can turn even if the cylinder doesn't.

The cylinder will start to turn soon enough, give it a push. When it does start to turn it will pick up speed and the slip sliding oil friction party between the two cylinders will get hot. Real hot, enough to heat your house.

Here's the groovy part, what we call "The Stirling Stroll" up here in Washington State just north of the state of confusion.

It will get hot enough to run other Stirlings from their hot end, like plugging a male plug into a female to transfer the energy down the line, it's a great way to stay warm in the winter time.

Here's where you really get your groove on, most of you don't have a 3 foot Stirling laying around, if you do it's up there on your Chimney paying for itself. Not to worry.

You don't need a stirling kids, patch that hole in the wall and just run it with a teeny weenie continuous duty PM electric motor small as a tea cup.

You can use old Restaurant supply soup pots for your first heater project, you'll probably need to find two different brands, because the same maker doesn't often make two pots with such slight size differences but if I know my kids, you'll find a way.

Little Johnny got some death threats and it had me on edge a little, this kind of fear and worry made me treat a good friend bad, cussing him out and telling him to go away. I'm ashamed of myself and now I'm mad.

And no one should be punished for their opinion even if that opinion is in agreement with someone out of favor with someone in power. Now that person can't even sign their name when they leave a Q or A, on some board because it get's removed right away.

That's going to stop, or someone will feel the full force of my wrath. Or maybe just a thousand long haired leaping leprechauns in custom tie dye hemp shoes all taking a sudden interest in Alternative Energy and everyone of them fans of your favorite foggy mountain dispatch, Johnny Cool Pants.

So that other board better take an example from the good nature of the one and only original otherpower dot com board, huh kids? Or they'll have an infestation of the little green drunken fellers caliming the place needs an original hero and Johnny Cool Pants will start giving away all the secrets of the universe,

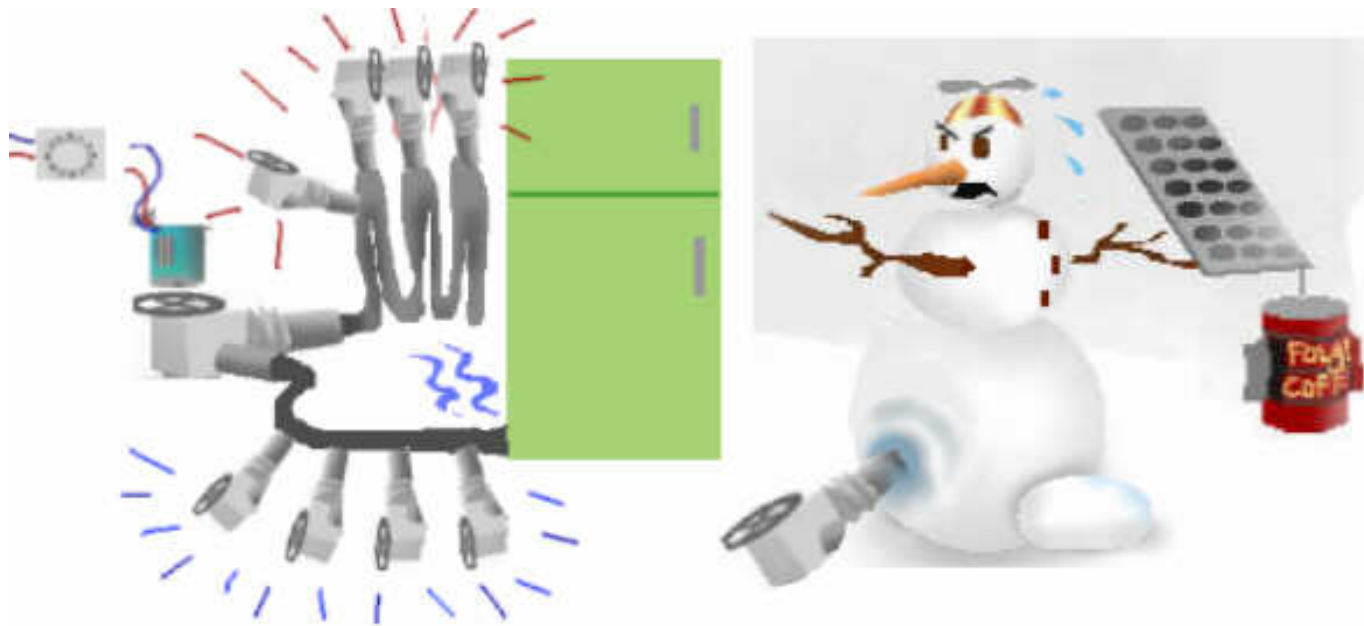

like this,

A sterling can be run backwards if you just find something to turn the wheel. The piston inside will run and the heat chamber become hot, hotter than a Brittany Spears wanna-be convinced you're the lead roady for the Back Street Boys. And the cool air chamber becoming cool, very cool, like Johnny's pants.

You can run your heater and your refrigerator from one Stirling hooked up to an electric PM motor, and a timer so it can take breaks through out the day and so it can take the whole night off and stay up watching re-runs of Dr. Who with you.

They use all sizes of Stirlings on the submarines, running off the heat of other engines, to running off the cooler sea temperature.

Then whacha do is plug in some Stirlings to those lines feeding the heater and the fridge and get some of that power back. Where ever you can find hot or cold.

Who loves you kids?

Bill you there?

I'm seriously interested in the jungle, especially botanical medicine.

As you know all or almost all medicine comes from plants anyway. They just grind it up, put it in a capsul and bill you with a brick enema.

I know it's off topic but if anyone finds interest in this, here is a site listing many plant medicine sites and links.

<http://www.puk.ac.za/library/subjects/pharm/alternative.html>

And this is a site listing what some of your basic kitchen spices can do for your health.

Bill where are you?

Did a Python get you?

Anyway I was thinking about all the heat in the jungle. Has to be a way to tap into that. I mean with the tree canopy blocking the sun "light" and hindering windmills.

There is a breeze in the top of the trees. Someone posted a comment about a man who charged his batteries during the depression by running an insulated wire up a tree.

The effect might be even stronger in the jungle keeping one end warm and the other end cooler (maybe down a well)

Got squirrels there Bill? Some kind of jungle squirrel? Monkeys? Well we have squirrels all over the Northwest here and I'm cutting off the limbs that allow them to cross to the next tree, (tree limbs, not squirrel limbs) and installing fatty roap bridges from some old discarded marine line.

I'm going to connect them with really springy springs and then suspend more springy springs hanging down to lines leading to hanging magnets inside tube coils (the way the "forever flashlight" works) the magnet just slides back and forth through the coil when you shake it.

Photo source: <http://www.thinkgeek.com/gadgets/lights/5a9f/zoom/>

I know it will not be a lot of voltage but it will be consistant all day long, those squirrels are busy little guys and the magnets will be bobbing up and down through the coils (about 20 of them) Then the voltage starts adding up.

Likewise a few anchored floaters upstream from my pond waterfall will jiggle a magnet in a coil all day long Jungle Java,  
No Troy I didn't make the freakin current or the squirrels! Sucessfully put one back together though, when I decided it was best to go with cutting the tree limbs.

\$#!+ Bill, I wanna live  
in the jungle too! Get me  
out of here. I'll increase  
your coffee production by 25%  
and limit my coffee consumption  
to 50% if you introduce me to a  
girl who looks like the actress  
in the movie "Salvador"

**i have been researching and planning**

for the last several years my trek to the simpler life. i have the lights figured out with compact florecent (sp) and i have the washer and dryer figured out, but i am down to re Fridgeration. because of the winter temps in kansas having some periods of time in the winter where freezing water is no problem, i figure to build an ice house that is connected to the kitchen by means of a refrigerator door and the inner shell for the shelving. and by putting up several thousand pounds of ice in a very well insulated ice house i figure i should be able to get my basic re Fridgeration needs met... assuming of course that the ice house will not be cold enough for frozen storage then a small efficient chest type freezer could be used to store frozed goods and make ice cubes for consumption. anyone doing anything like this? i figure an 8 by 8 styrofoam lined room can hold up to 40 or 50 thousand pounds of ice if stacked to the ceiling. what do you guys think? i figure if our fore fathers did it that way then it is good enough for me. bob g

Bob;

Welcome back, again.

Over the years I have used quite a few propane refrigerators. And as I fondly recall, several of these units had a tendency to freeze the contents if you were not careful with the settings. They accomplish this with little more than a "pilot light"

My point, you wonder?

My point is that Kansas, like Iowa, has a lot of heat available most of the summer. Summer is when you need cooling.

I'm no refrigeration tech but it sure seems like an absorbtion cooler could be rigged to work with some form of solar collector to run at "max" to freeze water or even cool a room if sized properly. Around here the Amish still harvest ice and while visiting ordering furniture in late July on a 100 degree day have had lemonade with ice in it. Considering the Amish here do not use electricity or propane I'm fairly certain it comes from the icehouse. It is amazing how long a few tons of ice will last even buried in straw so your super insulated opened to a frige icehouse idea seems sound.

Cheers.

TomW

Old Fashioned Refrigeration... ([none / 0](#)) (#2)  
by xeroid ([centurion27@lycos.com](mailto:centurion27@lycos.com)) on Wed Apr 16th,  
2003 at 09:21:10 AM MST  
([User Info](#))

I know absolutely nothing about refrigeration, but I just wanted to commend you on your lifestyle choice. If the industrialized world would adopt some of the philosophies and thinking of people like you and others on this board, pollution and energy crisis problems would soon cease to exist.

Bravo!

Regards, XEROID.

commended ?? who me? nah.... ([none / 0](#)) (#3)  
by bob g on Wed Apr 16th, 2003 at 10:36:44 PM  
MST  
([User Info](#))

not sure commendations are in order here at least where i am concerned. Don't get me wrong i don't plan on burning old tires in a fireplace for heat, but i am not planning this as saving mother nature from me, but rather learning to live with what mother nature provides. As i have stated as well as countless others it is far easier to conserve power, than it is to produce it. So i figure if i can trim my basic need for shelter, namely in square feet, and make it as thermally efficienct as i can, then my goal of using nature to provide for me is more attainable. Should i decide to build a multi thousand square foot lodge, i will either have to put up a few dozen wind generators ,, hundreds of solar cells, and burn a forest of trees every year just to survive. i dont see this as surviving but useing up nature and my back just to get by.... i figure keep it small,, tread lightly,, and maybe nature will provide my basic needs.. and if in the end result i get what i need, and dont kill my ecosystem, then i have not only succeeded but done a good thing. Perhaps others will either follow by example or at least take pause to think.. not a bad side effect in my estimation. i guess it is hard to read Thoreau's "Walden" and not do some serious rethinking of ones life, and followed by "five acres to independance" i end up with a big... "  
hmmmmmmmmmm, i wonder, could I? just maybe!!! bob gayle

Air Conditioning ([none / 0](#)) (#4)

by Dan M on Mon Apr 21st, 2003 at 02:45:49 PM MST  
([User Info](#))

As far as refrigeration (or air-conditioning) goes, I think there's a big difference between keeping ice frozen and using it for cooling. Here are a couple of numbers that could help: Melting one lb of ice requires about 150KJ of energy (or takes 150KJ of energy from its surroundings). Doing this every hour gives about 42 watts of cooling. 42 watts for an hour equals about 140 BTU/hour. Therefore, a 10,000 BTU air conditioner (when air conditioners are rated in BTU they mean BTU/hour) could be duplicated using ice but it would take about 71 lbs of ice per hour, or somewhere around 1/2 ton per day. These numbers are only based on the heat of fusion for water. You would get another 25% or so depending how close you got the water to room temperature before discarding it. As an alternative, bury as much flexible tubing as you can find as deep as you can get it (at least several feet) and recirculate water through it. If you have a coil of this in the house and blow a fan through it you have air conditioning. This doesn't help much with refrigeration though. Also, your 8x8x8 room hold just over 30,000 lbs of water (slightly less ice).

ice storage #'s ([none / 0](#)) (#5)

by bob g on Mon Apr 21st, 2003 at 11:42:22 PM MST  
([User Info](#))

thanks for the input, it was never my intention to get room air conditioning from the ice house, as for my est of how much the room would hold it was from memory of numbers i crunched 4 or 5 years ago, and i cant remember just how large a room i did the math on. could have been a 10 by 10 who knows. the idea here is for reffridgeration only, and for only myself and possibly one other, according to other sources 12,000 lbs a year for a family with a milk cow was the average 60 or so years ago. The point being that i think that it is worth the effort to get my refrigeration from an ice house if possible. as for air conditioning, i think i will stay with a room air unit, and use it in a smaller well insulated area, and try to limit its use. bob gayle

Underground dwelling ([none / 0](#)) (#6)

by Wolfles ([wolfles-@-netzero.net](#)) on Tue Apr 22nd, 2003 at 01:43:39 AM MST  
([User Info](#))

Bob, Have you thought of a berm or undergroud home?? I have studied it and the earts temp staysnear or at 62 deg. F My Aunt had a storm shelter for tornadoes and she kept her canning goods cool during the Texas heat. When I was a kid, I would go and cool off when playing and swip a jar of pickled peaches. It wasn't much more than a dug-out with railroad ties for the roof and four foot of earth on top of the ties. It wasn't much to look at, but it was cool and a safe place to be in a storm. MyWattsWorth

Re: re Fridgeration ideas... what do you ([none / 0](#)) (#7)

by cryonucleator on Fri Jun 27th, 2003 at 05:54:32 AM MST

([User Info](#)) <http://www.makehydrogen.com>

Bob g, can't add much to what everybody['s said, but I recall that about 20 years ago a guy got a big international cash award for his design of a huge underground ice block that he formed over the winter and used for cooling in summer. Kind of similar to ideas already mentioned.

For \*small\* and \*well insulated\* freezer unit, how about a large reservoir of extremely cold non-freezing liquid?? The res would have to be well insulated too, of course. Heat exchange (heat sink) array would need a sensor-valve-switch to shut off flow when winter temps rise above your desired max, say at -10 F. Then open again when temps drops to -10 F or lower. Sounds like a couple of the other writers here could calculate the res:freezer volume ratio. Might turn out to be kinda expensive, in terms of antifreeze medium. Luck to you! ---Dennis

One of the cool ways, I started looking into, is packet radio. Doubtless the ham radio ops already know about this. Basically, you plug your ham radio into your computer, and the computer uses the radio to broadcast data through the antenna. Bandwidth is pretty low atm, >9,600bps I think, and the first version needed someone to physically rebroadcast the data to the next RRB (radio re-broadcast) site. I think the max range was around 120 miles. The newest version of this (forget what it's called) sets each ham site up as an automatic RRB so that data is passed unattended. Both of these methods use some custom adapter cards that you can buy off the net as well as some driver software. The newest version I heard about uses nothing more than a computer sound card that is directly plugged into the mic socket and the PC sends the sound signal straight to the ham radio. I think specific software is required for that setup. Please correct anything that is out to lunch :) No with that in mind, once you have no requirement for a hard/land-line network, the sky is the limit just so long as there are ham RRBs close enough to you and they are set up for packet radio too. There is ample software for live voice communication over the internet and as the packet radio technology matures, no doubt the bandwidth and/or data compression will greatly improve too. Just do a web search for "packet radio".

Now that I'm learning about electricity and using OHMS law, I might look into Ham Radio. I got a radio, but I can't use it until I get some kind of licence. 30 years ago my Dad got a letter that said we're coming to get your rig! and its been hiddin under my bed ever since. I asked why they were mad and I guess 5kw is too much without a licence. He's gone now, but my room is exactly how I left it 20 years ago when I left to get married. Nobody thought I'd be gone that long, and them big ole boxes of tubes are still there.

There's a ham shack setup where I work, I'll check it out. I have put up antennas but the com expert just needed a coconut tree climber.

Some ideas ([none / 0](#)) (#2)  
by Adrian L on Tue Apr 1st, 2003 at 07:55:07 PM MST  
([User Info](#))

Yeah good question RonD,

I have thought about this question a lot, at this stage there isn't really a way to beat a standard phone line as yet. Maybe once mobiles start offering high speed internet access at affordable rates(and cheaper calls for that matter) their would be no need to have a 'on grid' telephone line for most places and that would lower your charges by not needing to pay the 'network' charge monthly.

But it's a user pays world, their should be an ammendment made to that quote 'death and taxes'... to 'death taxes and monthly payments of some kind to telecommunications companies'

It's getting harder and harder to live a cheap uncomplicated life thats for sure. I can only see it getting worse in the next 30 years as well. I think the people in their 40s-50s now are the lucky ones, back then you could live a simpler life. I'm in my twenties and i can tell you Stress and high paced living these days is already taking it's toll and most likely will be the death of me. Give me a solar/wind powered farm anyday over the 'burbs'.

Cheers,

Adrian L

Its funny how things changed ([none / 0](#)) ([#10](#))

by RonD on Mon Apr 7th, 2003 at 10:38:23 AM MST

([User Info](#))

Used to be phones were hard wired and tv's were wireless.

The Site I'm building at isn't exactly remote.

There is a utility pole, with telephone, cable and grid power right in the front yard (garden).

I hit it with the tractor everytime I mow. :)

I think its around \$26. for the phone.  
\$35 for cable \$60.00 includes high speed Internet.

So I guess its only \$86.00 a month. and about \$9 to have grid power backup.

Internet connections? ([none / 0](#)) (#5)  
by hvirtane on Sat Apr 5th, 2003 at 06:21:18 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Here, where I'm living  
(in Central Finland, near Jyväskylä)  
by far the cheapest Internet access  
is with a gprs mobile phone connection!  
There is one operator, dna, which is charging  
only 20 euro (the same in \$) for a month.  
The phone can be on all the time for that price.  
The connection is not fast, but it works.

What are your possibilities for Internet connections?

For ham radios Debian GNU/linux operating system  
is told to be very good and it is free!  
(I'm using Debian, but a gprs connection.)

Where is your place, actually?

Hi Norm,

I spent "some" time in the past couple of months fiddling around with hot wire cutters and now I've got a good reliable unit that really works well.

I started with plans from the net that used a Rad Shack xformer and a regular light dimmer which lasted about 1 hour, then the transformer smoked.

So I got another heavier transformer, and kept on truckin' but went through about 6 fuses.

My final configuration that really works well is as follows:

Hammond PH100JG transformer - 100 VA, 120 volt primary, 24 volt secondary (about \$35 from a local electronic supply place)

I use a Leviton fan speed control on the 120 volt side of the transformer. This looks just like a light dimmer but seems to hold up for this use. (less than \$10 Home Depot)

Then on the hot wire side of the transformer, I use 2 of those old ceramic ballast resistors they used to use in a lot of Chrysler cars in series with the wire.

For the wire I use 20 guage stainless wire which is available at Home Depot in 20 foot rolls for about \$3

I turn the unit on and set the fan speed controller to its lowest setting. Then slowly increase the setting until the wire is warm enough to melt the foam. I found a lot better results by just heating the wire barely enough to melt the foam. If the wire gets red-hot it will lose its tension and sag a lot in the middle.

The bow I made up out of 3 / 4 " copper pipe with a pair of 90 degree elbows. I use a couple of pieces of wood dowel in the ends of the pipe legs to insulate the wire from the bow. And a couple of small turnbuckles attached to the dowels to hold and tension the wire.

I found nicer cuts when the temperature of the wire is just hot enough to cut the foam, with a lot of tension on the wire. This way if the bow jerks a bit during the cut, it won't leave bumps in the cut.

If you need some pics of this setup let me know and I'll come back and post them!

Having fun!

Ted.

([User Info](#))

Hi All,

I built one of these years ago from plans in a modle air plain mag. It consisted of a power cord going into a triplet gang box wired to standard house lite switch (to act as a main), then wired to a dimmer switch then wired to a standard house outlet. Now install a cover plate.

The bow was made from 1/2" steel electrical conduit, with two 90 degree bends (using a conduit bender from the hardware store/rental center where I bought the conduit, sence I made the bends at the store they did'nt charge me for the use of the bender.) Then I went home and cut the ends off so the bow was 6" deep. Then drill a hole in each end (facing each other) about 1/8" from the end. In each of these holes I placed a spring, then insulators made from high density nylon, then I attached .035 stainless welding wire to the insulators, making sure the springs where each stretched out 3/4" or so. The electrical conections were made by each insulater with crimp conectors. I ran the one wire up through the conduit to the other side to make it neater and easier to handle.

The plans called for the use of a 10 amp battery charger, plugged into the above control box and hooked up to the bow. The dimmmer is used to vary the output of the battery charger. As mentioned in earlier posts you dont want the wire red hot but you do want it hot enough to melt the foam away from the wire or it will leave a stringy resedue, and if too cold the foam will glue itself back to gether after the wire passes through.

This worked for me on a 2' bow but NOT on my 5'er even with a 40 amp chager set to 200 amp boost. So I tried plugging the bow directly in to the control box... IT WORKED. The only problem I ran into was that I used the cheaper 600 watt dimmer switch and burnt it out after 40 or 50 hours of use while cutting recycled foam to insulate a friends 30 x 40 pole shed. The switch was replaced with the more expensive 1000 or 1100 watt dimmer switch, and is still working fine with more hours on it than the first one.

Good luck and play

SAFE,

Gordy

([User Info](#))

PS.

forgot to mention, once you get the dimmer switch set for the proper heat on your wire. Use a permanent marker to mark the switch's knob setting , and check it each time before you turn the main on. Got this idea after someone bumped mine and melted the cuttig wire when the main was turned on.

Gordy

[looking for non-electirc fan for wood stove](#)

I am looking for non-electirc fan for wood stove. I have a remote home with no electricity and want to put a thermocouple powered fan on the wood stove to improve heating. Alternate ideas are welcome.

Once again, google is your friend ;-)

Stirling fans have been in use for many years, and are still manufactured today.

Take a look at this one:

Google search for calframo fan they are a bit more sophisticated than a thermocouple and use a peltier device to run it. Ours has been spinning on our stove for 3 years or more.

Cheers.

TomW

The design at the bottom of the page will work nicely as a small fan motor. Just reverse the batteries periodically.

hello Robc. i don't have any sites for you to visit, but maybe this will help. my brother bought a portable band saw mill about 15 yrs ago. called a "wood miser" i think. made in ontario, canada. he has never had a problem and has cut an awful lot of lumber for himself and others. try finding on google or another search engine. you may see pics that will explain a lot for you.

good luck----zubbly

[Amp Hour Meter for Wind Generator?](#) | 1 comment (1 topical, 0 editorial)

Re: Amp Hour Meter for Wind Generator? ([none / 0](#))  
([#1](#))  
by [hydrosun](#) on Fri Nov 28th, 2003 at 06:44:20 PM MST  
([User Info](#))

You can use the 48 volt adapter to use a standard Triametric Meter. Of course an amp hour meter doesn't have to be powered by the circuit it's monitoring. I've got an old model amp-meter running off 12 volts monitoring the running total of my 24 volt Air 403.  
Chris

## [Magnets for Lithuanian Schoolkids](#)

By [kell](#), Section [Magnets & Magnetism](#)

Posted on Tue Nov 25th, 2003 at 08:14:59 PM MST

[Wanted](#)

Lithuanian school wind power project

I sent some neos to the Lithuanian teacher that asked for help on this board recently. To do their project they may need different magnets from the ones I sent them. They might need magnets that are flat. So I'm reminding the people on the board that saw that posting from the Lithuanian teacher, and letting those who didn't see it know that those kids may be needing magnets. If we can take up a collection we could have a supplier send the magnets directly instead of having several people all paying \$20 each just for the shipping costs for a few magnets to go overseas. To do it this way I would first e-mail the teacher and ask what magnets he needs. I would be happy to act as coordinator/treasurer in that case. Any ideas? Maybe the admin here will have something to say too.

It sounds like they have quite a neat project there and it's great that folks have offered to chip in!  
We like to donate to this sort of thing, and it's really not necessary for you all to chip in like this, though the offer is very kind. It's actually the support of customers and folks who participate on this board which help to make the magnet side of our business work out well enough so that we can help out in situations like this.

We've sent him enough magnets to build a good machine I think. On the way to Lithuania are 24 of the 1" X 2" X 1/2" blocks + a set of Hughs plans. Hopefully we'll all get to hear a bit about the project! Im not sure if they'll build Hughs machine or experiment, but the plans should help out a bunch either way.

Maybe somebody have unnecessary Neos and could make donation for pupil's club?

Dear Sirs, it's my the first posting and maybe i'll be funny. I am social tutor of pupil's technical creation club "Vejavaikiai" (Wind's kids) from small Lithuania town Naujoji Akmene. My pupils are interested in homebrewed electricity too. We have made some wind mills using car AC alternators. Now we are going to make a new alternator using Permanent magnets.

Maybe someone has unnecessary Neos and you could make a donation for our club? It would be a great X-mas present for my pupils and they would be thankful very much for your help. Any proposal we are looking forward to hear from you.

Thank you in advance.

Virgis

([User Info](#))

I have some neodymium magnets left over from a project. They are not flat; the poles are located on curved surfaces. I think I have three of each polarity (north in south out, and south in north out). Most people use flat magnets, but I will send these magnets to you if you e-mail me. My e-mail address is [kellrobinson@yahoo.com](mailto:kellrobinson@yahoo.com)  
Good luck and best wishes for the kids.

## [Radiant light from gas flame for solar power?](#)

By [hiho1](#), Section [Weird Science](#)

[Wanted](#)

Posted on Fri Nov 14th, 2003 at 08:06:42 AM MST

Ahh, Question.

Can someone please tell me if the light from a natural gas flame can be used as power source for a small solar cell? And if not, is there something that can capture the non-direct radiant heat from a natural gas flame to generate a small source of energy? Anyone? Bueller?

Actually, you might e better served to get a peltier junction and place it closer to the flame (not in the flame) with a heat sink on the other side.

DS

There is a device called the Midnight Sun sold by Alternative Energy Engineering that runs on propane and produces electricity. It was developed by Western Washington University and JX Cristals. It has a central white hot flame surrounded by special photovoltaic cells that work on the infrared frequency. I don't have the specs in front of me, but I think it put out 120 watts. the idea was it would work as a room heater and create electricity at the same time. Not as much electricity as a fuel cell but still a quiet nonmechanical way to convert some of the energy into electricity. The price I remember seeing was \$2300. Though high, it does replace a propane heater and a generator, so might be worthwhile in some situations.

I don't know what a regular solar panel would do , but I know it's voltage goes down with higher temps, so probably not much.

[suggestions on resin choices...](#)

Well, I've tried this hobby store resin for my machine... the cool thing is its clear, ya know the same resin thats used in those paper weights that have coins floatin in em.

The problem is its brittle, and can crack easily. Just curious as to the other types of resins that are available.

Was hoping for the clear see through look, but much stronger.

Any suggestions, and possible places to find such and item?

Ivan.

Two sources. There are many plastics, resins, mold making supplies, etc. at [www.smoothon.com](#). There may be something at that web site which can be of use to you. Also try [www.fiberglasssupply.com](#). Is it possible you could reinforce the plastic part (I assume you're making a prop) with carbon-fiber rods?

Re: suggestions on resin choices... ([none / 0](#)) (#2)  
by [monte350c](#) on Thu Oct 23rd, 2003 at 08:50:07 AM MST  
([User Info](#))

Hi!

In my early wind machine experience I've used 2 types of resin so far.

The first is plain old fiberglass (styrene-based) resin. It's:

1. The type you add a few drops of hardener to a lot of resin.
2. Very stinky!
3. Dries semi-clear with a greenish or purplish hue.
4. Seems quite good for casting stators.
5. Is quite cheap.
6. It's fairly brittle when it dries.

The second type is epoxy resin. It's:

1. The mix is 5 parts resin to one part hardener.

- [More on Wanted](#)
- [Also by headhunter](#)

2. There's hardly any smell at all.
3. Dries clear.
4. Works well with styrofoam, ie. doesn't melt it.
5. Is more expensive (one quart of resin & hardener = about \$45)
6. It's got a small amount of give to it when dry.

I have found the epoxy based stuff from West Systems (<http://www.westsystem.com>) is nice to use. They supply a set of pumps with their product for about \$10. The resin pump is 5x the delivery per stroke as the hardener pump, so you can very easily make just the amount of epoxy as you go along in the job. 1 pump of resin, then 1 pump of resin. It does take longer to set up than the styrene based stuff, my wing profiles took about 8 hours to fully harden up.

I found the styrene based stuff at a local auto parts supplier, and the epoxy I got came from a local marine/boating supply shop. The epoxy won't stick to polyethylene plastic, so you can use 4 or 6 mil plastic film to line a mold. It just pops off when hard. Leaves a nice shiny surface too.

As a final note you can predict whether or not something will stick to epoxy or styrene resin by testing it with a bit of acetone. Generally if the acetone doesn't melt the thing you're testing, then the resin won't stick to it either.

Good luck and have fun! (styrene resin especially - outdoors or wear a mask!)

Ted.

([User Info](#)) <http://www.internetfred.com>

I use general boat or car repair resins. Any car parts and general stores have them. stuff is cheap, available everywhere. Can not see through it, but it's strong, does smell, mask is highly suggested. Fibers are suggested for strenght.

## [obtaining magnets for generator](#)

By [kell](#), Section [Magnets & Magnetism](#)

Posted on Mon Oct 13th, 2003 at 10:26:38 AM MST

[Wanted](#)

magnet shipper will not pick for polarity

I have a plan to convert an old generator (from a motorcycle) from field coils to use with permanent magnets. The motivation: enabling the bike, an old kick start, to start up and run without a battery. I was lucky enough to find neodymium magnets that are just the right size and curvature to fit inside the generator case, which is cylindrical, in place of the field coils. Unfortunately the supplier, All Electronics in L.A., California, refuses to sort magnets for polarity. Basically, it's "We ship and you take what you get." So I ordered extra magnets hoping I would get some with opposing polarity, but they were all the same. The supplier's web site is [allelectronics.com](#) and the catalog number for the neodymium magnets is [MAG-23](#).

Does anybody here have any suggestions? The magnets I got from them have the north pole on the outside (convex) face and the south pole points in toward the center of curvature. I only need one magnet with the polarity the other way around and I can build my project.

I have gone on motorcycle and car discussion boards looking to see if they have members in L.A. that would go to one of the All Electronics retail stores (with a pocket compass) to find a magnet for me, but got nowhere. So maybe I would fare better by finding another outlet that carries the same magnet -- seems like the manufacturer would sell them to more than one place. Anyway, I am looking for substantive help, and suggestions are welcome, but I don't want to get into a debate about the feasibility or merits of this project, or any technical issues -- I went through that already in the other bbs.

Another source, depending on your diameter needed, would be a starter motor from a lawnmower, or snowblower ect, or Ive even found them in small agricultural 12. spray pumps from agway or northern hyd. Might be a chalange to find right size. If the id was ok you could always shim the od to make work. Thinner magnets might reduce current, but it sounds like you only need to power a few lights.

Good luck!

I have a suggestion/

use <http://www.wondermagnet.com>

Dan B is a magnet expert, you probably could get some very good advice from him, especilly pertaining to the type used for these dual rotor design. Actually if you look at the top of the page "here" you will see a link to "our products" and thats a good way to get there.

as far allelectronics goes they specialize in used surplus stuff, this is not a source of "new" magnets and most likely what you get, will become out of stock, never to be available again.

The actual bonus to wondermagnet is you will get "free" tech support here, my hat goe's of to you Dan.

Re: obtaining magnets for generator ([none / 0](#)) (#3)  
by DanB on Mon Oct 13th, 2003 at 12:24:08 PM MST  
([User Info](#))

We used to have those very same magnets and could offer them in pairs but sold out last winter. Im not sure All Electronics has them both ways, and several other folks have told me that they were unable to get even numbers of magnets which are magnetized half and half.

We looked into having this size (or something very similar) manufactured, and due to the shape - they cost about three - four times what a similar sized bar magnet (flat) would cost. With that in mind, for most applications, I think perhaps it's wise to simply use a bar magnet which is thicker.

Re: obtaining magnets for generator ([none / 0](#)) ([#4](#))  
by JW on Mon Oct 13th, 2003 at 12:34:58 PM MST  
([User Info](#))

signweld,

I think you misundersood kell's posting. I believe he's trying to fix a magneto (for ignition spark) for his motorcycle engine or something like that. if Im correct the motorcycle engine has a kick start, and no battery or generating electrical system.

([User Info](#))

JW, I did understand Kells question as he wants to remove the field coils from a generator and replace them with pm's. He didnt state weather its use was for lights or ignition. either wayI I surmised that the generator was probabaly not of a automotive size, but more of the 2-3/4 to 3-1/4" dia size, for which I sugested the replacments, which are already in pairs. Maybe he will post size specs and wether or not he wants to make a 6 or 12v pm generator or a magneto.

Re: obtaining magnets for generator ([none / 0](#)) (#8)  
by kell on Mon Oct 13th, 2003 at 04:34:03 PM MST  
([User Info](#))

DanB:

I talked on the phone to a worker in their store on South Vermont Avenue in L.A. He put me on hold while he went to check the magnets, and came back and said they have them in pairs. They haven't discontinued them either -- they are still getting them from the manufacturer. So the magnets are there. With both polar orientations.

Since these magnets are still being made, maybe you should consider getting some more and selling them. I for one would sure appreciate it.

([User Info](#))

signweld,

My apoligize's , after I read the post more thourogly I agree with you, that could be the case. But the kick start thing thru me off, and in my my mind I automatically defaulted to magneto, for spark. And that remark he made at the bottom of the post about "I just need thses magnet's dont ask why" gave me a susspion that he was'nt trying to make a genny or alt.

sorry about that, I know from my reasearch that wondermagent has a very diverse selection of magnets 'not just the kind made for dual rotor genny's. As a mechanic, if i was looking for a weird magnet set, for repairing a magneto system ,that are commonly used on motercycle engines, that have no battery. or possibly try to installal magneto system, on a motercycle that used a coil and a battery. Thats where id look for them. especially if the motorcycle engine had no magneto system in the first place.

Again sorry about disagree'ing with you, I just wanted to bring the possibility to light. Besides if you have engine power, its a hell of alot easyier to just bolt on a small PM DC motor and use that as a genny, perhaps this is why kell said dont ask why.

-JW

Re: obtaining magnets for generator ([none / 0](#)) ([#10](#))  
by kell on Tue Oct 14th, 2003 at 10:15:42 AM MST  
([User Info](#))

It's not a mag, the bike has a conventional points-and-coil (Kettering) igintion system that requires a power source. By taking out the electromagnets ("field coils") in the stock generator and replacing them with permanent magnets I can get power at much lower revolutions. Maybe even enough that at kick the gen will power the ignition enough to put out a spark. No battery involved.

[ [Parent](#) ]

Re: obtaining magnets for generator ([none / 0](#)) ([#11](#))  
by JW on Tue Oct 14th, 2003 at 12:26:35 PM MST  
([User Info](#))

Kell,

Cool! what a great idea. see I knew there was a magneto involved some way, just kidding, LOL.

Sounds like a really "neato" project. I'm sure your endeavor will meet with success.

I heard this somewhere, but dont know personally, that you could change the value of the condenser to help the spark suffering from low voltage, at the expense of faster pitting of the points. Might be worth playing with if it starts hard. You might need a condenser / capacitor checker as I dont remember automotive condensers having a value printed on them. good luck.

[\(User Info\)](#) <http://www.windstuffnow.com/main>

The stirling beam engine is probably about the simplest to construct. I have plans for a "Tin Can" version of it on my site. If your looking for something that will actually make some power it will have to be fairly large depending on the amount of power your looking for. Still not a real efficient way to convert energy.

Some sites that sell plans or models...

[Question for a Genius! \(Can you answer?\)](#)

[Wanted](#)

Ok, Here are the tools.

Twenty 12 volt 4 watt light bulbs.  
One GM Alternator with Built in Governor.  
One Regular Old 12 volt car battery.  
One Water turbine.  
One pump. (pumps 3000 gallons per hour) And has 4.5 meters of head pressure.

Now with these tools would you have enough energy to run the 20 light bulbs?  
How much energy would you be producing? (Roughly)  
What would be the max rpm you would get?  
With the tools above what is the best setup?  
How long could you run the 20 lights off of a fully charged 12v car battery?

Anyone know the answers?

[Question for a Genius! \(Can you answer?\)](#) | 12 comments (12 topical, 0 editorial)

Re: Question for a Genius! (Can you answer?) ([none](#) / 0) ([#1](#))  
by Anonymous Hero on Wed Jul 2nd, 2003 at 11:10:32 PM MST

Ok I'll bite. Lets see ... If you lit up the lights to there optimum rating you'd be producing 80 watts ,, but..... That would depend on the flow in volume. Max rpm...depends on the flow and nozzle size. With the above listed tools , it would depend on the flow. The lights will run on a curve based upon the amp hours listed on the battery and the condition of that battery. If you want more help, you need to give us more info. Sorry.. Not a genius , but trying real hard, Jungle Bill

In general the power produced by a water turbine can be found by  $HP = \text{Flow}(\text{ft}^3/\text{sec}) \times \text{HEAD}(\text{ft}) / 8.8$ . So... Convert 3000 gal/hour to cubic feet per second... I calculate about .1  $\text{ft}^3/\text{sec}$ . Multiply by head about 14 ft. divide by 8.8 then multiply by eff factor of about .8 is about .13 hp. This can be converted to about 70-80 watts electricity. Now, you have twenty 4 watt bulbs = 80 watt usage. Seems like it could work, but the problem is that all the water pumped to 4.5 meters MUST be used to drive the turbine, which means that it must be channeled through a pipe or similar enclosure to build the head pressure, which means you don't have any water left for your decorative waterfall. Dick Agnew

Re: Question for a Genius! (Can you answer?) ([none](#) / [0](#)) ([#3](#))

([User Info](#))

You don't need a genius, you need a clairvoyant to know what items are in the "mystery system".

If you plan on running the turbine with water from the pump, you will need divine intervention to produce surplus power.

Re: Question for a Genius! (Can you answer?) ([none](#) / [0](#)) ([#4](#))  
by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Thu Jul 3rd, 2003 at 09:14:28 AM MST  
([User Info](#))

And -- remember that the inrush current when turning on the lightbulbs would be 3-4 times their running current, if they are incandescent. If they are fluorescent, it works the opposite way -- very low inrush current.

Cheers

ADMIN

([User Info](#))

Well, considering you would only need the lights in the evening when it gets dark. That may help a whole lot. :)  
The rest of the day, the battery is being charged.

flow rate is roughly 3000 gph or 10300 liters per hour.  
(times the head by the flow and times that by 10 will give you the rough power. = 133 watts

so with this flow and a small size turbine what kind of rpm could you get if it is turning the generator? How long could you run the 80 lightbulbs off the battery and alternator? And what kind of a setup would you use?  
Would you connect directly to the battery from the generator and connect the light directly to the battery?  
Would a gearing system to the generator be better?

Re: Question for a Genius! (Can you answer?)  
([none / 0](#)) ([#6](#))  
by Anonymous Hero on Thu Jul 3rd, 2003 at 05:53:46 PM MST

Sounds like my gazebo project, I want to get something back from my Koi pond waterfall which runs on a pump. But what do you need 80 lights for? Enchanted look, or a greenhouse? Anyway I wanted to skip the battery all together but I was told using a couple of batteries wouldn't be that much hassle or maintenance if you set it all up correctly. My advice is to just start making the system and see how much you get from it. learning by doing.

by wdyasq on Fri Jul 4th, 2003 at 06:46:09 AM MST

([User Info](#))

Insane,

You have given insufficient information.

To answer your "questions":

Now with these tools would you have enough energy to run the 20 light bulbs?

How much energy would you be producing? (Roughly)

What would be the max rpm you would get?

With the tools above what is the best setup?

How long could you run the 20 lights off of a fully charged 12v car battery?

And:

so with this flow and a small size turbine what kind of rpm could you get if it is turning the generator?

How long could you run the 80 lightbulbs off the battery and alternator?

And what kind of a setup would you use?

Would you connect directly to the battery from the generator and connect the light directly to the battery?

Would a gearing system to the generator be better?

\*\*\*\*\*

The answer of the energy to run the bulbs has been answered, by yourself and dagnew. There is an ~100% difference between your figures and dagnew's but, WTH.

The rest of the answer gets down to personal preference, knowledge and skills. If one has a constant

supply of energy, such as water gives, a battery is not always necessary. But, we don't know the style of water turbine you might select so none can venture to guess what speed it would run or, if you will need "gearing". Nor, do we have an indication of the condition of your car battery OR, what you need to pump.

I have been reading the archives on subjects of interest to me. The folks here are VERY free with their knowledge and information. I'm sure if you will do a LOT of "homework", you will be able to formulate a question these kind, knowledgeable and experienced folks can answer to your satisfaction.

Re: Question for a Genius! (Can you answer?) ([none / 0](#)) ([#11](#))  
by Insane on Fri Jul 4th, 2003 at 10:48:25 PM MST  
([User Info](#))

thanks for the comments, I realize there are variables missing. I just wanted to know for sure if it could be done and how to do it. (From what I found, it can be done.) Someone with a similar setup but with a 6000 gph flow is making 160 watts. So, In reality I should maybe be able to get 80 Watts. The turbine will be hand made. for such a small project. I am looking into the gm alternator, I may have to make one from scratch as well, but we will see. All a great learning experience. With this charging and no load during the main part of the day, will this hurt the battery?

Re: Question for a Genius! (Can you answer?) ([none / 0](#)) ([#12](#))  
by Anonymous Hero on Sat Jul 5th, 2003 at 03:26:26 PM MST

Dear Insane, Ok I see now,,, you are going to pump water to use the same water flowing down a pipe to create energy ,( not to pump the same water right, cause then you'll need to talk to experts like Dennis Lee, we on this board deal in the limitations of reality and math) . You are going to light up some cute lights and make a scientific water project? OK great. 3000 pgm pump up 4.5 meters. Very well thats 50 GPM X 10lbs X ~ 15 feet head = 7500 ft /lbs per min or about .22 HP or about 170 watts. 'Lets expect not more than 35 % efficiency = 60 watts available to you will home built turbine. I think it is always worth the time to build anything , so don;t let my 60 out of 80 bum you out, go for it. GM alternators will require a step up in speed. I would not use one , I would use a pma. Basically the sweet little homemade gennys

these propeller heads use on their wind machines. You can build exactly to your requirement. Also AC is really nice to play with if you genny is remote. You can easily modify voltage . Real nice. I farted around with car alternators enough, and the best one I came up with was a VW single wire , self exciting one and I used a DC/DC converter to bump up the voltage to 15 VDC. It ate about 10% in the process. Totally inefficient with Sears vaccum cleaner turbine, I was ABLE TO extract 25 % of the true nozzle torque. Bloody good fun though. AND ,, I had power in my barn for a friend who lived in there and only need a couple lights and a radio. The VW generator ran like silk for years. Jungle Bill

Degaussing... ([none / 0](#)) (#1)  
by xeroid ([centurion27@lycos.com](#)) on Wed May 7th, 2003 at 12:58:58 PM MST  
([User Info](#))

Have you tried a hammer?

(sorry, I just couldn't resist!)

I think there must be a way to to this with a coil of wire and a high voltage DC source...

Maybe one of the guru's on this board could elaborate...?  
Regards, XEROID.

Long ago.. ([none / 0](#)) (#2)  
by TomW on Wed May 7th, 2003 at 01:26:10 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

In a time when I did TV repairs we had degaussing coils to remove residual magnetism from picture tubes. These wre simply a large coil of fine wire you plugged into the wall and passed across the picture tube to neutralize residual magnetism.

I think demagnetizing permanent magnets would seem unlikely with "common materials" but its not an area i can claim to be knowledgeable in.

I will note that I think it would require a huge field of the opposite poplarity or alternating polarity to demagnetize anything of consequence. Bulk erasers exist for magnetic media but the difference between zeroing a video tapes magnetic data and zeroing a magnets field are orders of magnitude apart.

Cheers.

TomW

by Electric Ed on Wed May 7th, 2003 at 03:52:42 PM MST  
([User Info](#)) <http://www.electric-ed.com>

You will need a coil with Alternating Current. An old dual-voltage AC motor stator, connected for 230 v, (run winding only) and operated on 115 volts, is what we used to use for de-magnetizing tools. etc. I don't know if it would be strong enough for what you want to do or not. Ed

Currie..... ([none / 0](#)) (#4)

Currie Tempature ([none / 0](#)) (#6)  
by Anonymous Hero on Sat May 10th, 2003 at 12:17:03 AM MST

Once a magnet reaches it's Currie point it loses it's magnetic field. Cooling it down doesn't restore it.

Magnets are always losing their power as smaller magnetic domains are eaten by larger ones. Even super powerfull NIB magnets will demagnetize over a few hundred years. Less powerfull magnets leak flux much faster and can die in months. Entropy in action. :-)

[\(User Info\)](#) <http://windpower.jkcc.com>

Nice :) I've used a few different models of these mill/drills. Emphasis should be on the "drill" part as the pedestals are nowhere near robust enough for serious milling operations. It is very easy to over-stretch the capacity of these things and get some MAJOR chatter out of them. The best advice for these is to keep the exposed portion of the spindle as small as possible, and lower the head as far down the pedestal as possible. This helps a lot in reducing chatter. Also, using small, 4 flute cutters and using them to make multiple passes, instead of using bigger cutters and fewer passes takes the stress off the pedestal too.

Looks like you have a nice little carbide cutter on it too :) A mill/drill is an excellent little piece of kit for light work. Just be patient with it and it'll do a pretty good job for you. I'd like to get one for at home too. Either that, or a Shopsmith, as I've heard pretty good things about some of them too.

[Wanted](#)

Too busy. WAY too busy.

Too many buttons, options and clutter. Too bad you couldn't hit the main page and it shows you all the main forums listed vertically. Click on the forum you want (Wind, Hydro, Solar, etc) and you now have a list of message threads pertaining to the forum topic. Personally, I like expanded threaded displays so I can hit the newest one in the thread, but that's just me. The different message threads are arranged by the last message posted, this way, new messages to an old thread automatically bump it to the top of the thread list. A good example of this is at [bmistress.hyperboards.com](#) While I understand the board is new, it's one of the most cluttered forum apps I've seen. To me, even though the old board had great threads that get pushed out of sight too fast, it was clean, simple and you could get to the messages with little fuss. This has too many buttons an features, not all of which might be necessary. Additionally, there's no topicx for "TEST" or just a "RANT" so things like this get posted all over the place.

[waste water heat recovery](#)

By [marv](#), Section [Remote Living](#)  
Posted on Fri Dec 26th, 2003 at 05:07:24 PM MST [Water Heating](#)  
shower water system

This is a unit I built 3 years ago. It warms up the cold water going to the shower from the shower waste water.

Even if it heats the water a few degrees thats a little less comming from the hot water tank. It costs nothing to run, no maintenance and the savings add up year after year.

Thought you guys might want a look.

MARV.

I love stuff like this, If your warming up the cold water a little bit before it goes into the hot water heater you could be saving yourself a couple dollars a month, maybe a little more!

My only problem with systems like this is its hard for me to choose wich ones to use because you cant have them all. eventually you'll have a plumbing nightmare! :)

Here is a tube an shell heat exchanger I built for the  
exhaust of a 5 HP Briggs.  
The water inlet an outlet are ½ inch. Its all stainless steel.

Were I work we use waste heat from are air compressors  
to preheat water.  
They save \$ 10000 a year this way .

Oh by the way love that beast of a tower you built.

Old F

by Old F on Sat Dec 27th, 2003 at 12:07:59  
PM MST  
([User Info](#)) <http://www.oldf.homestead.com>

Marv

The compressors are 125 HP screw type and the oil is air cooled they run 24/7 . And they really crank out a lot of heat 140of to 160of air temp .

We had to install a 500 gal tank and a boost pump to raise the hot water pressure we had on the fourth floor of the building. Were we set it up it was only 20 feet from the compressors. And ties in to a 1500 gal steam heated water heater.

We placed a air to water heat exchanger over the hot air being exhausted by the compressor.

The water from the pumps bypass was plumed to the heat exchanger and back to the tank. We are only raising the water temp to about 90o F but this gave us one heck of a savings. It was only an after thought as we all ready planing to put in boost pump and tank in any way.

The best part for me was getting payed for something I like playing with : )

Now the Briggs tube and shell will be a test to see how much and how fast can I heat water with engin exhaust. Its one of many irons I have in the fire right now.

Right now I have been working on a tower design of my own.  
So much fun so little time : )

Old F

Re: waste water heat recovery ([none / 0](#)) (#6)  
by jt72 on Sun Dec 28th, 2003 at 01:46:55 PM MST  
([User Info](#))

Looks like a great idea. My problem is that my costs to replace the drywall I would have to tear out to get to my drainage would be far more than I would ever recover. This Spring I will be installing a "desuperheater" to my heat pump. The waste heat that is blown to the outside air at the compressor will be used to heat water that is recirculated to the hot water heater. As such, in North Carolina where we cool 9 months out of the year, my hot water costs during the Summer should be little or nothing.

Since the old tank hot water heaters are the biggest energy hog in the house, I expect to recover the cost of installing this thing in less than two years.

Jim

home brew water heater

This is my water heating system thats hooked to the wood stove. I flipped off the breaker on the electric water heater 4 weeks ago and this has supplied all our hot water needs since! (2 adults & 2 teens)

All the parts can be bought from a good plumbing supply shop exsept for the wood stove exchanger which I built.

The key to the system is the two fittings on the top & bottom of the water tank heat exchanger, they are 2"x 3/4"x 3/4" copper. There is a lip on the inside that has to be drilled threwh so the 3/4" copper pipe can go from the top right threw to the bottom.

I'm very happy with how it works. check it out!

MARV.

You need another circulator pump at the same location as  
the Drain Valve. This will help to store some extra hotwater  
heat in your waterheater. Otherwise your system is just  
working "On Demand".

Cool system though . . .

Woof The hot water circulates through the water  
tank on its own and the tank fills with hot water  
automaticly. We can have two-three showers in a row  
no problem. The water temp. in the tank stays at  
around 130'to 140'.

MARV.

by troy on Mon Dec 22nd, 2003 at 02:32:17  
PM MST  
([User Info](#))

Depending on where the heat exchanger sits in relationship to the water storage tank, you can get good thermosyphon action to keep the tank water hot.

The ideal location would be a high water storage tank and a low vertical heat exchanger, but even if they are side by side, there is often enough temperature stratification to make the thermosyphon work.

Best regards,

troy

MST  
([User Info](#))

Hi brock;

I made the exchanger from 3/16" stainless . It's basicly a box with baffles to direct the water. I'm running just water on the stove side. The water circulates all the time so it stays at 130\*-150\* not near boiling point.

You can buy heat exchangers that go right in the stove but this is what I did and it seems to work good.

Thanks for the intrest.  
MARV.

 Recycled engine heat as you drive

Hi,  
 Just wondering if anyone has tried putting an insulated tank (maybe about 100 gallons) in the back of their pickup truck and bypassing the radiator to allow the engine to heat the tank full of water. It could be valved to turn the radiator back on if the tank gets too hot. A friend & I were discussing the feasibility of salvaging this heat and using an internal tank heat exchanger to claim it back as domestic hot water. Maybe some type of quick connect system to the house water supply. I'm already doing a similar process with my woodstove boiler with heat exchanger. Thinking of the wasted heat an internal combustion engine wastes, this would have to be better than dumping the heat to the atmosphere without first using it. Just thought I'd throw this out to the forum for feedback.  
 Bretco

Re: Recycled engine heat as you drive ([none / 0](#)) (#1)  
 by [kell](#) on Tue Nov 25th, 2003 at 07:49:54 PM MST  
[\(User Info\)](#)

Sounds great in principle. The devil is often in the details. You may need baffles to keep the water from sloshing and destabilizing the vehicle. You'll be hauling hundreds of pounds of water (and using up more gasoline). You'll have to pump that water into the house somehow every time you get back from a car trip... and when you go somewhere and park overnight while the water cools off all the extra gas you burned will have gone to waste, along with the wear on your suspension. That, or you leave with an empty water tank and have to find somewhere to fill it up for the trip back... but once the water is warmed up the extra gas expended to haul the added weight of the hot water will have been wasted.  
 An appealing concept perhaps, but I have to say I can't think of a way to make it work in the real world.

Bretco

Here is something that I use with my wood boiler that could all so be used with engin exhaust.

For a heat exchanger for domestic hot water I used a old propane water heater with the burner that had gone bad removed.

I welded 3/4 inch fittings to the flu and pumped water from the stove thru it works like a charm.

Seeing how they are designed for high temp combustion gases in the first place they should be a good fit for engin exhaust.

And they can be had free for the hauling.

Old F

Re: Recycled engine heat as you drive ([none / 0](#)) ([#2](#))  
by zmoz on Tue Nov 25th, 2003 at 08:01:16 PM MST  
([User Info](#))

Also, it would probably take quite a drive to warm up all that water. Before that happens, your engine is going to be running much cooler than usual, which is NOT good for it in the least and causes even less gas mileage. (in addition to the extra weight you are carrying) Your engine is designed to run with ~200 degree water circulating in it, not cold water.

Re: Recycled engine heat as you drive ([none / 0](#)) (#3)  
by bretco on Wed Nov 26th, 2003 at 05:31:10 AM MST  
([User Info](#))

I was thinking of retaining the thermostat to maintain engine temp so it still runs normally and 100 gallons of water (800 lbs) would definitely drop the mileage somewhat, but with an engine that is probably already only 20% efficient, with the rest wasted heat, capturing that heat has to have potential benefit. I think I'll try an experiment with my F150 and an old oil tank in the back and see if there's possibly any value to this idea. I'll post results if anyone is interested.

Bretco

Re: Recycled engine heat as you drive ([none / 0](#)) (#4)  
by Adrian L on Wed Nov 26th, 2003 at 06:59:38 AM MST  
([User Info](#))

What would be better would be a heat exchanger around the motor coupled to some sort of steam turbine to run a generator, which charges a couple of deep cycle batteries in the back, batteries are heavy, but a couple of 30kg batteries wouldn't effect the milaeage much and store a good 2-4kw max.....

With all these hybrid cars around im surprised they haven't bothered to make a prototype that does this, we all know how much a car engine wastes energy in heat!

Adrian L

Re: Recycled engine heat as you drive ([none / 0](#)) (#6)  
by zmoz on Wed Nov 26th, 2003 at 03:01:01 PM MST  
([User Info](#))

Thermostat isn't really going to help you. As soon as it opens a flood of cold water will come through and make it cold again...then the thermostat will close again, heat up the water, open, get cold, close, ect. Sounds pretty bad for the engine to me....

[ [Parent](#) ]

Re: Recycled engine heat as you drive ([none / 0](#)) ([#9](#))  
by bretco on Wed Nov 26th, 2003 at 10:49:05 PM MST  
([User Info](#))

Hi Zmoz,  
But isn't that what really happens anyway when the thermostat opens, a flood of cold water (from the radiator, instead of the tank) constantly makes the thermostat cycle from closed to sort of open until equilibrium sort of lets the thermostat "modulate" the water to the engine core.  
I'm thinking that the engine won't really see the difference if I use a tank in conjunction with the radiator and the original engine thermostat.  
By the way, I'm still working on my PMG wind generator that I've been gathering info from the otherpower board for some time. I just need to move myself where the zoning rules for my town don't go so far as to look in your underwear drawer to see if you can put up a winmdill! :)  
Bretco

[ [Parent](#) ]

Re: Recycled engine heat as you drive ([none / 0](#)) ([#11](#))  
by zmoz on Wed Nov 26th, 2003 at 11:52:03 PM MST  
([User Info](#))

The problem is the small amount of coolant in your engine heats up in just a few minutes. With 100 or more gallons of water...you would have to go on a REALLY long drive just to get it to heat up, and all along the way you'd be running cold water through your engine. Did I mention that was bad for it yet? ;)

[ [Parent](#) ]

Re: Recycled engine heat as you drive ([none / 0](#)) (#14)  
by monte350c on Thu Nov 27th, 2003 at 10:34:15 AM MST  
([User Info](#))

Hi All,

An automotive thermostat will open basically as needed - it doesn't have to be all the way open or shut. It will open only as much as the temperature of the water passing over the expansion capsule. A good example of this is an automotive engine installed in a marine application (Mercruiser stern drives for example) where lake or sea water is used directly for cooling. If you have a 190 stat in it, it will run at 190, taking in only enough cold water to maintain that temp.

Ted.

Re: Recycled engine heat as you drive ([none / 0](#)) (#7)  
by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Wed Nov 26th, 2003 at 03:51:02 PM MST  
([User Info](#))

If I was going to build such a system, I would leave the original cooling system essentially intact. Run the engine coolant through a heat exchanger to heat extra water, do not let the two systems come into contact. I absolutely would not drink or bath in water that has run through the cooling system of a car, propylene glycol(antifreeze) is a fairly nasty poison. If the engine's thermostat controlled when coolant flowed through the heat exchanger, there would be no more temperature swings than there are when the coolant flows through the radiator. Valves could be used to select whether coolant goes to the heat exchanger or the radiator. Hth.

Demetri  
Always be the lead dog.

Re: Recycled engine heat as you drive ([none / 0](#)) ([#10](#))  
by bretco on Wed Nov 26th, 2003 at 11:06:16 PM MST  
([User Info](#))

Hey Demetri,  
I would'nt dream of interchanging the glycol coolant from my truck to the house domestic water system. I'm already running an isolated system from my wood boiler that heats my domestic water via homemade heat exchangers ( my last gas bill showed about \$2.00 usage for Oct-Nov in Vermont.) I totally isolate the "dirty" woodsove water from the "clean" city water with lots of copper tubing heat exchangers. Anyhow, I think maybe the experiment in itself might be worthwhile in establishing how much "waste" heat can be reclaimed from a vehicle, and I think it won't be all that difficult to rig up a way to "suck" the heat from my truck tank to the house tank, after all, my wood boiler is sort of doing the same thing, but now I will have to "download" the hot water to my house system, quick release valves etc.

[ [Parent](#) ]

Re: Recycled engine heat as you drive ([none / 0](#)) ([#8](#))  
by dualsporter on Wed Nov 26th, 2003 at 03:51:53 PM MST  
([User Info](#))

Sounds very interesting. Definitely want to hear about your results. Major downer, as I'm thinking, is related to where you are located. If you are in a cold climate where freezing temp.s must be delt with, and you use... say a 250 gallon oil tank... with a 50/50 mix of antifreeze, you're looking at investing in 125 gallons of antifreeze at \$4.00 / gallon (wholesale), you've got a \$500 experiment going. Maybe put a copper heat exchanger loop inside the tank and only fill the tank about 2/3 full of plain water. Reduces your cooling system volume (as compared to other method) and will probably survive being frozen. You'd just have to drive a little (ahem) farther to melt it before good heat rise could occur. Keep us updated.

Dualsporter

How to figure BTU's to boil water

I know this formula has been posted here before, but for the life of me I can't find it. If you build an experiment to heat water, how do you figure the BTU's?

Many thanks,  
Mark

1 Btu is the energy required to heat 1 pound of water by 1 degree F  
Dave from PA

Re: Figuring BTU's ([none / 0](#)) (#2)  
by [JW](#) on Fri Nov 7th, 2003 at 07:22:12 AM MST  
([User Info](#))

I agree with dburt.

BTU= which is the quantity of heat or thermal energy required to raise the temperature of one pound of pure water one degree F.

SI system of units, the unit for thermal energy is the joule(J) One kilojoule (kJ) 0.9478 Btu. the watt(W), equal to joule per second (J/s), is used for power, where one watt 3.412 Btu per hour.

takes 970 btu to evaporate (convert to steam) one pound of water.

-JW

JW, do you have any formula's on the volumn of steam produced for a given amount of boiling water? Such as CFM at a given pressure/area?

Have Fun  
Ed

[ [Parent](#) ]

Re: Figuring BTU's ([none / 0](#)) (#4)  
by JW on Fri Nov 7th, 2003 at 02:00:30 PM MST  
([User Info](#))

Hi Windstuffnow,

Yes the ratio, or coefficient of expansion for water is 1600 to 1. you could use volume of water x 1600, then convert as necessary to cubic feet, the per minuite part gets tricky, as well as btu input requirements. I recomend steam tables for this...

Another examble that might be helpful is Liquid Nitogen, its coefficient for expansion is between 600 and 700 to 1. as you can see water is a supieror working fluid.

Hi Ed,

I found this set of online thermal problem calculators a while back:

<http://kahuna.sdsu.edu/testcenter/testhome/index.html>

specifically look at the "States" link for a calculator that will solve CFM/pressure type problems. Keep having fun!

Ted.

Run the pool heater only when there is heat to get

I ran across this site while searching the "Kill a WATT" device (cool thing) from an earlier post. They have a Solar Cell system that directly runs the pool pump only when the Sun is out.

<http://www.etaengineering.com/poolkits.html>

I thought it was a Hot idea. I should have a system that only runs the pump when there is heat to recover. The timer idea is great , but if I ran the system from a solar cell triggered pump system, I would save power and get more heat.

right ?

by [Homebrewed12vdc](#) on Fri Oct 17th, 2003 at 04:18:38 PM MST ([User Info](#))

Well I well tell you my experience with solar heat, I have a solar panel connected to 12v computer fans that push air through my solar air heater. I would think the saem principle would work for you, obivoiusly the brighter the sun the faster the fans run, same thing should happen with a pump, so it should be a very efficent set up for you. Hope this helps.

I need advice

I need to know what type of things I can use to heat water in front of a waterwheel so i get 365day power. I was thinking of puttin 2 stove-type elements into a pipe and closing if off and making that warm up the water, what other things could I use that I can build my self?

by Electric Ed on Sun Sep 21st, 2003 at 07:57:54 PM MST  
([User Info](#)) <http://www.electric-ed.com>

That could use more energy than the installation could generate.

If you restrict the flow so that it is moving really fast, it will take a lower temperature to freeze it.

Electric Ed

I would think if the water is restricted where it has to flow entirely thru the waterwheel and there is enough water flowing that it will never freeze especially if it is an overshot waterwheel? Have you had experience with this waterwheel or will this be a first time? It would probably help if you could describe it a little more...even a small stream dammed so you have a three or four foot head would be quite effective...just my thoughts. (:>) Norm.

well its an overshoot but the flow is restricted. The creek will freeze normally so im trying to keep it running. I can make the flow more intense by blowing up a damn farther up stream. Someone told me to put a tube with holes underneath the water and blow air into it. It sounds like a good idea. Also wouldn't an overshoot be more likely to freeze? It is my first time and the damn is about 4 feet high. Im living in an area where it can reach -20 degrees celsuis but usually -10 or so.

Air bubbles can be used to prevent water to freeze.

Here is a link to see what air bubbles can do to prevent water from freezing. This application is for a pond, but I guess sanme pricinple could be used if the flow of water is not strong enough to prevent water from freezing.

<http://pondwindmills.com/>

Anyway it could, at least, give you some ideas.

Heating it would waste too much power. Why don't you build a still & dump alcohol in front of it. That's non-toxic antifreeze. And if it doesn't work you will still have some use for the product.....

Re: How to keep water from freezing ([none / 0](#))

([User Info](#))

Alcohol non-toxic? Why don't you just dump big bricks of salt in there?

Just because it's non-toxic, doesn't stop it from being a total environmental disaster.

The air bubble thing might work. It's been known to keep harbours ice free and things like that, but it's only going to work if the stream is fast enough not to freeze solid.

Cya,  
Chris

nothin

Hello,  
if you check a commercial site about solar water heating, there is one element, the boiler with the pipes inside, which is a very expensive unit.

This heat changer is to transfer the heat of the solar-heated antifreeze liquid to the water. And of course it is quite good insulated.

Is there anybody who have made one like this at home? What materials do you use for this?

The factory made boilers are usually covered steel, what i think cannot be hurt for modification...

thanks for any info,

viktor

Here is what I am using for a heat exchanger its and old gas fired hot water heater with the burner removed and the flue that runs though the middle of the water tank is welded shut with fitting

to match your plumbing.

The hot food grade antifreeze is pumped through the flue and heats the water in the tank.

This gives me a heat exchanger and hot water storage all in one. The pics show the water heater with out burner and outer skin and fittings welded in.

I am using mine with an out door wood fired boiler that heats my home.

Works great and the best thing is that water heater was free for the hauling

Hope this helps

Hi,

thanks, your one is the one i look for.

is its material stainless steel or simple painted steel inside?

if painted then what did you use for the paint? or if the paint is original, how did it survive the welding? how is about corrosion inside? what is the heat changer pipes made of? if copper then how did you prevent corrosion between copper and steel?

thanks!

viktor

Viktor

What I started with was a house hold hot water heater or as you say boiler it used a natural gas burner to heat the water. The burner went bad an that is why I got it for free. The tank has all ready has one 3 inch pipe that runs thru the tank this is the heat exchanger it just steel and welds easily.

Hope this help

Old F

Have fun

New pool Heater

---

Hi all,

Well, I took the plunge last week and bought a single solar panel from a company to see what the difference was between my nice homemade system and a professional one. Well, I'm impressed, and depressed. I guess I am glad I'm impressed because the professional solar panel was expensive. Anyway the thing puts out tons of water, and from what i have read, it's not just heat you need it's heat AND flow. You can burn your finger with a match, but you can't heat a pool - meaning my little 1/2" tube homemade solar system is nice, but it's not going to do a great deal to heat an 18 foot above ground pool which is 5 feet high, - that's a LOT of water in there.

Once I got the professional system running today with the very large 1-1/2" tube, I quickly realized my that my system although cute was not anywhere near as strong as this one panel.

In any event, I am glad i tried using black hosing to heat my pool, and indeed it DOES work, no matter what any salesman will tell you, - you just need enough flow to get a pool warm.

I now want to buy another 4 panels from this company, - each kit or "panel" is 40 sq.feet, and with 5 panels, that makes 200 sq. feet, which should be enough to do my pool... - most places suggest 60% of your total area of pool.

In my case the pool is an 18foot, round above ground pool, so that's 256 sq. feet approx, so I'm well over the 60% needed to heat that pool quickly.

Anyway here are some images to check out.

Mark.

Does this mean my HOMEMADE solar system failed ? - by all means NO... and that's a very positive NO !, if I had the room - say I was living out in the country or had a lot of propery, I could use more black hosing and would have very good sucess with my homemade system.

What you see in the images is ONE panel - eventhough you see 4 pieces, it is actually only one panel or "kit" ... which equals 40sq feet.

Install was easy, and I'm more than impressed. Now to find somebody who doesn't scare easily and install this and other panels on my roof.... I have a 2 story house, and it's just impossible for me to even put my life

[New solar system \( professional \) - I'm impressed.](#) | 4 comments (4 topical, 0 editorial)

Re: New solar system ( professional ) - I'm impres ([none / 0](#)) ([#1](#))  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Sat Aug 23rd, 2003 at 01:55:26 AM MST  
([User Info](#))

I have a small question.

Would't you get hot(ter) water if you "recycled" it? Simply have a small output flow, and simply run the water in the system a bunch of times, while just a little bit gets out. Then the water inputted would be warmed quicker by the already hot water.

-Andrew

Re: New solar system ( professional ) - I'm impres ([none / 0](#)) (#2)  
by thebbqguy on Mon Aug 25th, 2003 at 08:12:13 AM MST  
([User Info](#))

Hi Andrew,

The professional panels are very effecient, that there's no need to recycle the water again into them, - they put out pretty hot water the first time, and the more panels the hotter the water.

I got an email from my brother this morning saying he was talking to his friend this weekend and the guy was saying that the 4 panels he has hooked up on his roof ( they are professional ones ) as you see in my images, - anyway the water is so hot that he can make coffee with it. That's pretty darn good.

My brother also knows the guy "aint" fibbing, as he was in the guy's pool a few weeks ago and it was 94 degrees ! - his wife had forgotten to turn the darn solar system off !

I wish I had that kind of problem. Anyway I've just ordered another 2 panels this morning, and will hopefully get them this Thurday, and that will make a total of 3 for me.

I also found out that solar panels on a roof can cause major damage to your shingles, - because of shifting due to the constant movement of water in the panels and tubes. I have therefore decided to build a structure on my lawn for my solar panels. My home is only 4 years old, and the roof is under warranty for 15 years, -if I place the solar system on the roof, and in 5 years the shingles are worn through the company that did the job will NOT honor the warranty. - Too much of a risk for me, so I'm keeping them on the ground.

I'll build a "deck" of sorts made out of pressure treated lumber, cover it with shingles, and then attached the solar panels on there. Much cheaper than replacing a roof at \$5,000.

anyway that's it for now.

Mark.

Here are some new pics I took of the solar panel.

Pump? ([none / 0](#)) ([#3](#))

by Demetri ([corvettemach1@yahoo.com](#)) on Mon Aug 25th, 2003 at 11:48:51 AM MST

([User Info](#))

Does the professional heater have it's own pump?

Demetri

Always be the lead dog.

Re: Pump? ([none / 0](#)) ([#4](#))  
by thebbqguy on Mon Aug 25th, 2003 at 11:55:47 AM MST  
([User Info](#))

Hi Demetri,

Nope, none needed, it just uses your existing pool pump, which is strong enough to power it. 3/4 to 1hp is what they ask for. I have a 1.5 hp, so I have the valve that goes to the panel closed down about 80%, and still I am getting a big water flow.

I just also ordered 3 more of these panels today, so they should be here by Thursday, and by Friday I'll have 'em hooked up, so I'll post a few more pix of the 4 panels hooked together.

Mark

[Water Heating](#)

nothing

Hi,

I would like to ask you for opinion only. If there is someone who has experience with brand solar heater and homebrewed ones also.

Is there noticeable efficiency difference between these? I mean in cold winter days how much higher is the brand solar heater temperature than a homebrewed (copper pipe, black painted, glass covered)? The price is about 4:1 so thats why i am interested in it...

thanks for any comment,  
viktor

by [thebbqguy](#) on Thu Aug 21st, 2003 at 06:41:42 AM MST  
([User Info](#))

Hi Vic,

Well, good question ! ,

I just bought a professional solar system made by Enersol last week, and it's expected here at my house today !

I bought one panel - a 4x10 size - so that's 40 sq feet.

I'll see what kind of heat I get out of it today. I was going to buy a few of them, but thought maybe I should try one first, and see how better it is than my homemade systems.

Anyway I'll be posting images of the professional one maybe today or tomorrow.

you can see my homemade systems here:

<http://www.powershotgraphics.com/pool>  
<http://www.powershotgrahpics.com/pool2>

in the second one, - I have now redone the tubing and have coiled it properly

Re: homebrew vs brand solar heaters ([none / 0](#)) (#2)  
by thebbqguy on Thu Aug 21st, 2003 at 07:02:20 AM MST  
([User Info](#))

Hi Viktor, sorry for the mis-spelling on your name.

You asked for an opinion, and i didn't quite do that in my first post.

I have spoken to several people on websites that sell professional systems, and they all say that you cannot even begin to compete with a professional system.

I do tend to agree.

Why ?

Because they make use of the sq. footage of an area, 100%, a 4x10 sheet = just that, 40 sq.feet

I have a 4'x8' sheet of plywood - in theory that's 32 sq. feet, but...  
much of my 4x8 sheet is not usable, the corners, and also the middle where I was not able to bend the pipe,  
and had to stop my coil there, - so in reality,  
that 4x8 sheet of plywood with blackpipe has a LOT of wasted space.  
Look at the image below.

Also, let's remember that most black pipe homemade systems are 1/2" pipe....  
the professional ones are 1-1/2" pipe ! .... the gallons per hour these things push out is unbelievable, so  
there's just no comparison. I like tinkering, and don't have tons of money so I made 3 homemade systems,  
but scraped up money to buy one professional panel to test, and keep. I have put in all the tubing this week,  
in anticipation of my professional solar panel's arrival. I have it running from my pool's pump, under the deck  
and into a part of the backyard where I'll put the solar panel on the ground and test it.

Re: homebrew vs brand solar heaters ([none / 0](#)) (#3)  
by wdyasq on Thu Aug 21st, 2003 at 05:10:26 PM MST  
([User Info](#))

I think the real product missing is the Dollar per Unit of energy acheived. A more personal unit might \$ per unit ENJOYED.

While the folks with the high efficiency hot water heaters can claim X Btu/sf/hr they can't match the pleasure of a warm shower from a dark colored hose simply warmed by the sun.

Ron

Re: homebrew vs brand solar heaters ([none / 0](#)) (#5)  
by thebbqguy on Fri Aug 22nd, 2003 at 03:39:32 PM MST  
([User Info](#))

HI Viktor,

As promised here is a pic(s) of my new solar panel.

I AM impressed with it, and it blows away my homemade one, that's the sad part, but I am glad, as I paid good money for this one :-)

In one image I talk about the flow rate... the professional panel is 1-1/2" so no wonder it put so much water out - now we're cooking with gas, I mean solar :-)

Considering this is only one panel, I can't even fathom what 5 of these would do on my roof, - I do now believe my brother when he said a guy's pool was at 94, and that the guy has to turn the solar system off and can't keep it running all day, - the water flow when 4 panels are hooked up together is amazing, considering that each panel can handle a lot of water. ( 10 gallons MAX per minute per 4 sections) - which I have here..... but I don't have it running at 10 gpm.

To seriously heat my pool I need at least 4 of these panels, which are 4'x10'.

poolguy@PowerShotGraphics.com

by bewotec on Sat Aug 23rd, 2003 at 01:35:56 AM MST  
([User Info](#))

Hello,

is this DIY kit also a non-glassed one?

so only because of the good engineering and the satisfying material, it has 4 times better efficiency than the homebrewed one.

i am impressed and sad also.

thanks!

viktor

[ [Parent](#) ]

Re: homebrew vs brand solar heaters ([none / 0](#)) ([#7](#))  
by troy on Sat Aug 23rd, 2003 at 08:39:57 AM MST  
([User Info](#))

The key difference between the commercial unit and the homebrew unit is the average length of run. It looks like the commercial unit has many pipes of short length in parallel, while yours is one long pipe. Might be interesting to do those temp measurements on your unit to see what the temp is as you go further down the pipe. If you stop gaining significant heat at 40 feet, you could just make yours a lot of shorter parallel pipes like the commercial unit.

Best regards.

troy

Re: homebrew vs brand solar heaters ([none / 0](#)) ([#8](#))  
by thebbqguy on Sat Aug 23rd, 2003 at 11:26:57 AM MST  
([User Info](#))

Hi Troy,

Interesting, yes I would love to measure that.

I will tell you though, for the homemade systems, the longer the tube the better.

I know just from experience.... I made a smaller solar system, - incased in a box, and I have now given up on it, - even with the plexiglass, the amount of tubing I used, about 120 feet, is just not long enough to do any real heating.

My local pool places sells "homemade" systems just like this using the exact same black tubing ( which is available at all hardware stores ) and they recommend a minimum length of 500 feet.

When I bought my own tubing it came in a 400 feet length. I remember testing the water, and water temp was so-so.... so I bought another 200 feet and added that to the 400 .... guess what .... water temp was MUCH higher !

but yes, you are right on the money, there IS a a point where the tubing stops being effecient in terms of heat vs the length, but what that length is, I just don't really know exactly.

Mark.

Pool Heater

Hi all,

Just wanted to let you know that I have now posted images that show my progression through my first homemade solar enclosure.

<http://www.powershotgraphics.com/pool>

I bought the 3foot x 5foot piece of plexiglass for \$18.xx at my local hardware store, and the rest I had hanging around.

At this point I have not arranged the pipe properly, - meaning I haven't attached it down, and coiled it in the box properly but that will come, and I'll add images this week when it's done.

Anyway I hope that this helps anyone out a bit if they are trying to build one.

The temp inside that box today is off the scale on my tiny digital thermometer, it went so high and then just went crazy giving "EEE" for error, so it's darn hot in that box.

I want to get as much black hose as I can coiled in there, - as it stand that's 100 feet of 1/2 tubing you see in there right now.

anyway thanks for reading :-)  
Mark.

[quote - "I want to get as much black hose as I can coiled in there, - as it stand that's 100 feet of 1/2 tubing you see in there right now."]

A longer length of pipe will not result in an increase in the temperature of the water, unless the rate of flow is very fast. The water is very likely up to it's maximum temperature after it has flowed through the first 25 or 30 ft. of tubing.

For pool heating, a larger volume of water is better and I believe you would get better results if you put any additional tubing in parallel with the existing.

Electric Ed

Looks to me like plastic sprinkler tubing. Should be able to find it at most any hardware store...very cheap.

Do you think a house central heating radiator painted black in a glass enclosure would work as well as the black pipe? I was thinging about doing this.

The best results I had so far with water heating is that first, no tubing overlaps. Second, the more in "parallel" the better. Third, maximize surface area. My best result was 10 tubes zig-zaging next to each other. All with common start, ends. On sunny days it was getting so hot it was spitting steam and scalding hot water out. Although, the best of the best, I heard it parabolic. The closer the focal point to the actual mirror, the less adjusting. These can get well above boiling, as much as 400-700 degrees!

-Andrew

Your heater is pretty nice for a first.

Hi Guys,

thanks for the comments :-)

- That tubing is 1/2" ..... it's regular black utility or "drainage" tubing that they use in grocery stores in the meat section, from what i have heard, it is a food grade pipe, so I guess it's good for human consumption if you have it hooked up at a cottage for water hook up.

That tube cost me \$9.98 for 100 feet - very inexpensive I thought.

400 feet cost me \$39.99 - no savings but a longer length to work with.

If it is say \$10 for 100 feet here in Canada, that stuff has to be about \$7 maximum for 100 feet in the United States.

Go to your local hardware store and check around - I found mine in the back of the store with all the sump pumps, etc.

I first bought 100 psi rated tubing which was a bit more expensive, \$3 more for 100 feet, but when they ran out, I bought 75psi rated tube ( 100 feet \$9.98 ) and it works fine.

If anyone wants a close up image of the writing on the actual tube let me know.

anyway thanks again for all the help and comments.

Ed, I really want to get a little test going with your theory about parallel tubes, but darn, the other day I had 100 feet of tube hooked up and the water was flowing at a good rate, and it was COLD :- ( .... when I added another 100 feet to it, at the same rate ( in series ) - meaning I just made the tube longer, the water from it at the same flow was MUCH higher.

I also noticed that when I had 400 feet of black tube, and added another 200 feet to it, to make 600 it made the water much warmer.

The only way to get hotter water from a small length of tube is to really slow down the flow - this is what I have found from actual experience, so I'm just not sold on the idea as of yet :- (

From my experience - the longer the tube is, - say 500 or 600 feet, - the longer that water is inside the black tube, and in essence is sucking up heat from the sun.... if the pipe is super short, - it has no time to grab solar heat from the tube, because before the water has time to heat up, it's already pouring out of the end of the hose..... I don't know, am I just not getting the point ? I don't know :- (

Mark

Re: New enclosed solar heater using black pipe - t ([none / 0](#)) (#7)  
by troy on Wed Aug 20th, 2003 at 09:29:43 AM MST  
([User Info](#))

You're always looking for the best compromise. Longer dwell times (very low gallons per minute through the pipe) gives hotter output, but less of it. Furthermore, the hotter your pipe gets, the more you lose to the air, lowering the number of BTU's that actually make it into the pool. So, for a given 4x8 panel, high flow will give cooler output, but more BTU's into the pool. 500 gallons of 78F water is better than ten gallons of boiling water.

Optimal pipe length can be determined by measuring the temperature at regular intervals along the pipe. Then graph those numbers and when the temperature curve stops going up, or goes up very slowly, you've just passed optimal pipe length. This graph will only be valid for a particular flow rate and a particular input temperature and a given collector design (glazed, unglazed, insulated, whatever, each collector type will be unique in it's optimized pipe length.)

At some point someone made a comparison to the enclosed solar oven they built, which is thermodynamically a much different animal, in that there is no active heat transfer out of the oven. Of course, the oven will get much hotter, and then it has to be insulated and glazed to prevent losing that. But your solar pool heater panel is actively "cooled" by the pool water, so you'll never get very high temps, which actually improves efficiency.

The lower pipe temperature is why glazing doesn't make such a big difference, some difference, but not triple or more like a stagnant solar oven. What WILL make a big difference, is collector size (more pipe, more panels). You only get so many BTU's per square foot of sunlight.

Good luck, have fun, keep experimenting!

troy

The Pipe I used for my pool heater was much larger diameter than the pipe that the pump was designed for. This did 3 things: it reduced the Head backpressure that the pump sees ; it slowed the water down a great deal so it dwelled inside the heater pipes for a longer period ; and it increased the surface area of the pipe to the Sun.

One thing that I thought was interesting was that millions of super tiny bubbles were constantly coming from the return line in the full Sun. At first I thought the system had an air leak, but later checks convinced me that it was sealed up fine.

This may be a hair off the beaten path but, food for thought I hope. Years ago, when solar was the craze, we built numerous solar homes. The common factor of all was the solarium. This space started in the basement, up to the ridge pole and down to the basement on the opposite side. Air currents could flow completely around the inner shell. The floor of the solarium was about 6" of white rock. On this strata, black plastic barrels filled with water were lined up against the inner wall, also painted black. Sunlight filtering through the solarium glass would be reflected from the white rock onto the barrels and wall. The air currents produced were amazing. Getting to the point: Instead of using air as the heat transfer medium in the heater, why not use a non freezing liquid. The heat transfer would be greater and lasting.

Just a thought.

Inquiring Mind <'>< Chance favors the prepared mind whose hands do the work!

Re: New enclosed solar heater using black pipe ([none / 0](#)) (#10)  
by thebbqguy on Mon Sep 8th, 2003 at 08:14:58 PM MST  
([User Info](#))

Just a quick update here,

Since the 21st of August, I started slowly buying professional solar panels, and today my 3 shipment arrived, so now I have a total of 6 panels.

Each panel is 4x10 feet ( 40 sq feet )

Let me just say something, I really enjoyed fiddling around with my homemade black hose system, but after buying my first professional panel that uses a 1-1/2" tube, I was sold on them.

Here's an example - today my pool was at a cool 68.2 degrees in the morning, - about 11 am.

I got my shipment of 2 panels ( I had 4 at this point ) anyway I installed the 2 I just received, got the whole thing together and had it up and running about 1:05 pm, well, by 5pm - when I shut the system off, I had the water up to 75.9 degrees.

That would have been IMPOSSIBLE with my homemade solar tubes, - they are 1/2" pipes, and even with 3 of them running, it doesn't even compare to the professional system. Water comes out of the professional panels so quickly that the water is being turned over at such a high rate, I was getting a 1.2 degree temp increase in only 30 minutes ! my pool at one point during the day. As the day went on, that decreased slowly but still that's just amazing !

I use my little stopwatch, a piece of paper and I write everything down, - I took temps each 30 minutes by the way. Anyway you also have to consider where I live, - I live in Ontario Canada - Ottawa - and it's cold here at night, - getting down to about 6 degrees above zero now during the nights, and only about 21 degrees during the day ( that's about 69 degrees F ).... today for example I had a high of 21.5 degrees on my outdoor thermomter, - that's not very warm, but still the panels pushed a heck of a lot of water.... anyway sorry for the long story, here's a picture taken today.

P.S. - you can see my homemade 4x8sheet of plywood with my tubing, a long time to wind and attach that, and in theory that total sheet of plywood would yield 32 sq.feet of area, but.. but look at the huge area in the middle.... very depressing, but i couldn't do anything about it, so in reality, that 32 sq feet is probabally more like 25 sq feet of area.... it's a lot of space for nothing :- ( I did have fun though.

Btw, I forgot to mention, that pool is an 18foot above ground, ( you can see it there ) and it is a new model for this year, - it is 52" high instead of the normal 48" high that was the standard last year.... there's a lot of water in that pool.

anyway those 6 panels yield a total of 240 sq feet of area ! - my pool equals 256 sq feet. Most companies suggest you buy a good 60% of the area of your pool, but in my case those 6 panels equal 93.75% coverage - so I'm doing well, - I just wish I had a large yard. I'd love to have a good 10 panels, - yes I'm a nut for fast free heat :-)

Pool Heater ??

[Water Heating](#)

Hi all,

As you may know or maybe not, I have made a homemade solar heater for my 18 foot above ground pool. ( Surface area is approx 256 sq feet )

Images and info about my setup are here: <http://www.powershotgraphics.com/pool>

Now, - I wonder if anyone can shed some light on this for me,

I currently have a piece of 4'x8' plywood.... I took regular black tarpaper ( roofing paper) and stapled it down on this sheet of plywood.

image of plywood and tubing:

On top of it, I laid down and attached 500 feet of black tubing ( 1/2 " )

Now, I want to know, if I took this sheet of plywood and tubing, and built a frame around it, say out of 2x4 wood, so I have a frame completely around the plywood, now I would take a sheet of plexiglass from my local hardware store, and scew that down on top of the 2x4s that are on the 4'x8' sheet of plywood..... do you think that this would yield any real improvement in the heat being generated from that black tubing ?? .... plexiglass is about \$80 a sheet of 4'x8' so I would love to have any comments, on if this is worth the extra time and money.

Any help would greatly be appreciated, and if you do post something, please send me an email at : mark@powershotgraphics.com .... for some reason I am checking off the "alert me if there are responses to my post" but for some reason I'm not getting any alert in my email box that somebody has posted to my questions ( others I have posted in the past )

anyway thanks much in advance :-)

Mark

I would assume it would make a big difference. I have not made any of these solar heaters you talk about but if you think of it like this... you probably have this solar heater mounted outside where it can get plenty of sun. It is subjected to breezes blowing around it. This will start to cool the tubing and disperse the heat. If you make it a sealed enclosure, the temp will rise quicker and give you a more consistant output so to speak. This is how a green house works. Plexi might be easier to handle, but I would go for glass although it might be more expensive, it might work a little better than plexi because of its ability to pass sun light easily (plexi might become cloudy after a couple of years) and its ability to retain heat (insulate). Have fun!! RoyR

Can't see how it wouldn't help.. ([none / 0](#)) ([#2](#))  
by TomW on Mon Aug 18th, 2003 at 09:16:14 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

I have to agree with Roy here.

The air temperature inside a glazed area will be much higher than outside ambient air temperature. Your coils can't help but absorb that. They will lose less heat to the night air too I think.

Cheers.

TomW

Hi guys,

Thanks much for the responses.

One question, can somebody explained that word " glazed" for me.... does this mean the area that is inclosed in with glass ?

I've seen this term several times, but have not really known what it means.

Thanks also to the owner of this website, I didn't know you could show an image in the actual post, boy that really makes it easier for the reader, so thank you for that :-)

anyway wow, so I guess this is something I need to try out in the near future :-)

I was kind of hoping that plexiglass would be as good as glass for the rays of sun to penetrate, glass is so easy to break :-)

anyway thanks again :-)

Mark.

glazing ([none / 0](#)) (#4)  
by TomW on Mon Aug 18th, 2003 at 11:53:00 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Mark;

"glazed" simply means [to me] "covered with glass".

And on another note:

I would stay away from plexiglass for several reasons.

Expensive.

Clouds with time and scratches easily.

I think it would sag in that size in a horizontal position.

For an ultra cheap way to test it try clear plastic "visqueen" it won't last long but its dead cheap in rolls.

Cheers.

TomW

Re: glassed in black tube = higher heat yield ([none / 0](#)) (#5)  
by troy on Mon Aug 18th, 2003 at 01:13:54 PM MST  
([User Info](#))

The answer to your question all depends on how hot the tubing on the plywood sheet gets. In a typical pool heater, there's a lot of water going through the tubing so they never get very hot, less than 100F typically. IF that is true, adding a layer of glazing will likely REDUCE performance because even glass absorbs about ten percent of the light unless you get special low iron glass.

On the other hand, if the tubing is considerably hotter than ambient air temp, say 150 or more, then you might gain some performance, but not a lot, since the ambient air temperature is fairly warm in the summer when your getting real heat gain.

Here's an almost free way to find out. Put a 1x4" frame around your plywood sheet, cover it with saran wrap, wait 30 min, measure output temp, then remove saran wrap, wait 30 min, measure output temp.

The other clue about wether or not this is cost effective, is commercial solar pool heaters. The vast majority of them have no glazing unless you're heating your pool in the early spring/late fall, when you will lose a lot of heat from the naked solar panel.

Best regards,

troy

A sealed area will hold in more of the heat. Trapping the heat near the hose should provide a higher solar gain.

But I have to agree that Plexiglass may not be the best candidate for this task. If at all possible, I'd try to use glass. Maybe you can make several sections to use smaller pieces, rather than a large sheet. Clean it well. Seal the box well so bugs and vermin don't get inside.

You could be swimming in December, or even later.

([User Info](#))

Hi Guys :-)

I thank you for all your input on my question.

Well, I haven't been on all day, due to the fact I was out in the backyard building my little solar box.

I used wood that I had hanging around under my deck, and went over to the hardware store this afternoon also, and bought a piece of plexiglass - size is 3feet x 5 feet.

Anyway I built the thing today, and for today just threw the tube in there, and will do some serious testing on it tomorrow, when I mount it properly on the black tar paper I have put in there.

I have a few places where the wood is not perfect so there are pockets where air can get in and out.

I took about 20 high resolution digital images and will post those later tonight and give you a link, but for now, I'll give you a sneak peek at what I did.

There is only 100 feet of tube in there, and that really is not enough to make a

good solar heater from what I know, so I hope I didn't do all that work for nothing and only able to get say 200 feet of tubing into that small area. ( darn)

The 500 feet I have on the 4'x8' sheet of plywood really puts off some nice heat on a sunny day, so I kind of wish that was the one encased in a box.

Anyway here's an image :

[http://pages.infinit.net/logopro/IMG\\_5005scaled.jpg](http://pages.infinit.net/logopro/IMG_5005scaled.jpg)

From what I've read about solar pool heaters it's generally much more cost effective to scale up the basic design that you're already using. As you've already said, plexiglass is \$80 per sheet and you'll buy a \*lot\* of 1/2" poly pipe for that. ;-)

Putting the collector in a glass box will give you higher temperatures, but there's only so much energy to be collected per square foot. Have you got a nice big sun-facing rooftop to put it on?

BTH

I would defenitly use regular glass than plexy or Lexan. Glass has the property of allowing visable light to pass through ad degrade to IR ( heat). thats why the inside of you car get so freaking hot in the summer with the windows closed. It's also why 2 or 3 layers of glass are used in those "super insulated windows, the glass is real good at retaining heat.  
Dr.d

Try using a piece of clear "Coroplast" 4x8 sheet... it will give a degree of insulation from the air currents wiping away the heat fromm your board and pipe, and... only costs about \$4 a sheet... it does real well in the sun...I have a sheet at my business with a printed sign thats been out in all weather for 11 years...

Just a quick update here,

Since the 21st of August, I started slowly buying professional solar panels, and today my 3 shipment arrived, so now I have a total of 6 panels.

Each panel is 4x10 feet ( 40 sq feet )

Let me just say something, I really enjoyed fiddling around with my homemade black hose system, but after buying my first professional panel that uses a 1-1/2" tube, I was sold on them.

Here's an example - today my pool was at a cool 68.2 degrees in the morning, - about 11 am.

I got my shipment of 2 panels ( I had 4 at this point ) anyway I installed the 2 I just received, got the whole thing together and had it up and running about 1:05 pm, well, by 5pm - when I shut the system off, I had the water up to 75.9 degrees.

That would have been IMPOSSIBLE with my homemade solar tubes, - they are 1/2" pipes, and even with 3 of them running, it doesn't even compare to the professional system. Water comes out of the professional panels so quickly that the water is being turned over at such a high rate, I was getting a 1.2 degree temp increase in only 30 minutes ! my pool at one point during the day. As the day went on, that decreased slowly but still that's just amazing !

I use my little stopwatch, a piece of paper and I write everything down, - I took temps each 30 minutes by the way. Anyway you also have to consider where I live, - I live in Ontario Canada - Ottawa - and it's cold here at night, - getting down to about 6 degrees above zero now during the nights, and only about 21 degrees during the day ( that's about 69 degrees F ).... today for example I had a high of 21.5 degrees on my outdoor thermomter, - that's not very warm, but still the panels pushed a heck of a lot of water.... anyway sorry for the long story, here's a picture taken today.

Posted on Sun Aug 10th, 2003 at 08:51:50 AM MST

Just thought I would post info about my solar system in case anyone is interested.

---

Hi all,

Just thought I would post info about my solar system in case anyone is interested.

<http://www.powershotgraphics.com/pool>

I currently have 3 separate systems running for my 18 foot above ground pool. The pool is 52" high and is has a lot of water, - don't know, but somebody told me it holds 28,000 liters ( I live in Canada )

I know that 1 U.S. gallon = 3.8 liters.

anyway I have 3 systems, .... started out with one, but realized it would never work ..... as there's just too much water to heat up.

The first system I used black utility hose, - 1/2 " and have 500 feet of it. That worked so well, that I made another system and put that on the roof of my child's play structure outside .... that one has 400 feet.

Then this past week I bought another 600 feet of black hose and now have that running as my 3rd solar system.

All system are 100 % independant of each other, and all are running off the 1.5 hp motor that came with my pool, there's no strain on the motor by the way, which is great.

I push 8 liters of water every minute from each little 1/2 hose - and water is about 88-89 degrees, once the water has been running about a good 15 minutes.... when it first starts water is about 127 degrees F.

anyway let me do some math here:

8 liters of water from each hose per minute.

That's 24 liters total from the 3 black hoses per minute.

there are 3.8 liters in 1 U.S. gallon.... so.....

24 divided by 3.8 = 6.3 gallons per minute.

so, 6.3 gallons x 60 minutes = a total of : 378 gallons per hour .

That's enough to fight the battle..... the first 500 feet of tube I had installed - only one pipe - was beautiful, but I quickly realized that this was just not enough to fight the pool, - when you have that much water in a pool it's just not doing much if not anything.

From what i have read, - if a solar heater is big enough for your pool, you should be getting about a 2 degree per hour rise - from the solar heater alone, and another 1 degree per hour from the sun with its passive heating, -so that's 3 degrees per hour increase which is amazing.

anyway you can check out my images at :

([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

The temprature rise of 2 degrees an HOUR seems a bit too high. I'm pretty sure that if you are getting a 2 degree rise in a DAY that you would be fine. My Solar pool heater was getting a 1 degree rise per day which I thought was perfect.

Where are you getting your Black Tubing and what type of stuff is it (flexable / stiff).

([User Info](#))

Hi Sean,

Thanks for the info about the glass. I will go price plexiglass for fun, but a sheet of 4x8 sheet is over a \$100 here in Canada.... I bought a small section about 2 years ago for a coffee table - about 3 feet x 2 feet and it was \$55.xx if memory serves me correctly.

Morning Tim,

With the professional solar collectors, you should be getting way higher temps than with homemade systems, I have read numerous posts that a system can lift your pool temp by a good 6 - 8 degrees in a day. -- This is totally normal, \* if \* your solar system is 100% that of the area of your pool.

My 18 foot above ground pool has 254 sq feet of area. In order for me to have 100% of that area, can you image how many 4x8 sheets of piping I would need to equal that area ? - my lawn would be full of sheets ( yikes ) !

My 4x8 sheet is not even totally full of pipe..... the middle of the sheet is empty because the black piping is not that pliable and started to kink when I got too tight of a circle in the inner part.....

Anyway in theory that 4x8 sheet of plywood = 32 sq feet ONLY !

My brother has a math "template" to figure out from the size of tube and the length of tube to tell you pretty bang on how much sq footage total you have in a certain length of pipe.

I originally started off my solar system with only one pipe running into the pool, I had 500 feet of pipe ( 1/2" ) running on this system.

Anyway eventhough the temp was coming out rather nicely - about 89 degrees, - I quickly realized that there was just not enough flow for the temp to rise that much.

I then added another solar piping system, - installing it on my children's play structure roof... this one has 400 feet of pipe on it.

I then thought, ok if 1 is borderline, 2 must be better, so how about adding in another ? ... so I went out and bought another 600 feet of black pipe and have that just spread out over black roofing paper on the patio right now.

- heat coming off this 600 feet of pipe, eventhough not tacked down and evenly spread out so sun hits 100% of it, is quite amazing, temps coming out of it are really nice - about around that 88-89 degree mark - running at 2 liters per 15 seconds.... - that's 8 liters per minute.... ( 1 U.S. gallon = 3.8 liters )

anyway when I turn on those systems at the beginning the water coming out is naturally very hot - so hot you can almost scald yourself.

I know that even with 3 solar water tubes running into my pool, the sq footage that is coming out of my 3 systems is just not anywhere near what should be... in order for my pool to get a 3-4 degree temp increase per hour, I would need 20 of those tubes

running into the pool - each running on an independant system... ( all my systems are NOT connected to the other systems) each is 100% independant of the other.

I did try running 2 solar systems together as one - meaning I connected the 500 feet of tubing on the 4x8 sheet, and the 400 feet on the children's play structure roof.... just connecting the tubes together.....

I noticed that the water temp was indeed higher, but the flow was not..... and from what i read, it's temp, but ALSO flow that makes a good system..... if flow is too low, then you don't achieve much..... so I broke them into 2, and get a much better heating system from that... - a guy from one of the professional solar collector companies actually told me to do this, but I won't mention names.

Tim, that hose - it was \$9.99 for 100 feet.... they also sell it in 400 foot lengths, - that was #39.99 ..... I bought it at my local hardware store.... the guy told me they use it for drainage at cottages and is a standard tubing that is found all over the place. - they use it in grocery stores also for certain parts of the plumbing.

Anyway the first 400 feet of it I bought , I bought 100psi rated tube, which was \$10 more for the roll... so that was \$49.99 .... but when I went back to get more, they only have the piping at 75psi, so I bought that, - it was cheaper, and I just don't see the need for the extra 25psi... - if they had it, I would have bought it, but none was in stock.

The pipe is pretty pliable, but NOT as pliable as garden hose, but it is indeed pliable enough to work with totally fine.

anyway sorry if I went on like a broken record.

If you look at the professional solar collectors, you will see that they use huge piping that goes to and from the actual solar collector ( panel ) that sits on your roof for example.... each collector can push out a good 2-4 gallons per minute ! - so imagine when you have 8 of those collectors on your roof !

\* good example \*

My brother lives in Vancouver - they get a lot of rain there, and weather is nowhere near what it is like here in Ottawa ( we get much hotter summers) he went to a friend's house about 2 weeks ago..... my brother said the guy's pool was 94 degrees !!!

How was this possible ? ... well when the guy bought the house, it came with the pool and a professional solar collector system - the roof is full of collectors, and the piping going to the pool pump motor is the standard 1-1/2 or 1-1/4 inch size..... anyway the guy told my brother that he has to turn the solar system off all the time because the pool gets too hot ! - anyway that day his wife had left the system on, and so the water was way too hot to be refreshing.

\* I wish I had those problems :-) \*

Anyway that goes to show you the power of solar collectors, if they equal the sq footage of your pool - you can get amazing water temps. - I've read some

of the really high quality collectors available boast a temp increase in your pool of 10 degrees - provided you have 100% coverage in sq footage on your collector.

Right now I guess I have what... about 1/6th coverage in sq.footage, so I am nowhere near what i should be.

If I lived further out in town, had a large property, I would buy 10 sheets of 4x8 plywood, and coil 400 feet of black tubing on each one .... now imagine the solar energy that would come off something like that - wowie !

Mark.

<http://www.powershotgraphics.com/pool>

I'll take some new pictures today of the connections to my pump, as the website at this moment doesn't reflect the 3 seperate connections for each of my existing solar systems.... - I have installed "y" tubes onto the pool filter system, right near the pool, and each of the "y" connectors attaches to a black 1/2 tube ( the solar tubes) ... and each "Y" has a valve to turn off each and any of the tubes at any time.

by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Mon Aug 11th, 2003 at 08:01:27 AM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

The pipe is so small and it is so long. Pipe has resistance to water flow. This resistance is called `Head' and is measured in feet, as if the water were being pumped uphill for that number of feet which loads the pump down. Here is a link to a chart showing the friction Head for all pipe sizes and flow rates.

<http://pump.net/frictiondata/fricofwater.htm>

they don't list PVC pipe so scroll down the page and select 1/2 copper pipe then find your flow rate on the chart and you'll see the resistance to the water in feet. Also any fittings in the system (like 90 degree elboes) has head resistance. The chart for pipe fitting head resistance is at the top of the page linked to above.

.....

The pool heater I built was raising the temperature of the water by about 1.7 degrees as I measured the difference between the pool water and the return water from the heater. Plus the temprature of my 2500 gallon pool was rising by about 1 degree per day. unfortunatly my pool developed a leak and drained itself, but before that happened we were swimming in 88 degree water, up from 76 degrees on the day I got it operational. We are planning to try and return the pool to Wal-Mart for replacement.

([User Info](#))

I know this would be an absolutely HUGE pain in the butt, you'd never drain your pool specifically for this(Geez, what would you do with all that water? And your water bill from refilling it? Assuming you don't have a well.), but if you ever have your pool drained sometime, you might consider painting the bottom of it black. Or maybe a cool picture in predominantly dark shades.

Demetri  
Always be the lead dog.

The problem with a pool painted a dark color for heat is that you can't turn it off if it gets too hot . . .

([User Info](#))

Hi Demitri,

I'm super lucky, where I live in Canada, - we have no water meter, so you use as much water as you wish, and that's the end of story.

Lucky we live where there's never a shortage. We have so much water we sell it to many of the upper States in the U.S.A.

As for draining, it's as easy as pie, you just run your drain hose, which is a flexible baby blue hose out to the street and let it go, there are sewers in front of every house, so that's quite convenient.

Mark  
<http://www.powershotgraphics.com/pool>

Re: Homemade solar pool heating ([none / 0](#)) (#9)

by Electric Ed on Mon Aug 11th, 2003 at 08:08:53 PM MST  
([User Info](#)) <http://www.electric-ed.com>

It is nice to see people making use of all that "free" solar energy.

However, I believe that for heating a large volume of water to a relatively low temperature, such as for pool heating, a collector with more parallel branches would be more efficient.

You described three "branches" of 400 ft, 500 ft, and 600 ft, using a total of 1500 ft of pipe.

I would recommend, say, fifteen branches of 100 ft each instead. Of course, the down side is that this involves more plumbing, and you would also need a higher volume pump.

There is a maximum water temperature that can be achieved with the pipe exposed to the air. The problem with the longer run is, if the water gets up to that maximum temperature in the first 100 ft of the run, the remainder of the pipe in that run is wasted.

Electric Ed

Re: Homemade solar pool heating ([none / 0](#)) ([#10](#))  
by thebbqguy on Tue Aug 12th, 2003 at 07:51:01 AM MST  
([User Info](#))

Hi Ed,

Wow, well you bring up a good point.

I'm going to do a test today and try using a 100 foot piece of tubing and take the temp of water flowing from it, once it has been flowing for about 10 mins.

The other day, I had a 400 piece of tubing running at 8 liters per minute, the water was warm.

I stopped the flow, added on 2 other lengths of 100 foot tube, so I now had 600 feet of tubing.

I turned the flow back on, and let it go for a good 5 minutes, and then checked the water temp - .... it was MUCH warmer than it was with the 400 feet.

This told me the longer the length the better ..... but you are right, there must be a happy medium.

I'm thinking of doing this, if your thoughts are correct about the tubes

I'll take a 1-1/2" black pipe ( used for bathrooms) ... the same size my pool filter is running on.....

I'll take that tub, and cap one end of it, - the other end will be hooked up to the pool filter.

Ok now I want to drill holes all the way along the pipe and slide my existing 1/2" pipe into those holes and have each length of pipe say a length of 100 feet like you suggest.

I don't know, would it be more effecient ? ... I don't know how to attach the small 1/2" pipe into the larger pipe, maybe just PVC glue would do it.

Anyway, don't know if this would be more effecient, but

would be a fun project.

Mark.

### [Splicing PEX tubing](#)

By [Wyomingbob](#), Section [Remote Living](#)

Posted on Fri Jul 4th, 2003 at 08:51:06 PM MST

[Water Heating](#)

must never ever leak

What's the absolute surest and proper method for splicing a run of 1/2" Heat PEX that will be entombed in concrete as part of a hydronic heating system? I know, I know -- don't splice at all. We really tried to avoid it, honest. I need a method that will last 300 years, in concrete, running very hot propylene glycol, and never ever leak even after a million heating & cooling cycles. Help?

([User Info](#))

Mr Wyoming,

<http://www.pexconnection.com/heating/oxygaurd.htm#heatpex>

Has 1000' lengths of 1/2" PEX.....

You must be building a big building or have some cheap PEX you are using....

Or, just plan on making the splices wher you can get to and fix them.

Ron

Re: Splicing PEX tubing ([none / 0](#)) ([#2](#))  
by [Wyomingbob](#) on Fri Jul 4th, 2003 at 09:21:20 PM MST  
([User Info](#))

I had a 1000' roll of PEX. It is top-grade stuff, and the building isn't that big. A mid-course change in the heating system design left me short of the manifold. The splice will be under concrete and inaccessible. This cannot be that hard.

As well as I can remember you can use one of the pex union fittings that use double O ring seals and protect it by covering it over with large shrink tubing before covering it with concrete. For additional peace of mind you can replace the O rings with neoprene or silicone types that will have a much longer lifespan. I imagine you will be pressure testing the system before doing the concrete pour. Good Luck Tom S.

Re: Splicing PEX tubing ([none / 0](#)) ([#4](#))  
by troy on Sat Jul 5th, 2003 at 12:15:07 PM MST  
([User Info](#))

You could always put the splice in a box with an accessible cover that looks nice in the floor. I'm a belt and suspenders kind of guy myself. Isn't there some variant of Murphy's law that states that the likelihood of a plumbing joint leaking is inversely proportional to its accessibility?

I know you're busy like crazy, but I am fascinated by radiant heat so if you could give us a little description of your project some time that would be great. Is your pump/control system off the shelf or did you come up with a less expensive home-brew solution?

Good luck and have fun!

troy

Re: Splicing PEX tubing ([none / 0](#)) ([#5](#))  
by Wyomingbob on Sat Jul 5th, 2003 at 03:31:08 PM MST  
([User Info](#))

Hi, Troy. Think I've found the standard method: barbed brass insert coupling, crimped w/ O-rings (prolly two each side), then sealed w/ heat-shrink or that waterproof vulcanized electrician's tape.

The system isn't under any real pressure, just a couple of pounds from the slowpump. I knew there had to be a common fix, because at \$550 per 1000' roll, installers couldn't afford to no-splice every loop & wind up with a bunch of useless short rolls in the warehouse. And damage can happen during installation. (Some job orders do specify "no splices", tho.)

Local ACE Hardware actually had all the goodies, including plugs & schraeder valve fittings for pressure testing. Even lent me the crimping pliers gratis.

The reason I ran short is cuz I changed the system design a bit on the fly, which is quite typical of me.

The entire slab sits on 2" of styrofoam, called Insulworks: these are 4'x4' pieces w/ grooves milled so the PEX just snaps in & is secured by plastic staples. Two zones of the hydronic system are purely distribution: (1) back bedroom, office, and part of living room; (2) bathroom, mudroom

hall, and master bedroom. Third zone is the troublemaker. It leaves the manifold, warms the bulk of the living room, then does many tight turns in the solarium, where dark concrete and sloped glazing should mean a net temp gain on cold sunny days. So it's a mix of distribution and collection.

Then I was going to return to the storage tank, but figured heck, may as well use this reheated glycol to warm the kitchen. That's when I ran short.

Choices became: overextending loop (2) to carry the kitchen; adding a fourth zone; or splicing more PEX to loop (3) and putting that reheated fluid to good use.

The bathroom floor, BTW, is a product called Warmboard: basically 1-3/8" thick OSB with an aluminum sheet surface and tracks for the PEX.

Haven't quite sorted out the controls yet: it's going to be pretty basic, with maybe one floor temp sensor in the LR and I'll balance the other zones by tweaking manifold valves manually. Not putting thermostats or electronic valves on each loop.

That's an expensive pain, and uses parasitic power.

The solar HW collector will have its own pump and differential thermostat. Or I might just slap a 12VDC slow pump and 50 watt solar panel right on the collector and call it good. Glycol in both the collector and hydronic systems; domestic hot water is in a 60 gal tank with dual stainless heat-exchanger coils inside. After six months of futile searching, I finally found a reliable supplier of solar tanks at a decent price: Tam Jass tanks from SPNW in Oregon. Thermomax wanted about 2.5 times as much for a lesser tank. And SPNW will cut in bulkheads for water heater elements for only \$60 per, so my wind turbine dump loads are taken care of. The the DHW leaves the tank and goes to a demand LP gas water heater which modulates to zero BTUs if the water is hot enuf.

Sound like a nightmare plumbing job? Fraid so. I love electrical, but plumbing just sux. Icky.

Hey thanks Bob,

That's what I'm thinking, a combination of low tech with some informed tweaking. More simple, more reliable, more affordable, more serviceable, with a reasonable amount of control.

Best regards,

troy

by Anonymous Hero on Sun Jul 6th, 2003 at 02:33:45 PM MST

Wyoming, I built a hydronic system back in Canada. I had a special tool that stretched the PEX and allowed a shrink fit . It worked well and maybe you could use 1/2 "copper as a union. I described my system on remote living a couple months ago. Check it out. Jungle Bill

### [Hot water heating element temp. ?](#)

By [Dave B](#), Section [Homebrewed Electricity](#)  
Posted on Tue May 13th, 2003 at 05:17:34 PM MST  
Does anyone know ...

[Water Heating](#)

the surface operating temperature of hot water heating elements, specifically a 120 VAC 1500 watt element at full power ? I will be testing these with the variable AC from my alternator, I know they should be submerged to avoid burning them up and need to see if I'm in the ballpark with the temp. range etc. I know I can measure current, voltage etc. but wondered if anyone knew the surface temp, might be easier for me to test if things will work for me as planned. Thanks, Dave B.

[Hot water heating element temp. ?](#) | 6 comments (6 topical, 0 editorial)

heater element surface temperature ([none / 0](#)) ([#1](#))  
by [mkseps](#) on Tue May 13th, 2003 at 06:35:49 PM MST  
([User Info](#))

The heater element is no different than the surface element of an electric stove. If energized in open air, the element will get red hot indicating a temperature of over 1200 degrees F. If left in this mode, the element will burn itself out.

Heating element ([none / 0](#)) ([#2](#))

([User Info](#)) <http://www.windstuffnow.com/main>

Dave, simply pull out one of the elements from an electric stove and use this as a test unit. Measure ohms on the unit and calculate the wattage it will handle... If you get it to glow your in the ballpark.

Why is it that the stove coil doesn't short out when you place a pan on it? Ok we won't worry about that at this point...

Have Fun!  
Ed

Thanks guys, I actually did pull one of my stove elements out and checked it out. Shows 38 ohms for the small element. I can get one hot water element quite hot spinning the alternator by hand but at 10 ohms I'm doing alot of work just keeping it at approx. 100 RPM. I've got alot of experimenting to do and when I get my coils and magnets epoxied down I'll run up some real tests with a 2 HP electric motor I've got access to. Adding elements, series/parallel coils also along with adjusting the air gap to try to get where I'm going. It's a give and take but looks like a large blade set with alot of torque and not so much speed will be the way to go. I can spin up my alternator to 90 VAC no load by hand at 300 RPM. I'm hoping to pre-heat water and have the room for 100' tilt tower. Any thoughts on the size blade set and profile with as much torque as possible but still capable of 300-400 RPM ? I'm having a great time thanks to all of you out there. I'll post test results as I go.  
Dave B.

A little more info. ([none / 0](#)) (#4)  
by Dave B on Tue May 13th, 2003 at 11:37:28 PM  
MST  
([User Info](#)) <http://www.madbbs.com/users/bruggelog>

The stove heating element is rated for 240 VAC and @ 38 ohms. Doing the math this is approx. a 1500 watt element. The hot water elements I have purchased for testing are 120 VAC and at 10 ohms rate at approx. 1500 watts also. Is there an easy way to determine the torque needed to start and sustain an RPM of say 300-400 ? Will start up always require the most torque assuming I will be loading this with the low resistance of the heating element(s) ? I'm trying to keep this simple without variable pitch mechanisms etc. but switching or varying the load electronically depending on the RPM will be very beneficial for start up and efficiency at speed. I welcome any ideas or thoughts on a working circuit, I have very little time to bread board too. Just not enough time to play. Thanks, Dave B.

HP and Torque ([none / 0](#)) (#5)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on  
Wed May 14th, 2003 at 07:37:49 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Horsepower and torque:

$HP = \text{Torque} \times \text{Rpm} / 5252$   
example: 2hp = 35 ftlbs x 300 rpm / 5252

$\text{Torque} = \text{HP} / (\text{Rpm}/5252)$   
example: 2hp / ( 300 rpm / 5252) = 35 ftlbs

$\text{Rpm} = \text{HP} (\text{Torque}/5252)$   
example: 2hp / ( 35 / 5252) = 300 rpm

Have Fun!  
Ed

([User Info](#))  
<http://www.madbbs.com/users/bruggelog>

I'll be looking over all this good stuff and will be having alot more fun testing things out very soon. Any thoughts on a switching circuit to vary the load at different RPM or voltage ? I think you see what I'm wanting to do. I'd pay you if you wanted (another) little project. Sure sounds like you have the means but like most of us maybe not the time. Thanks again. Dave B.

Molecular friction heater

Say, does anyone know of anyone who has built this simple heater and achieved results?

<http://www.fortunecity.com/greenfield/bp/16/rotary.htm>

Peace,

TS out

Frenette ([none / 0](#)) ([#1](#))  
by [windstuffnow](#) ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Mon Apr 21st, 2003 at 06:55:36 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I built one several years back. It made a temperature of 130 degrees. As far as heating a whole house for \$30.00 a month... won't happen. You can take a copper, brass or aluminum plate and make a steel disc with magnets installed just like an alternator. Once the magnets are spinning close to the plates you'll get tons of heat. Much easier to build also. Submerge the entire system in a liquid and circulate the liquid through the house. But there is no free ride in either case... you put a half horse or more into it and you'll get less out...

Fun projects though...  
Have Fun as always...  
Ed

## [Novan solar hot water](#)

By [Wyomingbob](#), Section [Remote Living](#)  
 Posted on Sat Apr 19th, 2003 at 09:27:30 PM MST [Water Heating](#)  
 From Reagan's first term...

...comes an orphaned solar hot water system that needs a home. I am in market for same. But having a devil of a time finding information on this system. Perhap's y'all can help.

The bulk of it is called the Novan Optimizer -- allegedly the Lexus of SHW in the early '80s. Manufactured in Boulder, CO. System consists of: four 4x8 fin-type collectors, with the pebbled glass (which I've NEVER understood). A counterflow-type heat exchanger (probably double-walled), pipe-inside-pipe variety. Grundfos circulating pumps (2) and zone valves. Fluid reservoir, approx 30" long x 12" diameter, which was said to contain an "oily substance." Now empty.

Questions:

Know anything about this system?

Have any of you heard of 'Bray oil,' apparently used in lieu of Glycol on some old systems -- especially Novans? Could I flush the system somehow & switch to Propylene Glycol? Reckon the whole system, including two old Bradford White solar storage tanks (80 and 120 gallons) is worth \$3000? Or should I go w/ a smaller, new system? (I have a hankering for the Thermomax Mazdon system w/ dual-heat-exchanger tank, but that's gonna hurt to the tune of \$7000. Owwwch.)

Re: Novan solar hot water ([none / 0](#)) ([#1](#))  
 by Anonymous Hero on Mon Jun 30th, 2003 at 05:29:26 PM MST

I also inherited a Novan solar hot water system about which I know nothing. Can anyone supply any info on this system or manufacturer. I don't think mine is installed (or maybe adjusted) correctly because even on hot (100 degree) clear sunny days, the bottom half of the storage tank (80 gal) does not even get up to 60 degree even with no hot water usage.

([User Info](#)) <http://www.windgeny.com>

Here is a link to a pdf file which might help.

<http://www.hotwaterproducts.com/HTP/Pdfs/925%20controlled%20munchkin.pdf>  
I am doing hot water heat in a garage at present which iam using a gas hot water heater an expansion tank,temp sensor,a bleed valve to remove air,and a grundfose pump,a line voltage thermostad,and about 300 hundred foot of pex tubing which is tied to the wire in the concrete.You should use about one foot of tubing per one square foot of floor space.You would probably be better off buying product from a heating and plumbing supplier tha on the web!I have tried to find good info before but couldnt. Cant figure out how to post a pic!

radiant floor heat ([none / 0](#)) ([#2](#))

by [Anonymous Hero](#) on Wed Apr 2nd, 2003 at 10:01:12 AM MST

My next house will use radiant floor heating, so I've been doing the research on the proper tubing, pumps, solar assist, etc. Nice to know someone got the job done. Any specs on your pump? The tubing itself is cheap enough, it's all the commercial control circuitry that costs a fortune. thanks, troy

Here is a site with some nice units which you could put on your outside walls, <http://www.aimradiantheating.com/store/slimline.html> or you could epoxy tubing to allunium strips or solder copper pipes to copper strips,you could make a press for alluminum or copper by notching a piece of wood say half an inch then for experiment sake try a strip cut out of a beer can laying it over the wood and pressing it with a dowel rod down into the groove that way making a snap on fin system, you can also buy these for under floor heat! Good luck

## [Need circuit to switch between pump/gen turbines](#)

By [visionarynz](#), Section [Remote Living](#)

[Water Pumping](#)

Posted on Mon Dec 22nd, 2003 at 02:01:27 AM  
MST

something with two momentary inputs that will latch each way

I'm after a circuit that will switch a water source between two different turbines. One turbine is pumping water mechanically (a long way up) to fill a water tank, and the other is for power generation. Switching the water supply between these two turbines will probably be done with some sort of solenoid, but the circuit only needs to switch a relay, which will control it. I can solder it together, all I need is a schematic.

Now I'm guessing that a circuit to do this job will use logic gates, and it should be fairly simple, but I don't know enough to design it from scratch.

There will be a water tank with a magnetic float, and two reed switches. One reed switch will be at the top of the tank, and one will be at a lower level, probably about half way. What it needs to do is switch the relay one way when the float comes within proximity of the top reed switch, and then switch it back the other way when the float gets down near the lower reed switch. The input of the reed switches will be momentary, so it needs to latch one way, until the float gets back to the other reed switch. This also means I can have a momentary push button wired in parallel with each reed switch to click the relay one way or another when the water level is somewhere in the middle.

All going to plan, this setup should keep the tank between the upper and lower levels, and divert the water supply to another turbine for generating power whenever the tank reaches full. But not be switching back and forth every time a little bit of water is used from the tank, only when the tank gets down to the lower level, which will be about 1metre (3feet) lower. Also changing the mechanical pump to an electric one is not an option at the moment, and I think this setup could work just as efficiently and be much cheaper anyway. I've looked through a lot of schematics on the net, but I haven't been able to find one that does exactly this. Any links/help would be appreciated.

Visionarynz,

I would use a latching relay, say 12v, this will have normally open and normally closed contacts.

Each alternate pulse will latch then unlatch the relay, simple and faily foolproof, that said there are others on this board much less electronic challenged than me so hang on till one helps out.

regards Allan

([User Info](#))

Despite my crude drawing. You probably could do this....

The N.C. contact would be you state changer.

The lower limit switch would unlatch the whole deal.

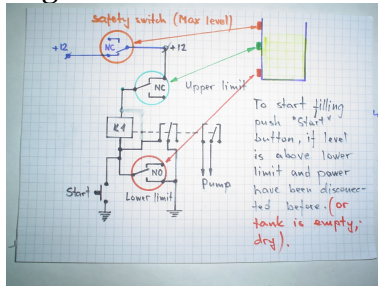

Cya,  
Chris

You might use a pressure switch from a water automatic system. Basically you only have to measure two different water pressures and switch the electric current on and off?

[membrane pumps](#)

By [bewotec](#), Section [Homebrewed Electricity](#)  
 Posted on Thu Dec 18th, 2003 at 07:07:23 AM [Water Pumping](#)  
 MST

Hello there.

Here one guy is making windpumps with homemade membrane pumps. These are 30-40 cm diameter, 10 cm high cylinders, which tops are from flexible plastic (gum). Its axle is moving up and down, like in a piston pump. But because it has no moving surface, it is better to maintain. (surprisingly high lifetime for the flexible top)

Anybody has a clue about plans of a membrane pumps, which can be made at home? (the guy of course keeps everything secret)

or do you have any opinion about it?

thx,  
viktor

Trash Pump ([none / 0](#)) (#1)  
 by [wdyasq](#) on Thu Dec 18th, 2003 at 07:53:29 AM MST  
[\(User Info\)](#)

There is a common type of membrane pump known as a -Trash Pump- in hte construction industry. Each pump chamber consists of and inlet flapper valve, an outlet flapper valve and the pump diaphram.

I have replaced diaphragms in these pumps, but never because of wear. They have all rotted due to old age.

Each type of device has its' own properties that may or may not make it superior in a particular use. Diaphragm pumps can have high suction and high head but are usually limited in the volume they can produce. In addition, large inlet and outlet valves can allow the passing of solids larger than centrifical or piston type pumps might allow.

ROn

I think it is easier to build at home as a piston pump, so i will try to make one.

(the thing is, that here there is no piston or thrash pump for reasonable price, at least i found no piston pump at all...)

Have a cylinder and two valves and a gum membrane and will see it.

viktor

## [HomeBuilt Float Switch - What about low level cutoff?](#)

By [oirlandos](#), Section [Remote Living](#) [Water Pumping](#)

Posted on Fri Dec 12th, 2003 at 05:31:18 AM MST

Hi folks, first of all let me apologize if this is off-topic.<br>

It has to do with the handy-looking (and cheap!) floatswitch made by the guys and described on [http://www.otherpower.com/float\\_switch.html](http://www.otherpower.com/float_switch.html) .

Here's my question: I can see this float switch working well to prevent overflow in a cistern - but what about turning off the pump when the water level at the spring got low?

Wouldn't this mean having the reed switch sticking to the film at some point? I'm thinking along these lines - the switch has to operate at a low level so it's mounted low down in the PVC tube. At some point the water level rises, the film rises with it until it touches the reed switch - then it sticks.

How did you get around this? Or am I totally wrong?

Hi,

What about using Hall Effect transistors and some small neos magnets at the positions you want off or on? A simple flip flop driving a MOSFET or other to activate or stop the pump. Put the magents in the end of a plastic dowel on a hunk of all thread brass, fine tune as needed for different water levels. Either thread the plastic dowel or double nut with brass nuts.

The hall effect sensor and flipflop are a great idea - BUT in my location I've had outdoor electronics fail so many different times from lightning that I hesitate to use them for a critical application like a float switch....if it failed and I didn't notice, the pump could burn out. I also worry about the extremely harsh, condensing environment -- tho I suppose the entire thing could be potted in epoxy.

However, I think my next electronics project is going to be a water system status panel. The challenge is that the house is 480 feet from the spring. I think I have enough wire in place to make a system monitor that will show -- pump running or not, status of both float switches, and a sensor at the cistern to show that water is actually flowing.

Re: HomeBuilt Float Switch - What about low level ([none / 0](#)) ([#2](#))  
by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Sat Dec 13th, 2003 at 11:24:37 AM MST  
([User Info](#))

Perfectly appropriate posting for here.

I did have a prototype of this low-level switch working at one time. I didn't want to have the reed switch submerged, OR the magnet (some concerns about possible contamination of the water by epoxy, or Neodymium if the magnet coating failed). So I used a rod with a magnet on it that extended above the water level inside a PVC tube, and a reed switch on the side of the tube. When the water level dropped, the magnet lowered to next to the reed switch and closed it, and both were still above the water line. There was an extension of the bottom of the rod, too -- long enough that the magnet could not travel down past the reed switch and accidentally turn the pump back on again, and so that it could not stick to the switch.

In any case, my problem was ice....the upper level of my well rings is still an icy environment and the water vapor condensed in the tube and froze, causing failure--clogged the whole tube with hoarfrost. I did not find a way around this, other than the possibility of re-building my whole spring house with more space and more insulation. So the project was never written up for our web pages.

In any case -- SJE Rhombus sent us new replacement float switches, one for low level and one for high. That's my next project -- installing them. Time will tell how well they work.

Hope that answers your question.

Cheers  
DANF

I have a deep well 220 ft water is at 40 ft my question is

I have a deep well 220 ft water is at 40 ft my question is i am completely off grid and run a trace swplus 2524 inverter that has 4x starting amps. i probably need to run a ac pump as i dont have much room for a bulk tank at the house to store from a slow pumping dc pump will this inverter run a 120 vac submersible pump or should i get the step up transformer trace offers and run a 240vac submersible? or is it really worth my time to try and set up a bulk tank and slow pump to it then pressurize the house with a dc pump? thanks for any help

I have a holding tank on the hill side above my house and when the pump comes on it pumps up to the tank which then gravity feeds back to the house.

I think the most important thing is actual watt/amp output of your inverter

verses the starting amps of the submersible pump you want to run.

The pump motor can pull 6 to 8 times more amps starting than it takes to run it.

As for switching to 240 it might be better for your pump motor but

won't reduce the watt load on your inverter.

RobC

Re: Deep Well pump's ([none / 0](#)) (#7)  
by desertratjack on Thu Nov 6th, 2003 at 08:06:45 AM MST

You might want to look into using the no surge, slow start ac pumps from Grundfos. They are as efficient and lower cost than a Shurflo dc pump. They come in many models for 120 volt and 240 volt and different depths and pressures. I used to use a small dc nemo submersible pump to pump to a holding tank and then a pressure pump (shurflo dc). Now I pump with a 1/2 hp Grundfos from 145 feet to a pressure tank. One pump that should last for 20 years versus two pumps that I had to replace every few years. I've also gotten a few for customers tired of replacing dc pumps and having well drillers getting too large and inefficient pumps for their solar systems. These pumps have been available for the last 3-4 years and are a lot less expensive than anything else I've seen for being this efficient. Apparently they have been used in Europe for awhile.

On your system you have to see how deep the pump is and add 92 feet for a 40 psi pressure tank to get the total lift that the pump would have to be rated. Check out the pumps at Backwoods Solar. They have a few models in their catalog but more are available. I think you can run a similar system to mine (120 volt 1/2 hp) if you don't draw the well down too far. If you draw it down to 240 feet you may need to have a bigger pump or accept a slower rate of flow. If you are far from the inverter or need a bigger pump then you can go with the transformer after the pressure switch so it doesn't become a phantom load. By the way the pressure switch can be anywhere in the plumbing so it can be close to the inverter system and then the power is run at 240 the distance out to the pump and down the well.

Re: Deep Well pump's ([none / 0](#)) (#5)  
by Chuck on Fri Oct 31st, 2003 at 06:27:32 PM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

I have a similar well, 200 ft with static level at 50 ft. We use a dankoff etapump with 240 watts of solar and a 1400 gallon storage tank. On a decent sunny day we can fill the tank from empty, but we don't usually have to. I would rather pull from a water tank than from the batteries.

The dankoff setup is a 60 cycle ac pump with 48v solar panel input. The controller does quite a job. There is no huge starting surge like on most AC pumps. The etapump will push from about 400 feet down and performance is related to how many panels (watts) you let it use. I get 3 gallons per minute at the hydrant, a bit more at the tank where the pipe is larger.

I did an unintentional test one week when I set the float wrong in the tank. The pump sprayed water out of the tank seals for 3 days without apparent harm to itself. Caused a bit of erosion (and embarassment) though.

Unfortunately, it's a little pricey.

Chuck

Re: Deep Well pump's ([none / 0](#)) (#6)  
by desertratjack on Thu Nov 6th, 2003 at 08:03:09 AM MST  
([User Info](#))

The surge amperage capability of my inverter is almost 3 times the continuous amperage. (8000 watts vs 2500 for TRACE SW 2512).

250ft well filling at 15 feet?

---

Hi,

I was just reading a posting by George (browning358) about his well (inside his new house!) so I though I'd ask you about a well question I'd had for quite a while and never had an answer to:

My brother-in-law and I share a well - thankfully the council here paid 75% of the cost of the drilling, pump & piping. It works very well - a bit too much iron (or so a water test said) and a bit too brown (because of the iron I think).

I was surprised when the guys drilling the well said that, although they'd drilled down 250 feet, the water was only pouring in at 15 feet down.

Do you think this is normal? Not that anything is going to be altered now anyway - it works - water comes out of the tap! :)

Thanks,

Derek

I have to agree with Seth, much as I hate to.

Probably time to hire a competent well driller.

If its dumping ground water into that uncased well then you are polluting the aquifer with ground water which is probably illegal and definitely not very good for the health of the aquifer, you or your neighbors. At least here, all wells must be cased and grouted to avoid this exact scenario.

I think this is the wrong forum for the question and it is not a question that can be answered and dealt with responsibly online. As far as I am concerned your well is seriously broken and needs the services of a competent well technician and it needed it months ago.

I just know this stuff because we just went through it here fixing up our 290 foot deep well. This "free" well water we use got a lump sum payment that month of about 6 grand to pull it up to state specs.

Just the view from here.

Cheers.

TomW

WELLLLLLLLLL, maybe when people need to make their own power they sometimes need to have their own water supply too.

Now that you mention it some knowledge of how to stay healthy and the use of natural remedies is good. Unless, of course, you blindly trust the medical community that pushes the drug company's pills and drugs that relieve symptoms but does not heal or promote good health.

Not ruffled, just stating my opinion.

John

### Submesible Pump

Hi Folks well put an offer in on some property along with a house and shop in Northern Ontario Canada. Everything seems ok but the realstate fellow said the owner had to put a new submersible pump as the old one was fluctuating a bit. He said he is going to put it in in a couple days and I have the right to go in and check it out before I sign the papers. It is a drilled well under the house. There is a crawl space were I can easily get at it and the well is 250 feet deep. It will come with a health inspection on the water. I was wondering how a fellow would go about checking the pump out and maybe how much water is flowing in the well if possible. This part is a bit new to me. Anyone that has one I would appreciate hearing from them. Also any info on checking a septic to see if it works well would be appreciated. Thanks George.

by robp on Mon Oct 20th, 2003 at 06:55:16 PM MST  
([User Info](#))

Never heard of a drilled well under a house either. Many older places up our way (South Eastern Ontario) have dug wells on veranda's or in summer kitchens but these would be over 90 years old.

hello Browning358. i would check with an actual well driller how to determine your flow rate in the well. as far as putting in a new pump, it is done with special black plastic pipe made for wells. lowering in the pump on a sharp 90 degree is not easy but quite duable. hope this helps.

zubbly

Re: Pump Info ([none / 0](#)) ([#4](#))  
by mkseps on Mon Oct 20th, 2003 at 08:29:09 PM MST  
([User Info](#))

I can't imagine a well drilled that wouldn't allow for some direct vertical access. It is possible that someone built a porch over it, but assuming you can gain access to it, this is a procedure to follow:

Open the access to the well and lower a weighted float into the well on a good nylon cord to find the well water static level. Using a calibrated measure (like a five gallon bucket) begin filling the bucket with water at full volume, counting how long it takes to fill the bucket(s) in one minute while maintaining a steady water pressure of let's say 35 lbs. This will give you the yield of the well in gallons per minute. 5 gallons is close to acceptable, 10 gallons would be great.

Let the pump discharge at full volume for as long as it takes for the water drawdown to stabilize. This will tell you the well capacity. While you are doing this you may want to check the water temperature. That temperature should be within a degree or two of the average air temperature in that region. Check with the weather service to obtain the average temperature. Remember, a well 250 feet deep does not mean that's where the pump is. It is possible that the pump is only 100 feet deep in a 250 foot deep well.

Have a well driller verify this. Lacking a well drills log, I would suggest you have a certified well drilled give you the true well specifications so you can make proper choices. I also suggest that the 'downpipe' be of copper and not plastic unless someone can guarantee that that plastic pipe can withstand the starting torque of the motor.

Gene

Re: Pump Info ([none / 0](#)) ([#5](#))  
by signweld on Tue Oct 21st, 2003 at 05:53:59 PM MST  
([User Info](#))

Black "poly" pipe is quite common around here (NY USA) and as for torque, they almost always use a rubber torque arrester that goes down with the pipe so the wires & pipe don't rub raw. The plastic pipe will bend quite a tight radius, and you could always cut a hole in the floorboards (or remove one) if you had to. I've put 1" poly pipe down the hole with only 4 feet of head clearance in the summer. Murphy's laws says plastic pipes are stiff in the winter and don't ever break in good weather. As for recovery rate, run the pump till it runs dry, wait say, 6 or so hours and start it back up & measure how many 5 gal pails you can until it runs out again. This will tell you the recovery rate. This is best done in hot dry weather when water table is lowest.

good luck  
signweld

by browning358 on Wed Oct 22nd, 2003 at  
12:56:25 PM MST  
([User Info](#))

Thanks folks for all the help. The owner of the property says he has ordered a new pump and is installing it on Saturday of this week and we have seven days after that to check it out.

Saturday is the day they sign the house offer as the fellow has to wait for his wife to get there to sign also. So in this household we all have our fingers crossed it goes through as our home is sold right now and we don't have anyplace to go. Along with that we have lived here for over twenty years and one gathers up a lot of things. We have to be out of here at the end of November so we can't fool around too long. I guess the only other solution would be for us to rent a place if this deal falls through and then go looking again through the winter or spring of next year. Give us a bit of a breather. That is if we can find a home to rent. I guess you can tell we are real nervous here. I am not a young chicken anymore or my wife and I have to tell you this has been real stressful on us. Well thanks again. Will keep you all up to date as things unfold. George

MST

[water wheel power](#)

Is it possible to build a water wheel that generates enough power to run a 12 volt water/sump pump? The reason for this would be to use the pumped water to run the generator and the water falling from the wheel could aerate my 550 gal fish tank.

Water from a stream is channeled into a pipeline to gain enough head (the vertical distance the water falls) to power the system. The water passes through a nozzle, where it accelerates, strikes the water wheel, and turns the generator shaft.

To determine the power available at a site, head and flow measurements must be taken. Flow is the rate at which water moves, measured in liters per second (l/s) or gallons per minute (gpm). This can be measured by channeling the water into a pipeline, then into a container of a known volume, noting the time it takes to do so. A weir can be used to measure flows in larger streams. Head can be measured by using a transit or by sighting along a level and using a measuring tape.

I believe head means the amount of drop in the water. Water has more force to turn your dynamo/alternator if it drops some distance.

Some folks use a pipe and channel the water through it. Then it drops and forces the wheel to turn.

I think drop is often dictated by the geography of your water feature.

I'm sure somebody will correct my misstatements.

Good luck!

Bach On

I believe the original poster wanted the "pumped" water to run the generator then let the water fall into his fish tank. Basically the way I read the post, he didn't speak of any outside water source to run the wheel. So no it wouldn't work since you would be coming into the realm of "free energy" machines.

([User Info](#))

If your stream is steady you dont need to run any water through a pipe that would be for a turbine,not a water wheel. You can use a simple undershot wheel. That is where the wheel simply sits in the stream and the water moving under it turns the wheel. Not fast of course but lots of torque. A simple gearing up to a small PM generator would be simple to do and would work fine for your needs. The 12 volt DC could then be used for aeration of the fish tank,pumping water or what ever you need. Keep in mind that water power is pretty constant unlike wind and your power output will add up even with a small generator. Good luck and have fun.

Re: water wheel power ([none / 0](#)) (#9)  
by woodsman on Thu Sep 4th, 2003 at 01:39:38 PM  
MST  
([User Info](#))

Hello,

I do not have an existing stream of water. The water flow to run the waterwheel would be supplied by the 12 volt water pump. I wanted the water wheel to run a generator of some sort to power the water pump. Then the water splashing/dripping would do the aerating.

[Water Pumping](#)

**Bike Pump**

You can make a "normal" bike pump pump water easily by inverting the seal. Normally they have a sort of one way valve built into the cylinder, but if you move the seal round the valve no longer works so the pump can suck water in and push it out. You might need to glue the seal onto the plastic if it is for long term use. Still needs one way valves for controlling the flow....

You can also use a single- or double-action Bimba air cylinder as a water pump. DanB had one of these set up years ago, before we owned any digital cameras, so we don't have an pics. He just put an eccentric pulley on it and ran it with a 12vdc windshield wiper motor to pump water to his house.

Cheers  
 ADMIN

Think I can hook a car water pump to a lawnmower engine?

People hook alternators to lawnmowers...so why not a car water pump? :) If I was to put a metal plate over the opening on the back of the pump, (where the engine normally would be) and then hook it up to a pulley with a lawnmower engine, would it work? I've never actually seen a water pump not attached to the engine...I'm just going by pictures I've seen online. If it worked how much water do you think it would pump?

[Car water pump?](#) | 3 comments (3 topical, 0 editorial)

Re: Car water pump? ([none / 0](#)) ([#1](#))  
by [wpowokal](#) on Wed Jun 18th, 2003 at 05:20:35 AM MST  
([User Info](#))

While it would work these pumps are designed for low head, therefore the quantity pumped would very much depend on how high you were trying to pump it, I guess any thing over 2m would be very small flow. Say ( and i'm guessing here) one metre around 20 litres / min.

You could also try washing machine pumps, also low head but already enclosed with a pully. Oh and you could run a dozen off a lawn mower engine.

regards Allan

Hi,

I made small gold drege out of the water pump off a big block ford doing exactly what you talk about. I made the plate and welded in pipe fittings on the openings on the block side, which was bolted down on a plate for th engine. It worked great. Never found much gold though.: -)

## [Stirling Water pump Idea #2](#)

By [Junkie](#), Section [Weird Science](#)

Posted on Fri May 16th, 2003 at 12:06:29 PM MST

[Water Pumping](#)

Another idea for a Stirling water pump.

Hi,  
I have another idea(two actually) for a Stirling water pump using a floating lever to open and close two valves. Each valve would let hot or cold air into the main cylinder. The hot and cold air being let into the main cylinder would make the air expand and contract, forcing water out, and sucking water in. I put the springs there to try and stop both valves being open at the same time.

Anyway here are some animations of what I mean...

### [Lever type stirling](#)

This animation(above) lacks springs between the blue part of the valves and the red part(which touches the outside of the cylinder). The springs would push the red part as high as possible. The blue part which actuates the lever (and then the valves) is floating on the water.

### [Another idea](#)

Also the springs are missing on the valves in this animation. Your ideas/thoughts appreciated!

-Chris

Solar water pumps? ([none / 0](#)) ([#5](#))  
by hvirtane on Mon May 26th, 2003 at 01:51:29 PM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Your animations are really nice.

I see no reason, why these designs would not work.

There are many designs of water Stirlings available. If you will look for 'liquid piston Stirling engines' you'll find a lot of literature.

I've been playing with other ideas of solar pumps as well.

There is one post by me on 'the old board' concerning some ideas:

[http://www.otherpower.com/cgi-bin/webbbs/webbbs\\_config.pl?read=15026](http://www.otherpower.com/cgi-bin/webbbs/webbbs_config.pl?read=15026)

### [Septic system depth](#)

By [Wyomingbob](#), Section [Remote Living](#)

Posted on Sat May 3rd, 2003 at 07:18:33 PM [Water Pumping](#)  
MST

I'm getting mixed messages on freeze-prufing a septic system

I hear leachfields work better nearer the organic layer of topsoil, and I really don't want to excavate deeper than necessary, but my tank supplyer here advises burying the septic tank at least 30" below grade. Add the 5" of tank height, plus extra for a gravel bed, and we're lloking at an 8' deep hole. Then the D-box and leach fields will need to be very deep to maintain gradient.

It gets bloody cold here, yes. The soil is limey sand with cobbles in it, so drainage is great. Question: would I be better served with the deep installation, or should I risk a shallow install andbox it with foam, or what? I also worry about heat loss thru the manways (polyethylene tank). Desperately in need of advice!

[Septic system depth](#) | 3 comments (3 topical, 0 editorial)

Our System ([none / 0](#)) (#1)

by TomW on Sat May 3rd, 2003 at 07:58:34 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Bob;

Wherever you are you probabbly have to follow some darn code or another.

Having said that I will describe our system as I understand it. It was installed 4 years ago at great cost and to code, etc.

The 750 gallon concrete tank is buried such that the top is under maybe 4 to 8 inches of sod and the actual concrete lid is nearly flush with the surface. We have a planter on top to mark and cover the cleanout lid.

The drainfield is 18 inches deep and there are 2 runs of about 200 feet each. Its the minimum allowable septic system for a residence and sized for 4 people I believe.

It gets damn cold here for months at a time and water lines need to be 4 feet or deeper minimum. So apparently at least in our loamy soil the freezing isnt a problem. I think it needs to be close to the surface [drainfield] to operate properly.

Just how I remember seeing it done. I am no expert at all.

Cheers.

TomW

Simple Stirling(maybe solar) pump idea.

Hi all, I have an idea for a simple stirling pump, I have no idea if it will work, and I've never built a Stirling engine. I have made a little animation [here](#) The idea is the the air is cooled and contracts sucking water in, the displacer which floats on the water moves the displacer so the air is on the hot side. That should force some water out.

What do you think ? I dont think the air will contract enough to suck a decent amount of water in ?

-Chris

[Stirling Water Pump](#) | 3 comments (3 topical, 0 editorial)

sterling water pump response ([none / 0](#)) ([#1](#))  
by Fancy Pants on Tue Apr 29th, 2003 at 08:42:02 AM  
MST  
([User Info](#))

Well, if you know me, I like anything Sterling, and a zillion other ideas.

I think the water would keep it cool enough to run 24-7 and smoother, maybe faster, and maybe give it more power, because of the temp changes drawing the water.

But this might first create some problems too with standard designs not made for pumping and that kind of cooling.

But I think a few minor design changes can really become something, using the pumped water as a coolant too.

Then some old used cooking oil and a wick is all you need.

Too many ideas ([none / 0](#)) ([#2](#))  
by Junkie ([madscientist@blownup.com](mailto:madscientist@blownup.com)) on Wed Apr 30th, 2003 at 03:29:56 AM MST

Play around with what you want it to do and how that could be accomplished best on paper or Cad program. Making any changes with the water in mind, and the pumping, what ever your needs are.

If you don't care how fast it pumps, it might do it with out the flame wick, depending on the water temp, (vs. air temp) run them backwards on a snow cone, ya know? Stick a big one out a hole in the wall and run my kin folk clan's Cylinder Heater all winter long, free. Dig?

[Centrifugal pump](#)

By [Techstuf](#), Section [Homebrewed Electricity](#)  
 Posted on Fri Apr 18th, 2003 at 01:32:52 PM [Water Pumping](#)  
 MST

Centrifusion or just Confusion?

After careful consideration, I find the following site to be one of the most intriguing and informative sites I have ever come across:..... <http://www.frank.germano.com/>  
 ..... Kudos to Mr. Germano for choosing such a brilliant man as Viktor Schauberger to emulate. As I lack the resources to recreate the complex whirl tube structures....I propose the following for any that are interested: Imagine making a prototype centrifugal pump from 3" id pvc pipe. Take a 1' piece and attach to an elbow piece and then join to a 6' piece. Now duplicate the current assembly so that you have 2 elbowed pipes. Join them together with hose clamps at the 1' sections such that they are back to back with the 6' sections pointing directly opposite one another. Attach an apparatus for hanging the assembly such that it is able to spin freely with the two 1' sections back to back facing downwards above a cistern of water and the two 6' sections parallel with the water's surface pointing away from one another. Provide a motive force for the assembly to spin. Attach choke tubes or other such venturi effect nozzles to the end of the tubes so that the water is constricted somewhat and induced to increase it's flow speed and be directed upon exiting the ends of each tube in a manner that supports the spin direction of the assembly. Something to push against here such as a cylindrical vane assembly or other such beneficial arrangement to augment the forward motion of the spinning tube assembly would be beneficial. So, what we are trying to do is tap into the power of the centrifuge to extract water from a static source via centrifugal force induction to migrate outwardly where the compression force on the water is quantized such that at the outer periphery, the massive pressure is used to spin a turbine assembly to provide electricity to the motor that spins the assembly or used to directly augment the spin of the assembly via vector jet dynamics. Surely, one can already see potential uses in a variety of geometrical configurations such as upright funnel within funnel and disk arrangements that would magnify the energy potentials involved..... The whole idea being to provide a "liquid flywheel" that instead of being spun up to provide energy storage release with resultant speed decrease, is used to constantly replace it's loss of mass in that a constantly outwardly migrating mass, ie. water, is used to produce energy. I believe that if the process is done correctly, high efficiencies can be observed..... Peace, TS out..... PS. this is not to say that, in my opinion, one can improve upon Schauberger's results via this method, only that one might find a simpler design that may work.

Did the greeks really get 500 gallons of water a day from a big pile of rocks?

Rex has really done some research...

<http://www.rexresearch.com/airwells/airwells.htm>

Some good schematics to be had here. Peace, TS out

Hi,

this article you have pointed out is really good.

Do you know about good articles available on the subject

'To use a wind turbine to pull air through the pipes, something similar as in Courneya's first air well?'

Hannu Virtanen

I can see how they might have. It amazes me the amount of water which will collect in my boat here in Florida due to condensation between the inner and outer fiberglass hulls. Maybe 5 gallons in a couple of weeks. There was a newspaper article recently about an abandoned boat sinking at dock solely due to collected condensation. I had a hard time believing the article for other reasons, but it could happen. Chuck H.

It took me a couple of days to click through to that page but it has some amazing old technology.

Air Wells, Fog Fences, Dew Ponds. Simply amazing low complexity water resources.

Been pondering a solar distiller for drinking water but may attempt to devise something along these lines.

Thanks.

Cheers.

### [Water well advice needed](#)

By [Wyomingbob](#), Section [Remote Living](#)  
Posted on Sat Apr 12th, 2003 at 10:31:16 AM [Water Pumping](#)  
MST

A long way to drill for water this bad, but....

I'd appreciate a little wisdom toward installing a submersible well pump. Basics: 135' head, 5 gal/min well; 3/4 hp Flotec 4" submersible pump (3-wire, 230 VAC), connected to an off-grid power system. Only 60' to the house. It gets really cold here -- frost line approx. 50" deep.

Thinking of a 'pitless' install with supply lines and cables just laid into a trench. Must the pipe be laid fully below the frost line? Will proly share trench w/ solar hot-water supply & return lines; perhaps box the whole bundle in rigid foam? Tape power cable to well supply pipe as 'heat tape'?

Drop pipe: prefer the spooled poly pipe; does that work okay hanging from a pitless connector?

Supply pipe (well to house): someone recommended either copper or galvanized over PVC, as they can be thawed via electric current if they do freeze. Thoughts?

Electrical: I want to put the control box in the pumphouse & just run UF cable from house to well. AWG 12-3 should suffice, shouldn't it?  
TIA!

pitless ([none / 0](#)) ([#1](#))  
by troy on Sat Apr 12th, 2003 at 10:46:43 AM MST  
([User Info](#))

I installed pretty much the same setup in Ontario Canada, which is actually less cold than where you are. I elected to go with the pitless adapter rather than a heated pump house, and it worked beautifully. I used 1" poly down the hole and in the trench. I would want it below frost line though. Installing an insulated box/channel/tunnel of say, 2" blue styro should do it too. And don't forget the safety rope to the pump itself. Have lots of fun! troy

Oh yeah Bob, I forgot to mention that I used double hose clamps in the well, and made absolutely sure they were top quality clamps with both stainless screw and stainless band. Lots of them skimp on the screw and it rusts out in wet conditions like a well. But hey, I've seen you're high quality work, and I expect you knew all of that already. Good luck and have fun! troy

pump application info ([none / 0](#)) ([#3](#))  
by mkseps on Mon Apr 14th, 2003 at 06:00:19 PM MST  
([User Info](#))

Your choice of 12 ga wire is a good one. By my calculations, you have 60 ft. to the house with 135 ft. down the casing. This gives you a total of 195 ft. Your pump consumes about 6 amps at 230 volts. With a 2% power loss in the wire this will give the pump motor a voltage of 225 volts with a power loss of 28 watts and a load power of 1352 watts. I suggest that you use a 1 in. copper down pipe as well as copper into the house. Plastic pipe is only recommended if you use safety rope supporting the pump as well as anti rotation blocks to prevent the motor torque from twisting the down pipe during startup

[Tower math ?](#)

By [Old F](#), Section [Homebrewed Electricity](#)  
 Posted on Wed Dec 31st, 2003 at 05:02:32 PM MST [Wind](#)  
 counting my toes and pulling my hair : )

Tower math ?

I am crunching some numbers for tower loading and I have run in to a snag.  
 I have work out the thrust load of the wind generator at the top of the tower  
 And the tower drag load.

Now here is the snag the example I am working from says to add the thrust load  
 and tower drag load together and divide by 10 this come from the base being 10 foot  
 square to come up with the lifting force on the two legs opposite the pivot point.

This example is for a four sided tower and I have a three .  
 My base triangle is six foot  
 on a side do I divide by six to come up with the lift force or is there more to it than that. I am thinking there is.

Old F

[Tower math ?](#) | 5 comments (5 topical, 0 editorial)

Re: Tower math ? ([none / 0](#)) ([#1](#))  
 by [kell](#) on Wed Dec 31st, 2003 at 06:15:12 PM MST  
[\(User Info\)](#)

The tower in the example has attachment point(s) 10 feet from the axis of pivoting. Yours has an attachment point 5.196 feet from the axis of pivoting, if I did the geometry correctly. Now if in the example dividing by 10 gives you the total lifting force at the attachment point(s), then for your own tower, dividing by 5.196 will give the total lifting force at the attachment point. But one point (the triangle vertex) will take all the force. The example tower has two feet attached to the ground, or a ten foot connecting rod attached to the ground or however it's built. And I hope your load figures are in foot-pounds, so that when you divide by feet, the final result comes in pounds, which are a unit of force. Only way it would make sense. Foot pounds are a measure of torque. Like if you apply 50 lbs force to a lever at a point 30 feet from the fulcrum you get 1500 ft lbs of torque. If the lever sticks out 10 feet on the far side of the fulcrum you get 1500 ft lbs divided by 10 feet = 150 pounds force at the far end of the lever. Why can't I get carriage returns on this posting?

Kell;  
You asked:  
Why can't I get carriage returns on this posting?

The answer is because you need to set your comment posting format preferences to "auto format" and you likely have it set to "html formatted".

In case your not sure where that is it is between the Preview and Post buttons just below the text entry window. You can also set it in your user preferences. Cheers.

Thanks Kell

The force is measured in foot pounds. Should have said that in the first post.  
With that snag out of the way things are starting to make sense.  
And the numbers are falling in to place better than I expected.  
Tho I will add an extra 15 or 20 % as a safety factor.  
Looks like I am well on my way of meeting my goal

A 30 foot tower and from the of looks things now a free stander

Rated for an 8 foot diameter blade set in a 60 mph wind an supporting up to 200 pound of machinery.  
Now off to gather some more data on strength of materials

Kell many thanks till your better paid

[\(User Info\)](#)  
<http://timmythy.home.mindspring.com/timmy.htm>

I'm not an expert, but I'll explain how I understand it all . . .

You should have an even number of magnets on your rotor. They should be arranged with the North of the first magnet facing up, the next magnet should have it's South facing up, and your magnets will alternate North, South, North, South, etc all the way around the rotor. If you have an Odd number of magnets then you will end up with a place on the rotor that has 2 magnets that are North sitting next to each other.

What is happening here is . . . As a magnetic North passes over one of the coils it will produce a Positive voltage swing, lets call it a 3 volt positive swing for this example. Then when the next magnet which is a magnetic South passes over the same coil, it will produce a -3 volt negative Voltage swing. This has the effect of doubling your voltage to 6 volts AC. A swing from +3 to -3 is 6 volts AC. Because of this the Frequency of the AC output will be 1 cycle for every 2 magnet passes over the coil.

Highest output will come from the same number of coils as magnets, but this setup will also cause the worst cogging, which is the added drag as all the magnets are crossing all the coils at the same time, and then no drag as all the magnets cross between the coils.

To get the highest voltage, your coils should be wound where the hole in the center is the same size as the magnet. If you are winding the coils to work with the magnet like this then you will need a space between the magnets or you won't be able to fit enough coils in there.

>Do the magnets have to be an even number on the disks?

Yes, assuming you want to generate a decent sine waveform.

>Can the magnets touch side to side or is an airspace needed?

They can touch, but this reduces the flux available to induce current in the coils.

>Is there a formula for the number of coils to the number of magnets?

Several. It depends on what you want to do as to which you use. example: For single phase a coil spanning to the center of two adjacent magnets (of opposite polarity) with a center hole roughly the size and shape of a magnet works. For 3 phase it gets a bit trickier.

Look in the archives of this list for more info than you would ever want.

Chuck

Re: Axial Flux Generator ([none / 0](#)) (#4)  
by charged on Wed Dec 31st, 2003 at 06:09:20 AM MST  
([User Info](#))

Here's a thought.

Make three rotors, all with an even number of magnets on them.

Then wind a matching set of stators for each rotor. The stators don't get solid cores. Wind steel mechanic's wire on the coil form in tandem with the magnet wire. This gives you an integrated low-loss ferrous core.

Put all three on the same axle and offset them so that axle can never cog.

Each set of stators is gets a wired in series with a single rectifier diode.

The three rectified outputs are wired to a common electrolytic capacitor.

[Ed, am I close ? \(blade design\)](#)

By [Dave B](#), Section [Homebrewed Electricity](#)  
 Posted on Tue Dec 30th, 2003 at 01:34:28 AM MST

[Wind](#)

As I promised ... my alternator specs.

Ed,

My alternator outputs 100 VAC @ 400 RPM no load. My stator of 18 coils AWG 18 (series wound 100 winds each) measures approximately 8 ohms total resistance. Plugging in the power formula you helped Jerry with for a given blade set I get the following for a 12' diameter 3 blade with 14" at each blade root and tapering to 4" at the tips in a 25 MPH wind (40% blade efficiency) I get 1778 watts possible. Is this close ? Now figuring in 70% alternator efficiency I get approx. 1245 watts. Am I doing this right ? If so and looking at the blade design program of a 12' TSR-7 3 blade shows approx. 1500 watts @ 25 mph wind. This all seems to fit pretty well. Any suggestions or comments would be greatly appreciated. Again, no batteries but direct to heating element(s) through a variable load controller based on RPM. (a single 120 vac 1500 watt heating element measures approx. 10 ohms.) Thank you very much for your reply. Dave B.

[Ed, am I close ? \(blade design\)](#) | 7 comments (7 topical, 0 editorial)

Re: Ed, am I close ? (blade design) ([none / 0](#)) ([#1](#))  
 by Rich G on Tue Dec 30th, 2003 at 04:41:10 AM MST  
[\(User Info\)](#)

Hi,

Looks to me like 100 volts through a total of 18 ohms will produce 5.6 amps. The total power will be (5.6 x 5.6) x 18, which is 556 watts. 247 watts will be disipated in the alternator and 309 watts will be disipated in the load. I am asuming that the 100 vac is rms. If the alternator turns faster, say 600 rpm, and the open circuit voltage is 150 vac then 8.3 amps flow and total power is 1250 watts with 694 watts disipated by your load.

If I understand whats going on here, it would be really good if you could lower the internal resistance of the alternator. An alternator resistance of 4 ohms would increase the power to the load by 65%.

In all fairness, I don't know much about this. I have never build one and the above has nothing to do with blade design!

I would like to know more about your stator and the magnets your using. I want to build an alternator for a stationary engine and I don't have anything to base performance expectation one.

May the wind on your blades be fair!

Rich

Dave, that sounds about right on the prop. I have no experience in driving a heater element and I'm not real sure how to calculate the outcome. Looks like riches comments make sense and his numbers seem to fall in place using ohms law.

Plugging in some numbers in the blade designer, it looks like you'd need to drive the alternator at a 2 to 1 ratio to achieve the output your looking for at 25 mph. Thats more of a calculated guess.

Is there a way you can adapt it to a small engine and carry the load through the rpm range the prop would be driving it. This way you can get actual output readings at a given rpm driving the load. This would give you a better idea of what will be needed in the way of a prop. Your still guessing on the efficiency unless you can get a torque reading from the stator ( pony brake set-up), but it may at least get you closer to the actual performance.

Have Fun  
Ed

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Ed & Rich

Thank you for your information and suggestions on my aplication. I know I can't get blood out of a rock but it looks as though I could at least pre-heat or pre-warm some water anyway with hours of wind averaging 10 mph or better and a very well insulated maybe smaller tank (20 gal ?) I need to focus on getting all this together with some guessing and your help and get it flying. I'll learn more about my next one than if I keep trying to improve what I have without flying solo yet. The numbers dont lie, I can speed things up, double up the magnets (again), squeeze down the airgap, rewind a more wire efficient stator, go with 3 phase, go bigger, bigger , bigger STOP ! It's a love/hate, I'm going to the garage to work on my tower. Just one more question, do you think more of a drag type (fixed pitch) 3 blade set for lower rpm but more torque would be a better option than carving the twisted profile the blade program shows ? I'm done. Thanks again,, Dave B.

[ [Parent](#) ]

Re: Ed, am I close ? (blade design) ([none / 0](#)) (#4)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Dec 30th, 2003 at 03:17:59 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

There is good and bad to both designs. If your looking at a 10mph average the fancy prop may not reach its full potential until the wind picks up. Something like the old Aermotor mills are all torque, They seem to spin even when you can't feel the wind. The problem with those is the top speed of the rotor in a 35mph wind is 105 rpm. ( Thats on an 8ft dia unit). So on the drag type 3 blade your only looking at a TSR of 1 or slightly higher depending on the angle and blade design. You'll definately need a re-drive to get the rpms you want at the alternator. All in all your dropping efficiency. The fancy prop, direct drive is still the most efficient way at this point.

Sounds like you have a unit that could take a good bite out of the electric bill already then put up a couple solar water heating panels to offset the hot water... also put a coil in the furnace and plumb it in to a heat exchanger on the water heater.

Capture as much waste as possible and recycle it. These are some of my summer projects this year...

Have Fun  
Ed

I think I'll attempt to carve as close to the blade design as possible for a 12' rotor maybe tsr-7. I realize how important the "root" and drop is for the torque of this design. Most on this board for both ease of construction with materials available (2X) and their application (charging batteries) have not gone full blown on this part of the blade and not been sorry. I think I would be as I need all the torque I can get and the speed when possible. I know it ain't going to be cheap gluing these up with select lumber but I've gone this far so no skimping on the heart of this thing, especially 12' possibly spinning at 400 + RPM at times seems kinda scary. Any suggestions on glue and lumber and any links that could help me out ? I've been out in the garage all evening cutting & drilling tower sections, a heavy 3 sided I hope to convert to a guyed tilt up between 80-90' Going to need some creative fabricating / engineering for the hinged base but I've got some very good contacts. I also like the heat exchanger idea in the furnace, just not enough time. Any info . is much appreciated, thanks again. Dave B.

Ive gone the gluing route of gluing good boards together. It works fine. A while back I found a old cabinet at a thrift store for 5 bucks. The wood caught my eye. I tore it apart to make some blades. I found out through a search that it is basswood. No knots, very light and very fine grain and you talk about something easy to carve, its like butter and it didnt splinter. The blades I carved were out of a chunk 40 inches long by 1 3/4 thick by 10 1/2 wide. I made 3 out of this section goin from 3 1/4 to 2 inches at the tips 40 inches long and they come in at 14 ounces each unpainted. I guess this wood is fairly reasonable. i saw some on ebay. I dont know how it holds up. JB

Hi,

I think that one of the most important things is how strong winds you happen to have.

With slow wind speeds an air foil rotor is not the best, I think.

With one of my friends we made a modified 'reinikainen' wind rotor so that we used 2 x 7 (pieces) 3 m long wooden strips. Glued and screwed them crossing each other so that on the tips only 2,5 cm of the strip was on the top of the previous strip. Every second going 'west - east' was cut on the middle so was every second of the 'north -south' strip. A four blade really fast made wind rotor was formed.

I think you got the picture. A modification of these: [http://www.otherpower.com/cgi-bin/webbbs/webbbs\\_config.pl?read=14319](http://www.otherpower.com/cgi-bin/webbbs/webbbs_config.pl?read=14319) Finally the edges were smoothened a lot. The whole thing was painted well. It works on really slow wind speeds much better than a perfect air foil blade of 4 m the generator had earlier.

But of course if you often have got 25 mp/h winds an air foil rotor is better.

- Hannu

How much power from this blade?

Hi Blade GURUs

I'm intrested on how much power I could expect from this 43 inches tip to tip 3 blade prop? Let say at 25 mph. Its 5 inches at the root tapering to 2 inches at the tip. Starts out at 23 degrees at the root to just a few degrees at the tip.

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Jerry,

You beat me to the punch, I hope you don't mind me riding along with a similar request to the "blade experts". I need as much torque (power) as I can get from 0-400 rpm up to 30 mph from a 12' diameter 3 blade set. This looks like about tsr-7. Is the blade design program geared more toward "high speed efficiency" or would this be the best all around design for torque also ? I plan to heat water direct with my variable load controller NO BATTERIES. Thanks Jerry and to anyone who responds on this subject. Dave B.

Dave,

It's difficult to match the full torque range because of the cubed power coming through the blade at different wind speeds. It would probably be best to match the average winds in your area. For instance we have a relatively low average 6-12mph I typically set them up to perform best in that range. We quite often have higher winds in the range of 12 - 20 mph so anything extra is a bonus although they tend to drop efficiency as wind increases.

The blade designer program will work with all efficiencies, simply change the efficiency number in the efficiency box. I use an overall efficiency based on the alternator and expected blade efficiency so if your expecting say a 40% blade and a 70% alternator then the number to plug in would be (.4 x

Hi Jerry,

The power you'll get from a given size blade pretty much remains the same regardless of angles. The angles, however, will tell you at what speed the blade will run at a given power output or wind speed. Also, each blade set runs at different efficiencies depending on the air foil. A simple formula for finding power output is...

$.00508 \times \text{blade area} \times \text{windspeed}^3 \times \text{efficiency}$

So at 25mph your 43" blade could make...

$.00508 \times 10 \times 25^3 \times .30 = 238 \text{ watts}$

Thats assuming the prop is 30% efficient, it could be higher or lower.

Another thing to consider is the alternator efficiency... If your alternator is say 80% efficient attached to the 30% blades your actual output or over all efficiency would be  $.3 \times .8 = .24$  or 24% overall. So you'd end up with only 190 watts actual output not including any other losses.

A good airfoil will run in the 40-45% efficiency range.

Have Fun  
Ed

Thank you Ed for the great info. We have a wide range of wind here in Western NY but all charts say around 12mph annual average. Sustained winds of 20+ are very common during the winter so it's tough to guess at my design for my application. If this wasn't my first one I'd have a better feel for the specs. I have no easy way to physically measure the power or torque needed under load while I'm testing, pony brake is out. I'm going by feel and guess and just wondered if I'm better off going with more torque and sacrifice some speed, I know I can't have my cake and eat it too. This is great fun, you sold me the silicon steel a while back and I may be in the market again, I'm hooked. Dave B.

<http://www.windstuffnow.com/main>

Dave,

You can usually guesstimate reasonably well if you have a tested output on your machine. I usually make a chart for the rpm range and calculated output for the alternator. This way you have more of a calculated "guess" instead of pulling numbers out of the air and hoping for the best. Once you know your approx alternator output at a given rpm then it makes it much easier to match a blade with that performance.

As an example say your test showed your alternator was making 12 volts at 100 rpm. The resistance of the stator was say 1 ohm to make it simple, and the charging voltage was 12 volts

$$100 \text{ rpm} / 12 = 8.33 \text{ rpm per volt}$$

So at 200 rpm we can calculate what the output might be without any losses...

$$200 \text{ rpm} / 8.33 = 24 \text{ volts open (no load)}$$

Charging to a 12V battery would yeild..

$$(24 \text{ volts open} - 12 \text{ volts charging}) / 1 \text{ ohm} = 12 \text{ amps}$$

You can chart this at any rpm, I use a spread sheet to make it simple

RPM	Open volts	Amps	Watts
200.	24	12	144
300.	36	24	288
400.	48	36	432

And so on...

Then you can easily go on to matching a prop to perform in the range of your wind from

there.

Have Fun...

I have a new shipment of silicon comming in soon, I was going to pick it up but its a 5 hour drive and I didn't have the time to spend on the road. Its going to be trucked in instead.

I'll have about 500 lbs of silicon available shortly and some sample rolls which I'll list in a few days...

## [Tower wrecking](#)

By [Old F](#), Section [Homebrewed Electricity](#)

Posted on Sun Dec 28th, 2003 at 04:29:05 PM MST

[Wind](#)

Were can find a hand operated hydraulic pump?

I just got the top section of my tower done. And it is time to do some destructive testing.

I have a three inch bore double acting cylinder and a hydraulic pressure gage.

All I need now is a hand operated hydraulic pump.

I plan on bolting up the two sections on the ground and run a cable from the top to the base.

And the hydraulic cylinder will set at the center of the tower like an arrow strung in a bow.

This will be for side loading.

Then from a safe distant and behind a barrier. Just in case.

I will pump up the pressure writing gage reading an observations as I go.

With this information I can decide were to go from here.

([User Info](#))

I wonder why you intend to do this test. Do you want to see how much wind load your tower will take? Wind loading exerts external forces. The proposed test exerts internal forces.

The test you described could give you some idea how much sheer weight the tower would support, since the cable will exert a downward force on the tower at its uppermost point, as would a massive mill of some sort. But what mill is so heavy and tower so weak as to buckle in such a way?

A heavy mill poses a risk by making your tower more vulnerable to tipping!

Weakness will likely manifest itself where the sections of tower join and at the base. A tipping tower exerts the most moment (torque) at its base. Like a big lever.

The closest thing to copy wind loading and tipping would entail erecting the tower, attaching a cable to the tower somewhere between the middle and the top and pulling in a horizontal direction, insofar as possible.

Hello,  
New to this site, but i'll throw this in. Surplus Center has hand pumps with small oil tanks attached. i think they were used to lift the cabs of transfer trucks. seems they were around \$150. you might try one of the "power pak" sets used for auto body work (northern or harbor freight) Are you near a community college? they might have one or a hydraulics lab with pump and gauges. might be a good project for the class. forgive my spelling.

Hi OldF,

That's going to be a very neat tower! I like the design...

Here's a possibly easier and maybe safer suggestion - if you're just looking to find the buckling strength, you could support the tower in a horizontal orientation (like on strong sawhorses or something similar) at each end.

Then put a couple of empty barrels on top, in the center of the tower. Add measured amounts of water to the barrels until she buckles. Water is 1 kilogram per liter (or 8.34 pounds per gallon). So if you had a 50 gallon drum full it would put 417 pounds plus the weight of the barrel on it. Two or three barrels would probably do it. Or if you had an old oil furnace tank...

At least when it fails, the most danger will be from having a barrel land on you, or getting wet!

Good luck and keep us posted!

Ted.

Re: Tower wrecking ([none / 0](#)) (#5)  
by Old F on Mon Dec 29th, 2003 at 09:50:37 AM MST  
([User Info](#)) <http://www.oldf.homestead.com>

Kell

One of My design goals is a tower that is ridged enough to support its own weight and 200 pounds of mill during raising and lowering using guys just as safeties.

And not like pipe towers that are 100% guy wire dependent and are at there weakest during rasing and lowering.

I have no doubts that this design will meet that goal I want to find out what its upper limits are. Now I wont be putting any thing near that on it but it would be nice to know. Then I can start on wind loading.

My thinking is the stronger and more ridged a structure you start with for a guyed tower. The closer you can set the guys to the tower base even to the point were it take up just a little more room than a free standing tower. The guys will handle the bulk of the wind thrust load. And a ridged tower makes thing so much easier for raising and lowering.

Rob

And I am stubborn to : )

It my be hard to believe. In the same time or less than it takes to build a wind generator

You can have a nice tower to put it on. This design is a lot easier to build than a generator.

Rhud

I will check them out thanks

Monte

I was thinking about this but could not come with a handy way to measure the amount of water used I had the hydraulics laying around just needed a hand pump.

Old F

On the edge of the learning curve and loving It : )

Old F

It sure seem a shame to wreck such a nice looking tower!!! Seems like you can calculate the compression loads on 2 of those tubes and come up with a suitable number for wind loading. If you know the strength of the steel your using it shouldn't be to hard to calculate this out.

Looks like your having fun! Nice Tower.

If you've got easy access to a wrecking yard, go look at  
late '80's automatic transmission Hondas. The speedometer  
cable fitting on the transmission contains a hydraulic  
pump; you can see the two hoses coming out of it. I  
believe it is two bolts to remove the fitting. It can be  
chucked into a drill as a drive source, and I've had it to 150  
psi without trouble. Not very many gpm, so it'd take some  
time, but something to consider. Hope this helps.

Demetri  
Always be the lead dog.

by Norm on Mon Dec 29th, 2003 at 05:54:20 PM MST  
([User Info](#))

Hoist up about 400 pounds of cement blocks ....hook a  
pulley at the top ...launch a kite about the size of a hang  
glider when the wind kicks up to about 30 or 40mph. that  
ought to give you a safety factor of about 200 if it doesn't  
tip over and especially if it's a real gusty wind.Forces on  
the side of the tower should be negligable. Just kinda far  
out thinking maybe? Norm

Re: Tower wrecking ([none / 0](#)) ([#11](#))  
by Old F on Tue Dec 30th, 2003 at 10:32:52 AM MST  
([User Info](#)) <http://www.olf.homestead.com>

Oops never mind

I think its old age setting.  
I all ready have all the hydraulic power I need.  
I will just put the pressure gage on my Cad digger back  
hoe and run the engine at very low idle.  
Du (sound of palm of hand hitting forehead ).

If you haven't see a Cad digger check out the pics on my  
web site.

Thanks to all

## [Would this cheap material work for laminates?](#)

By [Sponge](#), Section [Homebrewed Electricity](#)

[Wind](#)

Posted on Sun Dec 28th, 2003 at 02:26:13 PM MST

Quick question about certain type of material :)

Hi,

I have arrived at the stage where I'm going to make my laminates. Still, finding proper material for laminations is quite in my surroundings over here.

I have found an metal strip, 1mm thick, 1.2cm wide, and like 1m long, the only suitable strip I have found at a Do it Yourself shop thing. (no idea about magnetic memory stuff)

But, I thought about another material basically without costs, which might just be as suitable as well. It's magnetic, and doesn't have magnetic memory I believe. No idea how to exactly translate this material to english, but cans with vegetables and stuff are made of it. (I think Cola cans too, although those might be aluminium). Well, a picture is sometimes better than words they say :)

(clickable)

Well, just wondering. I'm sure someone thought about it before? :)

Regards,  
Sponge

Don't know if it makes a difference or not , But  
A lot of Tin Cans are already lined with plastic on the inside  
Thin Metal, already a thin insulator applied to it . . .

The pieces of metal you use for a Laminate should  
be insulated from each other.

So , Yes it's good to have the insulation layer on  
there. But personally, I do not know if the metal in  
a Tin Can is teh best type.

Cheap though . . .

That's actually a unique idea! I tried to find out what type of steel they use in make them but didn't find anything. I would imagine its low carbon and then tin coated. Low carbon materials are easy to work with and much cheaper. My guess is it would be a good material for laminants although it would take alot of cans to make up a stator. The rings that add strength to the can may create a problem getting them tight together. If you have a slip roll you can flatten them out quite easy or a small hammer. Could be an interesting project none the less.

Have Fun  
Ed

[Wind](#)

Here are a couple of pictures of progress so far.

The tubing for the back-bone is 8x12 rectangular steel tube. The reducer ( increaser ) is a 17-1 planetary unit. The two generators started life as 480V explosion proof motors. We have extended the shaft on the first to drive the second. The first was reconnected internally to allow 240V operation and will be driven above slip speed to feed the grid when possible. The second will be converted to 480V DC and will feed heating loads and the new Windy Boy grid tied inverter. Normally only one will be in use at a time. The DC unit will help absorb instantaneous gust loads for short periods.

The main prop bearing is a caterpillar tractor ball bearing with a 5 inch bore and 11 inch O.D. The other bearing shown is the top yaw bearing.

Work progresses in fits and starts. We started late Nov. and won't have it up until early summer. I have a lot more pictures but with my connection it takes forever.

Garry

These blades are used on portable bandsaw mills the kind used for sawing logs. They buy the stuff in big rolls and then make blades out of it.  
Hard to say if it would make good laminates. They would probably give you a free sample.

They have silicon steel at salvage yards. They take apart large transformer things with sheets of silicon steel about 12" wide & 4 feet long. Its sold by the lb.  
5 cents or 20 cents I cant remember rite now.

## [Tower Fun](#)

By [Old F](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 23rd, 2003 at 04:48:12 PM MST

[Wind](#)

---

### Tower fun

Have the first ten foot section done.  
For a 30 foot guyed tower its based on the Wind Works plans for a free standing 30 foot octahedron module tower.  
That came out back in the 70s.

Many thanks to Don G for tracking down and getting permission to reprint them they helped a lot.

The vertical struts are 3/4 inch emt conduit and the horizontal triangles are 1 an 1/2 inch angle iron 1/8 inch thick. The sides of the triangles are 1 and a1/2 foot.

I went with angle iron so I would have a flats to bolt the sections together.

I put together a press using a 2 ton bottle jack to flatted the ends of the conduit

When I get the next section built is where the fun starts  
I want to do some destructive testing .I know from my small models that these things can take one heck of a compression load.

I want to find out what kind of load it will take to buckle it in the middle with a force applied to the side should be fun.

I have no doubts that it will meet my goal. And that is to have a structure ridged enough to support its own weight and 200 pounds of machinery on top during raising or lowering.  
Then the guy wires will handle the bulk of the wind load.

Way, cool! I've been a fan of Bucky Fuller for a long time.  
It's nice to see his work in a practical application (outside  
of domes.) I wonder what the difference would be with,  
say, 3/4" black pipe versus EMT? Certainly a weight  
penalty.

Do you think you need the guys? How was the  
free-standing version mounted?

Re: Tower Fun ([none / 0](#)) ([#3](#))

MST  
([User Info](#)) <http://www.oldf.homestead.com>

The base on Wind Works free standing tower is 6 foot  
on a side .

3/4 inch water pipe would make for a lot stronger  
tower but even then and with a full yard of concert  
for a foundation.

I wouldn't want to fly any thing over 5 or 6 foot dia.  
blade set if that.

With my version as a free stander

At this time I don't know just what kind of load it will  
carry. And that's why I am plan to some  
destructive testing . That and every so often I like to  
tear the hell out of things : )

04:59:50 PM MST  
([User Info](#))  
<http://www.olf.homestead.com>

Kevin

Pipe towers are a low cost way to go .  
But I want to get a way from having to transport 20 foot section of pipe or do any welding in the field if I want to go higher.

I have help raise some pipe towers for antennas and if you don't dot your I and cross your Ts thing can get hairy real fast . A pipe tower is 100% dependant on the guy for holding it up and during raising and lowering . A more ridged structure makes life a lot easier. And we are talking more than just compression loads.

That's why I am working with 10 foot sections that bolt together. I can easily transport the materials in my short bed pick up. And the finished 10 foot section weighs in at 41 pounds.

As for cost the conduit cost 14 dollars the angle iron was 5 cents a pound at the scrap yard.

Now that I am set up I can knock out a 30 or 40 tower' in a weekend or at most two.

As I work mostly by my self I want things I can easily handle. I not getting any younger : )

Old F

Re: Tower Fun ([none / 0](#)) ([#10](#))  
by DonG on Wed Dec 24th, 2003 at 03:34:15 PM MST  
([User Info](#))

The original Windworks tower plans were built with one inch conduit and a maximum length of 10 ft for a section. You've shortened the modules so you can use the lighter 3/4" conduit and retain the strength. It should be just as strong. The strongest vector is a triangle and these are just a bunch of triangles. I'm curious what your destructive testing will find and how it matches the engineering data shown on the plans for downforce and sideforce. I'm going to add an email address to the classified ad in case anyone else is interested. I stopped running the ad in Ebay. It would probably be cheaper for someone in SD to just get an old water windmill tower from NE. They're everywhere in that state. The single legged pipe towers have very little strength when your raising or lowering the tower compared to an octahedron module. I've also heard some people complain of tower vibration too. A guyed 1" conduit octahedron module will cost about \$35.00 for each 10 ft module figuring about five \$7.00 ten foot conduit sticks. A ten ft piece 3" pipe will cost you about the same and not be as strong and have no entertainment value. I'm currently restoring an old wind generator out of the 1940s and should have it on top of a 52' free standing octahedron tower at my new house this spring.

Re: Tower Fun ([none / 0](#)) ([#13](#))  
by DonG on Wed Dec 24th, 2003 at 08:08:37 PM MST  
([User Info](#))

It looks like your going to be OK with strength and your design has cut the cost even lower. I'm always amazed how much local interest you will get with this tower design when it is up. In the 70's an alternative energy business in Cambridge, MA put a twenty foot octahedron section up in front of their storefront to get more traffic through the door...it worked. I'm glad to see that your also having fun with this design. Unfortunately I lost my Jack Park 12-16 Helion plans in my many moves. You would have enjoyed his flyball governor and aluminum blade construction too.

[Wind -- How do you get the windmill power down the tower, since the mill yaws into the wind?](#)

[Wind](#)

By [ADMIN](#), Section [Renewable Energy FAQ](#)

Posted on Mon Dec 22nd, 2003 at 06:15:18 PM MST

Commercial slip rings are expensive...you can build your own, or go with a simple "pendant cable." Read on....

You can certainly buy commercial slip rings to send power from a yawing windmill down the tower. But slip rings rated at 100 amps at 12vdc would be incredibly expensive.

There are plans out there on the internet and in magazines for homemade slip rings. Most use carbon brushes and copper pipe, insulated by PVC pipe. Brushes from car alternators can be used. An example:

<http://www.fieldlines.com/story/2003/5/8/55448/19618>

and another example:

<http://www.fieldlines.com/story/2003/5/8/154641/0612>

DanB and DanF at Otherpower don't use use slip rings. We've always used a "pendant cable," which can either hang down and wrap around the tower or twist inside the tower. We also discussed this issue with homemade wind power guru Hugh Piggott... he also uses a pendant cable inside the tower pole. We looked at a commercial AWP wind turbine install on a 120 foot tower that uses a pendant cable.

Though for most folks it's hard to believe at first (until they try it), problems are rare with a pendant cable. A properly-furling wind turbine won't rotate much. We've never seen one do a 360 turn in less than a week. We put an electrical plug and socket at the bottom of the tower, and have found it necessary to unplug and untwist the pendant cable only once or twice a year, even in a turbulent wind environment! We also shut down our mills using this plug -- we plug it into a shorting block to shut down the mill for maintenance or during high wind events.

Discussion on slip rings vs. pendant cable:

<http://www.fieldlines.com/story/2003/5/8/55448/19618>

## [Servo motor-pipe genny update](#)

By [billf](#), Section [Homebrewed Electricity](#)

Posted on Sun Dec 21st, 2003 at 01:22:35 PM MST

[Wind](#)

Just a quick update on this project.

The unit is mounted on a short test tower of 13' height. I rigged up a quickie test panel and tied it into the main power panel for the axial mill.

Here you can see the big 8' axial mill on it's 65' tower in comparison with the servo motor mill with a 5' prop.

It's amazing how the difference in height correlates with

power output. It's also interesting how much wind shear there is within just 40 to 50 feet. The axial is on the left @434 watts with the servo on the right @30 watts.

Good output from the servo mill. The axial is putting out 640+ watts with the servo mill @372 watts. The leads go to a blocking diode. I'll try a 6 bladed prop this week and check out the difference.

[Servo motor-pipe genny update](#) | 2 comments (2 topical, 0 editorial)

Re: Servo motor-pipe genny update ([none / 0](#)) (#1)  
by billf on Mon Dec 22nd, 2003 at 06:22:10 AM MST  
([User Info](#))

Just a quick update note. Further testing using a hand held digital wind meter, power output looks like this:

9/10mph 4 amps@ 15vdc  
11/12mph 16 amps@ 15vdc

a little less than the spreadsheet but not bad for something so small. However start up is not as good in lower wind speeds. I noticed this morning the axial was putting out 60 watts in a 8mph wind and the servo mill had not started up. Probably a 6 blade prop should help out with this. Overall the axial still beats a servo motor handsdown but for a quick cheap mill for perhaps a cabin or camper, yard lights etc. a servo motor is an alternative.

billf

Re: Servo motor-pipe genny update ([none / 0](#)) (#2)  
by JB on Mon Dec 22nd, 2003 at 07:29:48 AM MST  
([User Info](#))

that really aint too bad for what it is and the initial investment. I think a 6 blade might start easy of course but I dont think You will get the rpm that is needed. That might be one of them high wind turbines with a 2 blade. Getting it up to the height of the other would be a much better comparison of course. Thanks for the info. JB

[Vawt or S Rotor](#)

By [Arno](#), Section [Homebrewed Electricity](#)

Posted on Sat Dec 20th, 2003 at 11:12:10 AM MST

[Wind](#)

This VAWT thing is making me nutty.....

I,m in my 70's and my math consists of 8th grade arithmetic.I cant quite figure out how to send a diagram so I'll try to paint some mind pictures.In the first one,I see a two blade S rotor but the blades are flat. When the wind hits them equally they dont do much. In the second picture, I see the same rotor but the left half is cupped and the right half is convex (?). This seems to spin a little. I guess the cup side captures the wind and the convex side thins it out a little and makes a differential. The next picture shows the same thing but theres a FIXED baffle at 45 degree's in front of the right side and the blades are spinning nicely. I guess the wind hits the left side and not the right side helping the spin. In the final picture, I see the same deal but two more blades have been added at 90 degree's and three more FIXED baffles at 45 degrees. This seems to funnel the wind from most directions. Ok fellows, please set me straight but without too much math. Windstuffnow and Electric Ed seem to be hot on the trail, and if vawt's have a future, I'd bet on them. Happy Holidays All! Arno

There's nothing to set straight. The technology is ancient and the principle of operation is simple, just as you describe. Such machines do have a future - terrible efficiency and perpetual 'discovery' by tinkerers.

Go to <http://www.ampair.com/> and compare the output of the Dolphin VAWT to the Hawk HAWT. The VAWT is admittedly smaller but the output is a tiny fraction of the HAWT. A machine like the Ampair 100 is about as reliable as a brick and no more complicated to build than a HAWT, with less materials.

If you just want to experiment, by all means have fun, but if you're interested in producing power, skip the drag devices and build a design that is proven efficient and reliable (see Hugh Piggot's books).

Good luck

The best Idea for the Savonius rotor that I've seen was from Electric Ed with the shrouded rotor, Here is a picture that I'm borrowing from him.

Hi Arno,

I'm not sure I'd do any betting at this point, VAWT's are still quite bulky and have their own set of problems. Personally I like the way they look, I could sit and watch them for hours ( if I had the time ).

Basically what it boils down to is.. Each side has a drag coefficient (Cd) and the object is to get the upwind side as low as possible and the downwind side as high as possible. On a typical Savonius machine the downwind drag is close to 1 and the upwind side is around 0.20 , This shows that its about 80/20 collection. You also have to factor in the speed that the downwind vane is moving away from the wind as well as add the speed the upwind side is moving into the wind. Adding vanes to direct the flow works fairly well and ducting works extremely well. The trick is to remove the upwind restrictions while enhancing the downwind torque. There are specific shapes that provide extreme drag resistance for the downwind side and other shapes that help remove the resistance on the upwind side. The shape that provides the highest drag is a "half tube" ( Like a pvc pipe split in half). This shape has a drag Cd of 2.3 with the C collecting the wind ( C <- wind direction). Unfortunately when you turn it around ( wind direction -> C ) it still maintains a drag Cd of around 1. If you add a shape to the nose but still keep the shape inside you can reduce it considerably ( <C ). As JJ pointed out a few posts back, adding an air foil to the front of it. Since its not a complete airfoil the air breaks up behind it and creates a turbulence and adds drag. This would allow you get the Cd on the upwind side down to around 0.4 or possibly a little less. The half airfoil shape on the "Lenz Turbine" brings it down to around .2 or slightly higher but we're still collecting the higher Cd of 2 on the downwind side or slightly higher. By adding a difuser or ducting the upwind side only sees its own speed ( plus a little turbulence). So now, basically we're collecting almost all of the power in the wind. If the ducting allows for collection of the entire area ( area of the turbine - both sides ) this forms a venturi, the venturi will increase wind speed as it approaches the downwind blades. Now your collecting at a higher speed than the wind coming into the inlet which offsets the downwind blade moving away from the wind. An open Savonius sees 12 mph wind and if the blades are moving 4 mph away from the wind then your only collecting from an 8 mph wind with the upwind side fighting 16 mph head wind. So you can see the benefits of the venturi and blocking the upwind side.<p> I think Savonius had the right idea using the "barrel" or "S" type rotor but I think it would do far better by spacing them out and adding an airfoil shape to the nose of the barrels. Also by adding a simple drum in the center would help direct the air into the barrel and create a low pressure to the back side of the turbine which helps carry the "barrel" farther behind the machine creating a longer torque period. Also adding 3 blades or barrels enhances the overall torque. Either, by ducting or removing the built in flaws can make a big difference in performance over the Standard methods...

Fun Subject!!

 Does anyone have this Jack Park book?

Some time ago, Jack Park authored a book entitled "Simplified Wind Power Systems for Experimenters." Is anyone out there familiar with this? What are it's contents? How many pages, illustrations, etc.?

Thanks for your help.

[JACK PARK BOOK](#) | 2 comments (2 topical, 0 editorial)

[\(User Info\)](#) <http://www.electric-ed.com>

I don't have that one, but do have a later book by Jack Park called The Wind Power Book (1981 - Cheshire Books) which I found very helpful.

It has 250 pages and covers the history of wind power, basic theory, calculations, and design. However, there isn't much on the actual construction details.

Electric Ed

[\(User Info\)](#) <http://www.windstuffnow.com/main>

Hi JJ,

Both books are quite good. Neither of them have any specific building but the one you refer to has alot of math and covers most turbines. This includes the Darrieus, savinous, multi-blade to the modern turbines. I would recomend both if you can find them. Both are similar and each seems to have a bit of detail that the other doesn't. He also goes into some hybrids that are kind of unique.

I found them in Half.com for a reasonable price. Both have been out of print for some time now.

Have Fun  
 Windstuff Ed

[S Rotors](#)

By [Arno](#), Section [Homebrewed Electricity](#)  
 Posted on Thu Dec 18th, 2003 at 10:55:32 AM MST [Wind](#)  
 Questions from a novice about an S Rotor

Say you have a small 4 blade S rotor mounted a foot or so above a flat roof.  
 I assume a wind hitting the concave halves and providing push is also hitting the convex halves and making some resistance. If so, would 4 stationary barriers close to but separate from the convex halves and at a 45 degree angle and as tall as the rotor make a dead area around the convex halves and funnel more wind to the concave halves no matter which way the wind blows? Sort of like a hydro turbine. Would this help efficiency?

Arno

Re: S Rotors ([none / 0](#)) ([#1](#))  
 by Norm on Thu Dec 18th, 2003 at 05:12:01 PM MST  
[\(User Info\)](#)

I believe the added complexity would far outweigh any gain in efficiency. I believe when you say S rotors you are referring to a VAWT? For starters on basic Savonius type wind turbines go to <http://www.picoturbine.com/> then for more advanced designs go to <http://www.windstuffnow.com> Ed has some excellent designs even some kits that you can purchase. Have fun! (:>) Norm.

## [pipe genny with servo motor](#)

By [billf](#), Section [Homebrewed Electricity](#)

Posted on Wed Dec 17th, 2003 at 07:27:54 PM MST

[Wind](#)

Here is a small mill using a servo motor and sch 40 gal. pipe.

Most of the items can be bought from the hardware store except for the servo motor which can be gotten from here:

<http://www.surpluscenter.com/item.asp?UID=2003040713341264&item=10-1840&catname>

This mill should be relatively easy to build. Keep in mind though it is heavy and will require a substantial sch 40 pipe tower for support (I'm using 1 1/2" pipe for the tower). You can use a 3 or 6 blade prop, 3'- 5' dia. depending on the output you want.

Note the motor is offset so at higher wind speeds it will turn itself out of the wind for protection.

- [Also by billf](#)

When testing is done the downlead will be run through the center of the tower (no slippings).

Note the PVC bushing on the inside of the furling pipe.

This is how the furling should take place. I mounted a light weight tail vane made from plexiglass on the tail so it will swing out earlier. Hope it works.

When the tail swings down, the tail boom hits the main mount and stops the tail from swinging around. When the tail is furled, the bottom rail under the motor will stop the tail from swinging too far up.

Bench testing shows the mill should cut in at around 325rpm (12vdc) and according to the spreadsheet I have this should work out to around 6mph. The purpose is to have a steady 100-150 Wh, 24hrs a day. We'll see.

Bill

Re: pipe genny with servo motor ([none / 0](#)) ([#1](#))  
by Jerry on Wed Dec 17th, 2003 at 08:57:28 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Bill

Looks like a real hevy duty genny do you know how much it weighs?

I used the same motor to build a genny for a sail boat. I think this guy was crazy cause the sail boat was small and he was sailing from Oregon to Mexico.

I built him the genny. It weighed 24 lbs. He returned an said it was to heavy for his small sail boat. I'm thinking your going out in the ocean and a 24 lb genny is too heavy. I woudn't go any where in that boat and for sure not to sea.

So I did my best to lightin it up. It ended up at 18 lbs and prety rugid too.

I used 2 of my Jerry blades 49 iches tip to tip. These blades are \$15 each. They weigh 9 oz. each. plus homemade hub and yaw system. The blades handeled 68 mph winds just fine. No furling on this genny. In high winds its making over 360 watts and seems to work great.

I'm flying 3 of these small gennies on my shop. They sure are cheap and easy.

All the yaw and tail boom and wing stuff was less than \$25 and light as a feather. Since this genny is so light I fly them on 1.5" EMT electrical conduit. The big box home improvement stores sell this conduit for around \$7 for a 10 ft pice.

([User Info](#)) <http://www.greeleynet.com/~cmorrison>

Bill,

Very interesting design. It'll be interesting to see what your offsets end up being when you test and adjust it. Amazing what can be done with pipes.

My initial reaction is that you might want a way to move the motor further out to the side. On the other hand I see an "L" piece on the end of the tail which should increase furling and it certainly looks like a light tail. Of course blade size will influence all that too.

I don't know if you have any bearing in the yaw assembly, but you might consider a thrust bearing if furling seems a little choppy.

Good luck and let us know how it works.

Chuck(M)

Re: pipe genny with servo motor ([none / 0](#)) (#3)  
by billf on Thu Dec 18th, 2003 at 04:58:18 PM MST  
([User Info](#))

The mount is heavy, probably 40-50 lbs. But once it's up in the air 40' it will get a lot of stress especially from thunderstorms. More metal=more strength. I'm more curious if the furling system will work. I have thought of using a bearing for the yaw mechanism. In fact a 1 1/16" axle bearing for a trailer glued to a 1/2" fender washer-glued to the top of the 1 1/2" pipe will work. However for now, since it's mounted on a short test tower, it will have to wait and it does seem to track alright for now. If the bearing idea works well for the small genny then I may adapt one for the big mill which does have some tracking problems at lower wind speeds especially after there's been a lull and the wind changes direction before picking up.

Bill

## [IDEA FOR LENZ TURBINE](#)

By [johnjach](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 16th, 2003 at 10:04:11 PM MST

[Wind](#)

How would this work for a "Lenz" turbine?

A question for Ed of Windstuffnow: Ed, instead of using the open "J" configuration on your VAWT, what would be the results if you used a "fat" airfoil like an NACA 0024 and "clipped" off about 25% of the trailing edge. If you used these in your "Lenz" turbine or a Darrieus, would you have an airfoil "lift" machine on the upwind leg and a "drag" machine on the downwind leg or would the "clipped" airfoil lose all lift properties because of the broken airflow from the missing trailing edge?

These are just some thoughts I had but maybe I'm trying to do something which is aerodynamically and physically impossible. I'd appreciate your thoughts and comments. Thanks again.

[IDEA FOR LENZ TURBINE](#) | 1 comment (1 topical, 0 editorial)

Re: IDEA FOR LENZ TURBINE ([none / 0](#)) (#1)  
by [windstuffnow](#) ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Dec 17th, 2003 at 07:03:03 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

JJ, that would work. If you keep the half tube in place on the inside and use a partial airfoil on the leading edge you'll still benefit in the lift and collect high drag on the downwind side. Keep in mind on the upwind side we want to basically offset the drag with lift to over come the losses and possibly add some power to the machine. Once the machine reaches a TSR of 1 or higher your no longer making power from drag. ( actually occurs at just below 1)

A drag machine produces it's best power at around a TSR of .33, anything above and up to a TSR of 1 the power starts to fall off drastically.

Fun Stuff  
Ed

Well I'll tell you, here I am in the Northeast, just like you, sitting on over a foot of ice covered snow and freezing my @#^% off.

I've been waiting for this Global warming for some time now so I can eliminate the need to heat my house thereby stopping the dumping of 12 tons of CO2 into the atmosphere each year. Has not happened yet.

Remebering back to the late 70's the fear was that we were heading into an ice age again. Has not happened either.

What's the next phobia?

AIRFOIL SHAPE NACA

$A \approx \frac{1}{4} B$

THE TUBE IS IN THE THICKEST PLACE OF THE AIRFOIL

# A Water Pump using solar hot water as the power supply

## *General:*

The working of the pump is based on hot water and cold water inserted cyclically in an expanding and contracting aluminum tube.

Water is heated in a hot-water container using a solar panel and a heat-transformer.

## *The working cycle of the pump is as follows:*

- 1) Hot water is inserted in an aluminum tube. The tube expands because of the heat (about 2mm for each 1 m and 100 C temperature difference). The expanded tube pulls the piston upward. Hotvalve1 is open.
- 2) The hot water is taken out from the bottom of the tube back to the hot-water container. Hotvalve2 is open.
- 3) Cold water is inserted in the tube, which contracts pulling the piston back to its original position. Coldvalve1 is open.
- 4) The cold water is taken out from the bottom of the tube. Coldvalve2 is open.
- 5)=1) Hot water is inserted in the tube.

## *Notes:*

### Note1:

The efficiency of the machine is totally unknown, because this kind of engine has probably never been made before.

### Note2:

The power tube must be supported to prevent it bending.

At the same time it can be thermally insulated by putting it inside a tight wooden tube.

### Note 3:

Various technical problems are yet unsolved. For example: does the metal tube fracture because of expanding-contracting cycle?.

### Note 4:

The operation of valves will be easiest to arrange using the power of the lifted water.

# THE AQUILIA SOLAR WATER PUMP

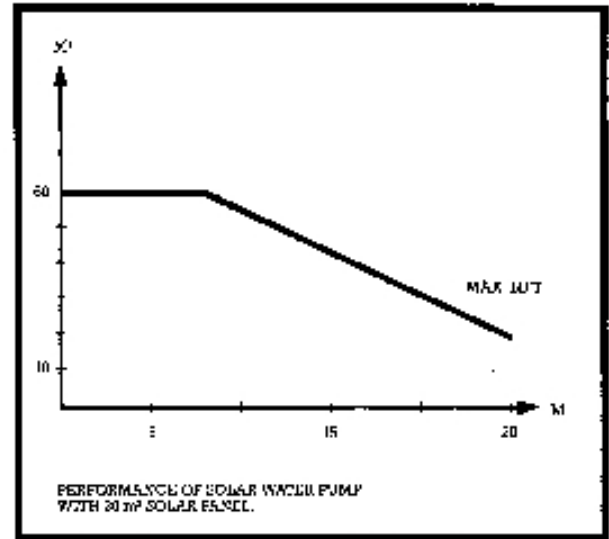

**The Aquilia Solar Water Pump is a unique, simple way of utilizing solar energy for pumping water.**

The system is self-contained and works independently of outside energy sources. All circuitry is enclosed within the system and requires no adjustment. The pump is highly reliable, requires little maintenance and has a long lifetime.

The Solar Water Pump combines suction and pressure to raise the water, which gives a maximum static head of 25 metres.

The Aquilia Solar Water Pump with a solar collector area of 16 m<sup>2</sup> fulfills the World Bank specifications for Category B and C, which are as follows:

Category B - 60 m<sup>3</sup>/day at a static head of 7m  
 Category C - 20 m<sup>3</sup>/day at a static head of 20m  
 with an irradiation of 5.5kWh/day

The system is filled with water only. During sunshine hours the water in the solar panels will be heated and steam will be generated. The steam forces the float in the pump house down. This pressure causes the foot valve in the well to close. The water from the pump house is forced upwards and runs through the condenser into the water tank.

When the steam level in the pump house reaches the bottom level of the steam tube, the steam escapes to the condenser because of

## TECHNICAL SPECIFICATIONS

Energy supply .....	The sun
Key components .....	8 solar collectors, water reservoir for solar collectors, pump house, steam control valve, stand

the difference in pressure. The steam immediately condenses, and a partial vacuum is created in the pump house, which opens the foot valve and water is sucked up from the well refilling the pump house.

*The equipment is manufactured to metric standards, any measurements other than metric are approximate and for comparison only. The company reserves the right to change the technical specification without prior notice.*

Description of plans and kits available

# "Green Windmill"

**US Patent #**  
**5,823,749**

The system consists of a horizontally suspended square rotor wheel with a square rim supporting

four sails that are linked by cables in pairs. The sails are not unlike boat sails except that they reside in a horizontal plane. The linkage of the paired sails control the sails to form preferred shapes as they revolve into and out of the wind. This control adjusts the sails in a symbiotic action that reduces friction and turbulence in the advancing sails and increases drag in the receding sails. The two opposing linked sails produce a scoop and a wing shape. The scoop holds the wind and the wing rides the wind. The linked controls additionally dampen the sail action to insure durability of the sails.

Because the rotor rides the wind, rather than bucks the wind, it requires minimal tower structures and is roof mountable.

The rotor is vibration free because the tower does not interfere with the rotor. The resistance to the wind and the force acting upon the tower is directly proportional to the work load. This design is very durable indeed. It has been shown to withstand wind speeds in excess of 70 MPH without damage. Load sensitive sail cables that break under

**Bringing the Art of Sailing to Land**

predetermined loads can protect sails, pumps and equipment in extreme conditions.

As will be seen in the following pages, there are many novel applications made practical as well as fun by this convenient and economical windmill design.

A choice of sails can be used for different performance requirements. Full sails such as the ones shown in the above illustrations produce high starting torque and slower speed. Half sails, in which only the top portion of the sail is employed, produces higher rotor speeds with lower starting torque. Different sail configurations can provide the right combination for a particular application.

**-Already in 30 countries-**  
Extraordinary. Which works.

### Energy from Wind

Wind turbines turn wind energy into electricity and charge it into batteries for use. Man, who utilizes this free energy source, is independent. He is independent on electricity grid, on location, on tariff changes. But power production of wind turbines depends on conditions - on wind speed, turbulence and the changes of wind direction. Unfortunately the conditions are not always as optimal as in sales speeches. Most turbines don't simply work. There is one turbine, which works.

### Why Windside Turbine is the best on the market?

WS-Turbine works, when others don't, with gentle summer breeze and in a violent winter storm. It works, when others are in deep frost. WS-Turbine produces electricity at least 50 % more in a year than traditional propeller models. All the year round. Many things make it extraordinary. And therefore it gives the best value for the money. Not being expensive any more.

### Long-lasting

WS-Turbine produces electricity year after year, long after the others have been wrecked. It is made of special steel, aluminium, glass fibre/wood and stainless steel. Need of maintenance is minimum. It is investment for tens of years. Do not wonder, if it works in year 2100.

### On Nature's Terms

WS-Turbine doesn't keep noise. Doesn't kill birds. Soundless and safe Turbine can be erected in the middle of a population center, and even a child can stop it. Besides it's beautiful.

### Professional

WS-Turbine can be used, where electricity is needed and where the grid is not at hand. Or where power cuts are expected - or unexpected. The Turbine is used in ice fields of Greenland and sands of Sahara. It is used in extreme conditions. Used by professionals.

The Turbine gives light, heat and cold. Current for measuring systems. Water is lifted, signals given, areas guarded, spaces ventilated. In desert. On the ocean. On mountains. In lonely places. Far away. Where electricity is needed.

### Extraordinary. The Best.

## **Background**

Windside Wind Turbine was developed in 1979 by Mr. Risto Joutsiniemi. The Turbines have been made to order since 1982, and so far they have been delivered all over the world. Professional users have been the major customer group from the beginning. After the devices gained more publicity, the turbines were wanted also for civil purposes. The production plant is situated in Pihtipudas, Middle Finland, 400 km south from Arctic Circle.

## **Efficiency**

WS-Turbines are tested and rewarded. Measurements made a.o. on the circumstances of the Archipelago of Finland proved that WS-Turbine produced 50 % more electricity a year than traditional propellers with the same swept area. The average wind speed prevailing in the world is approx. 3 m/s. The special WS Vane Construction makes the Turbine able to utilize winds of 1-3 m/s, which is insufficient speed to others. The WS-Turbine works also in storms, tested in 60 m/s, which is unbearable speed to others. Both these WS-facts are World Records.

Besides the wind speed, will the turbulence and wind direction changes effect on the power production of the turbines. WS-Turbine is able to utilize winds from any direction, even turbulent winds, unlike traditional models. WS Spiral Vanes always reach the wind at right angles.

## **Harmony**

WS-Turbine is in harmony with nature and human environment. It is totally soundless due to the spiral shape and the fact that the rotation speed does not exceed the wind speed. There are no flying ice blocks, leaking oil or cutting blades. The device is safe to people, animals and nature.

Due to its beautiful design and smoothly rotating structure WS-Turbine resembles a work of art. Several artists as well as landscape and building architects have noticed this, and the results can be seen already in ecological building.

### Thoughts on the stages of human evolution

If we look throughout our human evolution we find one thing that has always stayed as a constant. The need for energy.

Our entire society is based on the consumption of energy, without which our computers, lights and heating and cooling systems would not function without. So the larger question which everyone should ask is, what is the next evolution or paradigm shift that will occur in human evolution. We have been through the stone age, bronze age and steel age. We have been and are still now in the information age. What's next?

## Welcome to the Energy Age!

We are coming very rapidly to a major crossroads. Our dependence on fossil fuels cannot last, we know this. In the mean time, alternative energy sources must be sought with vigilance. The "space age" cannot be achieved until we overcome the energy age. We require such vast amounts of energy to launch a single vehicle into space that costs are extravagant in the extreme to do it. We need alternative fuels and alternative energy.

From a book entitled- The party's over- Oil, War and the fate of industrial societies- Richard Heinberg 2002-.C.J Campbell draws this graphic.

### World Oil Production: 1930-2050

Source: C.J. Campbell / adapted from *The Party's Over*

World petroleum production is at a peak and about to start its decline. The plots indicate a peak in global oil production somewhere between 2006 and 2015.

### Notes: Taking the long route to conversion

Chemical energy of coal is converted into thermal energy as it burns. The thermal energy is absorbed by water and produces steam. Steam is directed against the blades of a turbine, converting the thermal energy into kinetic energy. The kinetic energy of the turbine rotates a generator which converts the mechanical energy to electrical energy. This proves it is inefficient! Energy should be put to work in as direct a manner as possible. The long route of changing energy through several stages is costly and wasteful.

## Energy Conversion Matrix

To From → ↓	Electromagnetic	Chemical	Nuclear	Thermal	Kinetic (Mechanical)	Electrical	Gravitational
Electromagnetic		chemiluminescence's (fire flies)	Gamma Reactions (Co60 source)	Thermal Radiation (hot iron)	Accelerating Charge (cyclotron)	Electromagnetic Radiation (TV, Radio Transmitter, electroluminescence)	Unknown

### The four physical expressions of energy are; Radiated, Reflected, Deflected & Absorbed

---

Presently, there are seven known methods for **producing a voltage or electromotive force -EMF**

1. **FRICITION** Voltage produced by rubbing certain materials together.
  2. **PRESSURE** (piezoelectricity) Voltage produced by squeezing crystals of certain substances.
  3. **HEAT** (thermoelectricity) Voltage produced by heating the joint (junction) where two unlike metals are joined.
  4. **LIGHT** (photo electricity) Voltage produced by light striking photosensitive (light sensitive) substances.
  5. **CHEMICAL ACTION** Voltage produced by chemical reaction in a battery cell.
  6. **MAGNETISM** Voltage produced in a conductor when the conductor moves through a magnetic field, or a magnetic field moves through the conductor in such a manner as to cut the magnetic lines of force of the field.
  - 7) **MAGNETIC INTERRUPTION** - Voltage and current is produced when both magnet and wire are stationary and interrupted momentarily by shielding. This is different from above with exceptions.
  - 8) Other unfound and experimental

# MSIG - Magnetic Shaping and Interruption Generator

Created July 26-2003

Prototype

Working

## MSIG

### The Magnetic Shaping and Interruption Generator

**A totally new concept of power generator.**

#### Proof Of Concept

Built and invented by Fred of [www.internetfred.com](http://www.internetfred.com). on Saturday July 26, 2003. After reading "Basic Physics - for secondary schools" by Eubank-Ramsay-Rickard 1957. Chapter 22 of the book discusses magnetism.

**Note:** There are other interruption generators out there, but not like this one!

I have visited many web sites and looked at other designs on the internet, suggestions of using MU-Metal (magnetic shield material -expensive) or core rotation to cause interruption or shielding the magnet for a moment from a core produces a voltage-current using a core and permanent magnet embedded in the core. However, not one of the designs proposed the concept of "Magnetic Shaping for the purpose of interruption", this is the uniqueness of the idea that I have come up with and to my knowledge and as far as I know has not been done in this way before.

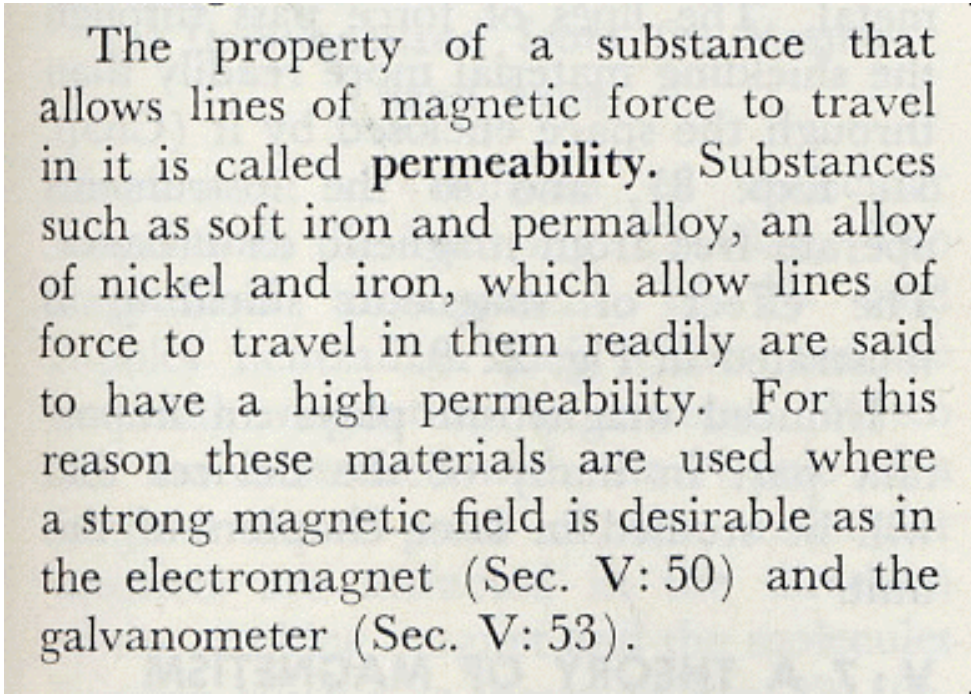

This week I was just scanning a basic physics book looking under magnetics when I came upon some interesting information which struck me as odd. It's not really that odd but the thought that I had required

immediate attention and experimentation.

When building a power generator we normally think in terms of moving the magnets or moving the core, but what if both were stationary? Would the generator produce output... no. What if the magnet was embedded in the core, would that produce output.. no... Ok, then what if the core was magnetically interrupted with a magnet embedded in the core, would that produce an output ??? That is what I'm finding out....**The answer is YES!!!**

**There is a third way in which to produce power in a generator!!**

**On page 263 of the book the following description was given for the property of permeability.**

A rectangular box containing text from a book. The text describes the property of permeability, stating that it allows magnetic force lines to travel through a substance. It mentions that substances like soft iron and permalloy (an alloy of nickel and iron) have high permeability and are used in electromagnets and galvanometers.

The property of a substance that allows lines of magnetic force to travel in it is called **permeability**. Substances such as soft iron and permalloy, an alloy of nickel and iron, which allow lines of force to travel in them readily are said to have a high permeability. For this reason these materials are used where a strong magnetic field is desirable as in the electromagnet (Sec. V: 50) and the galvanometer (Sec. V: 53).

**On page 264 the following image describes the effect of magnetic shielding, VERY INTERESTING!**

**What this means is that a magnetic field can be shaped, focused, diverted etc... And that is the key!**

I never really thought of magnetics this way before and after seeing this picture it hit me that this was unique and had not yet been tried before, to my knowledge. The shape determines where the magnetic field will ultimately be focused.. Very neat!

In order to protect such instruments they are frequently enclosed in a magnetic shield of some highly permeable metal. The lines of force pass through the shielding material more readily than through the space enclosed by it (Chap. 31, Exp. 8), and so the instruments operate free from magnetic disturbance. The effect of magnetic shielding is illustrated in Fig. 22:9.

**Ok, so now we have the basic theory and basics of magnetic shaping, now what can we do with it?**

**As soon as I seen this I thought of a new generator.... The rest as they say is history...**

---

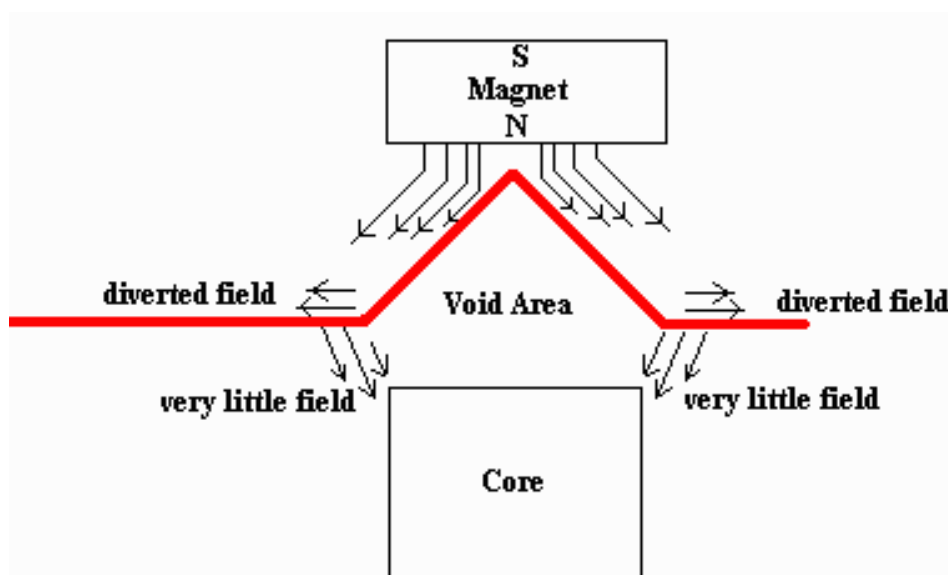

**As I began playing with the idea of shapes....**

This shapes the field, however the field is being redirected back at the core. Not right.. I wanted almost total diversion of the field. Shielding by diversion. This allows to much field to escape downward into the core, causing magnetic resistance.

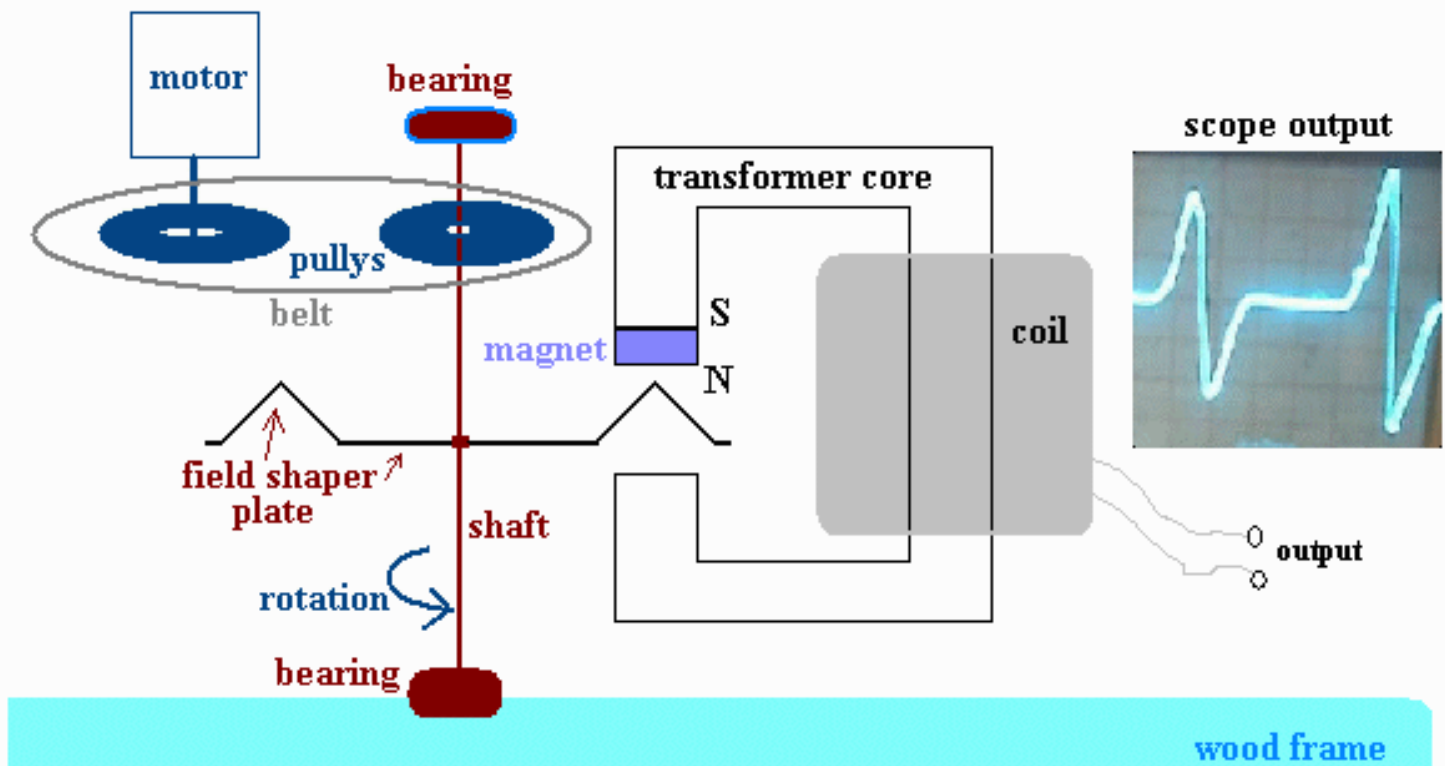

After about a dozen different designs, the secret lies in the concept of divide and conquer. The shape chosen for my final design is the tri-angle. It uses very little magnetic field strength to move through the field, only the tip of the tri-angle is really exposed to the magnet and since it slopes the total surface area available to the magnet and the magnetic field is a small percentage, but the field cannot penetrate through it, so it follows it, which leads outward and away from the core, this produces a total collapse of the magnetic field for a moment during it's rotation. It turns out that a simple design is the key to the success of this generator.

**The surface area's of greatest magnetic contact and drag marked in Green**

Much better, notice the shaping of the field. This produces very little resistance to both air flow as it swings around and magnetic drag by being pulled up or down. In fact the momentum will help it along. The angle of this triangle is what is important. Too steep and the void area might get too much field or too much surface area. Too sharp an angle would mean a larger gap reducing the output. This has to be played with to get it right yet.

**The magnetic field is shaped and diverted. As the shaft rotates it interrupts the static magnetic field in the gap and produces a voltage & current. This is a new concept - By Fred  
www.internetfred.com**

1v/div

**My Scope Says.... We have output from a static field without rotating the magnets or the field !!!!!**

The core is a transformer I sawed and cut a notch out of.. I then glued a magnet to the top of the cut and taped it together. I left the original coil core alone so I could use it for testing.. The metal field shaper is an old unused slot cover from a computer. In the back these slots are removed when installing hardware cards.. I then bent it to my shape and soldered it to the metal shaft. The pully's where glued.

Top view

I used bearings from an old VCR to hold the shaft in place. The rest is just simple pieces of metal and wood to hold everything together. The motor is just a simple 12VDC Motor. The pully's came from old VCR's as did the motor. I use a lot of old VCR parts when building, there are so many goodies to find inside them.

The transformer I just had laying around, I removed one of the coils (where the gap is now) and then cut the gap with a hack saw, I then ground it with a file to straighten it all out.

So, now I am in the testing stages..

## The Motor Tests

The motor drains about 200ma stable and does not change much, the motor was put on a variable power

supply and checked for voltage and current simultaneously. As the voltage increased from 4.3 volts DC to 12 VDC the current went from 200 to 275 ma. It did not go above this and the motor in general tended to stay and stabilize around 200 ma nominal. So the swing was not that great. If I locked the motor the meter went to 301ma.

Now, here is the interesting part, no matter if I shorted out the output coils or if I applied any load, no matter how large, the motor shows NO CHANGE ON LOAD!!! In voltage or milliamps. Nothing.. The motor senses no load!!!! No fluctuations.. To verify this we put another magnet under the motor and as soon as we did this the motor began slowing down and the milliamps went up.. So our measurements were confirmed. There was no load during shorting of the output coils.

I do not have RPM gauge but I estimate the motor speed to be between 2000 and 7000rpms for this 12 volt DC motor.

## The Coil checks

There are two coils on the core...

The first coil has smaller wire and many turns, has 14.4 ohms. At motor running 12 volts this coil produces 3.4 volts at 10ma.

The second coil reads 1 ohm. With the motor running 12 volts the output on the coil was .500 or ½ volt and the current was 100ma.

We did run 2 LED's off the output coils at 12 volts no problem, not bad for this size generator and for what I was doing.. As far as concept and ideas are concerned the "proof of principle" works... Need more research. It is both a current and voltage device since it is a transformer.

### Notice about the device and using the idea

The following is a very brief scientific approach to generator design using well known laws of electromagnetic induction principles. Only the basic fundamentals are covered.

---

## Basic Fundamentals

- Faraday's Law of Electromagnetic Induction

- 1) If the flux linking a loop (or turn) varies as a function of time, a voltage is induced between its terminals
- 2) The value of the induced voltage is proportional to the rate of change of flux

**Here we can see that induced voltages are the result of very rapid changes of flux. The more rapid the changes occur the higher the induced voltage.**

To induce large voltages you need a generator that has a rotor that spins rapidly, has significant magnets as the law suggests. The faster those magnets switch the flux in a coil, the more voltage will be induced into the coils, thus the higher the induced voltage.

Faradays Law is stated as

$$\text{induced voltage} = N \frac{\Delta \Phi}{\Delta t}$$

N=number of turns

$\Delta \Phi$  =change of flux inside the coil

$\Delta t$  =the time interval during which the flux changes

---

## **How can a very slow turning generator produce such rapid changes in flux?**

The secret lies in the diameter of the of a generator core size. The larger the core diameter the faster the magnets can produce rapid changes of flux induced into the coils. The more rapid the changes the higher the induced voltage as Faradays Law suggests.

- This concept is called angular velocity to linear velocity exchange.

Which means;

- With a constant angular velocity a larger diameter gives you a larger linear velocity at the circumference.

Angular velocity is measured in rotations per second thus;

**Rotations per second X the circumference (diameter X pi) = The linear velocity in seconds (or RPM's)**

In essence the greater the length of the radius or size of the diameter the faster the magnets are moving if placed at the circumference.

It all works out to the same thing.

---

Now Faraday being the smart guy that he was, also suggested that "it is easier to calculate the induced voltage with reference to the conductors, rather than with reference to the coil itself"

And another calculation pops out;

$$E=BLv$$

E = induced voltage (V)

B = flux density (T)

$L$  = active length of the conductor in the magnetic field (m)

$v$  = relative speed of the conductor (m/s)

**What I want to point out here is that the "length of the conductor", plays a significant role in the induced voltage.**

Notice: This is a single conductive wire, not a coil. The length of that conductor in the above equation is what is of prime importance. This means that the core (and rotor) must be "wide" to optimize the length of the conductor and thus the output. Also the equation states the "active length" of the conductor. I interpreted this to mean that the magnets must be long or as long as the conductor in order for the total conductive surface area of the wire to be active.

**Interpretation; A wide core is a requirement. The magnets are as long as the wire, the wider the core the longer the magnet.**

- The calculation also states the flux density.. The stronger the magnetic flux the larger the output. Thus a very strong magnet is called for to induce maximum voltage.

---

## Learned so far;

- The faster the rate of change of flux the higher the voltage (speed)
  - The concept of angular velocity to linear velocity exchange (speed)
  - The more the number of turns the higher the voltage (lots of turns)
  - The stronger the magnetic flux density from the magnet the higher the voltage (strong magnets)
  - The longer the active length of the conductor the higher the voltage (wide cores)
  - The longer the magnet to match the active conductor the higher the voltage (long magnets)
- 

## Magnetics

---

### **Magnets and making a long magnet from smaller ones**

Smaller magnets can be used inline if longer ones cannot be found. Doubling the length and the height produces a stronger overall magnet. Smaller magnets are cheaper, but you need more of them, so your not saving much. But they can be used in the above configurations if you already have them.

**Note:** a single long thin high magnet is better then several small ones as mentioned above. If you can, go for a single magnet, the forces will be much greater and will produce better output power. The stronger the magnets the better, but there is a trade off of magnet size to magnet output and pole size.

### Neodymium Iron Boron - (\*Neo for short) - (NdFeB)

Known as "Rare Earth" magnets, these magnets are the most advanced permanent magnet, they where developed in the 1980's. Neo magnets are available in sintered as well as bonded forms and are brittle. They have close mechanical tolerances. Almost all Neo's are anisotropic and all are effected by temperature. Most Neo's are coated with nickel, zinc or tin. They have excellent magnetic characteristics in terms of a high energy product and have a high coercive force, they are made of abundant raw material and are relatively low cost.

- There is some great information on the [www.wondermagnet.com](http://www.wondermagnet.com) website about magnetism. Read this FAQ.

## **! Advanced Magnetic Topics**

Hysteresis increases with changes in flux, changing flux to fast creates heat which decreases the coercive forces. To minimize this loss, keep the speed of the generator operating to below approximately 3800 rpm or so.

This web site has [Magnetic Formulas](#)

This [web site has tons of graphs](#) showing the energy products and BH curves of various materials

This [web site has tons of interesting info](#) on magnets

The graph below represents basic general Neo magnet properties. The other picture shows a general BH curve

- Most common neo's are 1.1 to 1.2 Tesla's in strength. Most magnetic materials reach saturation at 2.0 Tesla's
- You can guess the magnetic field strength from the rating and grade system for Neo's. eg; a N35 - This number suggests 3.5 inch's magnetic field strength in air.

● If someone could build a simple program for wind turbine builders to do calculations like above and below for simple magnetism and reduce the time for calculations it would be awesome! it would not need to be graphical, just do simple common magnetic equations like below, input variables and provide a data output. If you know of such a program please [contact](#) me.

Example Equation:

A magnet measures 1/2 x 1 3/4 x 1 1/2 inches and has an energy product of 37 MGOe (MegaGauss-Oersted). The field strength on-axis can be calculated with the following formula:

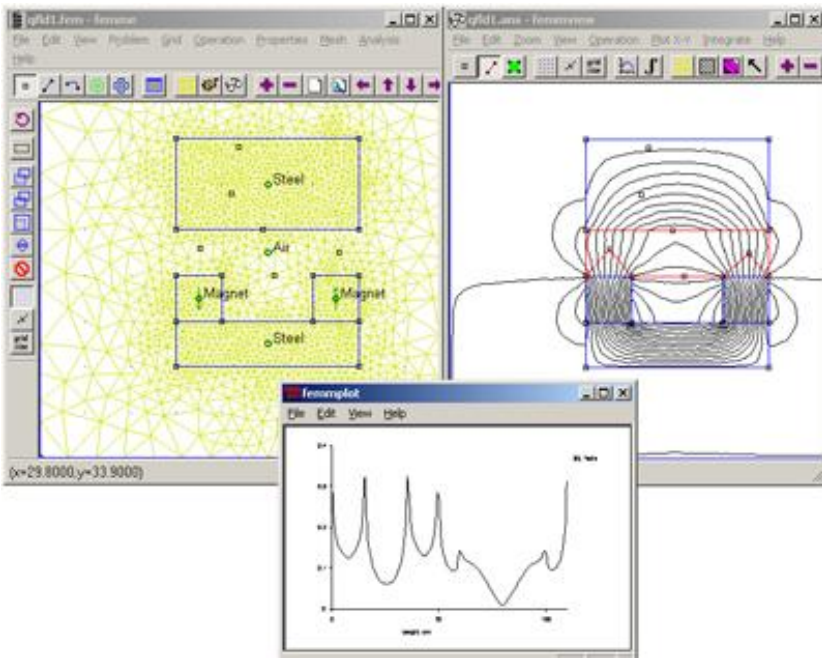

$$B_x = \frac{B_r}{\pi} \left( \tan^{-1} \frac{AB}{2X\sqrt{4X^2 + A^2 + B^2}} - \tan^{-1} \frac{AB}{2(L+X)\sqrt{4(L+X)^2 + A^2 + B^2}} \right)$$

- B<sub>x</sub> = flux density in gauss at distance X from the pole surface
- B<sub>r</sub> = residual flux density = 12700 gauss
- A = width of magnet = 4.42 cm
- B = height of magnet = 3.66 cm
- L = length of magnet = 1.27 cm

Below is a graph showing the theoretical peak magnetic field strength at various distances in cm in air using the above calcs.

A very neat and simple program called FEMM for magnetic mapping of materials- <http://femm.berlios.de> try this program, it's impressive for graphical magnetic display.

FEMM a simple graphical magnetic mapping program.

## How generators work - Basics

The magnet or conductor is revolving at a constant speed

The first picture shows that maximum induction takes place only when an alignment is achieved on both sides of a conductor simultaneously with a magnet and both magnet poles are facing the conductors at the same time. When the poles are in this position (first picture), maximum induction takes place, otherwise it does not. Voltage induction will only occur if the magnet or the coil moves.

## **THE CORE** and materials to use

The purpose of a core is to increase the magnetic field strength to compensate for use of smaller magnets which are cheaper and also to increase the power output per turn of wire. You can also use big magnets plus a core and get even more power.

- In other words the core takes what you have and makes it better.
  - A magnetic flux travels much more efficiently thru a ferrous core than in air or vacuum

The following are rules of thumb for power applications

- 1) Air – no core – not very efficient for power applications, but can be driven hard because it never saturates
- 2) Ferrite/iron powder resin core – ( laminate versus iron) –no eddy current- better at higher frequencies
- 3) solid iron – This is the best, unfortunately it suffers badly from eddy current losses which produce heat- at low turning speeds- bolts, screws and nails with coils on them can be used but in slow rotor applications with significant cogging and with substantial higher output. It works well but cogs. Air cool it and it's fine.
- 4) Thin laminate – The frequency handling is much better, has much reduced eddy current losses, is the best of both worlds between ferrite/iron resin core and solid iron.

It is important to coat all laminations with a thin coating of insulation to prevent electrical contact between the laminations and reduce the eddy current losses.

- if machining the laminates or making cores, reduce the burrs, and re-varnish core before coiling. Put a piece of thin cardboard in between the slots so the wire goes inside the cardboard to protect the wires.

installing cardboard protectors

---

## Learned so far;

- Lot's of small magnets can be used, but long magnets are suggested
- The stronger the magnetic field the more power can be generated (use Neo's')
- The more magnets you have the more lines of flux can be produced
- Magnetic calculations can solve a complex problem and indicate output power
- Power generation only works when the field is lined up with the wire or pole and in constant rotation
- A core material gives you more of what you already have, intensifies the fields and increases output power
- Insulation between laminations and poles is important
- Thin laminations are highly suggested to reduce eddy current losses

## Special Page On Generators

Oct 30 -2003

This a picture gallery and as such no major write up's on the construction of the devices. Sorry... I just don't have the time.

### Picture Gallery & High Voltage Designs w/info

*Yep, it's me...*

In my spare time on weekends, I build wind turbine generators. Most are concept proof of theory designs and devices. All are experiments in tweaking and correcting problems at some lower level. Working out the bug's you might say. Presently working on high voltage wind systems.

### Revisions... Flattening the coils

Flat- Wide, Long Coils...Does make a major difference.. Low output...Single Rotor. sometime in early 2001

# New Concept Generator - Innovative Design...

Hugh output, High resistance... **lot's of cog...** 3-5 volts per coil. 16 coils. Ceramic magnets...1300 Turns on a 3 inch bolt

Being presently reborn yet again....

## **New Innovative Design - Reducing the Cog.... Using Displacement..**

**Full Core- No Cog- Skewed Axial field PMG polyphase machine**

Magnet Layout

Coil Layout

By Bryan and Fred  
visit [www.internetfred.com](http://www.internetfred.com) for updates

Dual Rotor, No Cog.. Nominal Output. Using saw blades for testing... Test Rig..

# Revisiting an old friend... The Dual Rotor - More Wire Plays a Factor

Three hundred turns #20 coil, much too high of a resistance.. Nominal to low output - Starts high and drops on load

## Yet another revision - Alignment...

...  
good...Total alignment is key. Aug-Sept 2003

Much Better.. The output is

**New Concept Generator... Using cuts in a steel strapping laminate core to create poles**

First Set

Second Set

This generator performed well...Medium Output. Alignment good. Cog Low.. resistance low, lot's of smaller coils. June-July 2003

# New Concept Generator - Spherical Overlap Layout Dual Rotor - High Voltage Low Current Output

The idea here is to produce as much voltage as possible and to produce a new coil form where more coils could be used. Also to lessen the losses and maintain charging voltages for battery's no matter what. At 40 RPM's it will begin to produce 22.3 volts, at 60 it produces 32.5 and at 100 it produces 41. At 150 rpm it produces 51 Volts DC. By far the best generator for low speed end. Sept-Oct 2003

**New Concept Generator - Poured Stator Core with poles  
-Alignment perfect!**

Proof of concept... Presently Under Development. Coils are #20 - 25 turns per pole. It's total width is only 8 inch's -32 pole - Oct -25 -2003

The poured core is made of 90 % iron filings and 10 % fiberglass resin. It behaves like a piece of metal in a magnetic field. But has no eddy current losses.

**Newest News; High Voltage Systems Approach, a better way...**

**Lately I have come to the conclusion that low wind speed, high voltage generators that are low current is the optimal way to go.**

High voltage at low current has many advantages such as;

- 1) Low transmission loss, long and smaller lines can be used without large losses
- 2) Low resistance and loss to the creation, distribution and conversion of power. Utilizing a power distribution network.
- 3) Finer and more critical control over construction and distribution of wind generator power, conversion and control systems
- 4) High voltage DC power distribution is more effective with lesser loss
- 5) Multiple parallel generators are no problem on same transmission lines
- 6) The higher the voltage the better the lesser the loss
- 7) Generators that are effective and efficient
- 8) Generators that will start at very low wind speeds (breeze), becomes more effective with higher speeds
- 9) Low torque turning rotor because of control, filter and distribution networks. No strain on generator! provide power not load on generator. load is handled by controller and distribution system. **Produces less overall load on generator requiring less torque to turn.**

This is a critical overview of the newer generators that I am producing, they are in the hundreds of volts and average on a couple 2-4 amps max. The lower the amperage and the higher the voltage the better – in my opinion. But keeping within perspective...

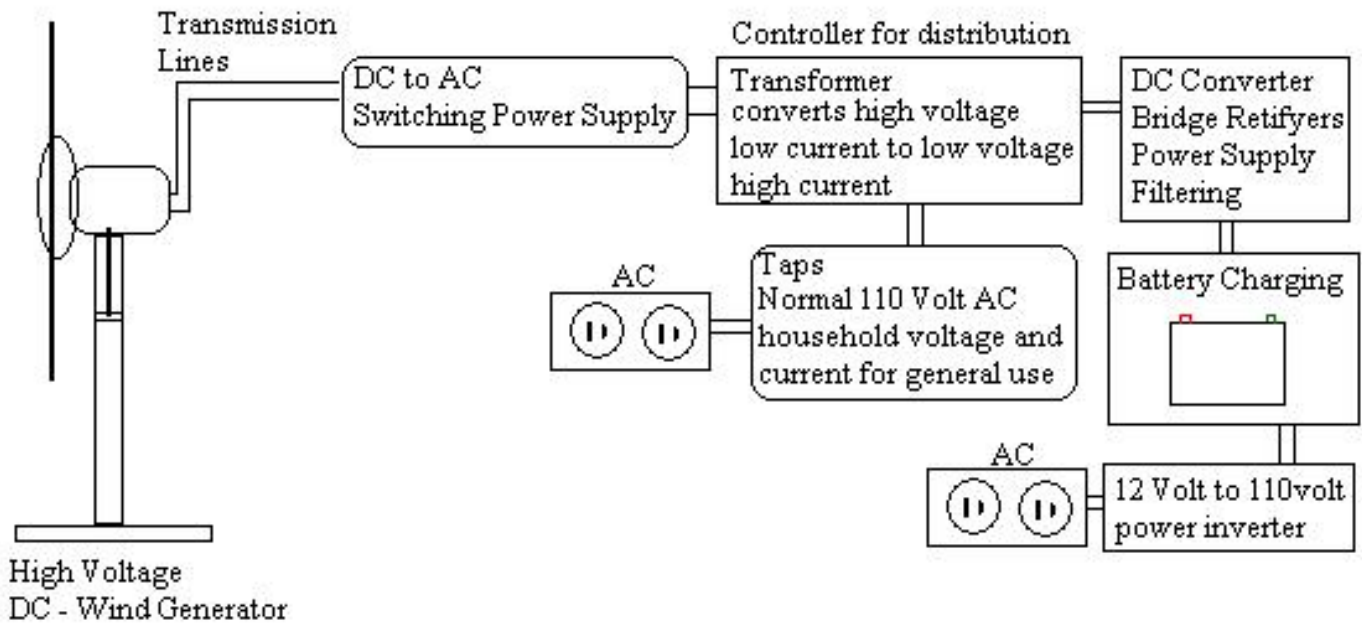

Take for example 250 volts x 2 amps = 500 watts or

Take for example 500 volts x 2 amps = 1000 watts

Power can be converted easily from high voltage to low voltage high current after transmission with very little loss including tapping off AC at 110 volts for general use. The generator works less hard for producing a decent output and will work in the slightest of winds. So it's almost always moving even in a light breeze.

As voltage increases current decreases, as voltage decreases current increases. Hence - Conversion from high voltage DC to AC with the use of switching power supplies produces smooth, ripple free, controlled, continues power. By using switching power supplies you decrease ripple and filter the power instantly. A smooth power is produced.

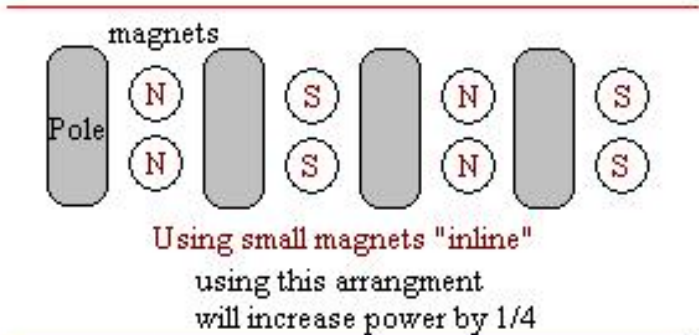

The

controller also contains filtering systems.

## Optimal Generator Design Thoughts

- Lots of small coils reduce overall resistance
- Core form is the way to go, produces much higher voltages. Use Cores
- Smaller wire can be used, bigger wire will reduce resistance but takes more space, # 20 gauge is good start
- More poles, more power more output
- Single phase everything - This is not motor design or household 3 phase design, maximize for voltage not current.
- Use more magnets, can be smaller, in line them for length not width, size dependent on pole size
- Small poles, lot's of them.. the more then better
- Alignment is key. everything has to be in alignment, phase is irrelevant!
- One coil per pole, series winding all coil hookups, again single phase maximize voltage
- Keep direction of coil windings the same on each pole
- Poured stator cores are good - at least 75% or more is metal filings, good for starting point
- Steel laminate strapping cores are better, thinner laminated strapping is even better.. harder to build and more complex
- Half the thickness or a core should be the backing of the core and half the for the pole / evens out the flux path, provides support
- Rectify to DC on pole then filter
- Larger blades to produce a constant overall rpm even in low wind speeds, consistency of motion.
- Large Rotors - This is an interesting one!! Overall liner speed with distance from center, the larger the rotor the faster from center the rotor outside is moving, the more cuts and faster cuts per pole the generator is producing and therefore the higher the output. The poles can now be in the hundreds as is magnets and be producing thousands of volts. The actual generator rpm's are low but the actual speeds on the outside of the rotor are fast. Major output from slow turning blades.

## Thanks go to;

A very special thanks goes first off to Bryan D. -- D for the Deep Thought, Deep Conversations. U Da Man!

[www.fieldlines.com](http://www.fieldlines.com)

[www.windstuffnow.com](http://www.windstuffnow.com)

Both Ed's, both Tom's and Mech you know who you are!! Thanks for the inspirations and thoughts!

And all those that helped along the way. It was worth it! Now lets build it already!!!!

Hi Dan,

Thanks for the close up views.

I would say that the blades probably expanded and contracted with moisture. When they expanded (in wet weather) the wood was crushed, and when they contracted they came loose. That's why you should not leave the axe out in the rain. (the handle gets loose)

I was surprised by the state of the low end stop. There is not usually much stress on that. Either there has been some heavy turbulence, causing the tail to slam down on its stop, or there has been some heavy vibration perhaps. I wonder is that a single phase machine? Vibration from the alternator could also work things loose.

I am surprised you can get away with such thin pipe between the guys and the windmill.

The anemometer position is a constant problem. Too far below the machine and it as less wind. Too close and it is influenced by the windmill. You will find that the relationship between windspeed and power depends a lot on wind direction.

The best place for the anemometer is on a separate tower upwind. Easier said than done though.

Hi Hugh,

About the thin pipe, it seems like to me if the turbine turns out of the wind early/with low rotor thrust a much smaller pipe would work. Dan's turbine appears to prove this, since that's how he makes them I've read. I like the idea of such a design since it seems like to me you can get a lot more out of a small setup, except for the rotor, since a large rotor will make a significant amount of power for a small alternator in LOW winds. And, it's not really much harder, time consuming, or expensive to make a 10 footer as opposed to a 6. I'm just hoping my design can hold up to the high winds using smaller pipe, guy lines, etc. like Dan's does. Btw, great book (Windpower Workshop), thanks for writing it as it's come in very handy. Now you just need to write

([User Info](#))

Hi Hugh - yes, I have no doubt it's due to moisture that the prop nuts are coming loose. The wood is definitely crushing beneath them... the nut's have not turned, they were still locktighted in their original position. I expect this will be something to watch for on all the machines we put up this summer. I've noticed we don't have this problem on Wards (the old one I made a couple years ago for him) because we made a solid steel plate to cover the front of the prop that went between the nuts and the wood. Everytime we check that it's still good and tight. I thought washers would be good enough (perhaps they are)... making the plate takes a bit of extra time, although I think in the future it may be worth the extra trouble.

The tail pivot... it would not be hard to make it stronger. I think part of the problem is that the notch was not landing in full contact with the stop... it was making contact at the very bottom first so all the forces used to be at one point. I think it has "worn in" so to speak and suspect it may not get much worse. Time will tell...

It is a 3 phase alternator, this is the machine I made in May, with a single magnetic rotor and laminates, so I don't think alternator vibration is a significant issue. It is however a very turbulent place. The tower is 45' high... I think even 100' would not get me out of the turbulence here too well. We have hills fairly close on both the North, and the South sides and lots of tall trees. It's fairly mountainous and the wind rarely comes from one direction for very long. I believe this is the main problem... to get out of this turbulent situation on our property would probably be impossible, but surely a taller tower would help.

Regarding the small pipe above the guy wires. I agree... it's very much pushing the limit. I never see it flexing, but it still makes me nervous. It is however stronger than it looks. The pipe is fairly thick walled stainless steel, which is much stiffer than common steel water pipe. There is also tight fitting steel pipe, the next size down - pounded down inside it all the way, and there is a 1" steel pipe (which you cannot see in the picture) welded to the back side.

(kind of a conglomeration of junk...). I have no doubt that a single piece of steel water pipe this size would bend over immediately, I know this just from testing machines on my truck! (I've bent a few pipes over on my truck while testing!) Hopefully next spring I'll have the time/resources to build a stronger, taller tower - I'd not feel comfortable putting any larger machine than this on my current tower.

I thought washers would be good enough (perhaps they are)... making the plate takes a bit of extra time, although I think in the future it may be worth the extra trouble.

The tail pivot... it would not be hard to make it stronger. I think part of the problem is that the notch was not landing in full contact with the stop... it was making contact at the very bottom first so all the forces used to be at one point.

I think it has "worn in" so to speak and suspect it may not get much worse. Time will tell....

It is a 3 phase alternator, this is the machine I made in May, with a single magnetic rotor and laminates, so I don't think alternator vibration is a significant issue. It is however a very turbulent place. The tower is 45' high... I think even 100' would not get me out of the turbulence here too well. We have hills fairly close on both the North, and the South sides and lots of tall trees. It's fairly mountainous and the wind rarely comes from one direction for very long. I believe this is the main problem... to get out of this turbulent situation on our property would probably be impossible, but surely a taller tower would help.

Regarding the small pipe above the guy wires. I agree... it's very much pushing the limit. I never see it flexing, but it still makes me nervous. It is however stronger than it looks. The pipe is fairly thick walled stainless steel, which is much stiffer than common steel water pipe. There is also tight fitting steel pipe, the next size down - pounded down inside it all the way, and there is a 1" steel pipe (which you cannot see in the picture) welded to the back side. (kind of a conglomeration of junk...). I have no doubt that a single piece of steel water pipe this size would bend over immediately, I know this just from testing machines on my truck! (I've bent a few pipes over on my truck while testing!) Hopefully next spring I'll have the time/resources to build a stronger, taller tower - I'd not feel comfortable putting any larger machine than this on my current tower.

Here is a thought on how to fiux the anemometer/downwind thing. . .

Put the anemometer on a swiveling arm and put a tail out the other direction a foot or two more than the anemometer. The tail will keep the anemometer upwind of the genny at all times.

just my \$.02 and worth!

Doug

Dan,

There is something in your post that I don't get. My poor brain can't figure it.

Usually we say that a windmill will overspeed in strong wind if not loaded (free wheeling). When loaded a windmill will slow down right ?

What I don't get is that you stated in your post that one of the reason your mill was running slow was lack of line lost and that by adding line lost your mill speeded up ? (In my perspective, lower line lost imply less load while higher line lost imply more load) What is that I don't get ? Can someone enlighten me ?

Regards Barnac

I am neither for, nor against, but quite to the contrary ;-)

By line loss... we mean resistance in the line.

Imagine if we short the line out... then the resistance in the circuit (except for that in the alternator) is 0 for all practical purposes... and it loads up the machine hugely causing it to turn very slowly. When it's turning this slowly.... the blade is basically forced to go much more slowly that it would like to, or need to in order to produce good power from the wind. (it's stalling...)

Instead of shorting it... we could unhook it completely for any load which would be pretty much infinite resistance and it would free spin, running dangerously fast and probably making lots of noise and not being very efficient.

The batteries are a load, but in our case the load was too much - it took too much. Just a small increase in rpm at the alternator resulted in a big increase in current and that curve didn't match up well with the power available from the prop over a range of windspeeds. By adding resistance it can increase in rpm some (to keep with the prop) and not have such

an immediate increase in current, so the prop is able to maintain at a higher, and more efficient speed over a range of windspeeds.

On the downside, were losing more power in the line. Basicly we've sacrificed a small bit of efficiency in the electrical end of things to allow the prop to run much more efficiently... in the end we come out way ahead on the deal. Our added line loss doesn't hurt us hardly at all in the low winds (7-10mph) where were getting 10 amps or less anyhow, but we do lose a lot of power when current gets higher. At 12 volts, when we see 40 amps current flowing (480 watts into the batteries), we are losing about 400 watts into heat just in the xtra line I added.... (not very efficient) - but were still gaining in the end. I actually think I will change the line and instead of 25', go to about 15', because that added line really allowed the windmill to speed up a bit too much I think.

Somewhere is the perfect balance! Again though... in the end we don't use it that way, because the machine does well anyhow in low windspeeds and if Tom cant use the extra power anyhow, there is little point in running it faster than necessary. It was a fun week watching/playing with these things...

Dan,

Knowing what you know now I'm looking for some advice. I'm the one who has built the Volvo alternator for pre-heating water. Can you tell me the width of your blades at the root of your 10' rotor ? Also an approx. TSR ? I notice that for ease of carving I'm sure that not too many people carve the root area and "drop" to the specs. given in the Excel blade program for most any given TSR & length. I understand that once the blade is turning the root area may not have much affect on performance but ONLY if the load is such that the added torque is not needed. This could be the case more times than not for charging batteries. In my application (and testing proves this out) I will want, and need all the torque and speed I can get at any speed as I will be adjusting the load to "crank" the power. I would rather see my mill turning

slower with the torque needed than to have it stall or be hard starting. Can you guess or do you know the rpm range of your 10' rotor for various wind speeds unloaded ? I'd like to hit 400-425 rpm in 25-30 mph furling say after 30 mph. Do you think the Volvo design is capable of spinning a 12' prop at these speeds or should I stick with whats been tested say the 10' and carve that root to spec. to get that torque I need ? Great information and thank you for sharing your thoughts based on your experience. Dave B.

([User Info](#))

Hi Dave -

The width at the root depends sometimes on what lumber I find available. Usually about 8" wide, and I prefer to find wood 2" thick, but usually its 1.5" thick. At the tips, I've been making them about 2.5" wide and about 3/8" thick, and on all mine the thickness has tapered to full board thickness at the root, and that taper has been a straight line. (not really proper at all... \*) At the root the pitch is as much as the board will allow. About half way between the root and the tip it's about 5 or 6 deg. So far... my blades have not been very scientific!

I've not done good measurments of rpm, but I'm guessing that my 9' machine (single rotor alternator) is probably running with a TSR of around 10. I believe the 10' dual rotor machines are running with a TSR between 5, and 7 in low winds (each one is different and the TSR changes depending on line loss and the nature of the battery bank). The 10' machines are stalling, probably around 15 - 20mph I think, so as windspeed increases the TSR gets less and less... and the blades become less and less efficient. Adding resistance to the line, having a wider airgap, using smaller magnets next time, putting on a larger prop OR rewinding the coils for higher cutin speed... any of these things would change that and allow the blades to run aat a more efficient speed.

So I think really... we try to make blades that \*like to run at a certain TSR when loaded by the alternator, but in the end it's the loading of the alternator that will determine what TSR they actually run at. My 9' machine runs a bit on the fast side, and the 10' machines are running a bit on the slow side, and changes in the line - and/or the alternator would bring them into more efficient operation. Actually - I think my 9' machine is running with reasonable efficiency over the range of windspeeds, and slowing it down would make it safer - but may cost me a bit of power. None of these machines

make much noise - probably the only one I hear any sound from the prop on is Daves (the one at the caboose) - where we had a 4, or 5 deg (cant remember) pitch at the tips. Hugh advised me to try a bit less - and they became almost totally silent. Even the caboose windmill is very quiet, but you do always hear a slight whooshing sound when its running.

When I make blades generally... I tend to work from blades I've made in the past that worked OK, - and I look at other peoples blades. I have a nice set here that Ed made which I use for "inspiration"... although I believe I make some compromises for strength. Mine are a bit wider and thicker at the tips than perhaps they should be... but I get nervous with wood when it gets too thin. I also keep my old windcharger in mind when I make blades, it had a straight pitch from root to tip, the thickness remained the same, from root to tip - and you couldve made the whole blade from a 1 X 4. (it was 6' in diameter if I recall). Bergy blades also have constant thickness and constant pitch from root, to tip - and they are quite efficient.

I could be wrong... but I think that blades are quite forgiving if you're not looking for absolute maximum efficiency... I think anything in the "ballpark" can be reasonably efficient. If you are usin the spreadsheet - I'd just design the prop for a reasonable TSR (like 7), and tune your alternator and your load untill it runs best.

Since your not charging batteries here, I should think you have a lot of flexibility by changing the load to get things matched up nicely.

Dan,

Thank you for your response on the blade info. Like you say, I will have quite a bit of flexibility with adjusting my load(s), cut in speed etc. as I will be designing a variable load controller circuit using solid state relays. I really will need the torque to keep things turning most efficiently in higher winds with my load adjusted properly. Hopefully through basement testing with my 2 hp electric motor set up running the alternator I can design an efficient auto load circuit depending on rpm. This is fun stuff. I think I may take it a step up to a 12' rotor after reading your comments or possibly a 10' with TSR 7 and carve it to spec. including the "extra" drop needed at the root for torque and startup. Thank you again for sharing your info. and photos. You guys have got me

hooked. Dave B.

Dan,

Knowing what you know now I'm looking for some advice. I'm the one who has built the Volvo alternator for pre-heating water. Can you tell me the width of your blades at the root of your 10' rotor ? Also an approx. TSR ? I notice that for ease of carving I'm sure that not too many people carve the root area and "drop" to the specs. given in the Excel blade program for most any given TSR & length. I understand that once the blade is turning the root area may not have much affect on performance but ONLY if the load is such that the added torque is not needed. This could be the case more times than not for charging batteries. In my application (and testing proves this out) I will want, and need all the torque and speed I can get at any speed as I will be adjusting the load to "crank" the power. I would rather see my mill turning slower with the torque needed than to have it stall or be hard starting. Can you guess or do you know the rpm range of your 10' rotor for various wind speeds unloaded ? I'd like to hit 400-425 rpm in 25-30 mph furling say after 30 mph. Do you think the Volvo design is capable of spinning a 12' prop at these speeds or should I stick with whats been tested say the 10' and carve that root to spec. to get that torque I need ? Great information and thank you for sharing your thoughts based on your experience. Dave B.

([User Info](#))

Hi Dave -

The width at the root depends sometimes on what lumber I find available. Usually about 8" wide, and I prefer to find wood 2" thick, but usually its 1.5" thick. At the tips, I've been making them about 2.5" wide and about 3/8" thick, and on all mine the thickness has tapered to full board thickness at the root, and that taper has been a straight line. (not really proper at all... \*) At the root the pitch is as much as the board will allow. About half way between the root and the tip it's about 5 or 6 deg. So far... my blades have not been very scientific!

I've not done good measurments of rpm, but I'm guessing that my 9' machine (single rotor alternator) is probably running with a TSR of around 10. I believe the 10' dual rotor machines are running with a TSR between 5, and 7 in low winds (each one is different and the TSR changes depending on line loss and the nature of the battery bank). The 10' machines are stalling, probably around 15 - 20mph I think, so as windspeed increases the TSR gets less and less... and the blades become less and less efficient. Adding resistance to the line, having a wider airgap, using smaller magnets next time, putting on a larger prop OR rewinding the coils for higher cutin speed... any of these things would change that and allow the blades to run aat a more efficient speed.

So I think really... we try to make blades that \*like to run at a certain TSR when loaded by the alternator, but in the end it's the loading of the alternator that will determine what TSR they actually run at. by DanB on Mon Nov 3rd, 2003 at 07:52:22 AM MST  
([User Info](#))

Hi Dave -

The width at the root depends sometimes on what lumber I find available. Usually about 8" wide, and I prefer to find wood 2" thick, but usually its 1.5" thick. At the tips, I've been making them about 2.5" wide and about 3/8" thick, and on all mine the thickness has tapered to full board thickness at the root, and that taper has been a straight line. (not really proper at all... \*) At the root the pitch is as much as the board will allow. About half way between the root and the tip it's about 5 or 6 deg. So far... my blades have not been very scientific!

I've not done good measurments of rpm, but I'm guessing that my 9' machine (single rotor alternator) is probably running with a TSR of around 10. I believe the 10' dual rotor machines are running with a TSR between 5, and 7 in low winds (each one is different and the TSR changes depending on line loss and the nature of the battery bank). The 10' machines are stalling, probably around 15 - 20mph I think, so as windspeed increases the TSR gets less and less... and the blades become less and less efficient. Adding resistance to the line, having a wider airgap, using smaller magnets next time, putting on a larger prop OR rewinding the coils for higher cutin speed... any of these things would change that and allow the blades to run aat a more efficient speed.

So I think really... we try to make blades that \*like to run at a certain TSR when loaded by the alternator, but in the end it's the loading of the alternator that will determine what TSR they actually run at. My 9' machine runs a bit on the fast side, and the 10' machines are running a bit on the slow side, and changes in the line - and/or the alternator would bring them into more efficient operation. Actually - I think my 9' machine is running with reasonable efficiency over the range of windspeeds, and slowing it down would make it safer - but may cost me a bit of power. None of these machines make much noise - probably the only one I hear any sound from the prop on is Daves (the one at the caboose) - where we had a 4, or 5 deg (cant remember) pitch at the tips. Hugh advised me to try a bit less - and they became almost totally silent. Even the caboose windmill is very quiet, but you do always hear a slight whooshing sound when its running.

When I make blades generally... I tend to work from blades I've made in the past that worked OK, - and I look at other peoples blades. I have a nice set here that Ed made which I use for "inspiration"... although I believe I make some compromises for strength. Mine are a bit wider and thicker at the tips than perhaps they should be... but I

get nervous with wood when it gets too thin. I also keep my old windcharger in mind when I make blades, it had a straight pitch from root to tip, the thickness remained the same, from root to tip - and you couldve made the whole blade from a 1 X 4. (it was 6' in diameter if I recall).

Bergy blades also have constant thickness and constant pitch from root, to tip - and they are quite efficient.

I could be wrong... but I think that blades are quite forgiving if you're not looking for absolute maximum efficiency... I think anything in the "ballpark" can be reasonably efficient. If you are usin the spreadsheet - I'd just design the prop for a reasonable TSR (like 7), and tune your alternator and your load untill it runs best. Since your not charging batteries here, I should think you have a lot of flexibility by changing the load to get things matched up nicely.

Dan,

Thank you for your response on the blade info. Like you say, I will have quite a bit of flexibility with adjusting my load(s), cut in speed etc. as I will be designing a variable load controller circuit using solid state relays. I really will need the torque to keep things turning most efficiently in higher winds with my load adjusted properly. Hopefully through basement testing with my 2 hp electric motor set up running the alternator I can design an efficient auto load circuit depending on rpm. This is fun stuff. I think I may take it a step up to a 12' rotor after reading your comments or possibly a 10' with TSR 7 and carve it to spec. including the "extra" drop needed at the root for torque and startup. Thank you again for sharing your info. and photos. You guys have got me hooked. Dave B.

That's quite a tower Dan, looks like something I'd make myself. :-) I've got giant timber bamboo(4" diam., 50 foot tall) planted, when that gets big enough I'll trade you a load for some magnets. ;-) Anyway, I was wondering what size pole you use at the top to mount your 10 foot turbines too and kind, thin conduit, thick water, steam, or gas pipe? Also, you wouldn't happen to have any idea of the force needed on your 10 foot turbines to get them to furl?  
Kevin

Hi Kevin -  
 At the top there's 2" pipe going all the way to the top (almost) with 1.5" pipe inside that, and the very top stub is 1.25" pipe which is dropped down inside the whole thing, but sticks up about 10" and the wind turbine sits on that. All the pipe is shed 40 water pipe except the 2" which is stainless. (junk I had on hand...)

Then, on the outside of the whole thing, there is a length of 1" pipe which is welded to the side, and drops below all the pipe by about 4' and its chained to the tree...

It doesn't seem to flex much... but a little. When I drop this next time (didn't get to it yesterday) I'll be strengthening things.

Hi Dan,

Sounds like if it's going to break it'll be at the top, right where the 1.25" goes into the rest.

That seems really small, based on Hugh's book and the hint of power available I saw in my own turbine, but if it furls easily (with little trust on the rotor), it seems ok. Especially since you've already had it in 80mph winds. :-) The reason I'm so interested is that I'm going with a 1.75" pole at the top 7 or so feet, then 2" the rest of the way down. I'm using 4 1/8" galvanized steel guy wires. I figure this is way more than enough to support the tower since it only takes around 70 lbs of thrust to completely furl the rotor, we'll see. :-) Thanks.

Kevin

[Motor generator Grid tie?](#) | 4 comments (4 topical, editorial)

Re: Motor generator Grid tie? ([none / 0](#)) (#1)  
by 5kw on Sat Oct 11th, 2003 at 11:49:54 AM MST  
([User Info](#))

Hi Dan,

Your idea will certainly work, whether it is worth the trouble or not depends on the fun factor of, spinnin the meter backwards.

An induction motor behaves as a generator when connected to the line and spun above its synchronous speed, ie a four pole motor typically rated at 1725 rpm on 60 hz, will start looking like a generator above 1800 rpm and reach full or rated power at approxamatly 1875 rpm ,or the same % slip above synchronous speed as it had below it as a motor. Note the slip is a function of load, the 1725 motor will run slightly under 1800 rpm with no load. All above speeds are for 60 hz power on 50hz sync speed would be 1500 for a four pole motor

To impliment the motor generator I would think torque, not speed, as the induction generator will hit a wall of torque at its rated slip. It is possible to push past this speed with enough horsepower , at which time the generator will become unstable, hoever if your pime mover has limited torque this is not an issue.

As far as safety goes, although the utility will insist on UL listed safety cut out relays, in the real world it would be nearly impossible to generate into a dead line with an induction machine as the machine requires lagging current for exitation but can only produce leading current. A capacitive line ( rare) could supply the lagging current but the electrical load would have to be very low to keep from damping out the whole process. Normally a utility failure would present a very high load. In any case a line failure would lose freq and voltage regulation within a few cycles( this is what trips the safety relays) .

Make the wind fun!  
Victor

Hi Dan,

Your idea will certainly work, whether it is worth the trouble or not depends on the fun factor of, spinnin the meter backwards.

An induction motor behaves as a generator when connected to the line and spun above its synchronous speed, ie a four pole motor typically rated at 1725 rpm on 60 hz, will start looking like a generator above 1800 rpm and reach full or rated power at approxamatly 1875 rpm ,or the same % slip above synchronous speed as it had below it as a motor. Note the slip is a function of load, the 1725 motor will run slightly under 1800 rpm with no load. All above speeds are for 60 hz power on 50hz sync speed would be 1500 for a four pole motor

To impliment the motor generator I would think torque, not speed, as the induction generator will hit a wall of torque at its rated slip. It is possible to push past this speed with enough horsepower , at which time the generator will become unstable, hoever if your pime mover has limited torque this is not an issue.

As far as safety goes, although the utility will insist on UL listed safety cut out relays, in the real world it would be nearly impossible to generate into a dead line with an induction machine as the machine requires lagging current for exitation but can only produce leading current. A capacitive line ( rare) could supply the lagging current but the electrical load would have to be very low to keep from damping out the whole process. Normally a utility failure would present a very high load. In any case a line failure would lose freq and voltage regulation within a few cycles( this is what trips the safety relays) .

Make the wind fun!  
Victor

Hi DanB,

Seems like a pretty good idea, a fairly straightforward circuit could be designed to set the on/off points for the motor generator. A while back I found a pretty good book (free!) online - <http://www.eece.ksu.edu/~gjohnson/> there's some info and ideas especially in chapters 5, 6, 7. The whole book is a good read with detailed calculations on a wide variety of wind topics, but it reads well not at all like a dry tech book. Keep us posted on your progress with this one. I have been thinking about trying an induction generator with a small gas engine to charge batteries. There's a site somewhere where a fella uses capacitors parallel with the motor. If I find it I'll post again.

# Dr. Gary Johnson's Renewable Energy and Tesla Coil Page

Dr. Gary L. Johnson taught electrical engineering at Kansas State University for 28 years before taking early retirement in 1994. He wrote a textbook "Wind Energy Systems" which was used in a senior elective course for many years. Prentice-Hall let the book go out of print and gave the copyright back to Dr. Johnson. The revised and expanded version was then used for several more years. This textbook is available at no charge in .pdf files, listed below. The file contents.pdf has a title page, prefaces, and table of contents. The files wind1.pdf through wind9.pdf are the nine chapters of the book.

[contents.pdf](#)

[wind1.pdf Introduction \(2474KB\)](#)

[wind2.pdf Wind Characteristics \(892KB\)](#)

[wind3.pdf Wind Measurements \(875KB\)](#)

[wind4.pdf Wind Turbine Power, Energy, and Torque \(563KB\)](#)

[wind5.pdf Wind Turbine on the Electrical Network \(477KB\)](#)

[wind6.pdf Asynchronous Electrical Generators \(503 KB\)](#)

[wind7.pdf Asynchronous Loads \(1184 KB\)](#)

[wind8.pdf Economics of Wind Systems \(204 KB\)](#)

[wind9.pdf Wind Power Plants \(270 KB\)](#)

In addition to traveling, gardening, and other retirement activities, Dr. Johnson has been investigating Tesla coils, especially the Extra coil directly driven by a solid state inverter. History and theory are covered in six chapters, and the inverter and associated equipment are described in Chapter 7. Additional chapters on experimental results will be available at a later time. Comments and questions can be addressed to [gjohnson@ksu.edu](mailto:gjohnson@ksu.edu). Some photos of sparks are given in the jpeg files.

[p213c.jpg](#)

[p213d.jpg](#)

[p213e.jpg](#)

[p213f.jpg](#)

Dr. Johnson has also been interested in finding yet another source of energy for the past two decades. He wrote and self-published a paper-back book called "The Search for a New Energy Source" which details part of his literature search on this exciting topic. Chapters 1, 4, and 8 are available as PDF files, listed below. If you want the entire document, send \$10 cash or check to Dr. Gary Johnson, Box 1032, Manhattan, KS 66505. If you live outside the United States, email Dr. Johnson and the details will be worked out. If you would like to be a part of an informal working group involving this search, let it be known.

DanB,

I have looked into doing this with engine powered generators for sometime. Once I contacted an engineer at tech support for ELLOT MAGNETEC. I was auditioning as a perspective buyer of a 155kw generator element. I asked the guy how do I connect to the grid with this thing? He then asked me what do you intend to drive the the gen-element with? I replied a 400hp V8 engine. He replied that the engine might be kind of underpowered for the application, but said I could do it, and the engine might wear out in a year or less.

I was told a "VAR POWER CONTROLLER" would keep the freq in phase. He seid it will actually throttle or govern the engine based on the freq in the main line.

There is also another way to do it with an inverter, but its much more experimental, you must use a Isolation Transformer thats rated for the "KVA" of what you expect the power company to buy. And apparently the the "VAR" reads the incoming modified sinewave and reads the output sinewave to the grid and interups the voltages to keep everthing "in phase"

to do this your output must be in the "neighborhood" and the isolation transformer helps in both cases. but I believe the "VAR" makes sure all the power you want to go "upstream" goes out to the grid correctly and in phase.

My best advice would be to find someone who "cogenerates power" with a diesel gen-set. And ask some questions about how they get "all" there output up into the grid. I have run across several people who have done this. but they are moving big power, over 50 to 500kw. They say they can just break even, between the cost of fuel and there needs in there factory, assuming they dont pay taxes on the power they use for themselves.

By the way I happen to have a 500kva isolation transformer just laying around, and will probnably be thrown out pretty soon. what I think is neat about these Isolation transformers is that they will put 3kw into the grid, or 400kw just as easily. depending what the control electronics tell it to do providing you have that much output. and the disconnects are inbetween to Isolation transformer and the grid.

If you want the Isolation transformer I have let me know you can have it, but it weighs about 1000lbs, and is in a nice indoor type cabinet with a control screen.

Re: Motor generator Grid tie? ([none / 0](#)) ([#4](#))  
by Beui ([REMOVE~beui@yahoo.com](mailto:REMOVE~beui@yahoo.com)) on Tue Nov  
4th, 2003 at 11:30:53 AM MST  
([User Info](#))

I found a bunch of information concerning VAR's and other items specific to phase matching from this manufacturer:

<http://www.basler.com/html/rscacc.htm>

This might help you with understanding how the pro's do it!

I'm thinking of doing something along these same lines with a diesel motor running on veggie oil and grid-tie the output! I might just break down and buy a whole diesel genset from ebay.

-Beui

## Voltage Regulator Accessories

Basler Electric offers a broad range of specially designed accessories to enhance voltage regulator capabilities over a wide variance of specifications. Listed below is general information on these types, with specific applications covered in the [Voltage Regulator Accessories Selector Chart](#) that follows. For more information, download [product bulletins](#) by accessory model name or download the [product manual](#).

## Remote Display Panel (RDP-300)

The RDP-300 is a human-machine interface (HMI) used in conjunction with the [DECS-300](#) Digital Excitation Control System to provide remote control, view metered quantities, and provide annunciation of system status and alarms available from the DECS-300 system.

- Touch-sensitive 6" diagonal monitoring screen
- Two-wire, RS-485 Modbus communication protocol
- May be located up to 4000 feet away from the DECS-300

Download [Bulletin SZW](#) for more information or download the [instruction manual](#).

## Paralleling Modules

Basler Electric offers two paralleling modules, the APM300 and the APM2000. Both units provide excellent reactive droop or reactive differential compensation. See the Voltage Regulator Accessories Selector Chart for the paralleling module offered for the different Basler Electric voltage regulators.

Download [Bulletin SPI](#) on the APM300; or for details on the APM2000, download [Bulletin SRJ](#) or the [instruction manual](#).

## Excitation Support Systems

Two basic types of excitation support are offered. One is the Series Boost Option that maintains a constant power input for the voltage regulator and the other is the Current Boost System that supplies needed excitation directly into the field of the generator along with the regulator output. Both types give excellent generator excitation support for short circuit conditions and motor starting. See the Voltage Regulator Accessories Selector Chart for the Excitation Support Systems offered for the different Basler Electric voltage regulators.

Download [Bulletin SP](#) for information on the Series Boost Option. To learn about the Current Boost System, download [Bulletin SQA](#) or [Bulletin SRR](#) or [Bulletin SPW](#). [Product manuals](#) are also available.

## Manual Voltage Controls

A wide range of manual voltage controls is offered as a redundant back-up to the automatic voltage regulator. The manual voltage controller allows for operator control of the generator's voltage when the automatic voltage regulator is removed from the voltage control loop.

Basler Electric offers three families of manual voltage controllers to fit your generator control requirements. These families are the MVC100, MVC200 and MVC300. See the Voltage Regulator Accessories Selector Chart for the Manual Voltage Controller offered for the different Basler Electric voltage regulators.

Download [Bulletin SPC](#) for information on the MVC modules; download [Bulletin SRU](#) for more information on the MVC100 and 200 series; [Bulletin SRK](#) for more information on the MVC300 series. [Product manuals](#) are also available.

## Power Isolation Transformers

Standard models are offered from 208 volts up to 15 KV for voltage matching to the power requirements of the regulator. Medium and high voltage units rated with a primary voltage above 600 VAC have primary line fuse protection and low corona characteristics. Both 50/60 and 400

Hz units are available. Consult the application chart in this catalog for specifics. For special applications, contact Basler Electric for custom designed products.

Download [Bulletin SP](#) or more information.

## Underfrequency/Overvoltage Protection

Basler Electric offers accessory devices to protect against generator underfrequency and overvoltage conditions. UFOV, for use with the SR Series regulators, gives underfrequency rolloff characteristics and overvoltage protection. The UFOV requires a separate breaker with manual reset for overvoltage protection.

Download [Bulletin SPD](#) for more information or download the [product manual](#).

## VAR/Power Factor Control

For cogeneration and other utility parallel applications, Basler Electric offers an SCP250 VAR/Power Factor Controller. This unit receives generator voltage and current inputs to monitor the reactive condition of the generator set. Control signals are sent from the SCP250 to the voltage regulator to maintain the generator's VAR or Power Factor within a regulation band prescribed by the customer. All solid state construction makes the unit easily calibrated on site and maintains levels within +/-5%.

Download [Bulletin UKR](#) for more information or download the [product manual](#).

## Excitation Limiter

For cogeneration and other utility applications, the Model EL200 and Model EL300 Excitation Limiter keeps generator field excitation within safe operating limits to prevent loss of generator synchronization and generator field overheating. Customer adjustments enable tailoring of the exciter system to the generator capability curve. See the Voltage Regulator Accessories Selector Chart for the proper Excitation Limiter offered for the different Basler Electric voltage regulators.

Download [Bulletin SRP](#) for more information or download the [product](#)

[manual](#).

# Exciter Diode Monitor

The EDM200 is designed to monitor diodes in rotating rectifier assemblies on brushless generators. When sensing a shorted or open diode, an auxiliary contact changes state for indication. The EDM200 connects the field output of the voltage regulator and senses ripple current to identify diode condition. It is independent and does not require connection to the rotary portion of the generator.

Download [Bulletin SRO](#) for more information or download the [product manual](#).

Hey guys,

Awesome pictorial guide to building a mill. You're approaching book status you know...

Hugh Piggot watch out, Ha Ha.

Keep up the good work.

Best regards,

troy

Nice job

I was wondering about the shape of the coils in relation to those 2 inch magnets as I have been curious as how to wind a coil for that magnet.

Another thought/question

After seeing your 3 stators in a pic for the three machines it got me thinking.

If you were building a three phase machine could you build 3 single phase stators then adhere them together to get you 3 phase stator. this would definitely make it easier, also each phase could be check prior to assembly and could be seperated if one phase ever needed changing.

Just a thought

Very, very, very interesting but myself can only take so much in from books or reading web pages and probably like yourself need that hands on class room environment to ask those questions which i need answers to. But i got to give it to you, you put the work in and got the output from that work and they look good...wish i could have something with big prop but not where i live (Damn!!!!). Theres mainly two things i dont grasp and thats the building of the props and how the furling system works, hey maybe i need to attend a course by Hugh!!! It has crossed my mind more than once and one day it might just become realality. I dont know how big your community is up there at otherpower but have you ever wonder of building a wind farm and having your own grid? Keep building them gennys cos i will for sure, even though mine look like toys in comparison they still have a purpose and that is to charge batteries. Love the site and the things you guys make.....sean

Just out of curiosity how much current does one of those produce at say 120 rpm? Well actually how fast would it have to spin to light something like a 40 watt CF? Norm.

([User Info](#))

Sorry Norm - I've not tested for that yet... I don't have a powerful enough test setup to test current over a range of rpm yet. A 40 watt CF though... wouldn't take much. I suspect probably you'd do that easily at 110 rpm or so, right after it hits 12 volts.

It seems that a very small increase in rpm = quite a current increase into the batteries. I don't think I've seen these ever exceed much over 400 rpm before furling out, just judging from the sound of the alternator. You can hear the alternator start humming shortly after cutin. I've sat/listened even on windy days, and I've heard it on occasion cover about 1 octave (the faster it goes the higher pitch hum).

My digital multimeter, which can measure frequency, doesn't seem to do well at very low frequencies.. the readings I get are chaotic, so Im unable to determine rpm that way when it's up on the tower.

I really need to make a good test setup where I can drive these with a gas engine or something to get some good data.

([User Info](#))

Sorry Norm - I've not tested for that yet... I don't have a powerful enough test setup to test current over a range of rpm yet. A 40 watt CF though... wouldn't take much. I suspect probably you'd do that easily at 110 rpm or so, right after it hits 12 volts.

It seems that a very small increase in rpm = quite a current increase into the batteries. I don't think I've seen these ever exceed much over 400 rpm before furling out, just judging from the sound of the alternator. You can hear the alternator start humming shortly after cutin. I've sat/listened even on windy days, and I've heard it on occasion cover about 1 octave (the faster it goes the higher pitch hum).

My digital multimeter, which can measure frequency, doesn't seem to do well at very low frequencies.. the readings I get are chaotic, so Im unable to determine rpm that way when it's up on the tower.

I really need to make a good test setup where I can drive these with a gas engine or something to get some good data.

Excellent job! Excellent web page too. I only have one question. Exactly how much air gap do you have between each of the rotors and the stator?

generally about 1/16" on each side, a bit less perhaps.... so the total airgap from magnet to magnet is about 5/8.

We actually made one machine with a smaller tail and a smaller 8' diameter prop. On that one we had to have a higher cut-in rpm, and allow the alternator to spin up faster. So on that one we opened it up quite a bit - almost 1/4" on each side! This brought "cut in" rpm to about 165 and allows the alternator to run faster without generating so much current, basically an attempt to "match" the alternator to a smaller prop. Not very good use of magnets though - if I was going to build an 8' machine I'd use smaller, or fewer magnets. We did it this way thinking that someday we'd probably want to upgrade the machine to a larger prop once DanF builds a stronger/bigger tower.

Hi DanB,

On the smaller prop do you think you would get away with only one disk of magnets and have, say, the front disk with no magnets at all instead of the bigger air gap? I'm thinking this because the magnets are probably the biggest expense and they could be added later with a new prop as an upgrade.

All the best,

Derek

Number four up there...never thought of that one. I wonder if a gaussmeter would be a good candidate for testing possible leakage in the area you're describing; or even just holding a small nail or paperclip on the steel in these zones to check for leakage?

E-man

yes - a gaussmeter would tell. Perhaps if I get a few spare min. today I'll do some tests.

It seems to me that pic #4 would only be the case if the steel backing that actually was used for the rotor was too thin and allowed to saturate with flux. If the steel disc was thick enough, it should neutralize the flux path throughout the entire steel rotor. Isn't this what you want,... enough strength in the magnet to hold itself to the rotor and not slide around. You want to focus the flux path very sharply between rotors. You do not want the magnets flying off of the rotors so that's why it is important to use a steel rotor that is thick enough to allow for the flux path from the back side of adjacent magnets to complete the 'outside' circuit'. When I say outside circuit, I mean the side of the magnet touching the rotor and not the side facing the stator. But your right Dan, this would only be a problem if the air gap was allowed to get too large. RoyR

Well - I should just test it...  
but I think, no matter how thick the steel, some magnetic field would leak back around the side of the magnet to the back side.. or to the steel surrounding the magnet. The lines of force should look for the shortest path "back home" - if the airgap is wide, right around to the back side of the same magnet might be the shortest path. It would be moreso the wider the airgap, or the further apart the magnets I think. Just guessing :-).. I need to get out some iron and test it I guess.

Re: Disk Magnet spacing in axial flux alternators ([none / 0](#)) (#6)  
by DanB on Tue Sep 16th, 2003 at 07:05:53 PM MST ([User Info](#))

that would surely work, except I think it would be a bit large to poke in between the two rotors. It also doesn't give a real good idea of the "strength" of the pole. It would definitely give some idea on a single rotor though.

The Gaussmeter works a lot like a compass, but has a very small probe. It tells polarity though, and field density.

that would surely work, except I think it would be a bit large to poke in between the two rotors. It also doesn't give a real good idea of the "strength" of the pole. It would definitely give some idea on a single rotor though.

The Gaussmeter works a lot like a compass, but has a very small probe. It tells polarity though, and field density.

I think that your pictures are qualitatively correct.

But I'm wondering about the picture 4. if there really is that kind of flux much with thick plates.

I'm more concerned about the empty space between the magnets in that sense that there is no flux at all in that area to hit the coils.

It means that you need higher speeds, when the gaps between magnets are bigger?

I think that there isn't any perfect layout, which is always the best and only good measurements will tell, what is the best configuration using different kinds of magnets.

With every layout there are some compromises to be made?

I would agree - no matter what you do, especially if were having a wide airgap... then some compromises are being made. Every move has its pros and cons.

Yet another interesting discussion. I would point out that a dual rotor alternator is allowed to have TWICE the "air gap" from magnet face to magnet face (compared to a single rotor, from magnet face to lams) with no degradation in performance or flux loss to adjacent magnets. In a dual rotor setup, each facing magnet of a pair contributes to the transmission of the flux. Think of it as the one magnet pushing the flux and the opposing magnet pulling the flux. But if you have a single rotor, the lams can't produce any "pull", but only contribute a better conduit for the push of the single magnet.

I don't have a gaussmeter, but it would be fun if the Dans could do a quicky experiment to confirm the flux readings between to neos 1/2" appart vs one neo (same size, etc) 1/4" space from lams. You would need a small hole in the lams to measure the flux at the face of the laminations.

Anyway, keep up the excellent work,

troy

DanB;

I dont have a good enough 9V battery for my Gaussmeter!

When I started messing with data logging with an RS232 meter to the PC I almost immediately dug out a 9 volt DC wall wart and a battery clip from the junkbox. Since the PC runs off AC I simply plug the wall wart into the power strip the PC runs off of. When the PC is powered up the meter is automagically on too.

Seems like in your case you generally would be using the meter in an area where AC is available so this may help. If you use a 9 V battery clip you can always pop a battery in there if you need to go roam with it. Those 9 volt batteries seem to go bad at the worst times. Just my \$0.02. Be aware that the polarity is "backwards" from how the clip may be marked when you use it this way! Mine had red for + and black for - which is good when it will hook to a battery but opposite when you use it as the battery.

Cheers.

TomW

Re: Disk Magnet spacing in axial flux alternators ([none / 0](#)) (#13)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Sep 17th, 2003 at 02:31:21 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've run some similar tests using my magnets for a dual rotor system. The magnets alone show 3200 gauss, on steel show 4500 gauss. Between two rotors and a 1/2 " gap I'm getting about 6800 gauss.

The same set up using 1/2" thick coils over a lamination I get about 4800 at the lamination.

Another setup with a slotted stator and the air gap is .02" reads 9800 gauss in the air gap. Doubling the magnets over the slotted stator jumps to 1.3 Tesla in the gap.

The dual rotor system is much better than the coil over iron system but still falls behind in the overall power you can achieve with a slotted stator. There are advantages and disadvantages to both systems but for the simplicity in building, coil over lams is the simplest, the dual rotor comes in second and of course the slotted stator last. Power wise and efficiency the order is reversed.

I've been contemplating a way to decrease the gap between the two rotors by using the overlapped coils 3phase wiring. I think that has bothered me most about the design. The inline 3phase version has to create all the voltage in fewer coils which makes the amount of turns high and the gap between the rotors larger. By spreading the coils out you need fewer

turns thus keeping the magnets closer to the flux.

I haven't built one as yet but my idea was cut out a ring in plastic. Drill the holes around the outer diameter that would represent the slots in the stator and saw through the top layer of each hole just wide enough to get the wire through. Once wired you would have a very thin stator. From there you would make a mold to make the mounting tabs and pour over the wire in those areas. Still working out some details on the idea but you get the picture. Another idea was to build 2 rings with hooks and wire it to the hooks, It would look like spokes in a bike but the wires would be allowed to spread out a bit that way so the later is still prime in my mind.

Have Fun  
Ed

Re: Disk Magnet spacing in axial flux alternators ([none / 0](#)) ([#14](#))  
by troy on Thu Sep 18th, 2003 at 10:08:36 AM MST  
([User Info](#))

Hey thanks Ed, excellent food for thought. A slick easy cool strong overlapped thin three phase stator seems to be a very elusive beastie. But I keep thinking about it...

Also, if I embed a 3/8" copper tube for cooling around the outside edge of the stator next to the coils, will the flow of electricity in the coils induce eddy current in the cooling pipe?

Best regards,

troy

9V battery woes ([none / 0](#)) (#12)  
by TomW on Wed Sep 17th, 2003 at 01:32:21 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

DanB;

I dont have a good enough 9V battery for my Gaussmeter!

When I started messing with data logging with an RS232 meter to the PC I almost immediately dug out a 9 volt DC wall wart and a battery clip from the junkbox. Since the PC runs off AC I simply plug the wall wart into the power strip the PC runs off of. When the PC is powered up the meter is automagically on too.

Seems like in your case you generally would be using the meter in an area where AC is available so this may help. If you use a 9 V battery clip you can always pop a battery in there if you need to go roam with it. Those 9 volt batteries seem to go bad at the worst times. Just my \$0.02. Be aware that the polarity is "backwards" from how the clip may be marked when you use it this way! Mine had red for + and black for - which is good when it will hook to a battery but opposite when you use it as the battery.

Cheers.

TomW

[Disk Magnet spacing in axial flux alternators](#) | 14 comments (14 topical, editorial)

Re: Disk Magnet spacing in axial flux alternators  
([none / 0](#)) (#13)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Sep 17th, 2003 at 02:31:21 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've run some similar tests using my magnets for a dual rotor system. The magnets alone show 3200 gauss, on steel show 4500 gauss. Between two rotors and a 1/2 " gap I'm getting about 6800 gauss. The same set up using 1/2" thick coils over a lamination I get about 4800 at the lamination. Another setup with a slotted stator and the air gap is .02" reads 9800 gauss in the air gap. Doubling the magnets over the slotted stator jumps to 1.3 Tesla in the gap.

The dual rotor system is much better than the coil over iron system but still falls behind in the overall power you can achieve with a slotted stator. There are advantages and disadvantages to both systems but for the simplicity in building, coil over lams is the simplest, the dual rotor comes in second and of course the slotted stator last. Power wise and efficiency the order is reversed.

I've been contemplating a way to decrease the gap between the two rotors by using the overlapped coils 3phase wiring. I think that has bothered me most about the design. The inline 3phase version has to create all the voltage in fewer coils which makes the amount of turns high and the gap between the rotors larger. By spreading the coils out you need fewer turns thus keeping the magnets closer to the flux.

I haven't built one as yet but my idea was cut out a ring in plastic. Drill the holes around the outer diameter that would represent the slots in the stator and saw through the top layer of each hole just wide enough to get the wire through. Once wired you would have a very thin stator.

From there you would make a mold to make the mounting tabs and pour over the wire in those areas. Still working out some details on the idea but you get the picture.

Another idea was to build 2 rings with hooks and wire it to the hooks, It would look like spokes in a bike but the wires would be allowed to spread out a bit that way so the later is still prime in my mind.

Have Fun  
Ed

Hey thanks Ed, excellent food for thought. A slick easy cool strong overlapped thin three phase stator seems to be a very elusive beastie. But I keep thinking about it...

Also, if I embed a 3/8" copper tube for cooling around the outside edge of the stator next to the coils, will the flow of electricity in the coils induce eddy current in the cooling pipe?

Best regards,

troy

Thanks guys,

DanCad rules! I have a feeling this page is going to get referenced a lot...

Keep having fun!

troy

ps, are you guys quietly plotting to produce an FAQ with DanCad illustrations??? This one would be a must have.

Hope so,

tr

Wow looks like a production line you going there, the way you Dans are going you could have your own community wind farm up with power supplied to all the houses up there. Of course that depend on the distance between houses and could get costly in cable.....sean

Looks good guys ! I especially like the lines of your blades.  
You're starting to look like real wood workers now.

I look forward to seeing what the power outputs on these  
stooges are.

Chuck

Great to see those 3 reaching completion. Looking frward to hearing about them cranking out the power.

As for grid intertie, the simplest solution is probably a Trace SW or a 'power station'. That would do a god job of turning the DC into grid AC. I am not sure if Outback have a product to do that for you yet.

Good work guys!

Mass production comes to otherpower. Who'd a thunk it.

Dan B, Dan F and the Otherpower guys:

Way to go! As always, I continue to be fascinated by your innovative and practical solutions for alternative power systems.

Looking forward to seeing the test results!  
Regards, XEROID.

Very nice Dan and thanks for the cobalt mags. :-) Im currently working on that machine. I just wanted to say that there is another way to make sure the faces of the mags match up on both rotors. What I do in assemble the dual rotor machine so that it has the rear rotor in place and then the stator just like you do. I then do all the common tests. When it comes time to match up the mags before gluing the second rotor, I mount the front rotor on backwards so that the magnet side is facing out (except of course there is no mags glued yet). I then take a paint pen and mark the two rotors so they only will go on in one direction only. I then take a "T" square and hold it perpendicular to the two rotors (edge wise). I hold the inside of the square to the rear side of the rear rotor so that I can follow and trace a center line to the front rotor. I do this all the way around the front rotor so that I have perfect increments around the side of the front rotor that line up with the mags on the rear rotor. I then remove the front rotor and lay the square across the face of the front rotor and follow my trace in to the center. This will allow you to see where the center of each mag should go on the face of the front rotor. You just have to make sure that you follow the poles over and write on the rotor "N" or "S" depending on which pole should face in (it will be obvious with the square when you follow accross to the second rotor). You then should place your mags and space them with the shims and thats it (well, glue and resin of course :-)) ). Wish I had a pic of how I did it. Hope you can visualize. Sounds like your having fun!!! RoyR

Nice job guys!!! But I have a question, you don't have a backing material in the back behind the coils... why not and whats up with this ???  
Good Luck!  
Fred.

Hi Fred.

The machines are all dual rotors, meaning that there are magnets in the front and back of each set of coils. No laminates are needed for such a set up since the magnets of the rotor in front are being attracted to the magnets of the rotor on the other side of the coils.

Aren't you working on a double rotor machine yourself? Same principle.

Xeroid.

There is fiberglass fabric on both sides of the coils, so hopefully the stator is strong enough! I'm not sure, but was that your question?

([User Info](#))

Howdy Dan. I take it these magnets arent as thick as the first one the caboose you built a few weeks ago. what is the approximate thickness of the goop you put over the top of the actual magnets themselves once you put the tape around the rotor. This should be a good comparison on the magnet strength. Looking forward to the results and the finish wiring . Thanks JB Dayton Nevada

[ [Parent](#) ]

Re: Too much fun! 3 windmills... ([none / 0](#)) ([#10](#))  
by JB on Sat Aug 2nd, 2003 at 12:19:27 AM MST  
([User Info](#))

My mistake there Dan. The magnets are the same. Im getting a clearer picture on this now. the bearings and everything on the back driving the front hub through the long all thread studs.i like it. I was wondering i got some delrin here or some kind of plastic about 3/4 inches thick. i was wondering if i might drill some big holes in the put the coils in the center and cover both sides with some thin aluminum. i guess the stator could be square and you could use 4 studs also. One thing I forgot is how much is one magnet supposed to cover in coil area. a coil and a third? i guess that is what it works out to be. 9 magnets 12 coils is that right. Getting late . Time to stop thinking. Later on. JB

Re: Too much fun! 3 windmills...

([none / 0](#)) ([#11](#))

by DanB on Sat Aug 2nd, 2003 at 10:16:12 AM MST

([User Info](#))

Hi JB -

you could probably make the stator from delrin, insert the coils, and glue them in there, that would work fine. Aluminium covers would be a bad idea though... you'd have serious eddy current problems! You might be surprised when the alternator barely wants to turn at all.

Making the mold from plywood is really easy, and we simply place the coils in the right spots (or try) and then bring all the wires out. When we mold the stator, we first grease the mold, then put down some polyester resin (I get it from Autozone in 1 gallon cans for about \$20), then we put down some fiberglass fabric to reinforce it, then we put in the coils over the top of the fabric. Then we mix up new resin and mix it with talcom powder and pour that over the coils so it pretty much fills up the mold. Then we put down more fiberglass fabric, and pour resin over that - and put the lid on the mold. It's real easy, probably a lot less work than messing with delrin and I think a bit stronger and less flexible.

You don't want any metal other than your copper coils in the stator...

by JB on Sun Aug 3rd, 2003 at 12:15:42 AM MST

([User Info](#))

Thanks Dan. Got ya covered on the stator . Ill make it all resin and fiberglass. another ??? Im not real hot on the wiring yet, in fact im a little slow on it. lets Call any of the nine coils #1. do we start off with one wire of 1 coil at a copper lug and then it is serised thru number 4 coil 120 degrees away then serised thru #7 coil 120 degrees from #4 coil then finished of with the remaining wire of #1 coil at the same copper lug we started with. Is this correct???????? and you do the same for coils # 2 -5 and 8 and 3 -6 and 9 taking them coils to their respective lugs for the total you got on this one of 3 lugs. If this is correct where do you go from here

and where do you pick up the ground wire. I noticed on the papoose windmill you had 6 lugs but i dont want to confuse myself more on this. can you clue me in.  
JB

Thanks Dan. Got ya covered on the stator . Ill make it all resin and fiberglass. another ??? Im not real hot on the wiring yet, in fact im a little slow on it. lets Call any of the nine coils #1. do we start off with one wire of 1 coil at a copper lug and then it is serised thru number 4 coil 120 degrees away then seriesed thru #7 coil 120 degrees from #4 coil then finished of with the remaining wire of #1 coil at the same copper lug we started with. Is this correct???????? and you do the same for coils # 2 -5 and 8 and 3 -6 and 9 taking them coils to their respective lugs for the total you got on this one of 3 lugs. If this is correct where do you go from here and where do you pick up the ground wire. Howdy Dan. I take it these magnets arent as thick as the first one the caboose you built a few weeks ago. what is the approximate thickness of the goop you put over the top of the actual magnets themselves once you put the tape around the rotor. This should be a good comparison on the magnet strength. Looking forward to the results and the finish wiring . Thanks JB Dayton Nevada

My mistake there Dan. The magnets are the same. Im getting a clearer picture on this now. the bearings and everything on the back driving the front hub through the long all thread studs.i like it. I was wondering i got some delrin here or some kind of plastic about 3/4 inches thick. i was wondering if i might drill some big holes in the put the coils in the center and cover both sides with some thin aluminum. i guess the stator could be square and you could use 4 studs also. One thing I forgot is how much is one magnet supposed to cover in coil area. a coil and a third? i guess that is what it works out to be. 9 magnets 12 coils is that right. Getting late . Time to stop thinking. Later on. JB

Hi JB -

you could probably make the stator from delrin, insert the coils, and glue them in there, that would work fine. Alumininum covers would be a bad idea though... you'd have serious eddy current problems! You might be surprised when the alternator barely wants to turn at all.

Making the mold from plywood is really easy, and we simply place the coils in the right spots (or try) and then bring all the wires out. When we mold the stator, we first grease the mold, then put down some polyester resin (I get it from Autozone in 1 gallon cans for about \$20), then we put down some fiberglass fabric to reinforce it, then we put in the coils over the top of the fabric. Then we mix up new resin and mix it with talcom powder and pour that over the coils so it pretty much fills up the mold. Then we put down more fiberglass fabric, and pour resin over that - and put the lid on the mold. It's real easy, probably a lot less work than messing with delrin and I think a bit stronger and less flexible.

You don't want any metal other than your copper coils in the stator...

([User Info](#))

Thanks Dan. Got ya covered on the stator . Ill make it all resin and fiberglass. another ??? Im not real hot on the wiring yet, in fact im a little slow on it. lets Call any of the nine coils #1. do we start off with one wire of 1 coil at a copper lug and then it is serised thru number 4 coil 120 degrees away then seriesed thru #7 coil 120 degrees from #4 coil then finished of with the remaining wire of #1 coil at the same copper lug we started with. Is this correct???????? and you do the same for coils # 2 -5 and 8 and 3 -6 and 9 taking them coils to their respective lugs for the total you got on this one of 3 lugs. If this is correct where do you go from here and where do you pick up the ground wire. I noticed on the papoose windmill you had 6 lugs but i dont want to confuse myself more on this. can you clue me in. JB

Make a mpg of the furling in action.. it would help for understanding greatly!!!  
Even if it was by hand.....

Great drawings Dan! This must be the notorious DANCAD software that everyone needs to have. I like it!

I've tried alot of different ways to furl these systems. Side furling, tilt, spring and a few stupid ideas of my own. The spring system works but has a built in problem... as the spring stretches it progressively adds more tention which means higher winds to achieve a reasonable furling. I must say that hugh's gravity system is the best I've seen (and used - with several under my belt). The simplicity and functionality of the unit makes it about the best choice for home building.

Have Fun!

Ed

I would agree that it is probably the best but has anyone managed to create one without having to do any welding? If so, pictures would be nice.

Martin.

I think, no matter what you do a bit of welding is necessary. I suppose you could figure a way to bolt it all together, but it would be a bit tricky...

I built one out of wood , "U" bolts , and hinge that worked out quite well. It was a small machine with a 6 ft prop. Used an Amtek motor U bolted to plywood with a 1.25" water pipe U bolted to the same plywood. The hinge was bolted on at a 20 degree angle and the tail bolted to the hinge. A steel tail stop was bolted to the top. A quick and fun project. Kind of a "windmill in a day" project.

Too much fun...

Ed

yes, I do like that system very much. I tend to wonder what the "upper limit" is for prop diameter used with this system. Undoubtably there are strange forces on the blades while it's furling, and while it's furlled... I suspect that in very large machines it might not work so well.

Hopefully... we'll never find that limit!

([User Info](#)) <http://www.windstuffnow.com/main>

I built one out of wood , "U" bolts , and hinge that worked out quite well. It was a small machine with a 6 ft prop. Used an Amtek motor U bolted to plywood with a 1.25" water pipe U bolted to the same plywood. The hinge was bolted on at a 20 degree angle and the tail bolted to the hinge. A steel tail stop was bolted to the top. A quick and fun project. Kind of a "windmill in a day" project.

Too much fun...

Ed

yes, I do like that system very much. I tend to wonder what the "upper limit" is for prop diameter used with this system. Undoubtably there are strange forces on the blades while it's furling, and while it's furlled... I suspect that in very large machines it might not work so well.

Hopefully... we'll never find that limit!

DanB,

BOINNNNG!!! I think I finally see the crucial piece of information that I've been missing!

Dan wrote:

"the tail is mounted on a pivot. In this case however, the pivot is offset to one side, AND IT IS AT AN ANGLE (about 20 deg usually) TO THE TOWER."

I had understood that the tail was not mounted perpendicular to the plane of the blades. I had assumed that was the 20 degree angle. But that is really what you are calling "offset to one side." THERE ARE ACTUALLY TWO ANGLES INVOLVED.

Viewed from the top - the tail is offset from the plane of the blades by some number of degrees. But the hinge is also mounted at an angle from the straight up of the tower. So the tail doesn't go straight up and down like a see saw. It's leaning.

This means that the tail vane may not really be exactly perpendicular to the ground. It may actually lean to one side at 20 degrees (in your example). So wind can exert force that gets under the vane to push it up.

What had totally flumoxed me was that I couldn't understand where the lift was coming from? I had missed the fact that the tail doesn't move up and down exactly perpendicular to the ground.

Sorry to waste so much bandwidth on this, but I just wasn't grasping the situation accurately. I'd missed the second angle.

Thanks Dan. You're my hero - (just not an anonymous one.) ;-)

I think he's got it ! ([none / 0](#)) ([#6](#))

by Chuck on Wed Jul 23rd, 2003 at 12:01:10 PM MST

([User Info](#)) <http://www.greeleynet.com/~cmorrison>

yes, I think you have it now.

For a little further illustration, or to confuse things more, depending... I show below my wind generator viewed from below during a calm. You can see some of the angles involved. Note that I didn't bother to make the tail perpendicular to the tower and it serves to highlight the furling angle.

Also, since someone asked, there is no welding on this particular machine's furling system. In fact there's no welding on this machine at all. I used a couple cheap pillow blocks and a 12"x1/2" bolt to hold the tail.

Re: Furling system ([none / 0](#)) (#7)  
by DanB on Wed Jul 23rd, 2003 at 12:15:44 PM MST  
([User Info](#))

Ideally the tail could, and probably should (but it doesn't really matter) be perpendicular to the ground in normal operation. The angle of the tail doesn't give it any lift... or at least, it's not necessary for that to happen. The tail is lifted only by the force against the prop.

([User Info](#)) <http://www.greeleynet.com/~cmorrison>

Actually Dan, I think it does matter. Angled the way it's shown in the picture the tail does provide lift itself, which is not desirable. My experience has been that this machine furls too soon and part of that I blame on the tail surface being at that angle. This is one of things I'm fixing this week.

Re: Furling system ([none / 0](#)) ([#14](#))  
by DanB on Wed Jul 23rd, 2003 at 05:24:32 PM MST  
([User Info](#))

Yes... I guess mainly I meant.. that if the tail is not square with the tower it doesnt matter too much, it means that it's probably got less surface area since it should be with the wind all the time, so if the tail is not vertical it has to be a bit larger. If in its resting position it's both not vertical and tipping down (or up I suppose) then it could get some lift from the wind which would not be ideal. So.. it should be vertical...

Itll be fun to see yours after that's fixed... it would benifit in both performance and appearance! I'm dying to see your next one too!

([User Info](#))

Hi Bach on

I actually never built myself one of these furling system.

I guess you have a grab on it now, but the fact that the tail vane rise is not caused by the wind exerting a force that gets under the vane to push it up, but simply because It's mounted on a pivot at angle relative to horizontal axis (22 deg relative to the tower or 68 deg relative to the ground).

In the spring system the pivot on wich the tail vane is monted is not on an anle relative to the vertical plane. It's parrallel to the tower and vertical to the ground (0 deg to the tower; vertical plane, 90 deg to the ground; horizontal plane) so when the system is furling the tail vane rotate around the vertical axis, staying in the same plane relative to the ground (horizontal).

Like a garden gate does when you open it. It's rotating around the vertical axis staying in the same plane relative to the ground (horizontal plane). Now imagine that the stupid snow plower strucked the gate post and bented it 22 degree from the vertical axis (the tower)and the edge of the gate is now barely touching the ground when close. Now what happens when you try to open the gate, the edge of the gate will rise relative to the ground... wright? The more you open it the more it rises relative to the ground. Cause now the gate rotate around an axis who is no longer vertical to the ground so the edge of the gate doesn't move in the horizontal plane anymore but keep going away from it the more you open it. Now what happens if you let go ? the door will close by itsel (well helped a bit by gravity ;-)).It's the same thing with the fridge's door when the fridge is not level i.e. on an angle relative to the vertical plane.

Now in the second furling system when the force of the wind against the prop rotate it away from the wind and as the tail vane always stays with the wind, the tail vane as no choice but to rotate around that 22deg of vertical axis and the edge of the tail rise relative to the ground.

Anyway, it's only my perception of the thing and I may be totally wrong...

P.s.: please furling guru if I'am wrong tell me :-)

Actually Dan, I think it does matter. Angled the way it's shown in the picture the tail does provide lift itself, which is not desirable. My experience has been that this machine furls too soon and part of that I blame on the tail surface being at that angle. This is one of things I'm fixing this week.

Yes... I guess mainly I meant.. that if the tail is not square with the tower it doesnt matter too much, it means that it's probably got less surface area since it should be with the wind all the time, so if the tail is not vertical it has to be a bit larger. If in its resting position it's both not vertical and tipping down (or up I suppose) then it could get some lift from the wind which would not be ideal. So.. it should be vertical...

Itll be fun to see yours after that's fixed... it would benifit in both performance and appearance! I'm dying to see your next one too!

Hi Bach on

I actually never built myself one of these furling system.

I guess you have a grab on it now, but the fact that the tail vane rise is not caused by the wind exerting a force that gets under the vane to push it up, but simply because It's mounted on a pivot at angle relative to horizontal axis (22 deg relative to the tower or 68 deg relative to the ground).

In the spring system the pivot on wich the tail vane is monted is not on an anle relative to the vertical plane. It's parrallel to the tower and vertical to the ground (0 deg to the tower; vertical plane, 90 deg to the ground; horizontal plane) so when the system is furling the tail vane rotate around the vertical axis, staying in the same plane relative to the ground (horizontal).

Like a garden gate does when you open it. It's rotating around the vertical axis staying in the same plane relative to the ground (horizontal plane). Now imagine that the stupid snow plower strucked the gate post and bented it 22 degree from the vertical axis (the tower)and the edge of the gate is now barely touching the ground when close. Now what happens when you try to open the gate, the edge of the gate will rise relative to the ground... wright? The more you open it the more it rises relative to the ground. Cause now the gate rotate around an axis who is no longer vertical to the ground so the edge of the gate doesn't move in the horizontal plane anymore but keep going away from it the more you open it. Now what happens if you let go ? the door will close by itsel (well helped a bit by gravity ;-)).It's the same thing with the fridge's door when the fridge is not level i.e. on an angle relative to the vertical plane.

Now in the second furling system when the force of the wind against the prop rotate it away from the wind and as the tail vane always stays with the wind, the tail vane as no choice but to rotate around that 22deg of vertical axis and the edge of the tail rise relative to the ground.

Anyway, it's only my perception of the thing and I may be totally wrong...

P.s.: please furling guru if I'am wrong tell me :-)

Basically this gravity system of furling is the same as used with Marlec small wind chargers for example.

With Marlec the hinge is on the far end of the tail boom.

My friends here are complaining that the system is not really good, when water goes in between the tubes in the hinge and so during the winter there is ice.

I'm still not sure, if the gravity system is better or worse than the old German system with another tail on the same plane as the prop.

I made small drawing of that system during an earlier discussion.

Re: Furling system ([none / 0](#)) ([#12](#))  
 by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Wed Jul 23rd, 2003 at 03:54:06 PM MST  
 ([User Info](#)) <http://www.scoraigwind.co.uk>

Thanks for such a clear explanation, DanB. So many people ask me about how that works.

There are problems with getting the best angle for the hinge. Each setting has some side angle and some back angle. I usually set it so the side and back angles of the hinge are almost equal so that the power output stays about the same over a range of winds. But the output peaks a little in the middle where the tail is climbing most steeply.

So when I get really fussy I use a different type of hinge with a cam at the top. The tail hangs off a belt or chain, that wraps around the cam, so that the axis of the hinge changes. That allows full control over the tail furling forces.

The Marlec version with only the vane hinged works after a fashion for a while until the force of the wind on the boom alone is enough to pull the rotor back into the wind.

The system with the side vane is great for a type of pump that needs the crank shaft over the well, but has no other advantages compared to the offset rotor systems. The side vane is unstable in operation and ugly.

My perspectives :-)  
 Hugh Piggott <http://www.scoraigwind.co.uk>

The level of professional courtesy around here should be some form of development model. Dude,, When I saw the DANCAD drwg#2 I started to salivate. What a fantastic design. On top of the fact the everyone is doing everything right. My hat goes of to you Hugh.^ You are correct the asthetic part is crucial

[\(User Info\)](#)

The fact that the lowest setting for the tail is actually [according to Hugh's plans] 100 degrees from the rotation of the blades is what puzzles me. Or 80 degrees [10 degrees off perpendicular]. In other words if the blades were 3 o'clock and 9 o'clock then the tail would be sitting at 11 o'clock not 12 o'clock with no wind. I read some where else that as the wind first hits the machine it settles it tail in the 12 o'clock position with the blades at 3 and 9 o'clock.

What I'm wondering is if you can actually use this to start the machine turning more easily? Let say that the root of the blade is 27 degrees. With the tail at 100 degrees [11 o'clock] would this actually for that time as the wind first hits the blades make the root of the blades 37 degrees and help with starting thr blades in light winds?

Now I haven't fully figured this out but off the top of my head it would seem that you would have to have a counterclockwise rotation, but would that help?

# HOMEBREW WIND GENERATOR

---

This page is about a windmill experiment. The windmill was built for under \$100, and although there is certainly much room for design improvement, it works fairly well and should provide some data to other folks who'd like to build their own from scratch! If time is money, and one has more money than time, it might be wise to buy a commercial machine, there are many good ones starting from about \$500 on up, however to build one at home is fun, and it can save a lot of money! It's my hope that "experts" (folks more knowledgeable than myself on this topic) will review this page and offer suggested improvements on our discussion board! This page will break down the components of the machine and in the end I'll discuss what I know about its performance!

## The Propeller

The propeller for this machine is a 3 bladed design. Although a 2 blade prop is simpler to build, they have the disadvantage of being harder to start. The other drawback is that when the wind changes direction, a 2 blade prop tends to vibrate

quite a bit while turning. This is hard on the prop, and the generator bearings. I made my prop out of spruce 1" X 4" boards. I tried to pick 3 boards which were knot free, had good vertical grain and seemed to have similar density. (they weighed about the same). Of course other types of wood could be used, this is what I had available. I've made very good props from redwood, ponderosa and lodgepole pine with no problems. I used 1" X4" (actually - it was planed down to about 3/4" X 3 1/2") because I wanted the prop to be light weight, I think this helps them start faster and preserves the bearings on the generator. It seems consistent with props I've seen on small commercial windmills. I carved my prop real fast, took about 2 hours. Undoubtedly, had I spent more time I'd probably have a better prop, but...I have seen folks spend a week on this stage and I feel it can be a fairly quick and simple project. I used "intuition" on both the pitch of the prop, and the airfoil shape. I simply marked 1/4" down on the thickness of the prop, so that over the 3 1/2" width the low end would be 1/4" below the high end. There is a LOT of information on prop carving, airfoil details etc on the Internet. The Lee-Jay manual, published in the 1930's also has good simple instructions for both propeller carving and building a windmill from scratch. See the picture below....

Once roughed out, I weighed each prop and planed them down so they were the same. I then bolted them together, two at a time, and further planed them down so they were reasonably balanced. Once all three blades were the same weight, I painted them, and bolted them to a hub (an old gear about 8" diameter). Once on the hub, I could put the whole assembly on a shaft, and spin it. I would observe the place in which the prop stopped, if it had tendency to stop in 1 place more often than others, I would plane down the heavy side(s) until it seemed perfectly balanced. (of course I had to paint those spots again!). The whole process of building this prop, and balancing it took less than 4 hours. It should be noted that all 3 blades, after being balanced, were NOT of the same thickness. At the tip, they varied from in thickness by over 1/8"! This could have been prevented by finding better wood, and taking more time in the initial carving of the prop. The main tool I used for carving this prop was a power planer. It should also be noted, this prop has NO twist, the pitch remains the same from the hub,

to the tip. Although unsure, I do not think this hurts, especially in a small machine. Total prop diameter is approx. 6 1/2'...although, to be honest, I never measured it! This is the same propeller I tested on my model A ford. [Click here](#) to check out that page! . It worked so well on the Ford test, that I figured it would hold up on a windmill. The only modifications I made since that test was to cut about 8" off the diameter and further balance it.

## The Alternator

The alternator used in this windmill is a 2hp induction motor which I took off a Taiwanese milling machine. I took it apart, and cut a slot into the armature with a metal lathe so that I could insert 8 Neodymium rare earth magnets, thus turning the induction motor into a permanent magnet low rpm alternator. The magnets are rectangular in shape, and curved such that they seem to be a good fit in the armatures of most induction motors 1/2hp on up. I cut a slot in the armature so that when pressed all the way down, the highest point on the magnets is flush with the outer diameter of the armature. The slot is cut so the magnets are a tight fit, and the magnets are glued in with epoxy. This is a 4 pole motor, so it requires 4 alternating poles in the alternator. To accommodate 8 magnets, I had to insert them in pairs, with two magnets of identical polarity beside each other. These particular magnets are surplus from computer hard drives and are available with both North, and South on the convex surface. See a picture of 8 of these magnets in a ring below. You'll find these same magnets for sale on our products page.

The alternator is wired so that it hits 12 volts at approx. 160rpm. Had I wired the motor differently it could have hit charging voltage at 80 rpm, but I was afraid this would limit the current too much. Of course, the output here is alternating current and it must be rectified before charging batteries. I used a 40 amp bridge rectifier to reach this end. We also offer large bridge rectifiers on our products page. It is very important that when using a diode, or a bridge rectifier in this application that it be attached to a suitable heat sink, or else it will get too hot and burn up! [Click here](#) to see our experiments page about converting induction motors into low rpm alternators.

## The Tower

The tower is probably the MOST important part of any wind machine, and is often the most neglected....this is probably the case here! I put this up in the middle of Feb, it was very cold, the ground was very frozen and I didn't have the ability to pour a proper concrete pad which I think would make for a nice tower base. I also have the disadvantage of being in a forest, with no level ground. Although this works OK, I feel a much higher tower would be appropriate. My windmill currently sits 36' feet above the ground. I removed one large pine tree, as I thought that would be the best place for the tower. I cut the stump off about 3' high, and notched it with a chain saw. The mast is made from a lodgepole pine. The base of it was drilled through so that it could pivot in the stump. The top of it has a steel assembly made from pipe, to allow support and pivoting of the windmill. I while assembling the windmill the tower was

supported off the ground by a small tripod made from lodgepole pine. A larger tripod was used for raising it. The tower is supported by 4 guy wires of 1/8" diameter aircraft cable with turn buckles on the ground for adjustment.

I simply used a truck, a long cable, and the large tripod to raise the mast, it went smoothly!

## The windmill chassis and tail

The windmill is really very simple. I started with a 3/8" thick piece of steel to which the alternator could be bolted. To that I welded a pipe, which fits over a smaller pipe on the top of the tower - this is what the windmill pivots on. There are no slip rings in this machine, I simply ran enough aircraft cable so that the machine could pivot several times before it gets tight. The power line from the alternator is slightly longer than this cable, the idea being that the aircraft cable will get tight just before the power cord. The tail sits back about 4' from the pivot, and is bolted into angle iron. Two 1/2" diameter steel rods serve to further support the tail. In home built windmills I've seen...tails breaking off seems a common problem. This part needs to be strong, and a well balanced prop will also help prevent metal fatigue. I offset the tail, and the alternator slightly from the pivot, in hopes that it would turn out of the wind should it get too fast. This was done intuitively, I have no specific data on how to do this right, but it was my intention to move in the direction of several home-built windmill I've seen before. See Hugh Piggots design!

## Performance

So far, so good. The alternator has a slight cogging affect, which keeps this machine from starting easily at low wind speeds (below about 10mph). This could be solved by a bigger prop, wider blades, or...more blades! I think should I try to improve this I

will use wider blades. Once started it keeps spinning well at very low speeds. We have very gusty winds, the direction changes frequently so it is difficult for me to offer specifics on output vs wind speed. Best output I've seen in high winds is approx. 25 amps, though typically it puts out 5-15amps (into my 12 volt batteries) in low, to medium wind speeds. It is possible that a regulator could be made with a matching transformer or possibly a linear current booster that would better match the load to the alternator and provide significantly more output, I've not tried this yet. This machine does perform much better than smaller ones I've made using surplus DC tape drive motors, and so far it has held up well to extremely high winds. It does seem to turn out of the wind somewhat in extreme conditions, although I doubt it needs to.

Again, building these at home is fun, and rewarding. Lots more fun, in my opinion than buying an expensive new machine! I hope that folks provide input about their own machines, and their comments about this one! This machine, although fairly quick and easy to build, is a culmination of several experiments....the prop, the alternator, the tower. Please check out our products page for a few of the items I used to build this machine and some interesting books!

### **April 8 update**

After about 8 weeks up, there was a breakdown! On the radio they were predicting 80+mph winds. I took care to go out, make sure all the guy wires were good and tight and did what I could to help insure its survival. At about 4pm I woke up to a most unpleasant sound. Although still running, and pegging the 20 amp meter it definitely had a problem. Turns out she threw a blade in extremely high winds. Considering the lack of time I put into them, it really came as on surprise and I was grateful for the data.

I found the piece of broken blade only 20' from the base of the mast. Turns out, the

blade definitely had a crack in it, before I even raised the windmill, I could tell by the paint which had seeped into the wood. The other two blades were still in fine shape, suggesting that the design would have been good, had I taken more care to use better wood in making the prop. This was especially surprising considering how long the machine ran in extremely high winds, with only two blades!

Rather than replacing the one broken blade, I decided to make a new prop all together. It's slightly larger, the diameter being just over 7 feet. These new blades are 4" wide at the hub, and 3" wide at the tip. The wood is much stronger. The pitch is similar, although this new blade has a little twist to it. Although it's been up for less than 24 hours, I can already tell it starts much easier. It's still real quiet even at high speeds. It should make for an interesting test, the tips of this new blade are only 3/8" thick. The blades are of good vertical grain pine, each one weighs exactly 11 oz.

Other good information from this breakdown...the tower. It came down and went back up very easily with no problems at all. I simply used an A frame built from lodge poles, my truck, and a cable. Total down time, 4 hours, thats how long it took to lower it, build a new prop, finish it and get her back in the air again!

In conclusion, I believe, judging from the improvements on the new props that this machine will probably hold up well over time. In watching it for a few weeks now it seems to do a find job producing up to 400 watts. In "normal" winds it produces between 100 and 200 watts. It seems to outperform some small commercial windmills, which I have also had opportunity to watch. It's very quiet even in high

[Difference between 12V and 24V](#) | 3 comments (3 topical, editorial)

Re: Difference between 12V and 24V ([none / 0](#)) ([#1](#))  
by [zubbly](#) on Wed Nov 5th, 2003 at 04:01:58 AM MST  
([User Info](#))

hello Guerrero. the best i can offer here is direct ratio.  
to double volt, you double turns and 1/2 the size of wire  
to triple volt, you triple turns and 1/3 the size wire  
to quadruple volt, you quadruple turns and 1/4 size wire  
your amp output will follow the decrease in wire size.  
double voltage= 1/2 amp output and so forth.

easy way to calculate 1/2 wire size is to count up 3 sizes.  
1/2 of #14= #17, 1/4 of # 14= #20. to be sure consult a  
magnet wire chart that gives circular mills of wire size.

if anyone has a difference of opinion with regards to ratio  
of turns versus wire size, please jump in.

have fun-----zubbly

### [Difference between 12V and 24V](#)

By [Guerreiro](#), Section [Homebrewed Electricity](#)  
Posted on Wed Nov 5th, 2003 at 02:59:34 AM MST

[Alternators](#)

<a href="http://www.fieldlines.com/">http://www.fieldlines.com/</a>

Can anyone help me with the following:

In order to build a PMG I've been searching in several places and I've found some very good tips, mainly from Mr. Hugh Piggott. However I've been having a question:

In the PMG, what should I modify in order to my output be 24V or 48V and not 12V??

Is it in the coils or in the bridge rectifiers??

If it's the coils is it in the number of turns, the thickness of the wire, or in booth??

Thank you everyone

Guerreiro

hello Guerriro. the best i can offer here is direct ratio.

to double volt, you double turns and 1/2 the size of wire

to triple volt, you triple turns and 1/3 the size wire

to quadruple volt, you quadruple turns and 1/4 size wire

your amp output will follow the decrease in wire size. double voltage= 1/2 amp output and so forth.

easy way to calculate 1/2 wire size is to count up 3 sizes. 1/2 of #14=#17, 1/4 of # 14=#20. to be sure consult a magnet wire chart that gives circular mills of wire size.

if anyone has a difference of opinion with regards to ratio of turns versus wire size, please jump in.

have fun-----zubby

It could be that wiring the coils in series will raise voltage and in parallel raise amperage, but I have wondered if the wiring size on PMA's is a good indicator of the intended voltage output- probably so.

hello Robotmaker. thankyou for the mention of use of some of my ideas as well as from others. being still relatively new to the genny field, i often refer to the advise of others who have already done and experimented in paticular fields with great success. sometimes the simplest ideas and solutions work out to be the best in the long run. the subject of slip rings does ring a bell to me as i have repaired many of these units for years. for some reason i seem to keep adding more projects to the ones i have not yet completed. i do have some ideas on simple slip ring assembles that can be made from discarded circular pump parts. need alittle time though. i will post when i complete the design and model. for now, accept the good advise from the people that have been there and done it.

keep having fun, its what it's all about--zubbly

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Thanks Zubbly  
I understand the time thing. It is a rarer commodity. I think the text is still there where you originally posted it. I will refer to it when I try this magnet style of motor conversion.

Again thanks very much for taking the time. Right now I'm winding coils for my small disc alt.  
100 turns of #20 wire on a 1/2 X 1 inch form to match the 12 small neos I'm using. I'm using unmodified plumers tape as lamination. Disc is 5 inches in dia.

I don't expect much from this little alt all though I would like to see 100 watts at least. Maybe around 750 rpm?

Now I'm speculating on how to glue down the laminations?

I'll post after testing this little toy. JK TAS Jerry

[quote]"Now I'm speculating on how to glue down the laminations?"

Try spraying both sides of the metal strip with spray-on contact cement. It insulates the laminations as well as holding them together.

Electric Ed

by Jerry on Tue Dec 16th, 2003 at 09:56:15 AM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hey Thanks Ed.

I built a small lamination wyinding machine.  
There are 3 spools. 1 to supply the lamination  
(plummers tape), 1 to supply masking tape and  
the 3rd to roll these 2 up on.

I do have lots of the glue at the stereo shop.  
May try that next time?

JK TAS Jerry

here are a few drawings for making props from pvc pipes. just a few observations from my own experimenting. i think using any pipe less than 3 inch diamater may be a waste of time unless it is going to drive a very small genny. i also suggest that you practice on paper towel tubes to get the idea of doing it instead of wasting pipe.

the first drawing is of a simple one piece prop. i have not given any dimentions other than how to cut. you must decide in your own mind the size of pipe and length. i will however give my suggestions.

begin by drawing a line from one end to the other (blue line) A to B. often there is printing on the pipe that will give you a good guide. next, draw a line at centre around the diameter (C to D). the junction of these two lines will be your exact centre of blade and this is where you may drill your hole for mounting to hub of your choice. E, F, G, and H ( red line ) is what you will end up with after you cut out at the red lines. my perspective with the drawing is not the best, but you may refer to my last posting on pvc blades to see what they look like. the outer round surface of the blade will end up on the opposite side the wind is blowing from, and the inside of the pipe is what will face the wind. i can suggest that the tip width should be approx. 1/4 of the outside diameter of the pipe. if you have a 4 inch pipe, your tip width will be 1 inch. if you equal the tip marks at the end of line A to B, you will have 0 degree at the tip. moving the tip marks to the side of line A to B will give you some degree of angle. i prefer 0 degree. the straight edge of the blade is your trailing edge and should be cut some what to the side of line A to B.

The angled edge of the blade will be your leading edge and should not be cut more than 1/4 the way around the diameter of the pipe from line A to B. **JUST A REAL GOOD TIP**, to mark the angled edge of blade, use a length of that black metal banding strap they use to hold crates together with. have someone hold one end on the mark and the strap will follow the contour around the pipe to the other end of the mark. a metal measuring tape works good too turned upside down. i prefer a small fine tooth hand held saw to do the cutting. scraping the cuts after with a sharp blade will give you a good finish. this style of blade seems to give decent starting torque and runs very fast. **SORRY FOR ALL THE LINES TO READ BUT THIS IS THE MAIN CONTENT OF THE INSTRUCTIONS AND AM TRYING TO COVER ALL POINTS. GO TO NEXT PICTURE.**

here is what i call a high torque blade. it does not run as fast as the previous blade but seems to provide tremendous torque. a good choice for an alternator with many poles. again, this drawing is not the best, so refer to last posting to see what it looks like. the widest part of the blade has been moved from the middle to the position between middle and end of blade.

here is a method of cutting multiple blades from a shorter piece of pipe. just lay out the pattern and cut. **DO NOT TAKE ONE CUT OUT BLADE AND USE IT TO TRACE OUT OTHER BLADES.** this will result in blades becoming narrower. mark each blade seperately. these blades can then be mounted in any number that you need and to what ever hub style you may design.

i screwed up on showing the last blade design with a hub point. you will have to look at the next posting after this one if i can get it posted. it is an interesting one in that by laying the two seperate

blades on the other, you can slide sideways either blade for fine adjustments for balancing. i think a lawnmower blade hub would be a good one for this assembly. hope it comes out on the next posting.

hope you can use these to your benefit and projects--zubbly

Thanks Zubby. You've done just what I hoped you would get around to doing one of these days. Even more detailed than I had expected. One little thought about finishing the edge of the blade ...old time wood craftsmen (before 2HP routers) used to use a tool to scrape the edge of their wood to fashion their own mouldings, anyhow by grind a curve in the edge of a section of saw blade about like this  
(  
, you can scrape a very professional rounded edge on the plastic blades. Ummm!  
Can hardly wait to get started on this next project. Thanks again for taking the time to share with us.  
Norm.

([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

How come you are putting the leading edge cut, forward of the A-B line? It seems to me that this reverse angle would give a slower RPM. I havent yet tried a Pipe Prop but I think that your leading edge should be cut along the same line for both ends of the prop.

Also a quick note on photos. I am using a Dial Up connection and it takes a very long time to get the pictures you have uploaded in BMP format. File sizes are much smaller for drawings in GIF format, and smaller for pictures in JPG or JPEG format . . .

. >=- W o o f -=<

Re: diagrams for cutting pvc props ([none / 0](#)) (#6)  
by hvirtane on Sat Oct 25th, 2003 at 11:32:43 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I completely agree  
with the problem  
of loading and the sizes of the pictures.

It is too painful to lad them.  
I gave up.

I think that any graphics program can save  
the pictures in .jpg format.

Hi,

it is not with the computer speed, but with the Net speed. I'm using a wireless Net connection (the very latest technology in the field). And that is quite slow. Happily I don't need to pay for the amount of the data loaded, but some others have to pay separately for each byte they load.

- Hannu

[ [Parent](#) ]

Re: diagrams for cutting pvc props ([none / 0](#)) (#7)  
by zubbly on Sat Oct 25th, 2003 at 05:22:38 PM MST  
([User Info](#))

hey woof. good to here from ya. just to clarify, the leading edge are the angle lines E&H. the horizontal lines G&F are the trailing edge. the reason G&F are cut on either side of A to B is to allow pipe material to remain to hold the two sides of the blade together. as far a posting the pictures, i am not the greatest at this and you will have to put up with it until i improve these skills. i also have a land line and it does load quite fast. ???

cut a blade and try out. read first paragraph very carefully.

zubbly

[ [Parent](#) ]

Re: diagrams for cutting pvc props ([none / 0](#)) (#9)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Sat Oct 25th, 2003 at 10:34:16 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

Here is what I was thinking about when I mentioned the leading edge being on the same line so the curve of the pipe isn't slightly reversed from optimum on the front edge. Notice that it's based on a circle in the center.

If I was'nt working so much these last few weeks, I would have a buncha cut up paper towel tube layin' around or flying in the wind . . .

. >=- W o o f -=<

Re: diagrams for cutting pvc props ([none / 0](#)) (#11)  
by zubbly on Sun Oct 26th, 2003 at 03:31:34 PM MST  
([User Info](#))

hi Woof. you should be designing these blades. your idea with the circle in the middle is quite brilliant! the line in the middle A to B however is the trailing edge, not the leading. you will discover this once you have cut a blade. the inside of the pipe is what faces the wind when complete. please let us know how this design works. i think that the circle in the middle will also add much more strength to the one piece blades.  
thank you for the constructive feed back.

zubbly

[ [Parent](#) ]

Re: diagrams for cutting pvc props ([none / 0](#)) ([#12](#))  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Mon Oct 27th, 2003 at 08:01:07 AM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

Thanks Zubbly

After looking at that last drawing for a while, I realized that the best way is like your first drawing at the top of the page, except with circles or ovals in the center, like this . . .

I'm thinking about pulling the Christmas paper off a tube and start cutting . . .

. >=- W o o f -=<

Re: diagrams for cutting pvc props ([none / 0](#)) (#13)  
by Budgreen on Mon Oct 27th, 2003 at 12:37:04 PM MST  
([User Info](#))

which blade style (standard or 'high torque') would give a lower startup speed?  
I think it would be fun to experiment with these on small steppers but in limited wind speed.

Re: diagrams for cutting pvc props ([none / 0](#)) (#14)  
by zubbly on Mon Oct 27th, 2003 at 06:43:08 PM MST  
([User Info](#))

hello. the high torque would be my first choice for faster start up. however, i think the design that  
Woof replied with could quite possibly be even better. whatever choice you make, have fun.

various plastic props

well finally i am getting the hang of posting pictures. took me awhile to learn to transfer pictures from digi cam to files. here is a picture of two one piece props cut for opposite rotation. the one on the left is for clockwise rotation and the one on the right for counter clockwise. the tips have been cut at 0 degree pitch. performance seems slightly slow on start up but do run very fast. i think these are 40 inch in length.

I really liked how this prop turned out. i guess what would

be referred to as the root, has been moved outward from centre to middle of the blade. start up happens in mild wind with great torque which i found out with the cardboard paper towel tubes that i first cut. the cardboard tubes are a good way of trying the design first. top speed does not compare with the props in the first photo. i think this design would be good for gennys with many poles.

this prop seemed to have the best overall performance. good starting with a very fast speed in higher winds. i think this one worked out better because it was cut from 4 inch diam. pipe. the length is 48 inch. the pvc pipe gets thicker with increased diameter. the 4 inch pipe is approx. 3/16 inch thick.

this is a picture of the first plastic prop that i cut. it is made from 2 1/2 inch abs plastic. a real piece of garbage. did not work worth a ----. the angles were all wrong and when i heated to try and correct angles, it turned like a limp piece of spaghetti. learned a lot from it though.

here is a picture of some of the " FREE " pipe stock i have collected. the green piece on the left is 8 inch diamater. i found it in the scrapp heap at a construction site with a crack on one side. by the scrape marks i think it had something very heavy drop on it. can still get a good size prop out of it as it is 8 feet long. it has about a 1/4 inch thickness. i think it will make a good prop for the 1 1/2 hp induction conversion i am doing. it is going to have 36 poles. the white piece is 6 inch diametor and about 6 feet long. thickness is close to 1/4 inch. i can't find anything wrong with it and can't quite figure out why it was in the scrapp other than having been cut.

these two pictures are the four foot cedar prop that i carved. my first wooden prop. the stock was 4 inches wide and 2 inch thick. learned a lot on this one too. loved the feel of carving wood. my next wooden prop is going to be made from a 1 piece 9 foot long piece of clear ash. it is 9 inches wide and 2 inches thick. a winter project.

i would like to sum up that i think plastic props are a good alternative for someone looking for inexpensive material ( scrapp heap ) and a good way of learning just how they work. i still don't use much science behind it other that what feels right and what i can do with the piece of material. i do intend to learn a little more theory though. by the way, the small little genny is what i tested all these props out on. it is a 108 volt dc motor that i bought brand new for \$10.00. it has a 3/8 shaft with only sleeve bearings. i have used the same hub for all the props. it does light a 12 volt tail light auto bulb. hope this info may be useful to some.

i think the cedar props ended up at the bottom of the page. i previewed before posting and the cedar props won't post. sorry.

keep having fun-zubbly

Thanks for the pics. I've been interested in this material for quite a while and its really nice to see how you're experimenting with different shapes.

I was wondering (since it appears that you don't have any tail furling mechanism) if the plastic blades exhibit a flutter at high speeds. In strong winds this often sounds like a helicopter.

Thanks,

Chuck

([User Info](#))

hello chuck. i have seen the mast bend to approx. a 45 degree angle in very strong winds. i then put some guy strings to reinforce the mast. the blade does make some helicopter noise in extremely fast wind, but not that loud, you can just here it. i have seen the blade so fast that the only visible part was at the centre.

thanks for viewing my post.

([User Info](#))

hi Rob. there has been no problem so far. although none of them have been up for more than 3 weeks. just really experimenting for now. for permanent service i will coat blade with aluminum paint. working on a couple more alternators right now that i think i will use a one piece prop from the 6 or 8 inch pipe. i should really have one up for a good year before i can comment on durability.

thanks-zubbly

Thanks for the good pictures. I've been wanting to experiment with these PVC props for a while but have been unable to do much with the info. I had but these pictures helped alot. I made my first prototype today and it looks pretty good. I still need to tweak it a bit but I think this should turn out to be a very good system for the time and money put into it.

Jim

well worth making induction conversion

hello zmoz. tried to reply to your posting 3 times. last one had 12 words and said subject line was too long. had to go this route. it is well worth converting induction motors. you don't need curved neos. look at my posting on converting 7 1/2 hp induction. tested out the other night at 3400 watts. capable of 5000 watts. the key is to make a matched winding and rotor. rewind with as many poles as possible and build rotor to suite. great frame, great bearings, great laminations.

have fun---zubbly

Hey Zubbly,

Did you have any way of measuring r.p.m. when you were getting 3400W out? I'd be interested in knowing the results. Also, how did you drive it for the test?

Thanks,  
Matt

Re: for zmoz ([none / 0](#)) ([#2](#))  
by [zubbly](#) on Sat Oct 18th, 2003 at 08:56:57 AM MST  
([User Info](#))

hello Matt. the drive pulley on alternator was measured with a strobe tach. also the cycle function on ampmeter confirmed 60 cycle@600 rpm. the stator has been wound to 12 pole and matching rotor. alternator was belt driven from a 7 1/2 hp baldor dc motor with variable speed control.

plastic props

---

hello everyone. the prop pictures that i tried to post before have mostly disappeared into thin air. thats even another story. anyhow, i just got some new pictures developed and even bought a new scanner and digital camera to help in my postings. these are only a couple of pictures, but more will be coming with full detail.

here are the six blades that i have cut out from a piece of 1 foot diamater plastic water main pipe. i have cut them at 6 foot and 3 inches long each. the tips are 4 inch wide and approx 1 foot at the root. one side is straight and the other side is curved from root to tip. after assembly with hub, the diamater will be approx. 14 foot. my strength in blade design is so far not acomplished. i just have basically "winged it ". it has been fun so far. i plan to use this prop on my 7 1/2 hp induction conversion. the material is 3/8 inch thick and very strong, but heavier than i would like. i cut a 3/4 inch strip of it and put it in the freezer. after two days, i cannot fracture it at all. i don't know the exact composition of the material but will find out.

i hope in this picture that you can see the profile. straight on one side and nicely twisted to the tip on the other side. by the way, this stuff is very tough to cut.

here is the photo of the pipe stock. it is 1 foot diameter by 6 and 1/2 foot long. i think you can see the twist in the picture. it is very easy to make the blades. i started out by cutting test blades from empty paper towel tubes. i then stood in front of the air conditioner for the tests, and was quite surprised at the results i got with speed, torque, and start up. i then made different sizes from pvc pipes and tested on a small genny outside to see what the results would be. today i mounted my first cedar prop with good results. it seems to start a little easier, but does not attain the speed that the plastic props do. on my 7 1/2 induction conversion, i will only need 600 rpm to attain my 230 volt 60 cycle output. hope you enjoyed this and got some useful ideas. i have been having a lot of fun. will post more info and pictures on plastic props soon.

i believe fun and laughter is measured in not how loud it is, but how long it takes you to get off the floor.

zubbly

---

Zubby: Your pictures would have been fine if you had simply put a couple of linefeeds or carriage returns after the text where you insert them. All fixed now. TomW

by Chuck on Mon Oct 6th, 2003 at 10:26:18 AM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

They look nice. I'm glad someone posted some info on using pipes for blade material. I definately look forward to progress reports.

Just a comment, and hoping I'm not misunderstanding your application... Don't expect your 14 footer to be pushing 600rpm very often. This high an rpm for cut in could be a problem. If possible, shoot for a number under 150rpm. Remember, the larger the rotor, the slower it will go for a given TSR (tip speed ratio) and wind speed. If the motor can't be modified to reduce the speed, this may be a case where a 1-2 or 1-3 gearing might be worth investigating.

Chuck

by JB on Mon Oct 6th, 2003 at 02:20:01 PM MST  
([User Info](#))

Zubby. Things are looking good but i was thinking a little like Chuck on this one. 600 rpm might look slow on a lathe or something but at 12 or 14 foot diameter I dont think You would even want that or seldom ever even get that. You will probably have to gear it up for speed. What size is that shaft on that thing. JB

[ [Parent](#) ]

Re: Plastic prop pictures (again ) ([none / 0](#)) ([#6](#))  
by zubby on Mon Oct 6th, 2003 at 05:16:48 PM MST  
([User Info](#))

hi JB. i just replied to Chuck and explained that the alternator will be geared up from the prop. will be looking to get a maximum of 200 rpm at prop. the alternator will produce 60 cycle at 600 rpm. the cycles don't really matter though on heating elements. the shaft on alternator is 1 and 3/8 inches. bearing on shaft end is a 6308 and a 6306 on opposite shaft end. the prop shaft will be supported on two pillow block bearings (thinking 1 and 3/4 inch) and will belt drive alternator from there.

thanks for your comments-zubby

[ [Parent](#) ]

Re: Plastic prop pictures (again ) ([none / 0](#)) (#5)  
by zubbly on Mon Oct 6th, 2003 at 05:07:33 PM MST  
([User Info](#))

hi Chuck. i guess i should have explained a little further. i will be gearing up to the generator. i would be scared to be in area with this prop going at 600 rpm. i think the tip speed would be somewhere in the 300mph area. i should further say that i won't be using gears but pulleys and belts. i am hoping to get somehwere from 150 to 200 rpm at the prop. the alternator is going to be connected to heating elements.

thanks for your comments-zubbly

([User Info](#))  
<http://homepage.ntlworld.com/s.amesbury/homepage.htm>

A similiar way to how i build props and surprising how well they work, i will try one day to carve a wooden prop. I use buckets my self but big ones are harder to come by. Its all in the name of fun for me just a hobby and i love to use junk as much as possible, my latest genny which is a converted induction motor cost me about £30;00 and that included the concrete for the mast!!!! Ok i used ceramic magnets but its working a dream. Soon i will get my site updated and show the board.....sean

Re: Plastic prop pictures (again ) ([none / 0](#)) (#7)  
by zubbly on Mon Oct 6th, 2003 at 05:20:52 PM MST

at 02:48:38 PM MST  
([User Info](#))

Zubbly,

You should be smiling in the photo, they are fine looking blades. I friend of mine that works with plastics told me to paint plastics with silver engine spray paint. The aluminum in the paint protects the plastic from UV damage from the sun. How are you going to attach the blades to the hub?  
John

Re: Plastic prop pictures (again ) ([none / 0](#)) ([#8](#))  
by zubbly on Mon Oct 6th, 2003 at 05:27:06 PM MST  
([User Info](#))

high John. thanks for the tip on the engine paint. i will paint them with that. i will be attaching blades to hub with a bracket that i am having made. bracket will be made from 1/8 inch aluminum plate with a 1 inch solid aluminum round bar welded to it. bracket will be fastened to blade with counter sink 1/4 inch bolts. aluminum round bar will be U-bolted to flat aluminum hub so that i will be able to adjust angle if needed.

thanks for your comments-zubbly

[ [Parent](#) ]

Re: Plastic prop pictures (again ) ([none / 0](#)) ([#9](#))  
by Garry on Mon Oct 6th, 2003 at 07:43:40 PM MST  
([User Info](#))

Please do not try to spin those blades with that hub. Metal fatigue on welded aluminum will break the hub in days. Centrifugal force will break them at a low rpm. Find a machinist who builds machine parts for farmers or an engineer with common sense who interested in your project. Good luck.  
Garry

([User Info](#))

hi Garry, thanks for the info. never considered fatigue in such a short time. got any ideas or does anyone else?

thanks-zubbly

[ [Parent](#) ]

Re: Plastic prop pictures (again ) ([none / 0](#)) ([#11](#))  
by Garry on Tue Oct 7th, 2003 at 11:32:05 AM MST  
([User Info](#))

If I were going to build a hub for myself that was limited to 250 rpm and 10 pound blades I would use 3/16 plate steel in a Y shape on both sides welded to at least an inch and a quarter shaft. The plates would be twistable with a six inch vise and an eighteen inch crescent wrench for pitch purposes. This would be a minimum and could be done with hand tools except for the welding.

Garry

[ [Parent](#) ]

Re: Plastic prop pictures (again ) ([none / 0](#)) ([#12](#))  
by troy on Tue Oct 7th, 2003 at 04:50:30 PM MST  
([User Info](#))

Hey, steel is cheap, especially second hand. A piece of half inch plate that size isn't that expensive. If they cut it with a plasma arc cutter, the labor is not that much different either. And I would put three triangular gussets between the plate and the shaft, using 1/4" steel plate welded on both sides.

There is a sign in my shop that says:

If it's worth building, it's worth overbuilding.

troy

by zubbly on Tue Oct 7th, 2003 at 07:08:01 PM MST  
([User Info](#))

hi Garry. do you mean to sandwich the blade between the two Y's, and weld the shaft to the bottom of the Y's? sorry, sometimes it is just hard to sink into my thick skull. heh heh.

thanks-zubbly

[ [Parent](#) ]

Re: Plastic prop pictures (again )  
([none / 0](#)) ([#14](#))  
by Garry on Tue Oct 7th, 2003 at 08:25:32 PM MST  
([User Info](#))

I was assuming that you were using three blades. You could use a piece of steel that was disc shaped but it would be hard to set the pitch that you want. If you cut out the parts that don't touch the blades you could twist the remaining strips to a pretty steep angle. By using two of these wye shaped parts, one on each side of the blades your hub will be many times stronger. After the pitch is set up the way you want then weld the center holes to the shaft. You would still be able the twist the arms slightly if you needed to by removing the blade bolts and twisting the arms separately. The movement after welding will be much more restricted than before. According to "Machinery's Handbook" a blade that weighs 10 lbs, that is 6 feet long, at 250 rpm would weigh 640 lbs. So the stresses are much higher than it would appear at first glance. The force goes up by 4 times if the rpm doubles. Hope this helps. My typing quota for the month is about used up.

[ [Parent](#) ]

## [7 1/2 HP induction conversion](#)

By [zubby](#), Section [Homebrewed Electricity](#)

Posted on Sun Oct 5th, 2003 at 02:58:50 PM MST [Alternators](#)  
conversion almost completed

hello again everyone, my posting on the 1.5 hp DC repair seemed to work, so here is the next one.

a little while back i had mentioned that i will be doing a 7 1/2 HP induction conversion. i had previously talked about in another posting about a special cage i was thinking about in order to hold the magnets in place. on this rotor i installed 48 1 inch diam. by 1/2 inch thick neo's. i began by turning the rotor down by 1.1 inches. this allowed me to maintain the original .020 air gap. the motor was originally a 7 1/2 hp, 1800 rpm, 575 volt high efficiency motor, totally enclosed, fan cooled. i re-designed the stator for 12 poles( more on this later with more photos) and i ended up with 12 rows of 4 magnets.i also skewed the magnet rows by 10 degrees to reduce cogging. the stator has 36 slots so the 10 degrees represents one stator tooth. i made the cage by first using a piece of plastic pipe and applied what is called pre-mix in layers until i worked up to about 1/8 inch short of the required diamater. i next turned in the lathe to a level finish. i next applied multiple layers of woven fibre glass cloth and resin and built up to more than the required diamater. i then lathed down to 1/16 inch less than finished diamater. in pictures you will notice that the cage has a hollow to it. this is to allow room for the epoxy encapsulant to fill in all around the magnets. by the way, this encapsulating material is specifically made to encapsulate motor coils, is class F ( 150 degree C ) and is extremely strong. in my opinion much stronger than fibre glass resin. i poured a 1/8 inch thick blob of it by 3 inches round, and when cured, i can't snap it. after i installed all the magnets, i formed the cage section with plastic, sealed, drilled holes in one end to pour in epoxy, and ended up with excellent results. here are the pictures.

Update [2003-12-16 10:46:59 by kurt]: pics reposted [here](#)

here are pictures of the cage after the 48 holes have been drilled in it. i think you will be able to see the hollow space allowed for the epoxy. this cage also ended up extremely strong with all the pre-mix and layers of woven fibre glass cloth.

here are the pictures of magnets being put into rotor. i may have inserted a wrong picture as i did with the DC posting. i hope you can see the skewing and the hollow space for epoxy encapsulating material.

here are pictures of the rotor after the encapsulating material has been poured in and formes removed. this is also a picture of my son Christopher holding the rotor. he has also taken a genuine interest in wind energy and has been a great help in my efforts. preliminary tests with a completed test winding of only 4 turns per coil have yielded excellent results. the permanent winding with 42 turns per coil has been completed and the testing is continuing. here is a picture of the unit being driven by a large DC motor from a balancing machine. the flat belt was fine for the testing with test winding, but cannot supply enough torque for the permanent winding. i hope to direct couple with a ten HP this week and make final tests. will let you know results later. any questions will be gladly answered.

having fun-----zubbly

here is the repaired 1.5 HP DC motor from previous post

Well i hope that i have finally figured out how to post pictures. lets see if this is going to work the way it should. in a previous post i was given a 1.5 hp dc motor gift. of course it was burnt. i have given the armature a complete rewind, dynamic balance and new bearings. the motor was tested as a motor and not yet as a dc generator. the motor is 180 volt armature, permanent magnet. i expect in the future that it will make a good battery charger. the motor has been repaired for the last couple of months, but it is not up and flying yet. i have been given a 30 ft. tv tower which i must go and take down next weekend. i think i have an advanced case of the BUG from this site and have a half dozen projects on the go at the same time. i will share these to date in the next posts. anyhow, here are a few pictures of the dc repair.

there may not be enough detail in the photo, but the wire is burnt blacker than toast and has even totally burnt out the wedges that hold the wire in.

i think i have picked the proper picture out of files to show you the permanent magnet assembly of the dc motor. they are big and strong, and run the full length of the armature laminations.

here is a picture of the armature that i am winding on the kitchen table. i am using class H inverter duty magnet wire, and all class H insulation. this class H insulation is good for 180 degree c and the magnet wire is good for 220 degree c. all top of the line materials.

here is a picture of the rewind completed. it has been dipped and baked twice in class H motor varnish, balanced- ( you can see the white blob of balancing compound on the winding ), commutator has been dialed to less than .001 inch runout, turned and undercut, and new bearings installed. i have also installed heavier gauge lead wire on the brush holder assembly.

the weather here is starting to get quite cold and hope i will be able to finish some of these projects before the snow flies. if anyone has any questions about this repair, please ask.

i have not forgotten about the plastic props i have been working on, and hope to get these pictures and info posted soon. thanks to everyone for being patient with me.

having the most fun in years-zubbly

Zubbly I see you finally got the hang of it JPEG pictures! Now finally I'll be able to see those plastic props...How do you figure and lay out the lines to cut? Well I guess that will be all forthcoming eh? Well good luck on your projects. Oh by the way is that a Leeson dc motor that you rewound the armature on? (:>) Norm.

Re: 1.5 HP repair ([none / 0](#)) ([#2](#))

([User Info](#))

hi Norm. that is a Leeson motor. it had only been used for a couple of months when a client of mine burnt it. my client bought a new 3 hp dc and was going to throw out this one. i asked for it and i received. this provides me with an almost endless source of units for wind gennys. i feel almost guilty-heh heh. the plastic props and diagrams will be posted soon.

have fun-zubbly

Zubbly: Quite a few years back my oldest son was given one from work(they had replaced it with a slightly larger motor)nothing wrong with it. ("Here Dad...Want a motor?") That was before I got interested in wind power. I really must get it hooked up to a couple of blades one of these days...a nice 2 bladed 6 footer maybe.... that would be a biggie for me, as the rest of my pm motors are ones from car heater blowers. Well anyway this is a Leeson 1hp 110vdc 1800 rpm. It's fun just thinking about it! (:>) Norm.

([User Info](#))

hi Norm. please let me know how your dc works out for you. i have had the dc that i wound done for well over a month now. the main problem i have is starting to many projects and not getting enough time to follow through getting them to fly. the 7 1/2 hp induction conversion is just about complete except for the final testing. am now looking around for a suitable free standing 60 ft. tower. just might not be able to finish before snow flies. this weekend i am going to take down a 30 ft. tv tower that was given to me. i will use this one for the leeson dc. i don't have a prop for the leeson, but i do have an eight foot length of i think 8 inch plastic pipe that i might cut a one piece prop from. hey, did you have a chance to look at my plastic blade posting and 7 1/2 hp induction conversion. let me know what you think. by the way, where do you live?

keep having fun---zubbly

question for Electric Ed or anyone who can answer

hello Electric ED, or whoever may comment.

please view the image as what i would call a wafer coil. imagine the black line as a thin sheet of plastic or fibre board. the red line is the coil wrapped around the fibre board so it is basically flat. now imagine the blue and green lines as your magnets, one on each side of the coil. assuming that there are steel plates attached to the magnets, and both legs or sides of the coil are being passed at the same time with the two magnets, would you still be creating useable flux and where would the flux path be? hope someone can answer this.

thanks in advance--zubbly

If your proposed design is similar to the sketch below, I believe it will not work.

There would be flux (purple) but it would be cutting all of the wires, that is, both "sides" of the coil in such a way that the induced voltage is trying to force current (brown) down in all the wires at the same time.

The result would be almost complete voltage cancellation.

Electric Ed

([User Info](#))

hello electric Ed, and thanks so much for your reply. your diagram is exactly what i mean. your perspective really nails it on the head. my idea was to get a way to really get those magnets close together. i understand what you mean by the magnets forcing the current in both sides of the coil at the same time, but i guess my train of thought figured that the current would follow the coil direction the same as if water were flowing through a water pipe. i will make a few experiments with this and will let you know the results. again thank you for your valued opinion.

When the coils are wound in a direction perpendicular to the direction of rotor motion, you must use the same polarity magnet on each side of the coil to generate a current. That is, the magnets on either side of the coil would need to be arranged such that either the north poles or the south poles faced each other. Not sure you could make such an arrangement work without a laminated steel core for the stator coil, though, but it would certainly be interesting to try. Leaving out a laminated steel core for the stator leaves at least two questions to be answered: 1) the magnets of the two rotors would want to repel each other, and what structural stress would this cause on the two rotors for a given air gap (e.g., air gap = distance between the faces of the two magnets)? and 2) would this same "repulsion" help redirect most of the flux back to the originating magnet in the absence of a laminated steel core?

When the coils are wound in a direction parallel to the direction of rotor motion, then the magnets on either side of the coil should have opposite polarity. That is, the magnets on either side of the coil would need to be arranged such that a north pole faced a south pole.

Please let me see your PVC Props !!  
I have good luck with the pictures, let me try to explain

On the righthand side of teh screen that you are looking at right now should be a box with your name on it (zubbly, if not then you are not logged in)

In this box click on "Your Photo Uploads", once in there you can control the images that you can put into your message posts. Upload your Photos at this point.

Then go back to the Message Board and click "Submit Posting" from the Menu Box on the top righthand side of the screen. In the "Comment box" enter your text. When you want to insert an image scroll down to the bottom of the page to the "User Files" box, click the downarrow and select one of the photos that you uploaded earlier, then click "Insert Image"

Scroll back up to your text and you will see some HTML code that represents your photo inserted into the message that you are posting. Do Not change or remove this code from the message.

Add more text and photos  
repeat as necessary

-- W o o f

Re: pvc props ([none / 0](#)) (#4)  
by zubbly on Sun Sep 21st, 2003 at 08:26:51 PM MST  
([User Info](#))

hey Woof, thanks for the info. i want to get these pictures up more that anything. i don't seem to have trouble posting drawings from paint, but seem to have trouble posting the pictures. i will master this eventually. i just cut out 6 blades from a 1 foot diameter by 6 foot plastic sewage pipe that i will be making a 13 foot diam. prop for my 7 1/2 hp induction conversion. i bench tested this weekend and was able to choke 5.3 kw out of it with full test winding. almost completed. there will be lots of pictures and text for this one. last weekend i completed the rotor with installation of 48 1" x 1/2" neo's, total encapsulation, and dynamic balancing. the unit is a 12 pole conversion. I WILL GET THESE PICTURES UP ONCE DEVELOPED.

Re: pvc props ([none / 0](#)) (#5)  
by Norm on Sun Sep 21st, 2003 at 09:29:51 PM MST  
([User Info](#))

Ah...Zubbly there you have it...the key!  
i don't seem to have trouble posting  
**drawings** from paint, but seem to have  
trouble posting the **pictures**. drawings  
and pictures are two different things and  
I can't quite explain but those are the  
clues perhaps someone else reading this  
can explain it better. The paint program  
is an integral part of your word processor  
so your drawings are in memory just like  
text. I think that if you follow Woof's  
instructions step by step you will be  
successful in posting your pictures. Good  
Luck! Keep trying ...I want to see those  
pics! (:>) Norm.

MST  
([User Info](#))

I don't think we can blame Rusty here :-)

Zubbly... looking at the picture, it appears you tried to upload a file thats a .wps

When you upload a picture, in order to keep the file size reasonable and assure that it will work, make sure that it's a .jpg, thats the most common picture format and itll work for everyone. .wps is a special microsoft "word perfect" file if Im not mistaken. Our server doesnt run microsoft ANYTHING and has no idea what to do with a word perfect document!

So, next time, try to save the file on your own machine as a .jpg before yo upload it and I think it'll work fine! Good luck!!

Zubbly,

That picture posting can be confusing - well, it was to me for a "while". I then started looking at the "properties" of a post that had the cursed things in them. Then I played with the the "review" button after I uploaded some pictures. I finally "GOT" the process.

I think almost anyone who does not think the "CD Tray" is a drink holder can master enough to effectively post here.

Ron

Re: inserting pictures with posting ([none / 0](#)) ([#2](#))

It's slightly different depending on where your pictures reside. If you already have your pictures on the internet, you just make sure your Scoop Comment Preferences are set to "Auto" or "HTML" and include an image tag like this:

```
<IMG SRC="http://www.mysite.com/photo1.jpg">
```

If you want the photos to reside on our server -- once you have created an account and logged in, whenever you do a "submit posting" or reply to a posting, there will be a "user files" box somewhere on your screen. To upload an image, click "view your files." You can either type the name of the photo to upload off your computer, or click "browse" to choose and select it off your computer. Then click "upload" and after it's done it will appear in your files list on the top of that page.

After it's up on our server, it will appear in the "select file" pulldown menu in your "user files" box. Just select it and click the "insert image" button to automatically paste the

Re: inserting pictures with posting ([none / 0](#)) ([#3](#))  
by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Mon Sep  
8th, 2003 at 12:44:14 PM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

OK I think I have got it.

If you are logged on you can upload files to the board. Do this first of all. Find 'Your photo uploads' on the right hand side (so long as you are logged on) and click there.

Then 'upload files' choose 'Browse', find your file and click on 'Upload'.

Now you are half way there.

Start a new post and do all that, and you will have a box on the upper right called User files. Use Select files to select the file you have uploaded and then click on 'Insert image'. Bingo.

Now of course you mor elikely to be are commenting on a post instead. You can still do it! Now 'User files' is at the bottom of the window. Once again select your file from the drop down menu. click on insert image. Couldn't be easier. Once you have found out where things are.

Have fun :-)

Hugh Piggott <http://www.scoraigwind.co.uk>

### pvc props

here is my first posting with pictures. hope it works. these are two pictures of props cut from 3 inch and 4 inch pvc. i will be making another posting with instructions of how to do it. i have not got a lot of science or equations in these, just winged it. did most of my experimenting with paper towel tubes first and stood in front of air conditioner with props on a bamboo sc sewer. i have one of these props on a very mini dc generator on top of the garage. works pretty damn good. these two props are 42 inch and 48 inch. i have a length of 12 inch diameter plastic sewer pipe that i will be making prop for my 7 1/2 hp 3 phase conversion. it will be a two blade approx. 18 feet in diameter. will post this story when completed. hope this works, here are the pictures.

[more questions on magnet spacing and sizing](#)

By [zubbly](#), Section [Homebrewed Electricity](#) [Alternators](#)  
Posted on Thu Aug 21st, 2003 at 08:48:38 PM MST  
[more questions on magnet spacing and sizing](#)

assuming that the ideal spacing for magnets is from the centre of leg to leg of coil, and that the width of magnet is the distance between legs, what would you consider the centre of coil legs when you have more than one coil in a group? suppose you are converting a three phase motor, 4 poles, to alternator. 36 slots, 6 groups of three coils, coil span of groups are 1-8,1-10, and 1 to 12. would you say that magnet width should equal the distance between coil legs of span 1-8, and that magnet spacing should equal centre distance of coil legs in span of 1-10? another sanario would be 36 slots, 36 coils, 2 coil sides per slot, and all coils have span of 1-8. would magnet width be the distance between coil legs of 1-8 span, and would coil spacing be centre distance of coil legs of span of 1-8? most diagrams i have seen on this site seem to refer to having one coil. when trying to convert a 3 phase motor to alternator you are usually dealing with more than one coil per pole group. these are just questions i have to ask. hope someone can clarify. thanks in advance----zubbly

[more questions on magnet spacing and sizing](#) | 4 comments (4 topical, 0 editorial)

Re: more questions on magnet spacing ([none / 0](#)) (#1)  
by Electric Ed on Fri Aug 22nd, 2003 at 10:50:14 AM MST ([User Info](#)) <http://www.electric-ed.com>

You said - "coil span of groups are 1-8,1-10, and 1 to 12."  
This sounds like the poles are concentric wound, one inside the other.

This is not an ideal layout for conversions. The best you can do is space your magnets (center-to-center) the same distance apart as the center-to-center distance between the poles (of one phase), and use the widest magnets you have space for.

If your motor had a lapped winding, like this-

-the center-to-center spacing of your magnets should be the same as the span of any one coil, which are all identical.

This type of three phase winding makes a much better conversion.

([User Info](#))

thanks for your reply Ed, i kind of figured that you would. i am quite familiar with lap wound stators as in the picture. just curious, are you or were you a member of E.A.S.A.? those pictures were distributed to easa repair centres for illustration of winding failures. since you mentioned lap winding, would you be concerned about the different polarities from the two coil sides in one stator slot cancelling out each other, or two different phases in one slot. i am just concered here that what works in motors may not work when being used as generator. looking forward to your reply, thanks-----zubbly

No, I never was a member of EASA, but have rewound a few motors, and converted an old three phase "Wound Rotor" (slipring) motor to a 120/208 volt alternator by rewinding the rotor to produce a 4-pole, 12 volt field winding. I use it for emergency power and drive it with a 10 HP gas engine.

(quote) - "would you be concerned about the different polarities from the two coil sides in one stator slot cancelling out each other, or two different phases in one slot. i am just concered here that what works in motors may not work when being used as generator"

Yes, it is quite possible that some winding arrangements will not work well for generator conversions.

[can you have too strong a magnet?](#)

hello everyone, i was just thinking. i know that in electric motor design that you can over saturate the core with flux and cause severe heating. in permanent magnet alternatures ( home brew ) is it possible to have too strong a magnet in the design and end up over stressing coils and saturating lamination core? i have not seen this posted before and was wondering if anyone can comment.

many thanks in advance-----zubbly

[can you have too strong a magnet?](#) | 10 comments (10 topical, 0 editorial)

Re: can you have too strong a magnet? ([none / 0](#)) ([#1](#))  
by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Wed Aug 6th, 2003 at 11:06:11 PM MST  
([User Info](#)) <http://www.internetfred.com>

I believe so. Saturation of the core would just limit the total power coming out of the unit beyond a certain limit. Once the core is saturated the material cannot withstand more then what it has, so in effect you can't push it any further then full saturation. I wouldn't worry so much about the coils as the core.

However, the thickness of the material is another matter all together... The thicker the core the more it can handle, so technically it's based also on thickness, the thicker the core material the more you can drive it with larger fields/magnets. Now this also plays into gap thickness and gap depth. The gap depth is a large determining factor of how far you can push saturation. If your coils are well embeded within the core (there is a limit here, depth wise), you can drive it harder.

Gap width is something else, most of us in this chat room space our magnets and core gaps equally (to match), however, there is another way according to gap width, magnet width and depth calculations and phasing.. but thats something else, sorry... I just ramble.

I agree with the advice given by iFred.

In an iron-core machine, if all other factors are equal, iron = power.

With regard to efficiency, the only practical alternative is the twin-rotor configuration.

### Twin Rotor Magnet Arrangement - "Edge-on" View

Magnetic flux lines are always in the form of closed "loops" called the "magnetic circuit." The flux lines are assumed to flow, in air, out of North magnetic poles and into South poles.

The magnetic circuit in a typical dual-rotor air-core machine is indicated by the black arrows in the enlarged section below.

Out of the bottom North, up through the coils, into the top South, to the left through the rotor disc to the top North, then out of the top North, down through to coils to the bottom South, and through the disc to their point of origin.

The flux density (magnetic strength) is constant across the width of the air gap and stator windings.

Electric Ed

Re: can you have too strong a magnet? ([none / 0](#)) (#3)  
by [scoraigwind](#) ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Thu Aug 7th, 2003 at 01:19:32 PM MST

Nice diagrams, Ed, that really helps visualisation.

The reality of flux in the gap is a little different, because leakage plays a very strong role, and so the lines curve toward the neighbouring magnets. This means the the flux is much stronger at the centre of the magnet face and close to the magnet face.

You can't really have a magnet that is too strong but some designs are better than others at using the strength. If I had really strong magnets, I would space them apart so as to get the best value from them.

([User Info](#))

I'm in agreement with this board as yes. First hand experience, core will saturated, and becomes a giant short that produces heat.

Hi Ed, I've notice that you have pictured the rotor iron discs directions going both parallel flow top graph, and counter flow in reference to the stator bottom graph. I'm missing something here?? I can visualize how the top will work, but the bottom makes it more challenging in what it looks like (to me anyhow) a flux cancellation point when two like poles will line up.

Yep!

[Quote]"you have pictured the rotor iron discs directions"

No, the arrows in the enlarged sketch indicate the magnetic circuit path - not the direction of the rotor rotation.

I keep thinking about those 2inch X 2inch neo Disk Magnets they have for sale on Ebay. It would be quite an engineering challenge to build a dual rotor machine with 12 or 16 of those big suckers pulling at each other across the gap. Not to mention how hard it would be to bring the rotors together during construction, or apart for repairs. But then maybe I could get 120vac at 200 rpm . . .

I would like to see your results.

In principle you might have quite easy ways to do it by using an axle with treads and nuts and pulling the disks near each other and apart by nuts.

[Alternators](#)

steel or aluminum blades

hello everyone,  
all the information i have seen and read about making props, have been based on wood.  
i am not that great when it comes to woodzzy blade carving and just don't quite yet understand the roots and angles and all the tip speeds. ( eventually it will sink in) i am more the hammer, welder, bend it type of guy. does any one know a site or have info on making blades from sheet steel or aluminum? just one other point of interest. now available in canada there is lumber made from recycled plastic in all standard board sizes and lengths. even has wood grain. guaranteed for a zillion years not to rot, bend, or splinter. has any one ever tried carving blades from this plastic wood? you would never have to paint it or coat it.

all thoughts appreciated

thanks in advance-----zubbly

I've always wanted to try carving blades with that recycled plastic board stuff, but Ive never got around to it yet. Too many projects. :-) I think the majority of us make props out of wood simply because its cheap, light weight, and it doesnt take long to make a set. Im sure there is much room for improvement. If you try making a prop out of other materials, it would be great to see pics. Just be careful of steel flying loose, it could be deadly. Ive always wanted to carve one close to perfect blade out of wood and make a fiberglass mold to make another three blades, but I havent gotten to it yet. Hopefully soon. :) Have fun!!! RoyR

i spent hours and hours looking at how to carve wooden blades. one day i just took a scrap 2 by 4 drew just a couple lines with a felt pin and took my 9 inch body grinder to it. in about 15 minutes i had a rough blade to look at 4 awhile. i improved on that. it really aint that hard, it just seems that way. forget the math and make it look like a blade for starters. The Jerry blades are a good start also to see what you might want to do. JB Dayton Nevada

Hi Zubbly

I've used steel blades in the past. I had them up 3 years with no problems but they were not very efficient. They were 40 inch 4 blade. They were off a very large fan. the most I ever got from them was about 150 watts.

The plastic Jerry blades work much better. I've seen over 1200 watts from these in a 4 blade at 49 inches (40 mph) and at \$10 each they're lots of fun.

They'll do 5 amps at 10 mph

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Hi,

1)  
there is one guy in Finland, who is producing in small scale blades basically the same way as modern jets are made.

His blades have got an aluminum skin and filled with polyurethane. There is as well a steel tube inside.

Please see pictures here:

<http://www.saunalahti.fi/~kkhuolto/pentakone/>  
(There is nothing in English there.)

One of my friends is using those blades. In principle they seem to be good.

Basically the technology how to make similar is not very difficult to master.

2)  
I personally like most the tube wire method.

Another friend of mine has made big tube wire blades for 15 kW genny. There are nearly ready made drawings by me for those blades in a discussion on 'the old board'.

[http://www.otherpower.com/cgi-bin/webbbs/webbbs\\_config.pl?read=15028](http://www.otherpower.com/cgi-bin/webbbs/webbbs_config.pl?read=15028)

3)

I've seen here one more method how to make cheap easy blades.

[http://www.otherpower.com/cgi-bin/webbbs/webbbs\\_config.pl?read=14319](http://www.otherpower.com/cgi-bin/webbbs/webbbs_config.pl?read=14319)

One of my friends in Australia has copied that design and he is telling me that they work better (start easier and go faster) than carefully carved NACA airfoil blades.

He made them with three 'blades' only, not six as the originals made by a wind turbine designer called 'Reinikainen' in Finland.

4)

In the great book 'Penryn Windmill book' there are good descriptions how to make old-fashioned 'multi-blade water pumper' metal blades of oil drum sectors.

- Hannu

I was a little intrigued by what looks like a flat multigroove belt drive...must be something like 6:1 ratio or more. Looks pretty good and feasible. probably lower maintainence than a chain drive to offset slightly higher friction loss. Most everything is a compromise, but I guess you really can't complain when it comes to free energy! Right? (:>) Norm.

Sailwings ([none / 0](#)) (#8)  
by hvirtane on Fri Jul 25th, 2003 at 06:49:20 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I forgot to tell about the simplest good 'blades'.

My good friend from Denmark John Furze has told me a lot about 'Cretan Sail wings'.

There are lots of descriptions concerning sail rotors in the literature as well.

One of the really good books to be again recommended is 'Penryn Windmill Book':  
The Penryn Windmill Book. Arnoldi. Canada 1995.  
It has got a good description of sail rotors.  
There is one good book by Dick Mann:  
Cretan Sail Windpump. Mann. UK.  
1983/1992. 0-903031-66-3.

There are other books , too.  
Here is a bibliography given to me by John Furze:

Shelter. Shelter Publications. Bolinas California USA.  
1973. 0-394-48829-6.

A Windmill for Serbia. Høite, Eriksen [FREJA]. DK.  
1978. 87-7344-005-1.

Sail Windmill. Bagsvaerd School Copenhagen.  
Denmark.

The Penryn Windmill Book. Arnoldi. Canada 1995.

The Wind Power Book. Park.  
Cheshire Bks/Van Nost. USA 1981.  
0-917352-05-X.

Cretan Sail Windmill. CAT.  
Machynlleth Powys Wales UK. 1977.

Technological Self-Sufficiency. Clarke. UK.  
1976. 0-571-11057-6.

Sail Wing. New Alchemy Institute # 3.  
Woods Hole Mass. USA. 1976.

Food from Windmills. Fraenkel.  
IT Publications. London UK. 1975.

Cretan Sail Windpump. Mann. UK. 1983 / 1992.  
0-903031-66-3.

-----

In my pictures below, the diameter of the whole rotor could be about the same as you intend to build your wooden carved blades.

For the sails the best material is said to be 'Dacron'.  
Good cotton will do as well.

The angle of the sails should be something like 5 - 7 degrees, when the ropes are tight.

These rotors are very powerful, but will not go very fast.  
Your PMG must have lots of wire in the coils.

But what I've heard sail wing rotors might be the really best for home builders.

We made one rotor like this about one year ago

with John Furze, Lars Camprat, Ville Vernerimo, Arjo Heinsola, Timo Jodat, Arvi Karhumäki, Olavi Nykänen and other friends from 'Technology For Life' at Keuruu Eco Village.

That rotor is not in use at present, but I hope to be able soon to instruct the ecovillage to complete the machine.

- Hannu

Re: steel or aluminum blades ([none / 0](#)) ([#7](#))  
by [wdyasq](#) on Thu Jul 24th, 2003 at 08:25:49 AM MST  
([User Info](#))

At one time the Gougeon Brothere (WEST Epoxy) had a report on the longevity of wood-epoxy/Carbon-Fiber/FRP (fiberglass)/steel/Aluminum. The report is worth reading and will convince one the safest blades are wood.

If one were to build molds, it would be advisable to build several "prototypes" of a "tunable" material until they got the best performance they could. The cost of molds needs to put over a large number of units - ask any Plastic Boat builder.

I think one solution might be to have the blades "CNC" machined of wood. I have a small "Homebuilt" CNC machine and could probably put out a 4' blade every half-hour once a design was set. This would allow one to make blades for an 8'-10' mill in an hour or two.

The CNC machining will also allow one to laminate "Blanks" with minimal waste and minimal machining of unnecessary material.

Ron

## [1.5 HP DC GIFT](#)

By [zubbly](#), Section [Homebrewed Electricity](#)

Posted on Tue Jul 22nd, 2003 at 06:11:17 PM MST [Alternators](#)

1.5 HP DC GIFT

hello everybody,

today i was given a 1.5 hp DC gift. this food manufacturer bought the motor 1 month ago and burnt it from overloading. they bought another one.

my question, is how if at all, can the output voltage have been calculated for being used as a DC wind generator, ( with out being able to run it ). the armature is burnt, and i can rewind it, but i don't want to wind it a second time if the voltage output is not ideal for charging batteries. the motor is permanent magnet, 180 volt dc armature. i know that i will probably have to get brushes with more copper content and larger wires on the brushes. the motor has two permanent magnets ( huge ), and two brushes.

here is the name plate data.

Leeson, 1.5 HP, 180 volt DC, 7.6 amp, 1750 rpm, cat#108262.00, MOD #c4d17fk19d, Duty-Cont., Frame-wms56cz, torque-54 inch/lbs, tefc, insulation class-H3, sf. 1.0

the motor has a 7/8 inch shaft with key way, mounting feet, and c-flange.

if anyone can help or suggest, please do so.

many thanks in advance-----zubbly

Re: 1.5 HP DC GIFT ([none / 0](#)) ([#1](#))  
by [doubter3](#) on Fri Jul 25th, 2003 at 07:14:49 PM MST  
([User Info](#))

Hi Zubbly,

If I am understanding your question correctly, you're wondering what the output voltage of your D.C. motor will be when it's used as a generator. If at 180 volts your motor runs at 1750 rpm, then you can assume it will generate about that same voltage when it is driven at 1750 rpm by an outside power source. I have one of the 2 HP Leeson permanent magnet treadmill motors that American Science and Surplus had (has?) for sale. I've tested it at various speeds and its voltage output is linearly related to its speed. I'm guessing most permanent magnet motors behave similarly. So your motor probably will generate around 90 volts when driven at half of 1750 rpm, or 875 rpm.

Volts/RPM = 180V/1750 RPM or RPM = Volts / 0.103  
V/RPM

So the drive speed necessary to generate 12V would be 12

$V / 0.103 \text{ V/RPM} = 117 \text{ RPM}$

Now the problem...there's always a problem. The windings in your motors are designed for a current of 7.6 Amps regardless of whether you want it to generate 12V or 180V. So the maximum power you can get from it at 12V is  $12\text{V} * 7.6\text{A} = 91 \text{ Watts}$ . Drawing more power from those windings will be inefficient and cause overheating and possibly failure. I'm using 12V just for an example since you didn't mention your desired output voltage, and higher output voltages would obviously yield higher power output.

If you're going to be rewinding the armature anyway, you could always rewind it with fewer turns of heavier gauge wire to increase it's current handling capability, but that would also require the motor to spin at higher RPM's to achieve the same voltage output.

Good luck,  
Doubter3

Re: 1.5 HP DC GIFT ([none / 0](#)) (#2)  
by hvirtane on Sat Jul 26th, 2003 at 02:58:17 AM  
MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I think that Doubter3's text is about correct.

Now, to rewind your machine is a big job.

Other possible solutions:

1)  
A DC to DC converter from 40 V - 180 V to 14 V  
and run the machine as it is as a battery charger for  
a 12 V battery.

These converters might be costly to build, but  
I bet somebody posting on this site knows about  
them.

2)  
Build a battery bank of 48 V made of four 12 V  
batteries  
in series and use the engine as it is as a battery  
charger  
for that battery bank.

I bet that there are ready made inverters, which can  
use  
that battery bank to get out of it 110 V AC or 220 V  
AC.

by zubby on Sat Jul 26th, 2003 at 02:20:33 PM  
MST  
([User Info](#))

hello Doubter3, your comments are exactly what i was looking for. there is a lot of extra room in the armature slots as it is. so when i rewind i will do it with a compromise of less turns and much heavier wire. i estimate with less turns and the existing extra room in the slots, that i can just about double wire size.

thanks again-----zubbly

[ [Parent](#) ]

Re: 1.5 HP DC GIFT ([none / 0](#)) ([#4](#))  
by zubbly on Sat Jul 26th, 2003 at 02:33:10 PM MST  
([User Info](#))

hello hv, your ideas are also very good, but i wish to keep the expense down as much as possible. i commented back to doubter3, but forgot to mention that i may convert the dc motor to 3 phase. if i am going to rewind anyway, i can make a set of slip rings, and get much more output from the unit.

thanks again----zubbly

**machining of neo's**

here i go again about neo magnets, another question.

once neo's have been glued to rotor and encapsulated with resin or epoxy, can the face of neo's be machined with carbide bit in order to get a rounder surface in order to make a smaller air gap between rotor and stator laminations? i would also coat face of rotor after as to prevent neo's from rusting.

thanks again-----zubbly

ya i did it. I took about .040 off of one . i had it epoxied real goog between the magnets it still puts out little red sparks at taking a couple thousands at a time cover your lathe ways and a lot of stuff around the lathe becomes magnetic and off course your tools like to jump up on the magnets but it went away. They say be careful of the fumes also. JB

## [converting 25 hp motor to alternator----need your thoughts](#)

By [zubby](#), Section [Homebrewed Electricity](#) [Alternators](#)

Posted on Sat Jul 19th, 2003 at 11:04:41 PM MST

### [converting 25 hp motor to alternator--your thoughts](#)

hello everyone, i am going to attempt converting a 25 hp motor to alternator. i intend to use it as 3 phase to power heating bank in forced air heating system. here is what it currently is. 25 hp, 1800 rpm ( 4 pole ), 575 volt, TEFC ( totally enclosed, fan cooled ). i will be stripping the old winding out and rewinding. there are 48 stator slots. i wish to have 230 volt 3 phase output, as this is the voltage requirement of the heating coils. usually, each bank of elements is 5 KW, 3 phase.

new winding will have 24 coils, 8 coils per phase- ( i will test voltage of one coil after rotor is complete )

the span of coils will be 1-4. the spacing of magnets on rotor will be equal to the centre to centre distance of coil sides. the width of magnets will be equal to the width of three stator teeth between coil.

with this coil spacing and stator teeth measurments, it works out to 12 magnets spaced 30 degrees apart. i will be using 12 rows of magnets on the rotor, round, approx. 3/4" inch diam. by 1/2 or 3/4 long. there will be 7 magnets per row as the stator length is 7 inches.

if anyone sees a problem with the coil/magnet combination, please give me your remarks.

now this is a lot of weight on the rotor with all those magnets, and i think i know a good way to hold them on. i will turn down the face of the rotor to accomodate the thickness of magnets. next i will construct a thick walled tube made of fibre glass. the tube will be bored to fit the rotor snugly and i will use industrial retaining compound to hold tube on rotor. then turn outer face of tube to the original diam. of rotor. before installing the tube on rotor, i will drill 12 rows of holes, spaced 30 degrees apart, parrallel with the length of tube for the magnets to be glued into. now install the tube on rotor, glue in magnets, and hope it stays together. by the way, the industrial retaining compound i refered to is made by LOCKTITE, or commonly refered to as thread locker.

does anyone know if i could make the tube out of aluminum or brass. would these materials short out the field of magnets?

before doing all this, i may make a similar unit out of a 2 or 3 horse power first to see how well it works.

if anyone has any idea of how big a prop i am going to need, let me know. keep in mind that this is going to be a low rpm alternator.

any comments will be very appreciated!!!! let them fly

([User Info](#))

Zubbly,

If I were doing this I would have the tendency to turn the rotor to proper dimension and glue the magnets in place. I would then wind the core with Kevlar thread and coat with epoxy. All of the Kevlar fibers would be oriented in the proper direction for maximum strength against the centrifugal force and the coating would be very thin.

The tube you are speaking of might be handy for gluing/bonding the magnets in place. All of the "spaces" might be filled with epoxy -- "Cast in place".

All in all, an ambitious project. I'm not sure I would build a "single purpose" turbine where if any part of the project failed, it was all for naught. Heat pumps are a lot more efficient than resistance heating. For the same amount of power, even a "homebuilt" heat pump might produce four or six times the "heat" as resistance heating.

Using this "pie in the sky" reasoning, DC motors driving heat pumps would require a wind turbine with a rotor 1/2 the diameter with 1/4 the loads on bearings, tower and related pieces. This relates to an easier to manage lifting and project. The "Quarter Scale" (but still a damn good sized project) would give you the experience to tackle a project of a size usually associated with government. And if one took money from the populace as the government does, they would end up in a state sponsored hotel with bars across the windows.

Ron

Re: thoughts ([none / 0](#)) ([#2](#))

by zubbly on Sun Jul 20th, 2003 at 06:09:05 AM MST  
([User Info](#))

hello Ron, thanks for your suggestions on the rotor. this is exactly what i am looking for, and i will incorporate all good ideas into project. the reason i am going this route is that i just about have an endless supply of these motors available to me. this 25 hp motor weights approx. 350 pounds with heavy cast iron frame and massive bearings. my heating system now is forced oil heating, and all i have to do is insert heating bank in air return just before blower. when there is wind, i will have additional heat. last year i spent over \$3000 on heating oil. my penalty for living in Canada. i loved your comment about " hotel with iron bars ", and at work we have a big sign that reads " PLEASE DON'T STEAL!, OUR GOVERNMENT HATE'S COMPETITION ".

i am still hoping to receive comments from others in

regards to the coil/magnet combination, projected kw output, and size of and style of prop.

thanks again-----zubbly

Re: thoughts ([none / 0](#)) (#3)  
by Smithson on Sun Jul 20th, 2003 at 08:52:36 AM  
MST  
([User Info](#))

Would 16 magnet poles work out better if you are winding one to four? How are you winding it? If coil one ends in slot four are you starting coil two in the same slot [Four]?

One thing you could do is use the wave winding to save wire. And if you have not bought the magnets yet then rectangle magnets would be more efficient. My thoughts only.

[ [Parent](#) ]

Re: thoughts ([none / 0](#)) (#4)  
by zubbly on Sun Jul 20th, 2003 at 03:39:30  
PM MST  
([User Info](#))

hello, and thank you for your input.  
the stator consists of 48 stator slots. i am still working on many methods of winding the stator. so far, i have come up with using 24 coils, and each coil fills two slots. span will be 1-4, #1 coil will sit in slots 1&4, #2 coil will sit in slots 3&6, #3 coil will sit in slots 5&8, #4 coil will sit in slots 7&10 and so on. basically you just keep missing a slot from the previous coil. all slots will be filled. you are correct about using square magnets, they would work better, but i think it would be easier to drill round holes in the tube that i mentioned rather than trying to cut square holes. i worked out the number of magnet poles based on what i have read on other postings. i remember that ideal magnet spacing was the centre distance of coil sides, and that magnet width was ideally the width of stator teeth between coil sides, and it worked out to exactly 12 magnets. ( please, if i am wrong here, someone jump in ). i will work out all possible ways first and then decide. also, it will be much less expensive for 12 rows of neo's rather than 16. one thing i forgot to mention in the original posting is that i am going to remove the laminations and skew by one slot so as to help or eliminate possible cogging  
you also mentioned about wave winding. one thing i learned over the years is that depending where you live or how you were taught, often we will say the same thing but with a different word. wave winding, basket winding, lap winding, concentric winding, pam winding, consequent pole, series pole, adjacent pole,

skip pole.

i guess you understand me now. also some will say a span of 1-4, some mean that the coil will sit in slots 1&4, and some mean that there is 4 teeth between coil sides.

would you please explain your wave wound?

often wave wound refers to armature windings meaning that the start and end of coil sit many commutator bars from each other, and series wound means that the coil ends sit next to one another in the commutator. SORRY FOR ALL THE RAMBLING!

thanks again-----zubbly

by zubbly on Sun Jul 20th, 2003 at  
08:12:25 PM MST  
([User Info](#))

hi Smithson, you were right about using 16 magnets instead of twelve. i drew all the coils including 12 magnets on graph paper and found that coils did not have an equal amount of magnet coming and leaving coils.

after drawing all coils and 16 magnets on graph paper, it worked out perfectly, with even magnet covering all coils.

thank you again----zubbly

p.s. still need more input from you fellows.

[ [Parent](#) ]

Re: thoughts ([none / 0](#)) ([#6](#))  
by Smithson on Mon Jul 21st,  
2003 at 08:15:37 PM MST  
([User Info](#))

Hello

I can't find the info on wave winding. It was from a dead address on the internet. Basically you would run your wire down one slot then without completing a full coil circle run the wire up the fourth slot [or whatever] and then down slot 7 and so forth in a serpentine arrangement. It saves a lot of wire and is easier to wind. That would be phase one, then you would wire phase two same way. The magnet width would need to fit in the legs of coil.

I have never done it and the only wiring I have read about is the concentrated winding type.

If your stator stack is 7 inches you might want to cut that in half. I read somewhere that the longer the stack the hotter it will run. Maybe thats why they make alternators with a thin stack. Also I'm winding a 5 horse motor, [concentrated winding] 3 inch stack, 48 slots using 8 of the big block ceramic magnets. 3x1x2 Smithson

wind side turbine

hello everyone, just wondering if anyone has tried building a modified savonius turbine. does anyone know where on the web i can find more info other than what WIND SIDE has one their site? would like to no more about how to design, match to expected load, design details, and how fast does this type of turbine rotate.

hope to here from someone.

thanks in advance-----zubbly

[savonius turbine that looks like cork screw](#) | 3 comments (3 topical, 0 editorial)

Re: savonius turbine that looks like cork screw ([none / 0](#)) (#1)  
by [dizzy](#) on Tue Jul 15th, 2003 at 08:42:34 PM MST  
([User Info](#))

I just found this board this week and have been thinking about building a small savonius this summer. Likewise I just found the Windside site from a post(thanks someone). There is also a company in Austraila called Satec that says they are developing a comercial Savonius but their web site also speaks of trying for two years unfruitfully. So of course I had to build a scale model 12" tall out of mat board this weekend on the helix version. Their design helix is at 68 degrees (per descifering their spec pages)and the concept should greatly reduce vibration from individual blades at 90 degrees. We may take a stab at mounting one on the roof. As many have said the speed will be at a maximum equal to the wide speed. I will be inquiring to Windspeed about vibration since they even show them on a roof. Hopefully someone speaks English there. But you have to figure their stiffest design it rated for 135 mph(90mps) and with winters in Finland they also must have proved reliable to be around for so many years.

The helix construction on the scale model was difficult to wrap. The first one so far did not have deep enough vanes even though it did spin OK given just a dowel for a bearing. The full scale one(4' high in our case since code has us restricked to 35'high and the house is 31' now) I'm thinking about starting by constructing a full foam core which will act like a mold for fiberglass. The core would be one half so it would be used twice to get the match between the side. I'm wondering after a static balance if it could be fixture mounted and balanced at speed on a computer tire balancer?

Seeing all these folks here making their own generators is my next research project to fully understand. Since this will be a slow RPM does anyone have any suggestions on what type of pole etc configuration may work best? I may try some sort of planetary gear arrangment to speed up the actual generator speed.

Thanks  
dave

Dizzy, dont use gears to speed up the generator, that is a big power waster. If you scan this board and also sites like scorigwind.com you can see some very good slow speed designs that will be much better than gears. As far as my thinking goes now the only reason to ever gear the speed up on a windgenerator is so you can use off the shelf components that are not really well suited for wind power. Slow is good and power can be generated if you build insted of trying to use something that needs speed.

Hi,

there is quite a lot information available concerning 'Savonius' type wind rotors on 'the old board' of the otherpower.com.

There has been some discussion on this new board as well.

Please see:

[http://www.otherpower.com/cgi-bin/webbbs/webbbs\\_config.pl?read=12283](http://www.otherpower.com/cgi-bin/webbbs/webbbs_config.pl?read=12283)  
[http://www.otherpower.com/cgi-bin/webbbs/webbbs\\_config.pl?read=14202](http://www.otherpower.com/cgi-bin/webbbs/webbbs_config.pl?read=14202)  
[http://www.otherpower.com/cgi-bin/webbbs/webbbs\\_config.pl?read=15075](http://www.otherpower.com/cgi-bin/webbbs/webbbs_config.pl?read=15075)  
[http://www.otherpower.com/cgi-bin/webbbs/webbbs\\_config.pl?read=13718](http://www.otherpower.com/cgi-bin/webbbs/webbbs_config.pl?read=13718)  
[http://www.otherpower.com/cgi-bin/webbbs/webbbs\\_config.pl?read=11653](http://www.otherpower.com/cgi-bin/webbbs/webbbs_config.pl?read=11653)  
<http://www.fieldlines.com/story/2003/4/3/95557/80233>

Concerning the types like 'windside'.

I have seen one self-made here quite near.  
The guy has made his turbine vanes of metal sheets.  
It is about 1,5 m tall, 70 cm wide.  
The generator is made of a washing machine PM motor. The gearing is 1:3.  
Seems to be working quite well.  
I have no details of the performance, but that project shows that the construction is not very difficult.

I think that it is best to make a direct drive alternator, something similar as the 'otherpower Volvo' alternator. If you will use enough wire in coils you can make it to charge batteries on really slow windspeeds.

You can estimate RPM of your rotor quite easily by using the estimate that the tip of the vane doesn't exceed the windspeed.

using multiple magnets in place of one

hi guys, i submitted a long thought with many questions about magnets. i guess it was too long and didn't make it to the board.  
question???? can you use multiple magnets stacked and layed end to end to take the place of larger magnets? can you use progressively smaller magnets end to end to form a tapered magnet?

thanks again in advance. zubbly

Stacking a second magnet of the same size and strength will give you more magnetic flux, but not double, more like 30-40% increase. Stacking a third magnet also helps, but even less. Side by side will work ok, but not as good as a solid neo of the perfect size/shape.

Best regards,

troy

I agree with Troy, you can stack them on top each other, but there is a limit to the power achieved and as troy mentioned, the correct orientation/configuration and size greatly matter.

neodymium is neodymium

A neodymium magnet is called that because of what it is made out of.

I believe the actual magnet material is neodymium Iron boron or chemically, NeFeB

If you hear about people saying samarium cobalt (sp?), ceramic, etc. that is the material that the magnet is actually made out of. (Never end a sentence with a preposition!)

I think most magnets are plated in something nonmagnetic anyways as to not affect the magnetic material inside (neos have mostly nickel plating, I seen a couple gold, and once in a while, zinc)

-Andrew

Dear Zubbly,

Neos are made from sintered metallic powder. Sintered means they start with small metal particles and crush them together until they bond. It's not a strong bond though. So if by bend, you mean break...

Best regards,

troy

Oh Yeah,

And I forgot to mention that the Curie temperature (at which they start to lose their magnetism) is surprisingly low, a few hundred degrees.

troy

is bigger better?

hi guys, i would really appreciate your comments before i take the actual plunge of building a large genny. please give your comments on prop size and style, tower construction, and approx. output of what i would like to build. where i work, my colleagues had just scrapped a 25 hp, 1800 rpm, 3phase, because the client was in a rush and bought a new one. here was the perfect frame and core that i was looking for. it has 48 slots that would allow me to make a 16 pole genny-3phase, with a perfect one inch span of 3 stator teeth that will allow me to use one inch wide neo's by 5 inch long. the span of coils would be 1-4, coil turns i have not determined yet as i would be doing a little trial and error. the rotor would be machined to accept 16 neo's by 1 inch wide by 5 inch long. i would have skewed the neo's by one slot as to help prevent cogging ( please confirm your thoughts here ). there are good buys out there on 1"x1/2"x1/8 thick. can i put these end to end to make up my 5" length and can i stack them on top of each other to increase their thickness? also how thick would you suggest that i stack them. after the rotor has been machined, magnets stacked, magnets epoxy encapsulated, and the rotor wrapped with resin glass tape and heat cured, i think i shall have a reliable unit. bad news though, after going to retrieve my unit at the shop, i found that the scrap dealer had already picked it up. oh well, won't be long before there is another unit. my intention is not to use it this year to charge batteries, but to supply a 3 phase heating bank that i will be installing in my oil furnace.i hope to be able to design winding for close to 230 volt 3phase low rpm. heating last winter cost me approx. 3,500 dollars for heating oil. any and all comments would be greatly appreciated. thanks to all in advance. zubbly

Stacking them does work but it makes it difficult to place them in position or more so holding them in place while the glue dries. A jig would be handy for this. Doubling the width increases the flux but not by 2.

Fun Stuff

Ed

I just order mine from Otherpower.com - under the products page.  
Even with the shipping, they are still cheaper than anything I've seen in Canada.  
Regards,  
Xeroid.

I just bought 5, 1 inch neo's from Lee Valley tools for \$12.95 can. for the package.I bought them to experiment.The stores are pretty well in every province except for Quebec.I will probably buy from Otherpower for the main project as Lee Valley's is limited in sizes. dondos

[Ed, am I close ? \(blade design\)](#) | 7 comments (7 topical, editorial)

Re: Ed, am I close ? (blade design) ([none / 0](#)) ([#4](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Dec 30th, 2003 at 03:17:59 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

There is good and bad to both designs. If your looking at a 10mph average the fancy prop may not reach its full potential until the wind picks up. Something like the old Aermotor mills are all torque, They seem to spin even when you can't feel the wind. The problem with those is the top speed of the rotor in a 35mph wind is 105 rpm. (Thats on an 8ft dia unit). So on the drag type 3 blade your only looking at a TSR of 1 or slightly higher depending on the angle and blade design. You'll definately need a re-drive to get the rpms you want at the alternator. All in all your dropping efficiency. The fancy prop, direct drive is still the most efficient way at this point.

Sounds like you have a unit that could take a good bite out of the electric bill already then put up a couple solar water heating panels to offset the hot water... also put a coil in the furnace and plumb it in to a heat exchanger on the water heater. Capture as much waste as possible and recycle it. These are some of my summer projects this year...

I think I'll attempt to carve as close to the blade design as possible for a 12' rotor maybe tsr-7. I realize how important the "root" and drop is for the torque of this design. Most on this board for both ease of construction with materials available (2X) and their application (charging batteries) have not gone full blown on this part of the blade and not been sorry. I think I would be as I need all the torque I can get and the speed when possible. I know it ain't going to be cheap gluing these up with select lumber but I've gone this far so no skimping on the heart of this thing, especially 12' possibly spinning at 400 + RPM at times seems kinda scary. Any suggestions on glue and lumber and any links that could help me out ? I've been out in the garage all evening cutting & drilling tower sections, a heavy 3 sided I hope to

by JB on Wed Dec 31st, 2003 at 09:25:49 AM MST  
([User Info](#))

Ive gone the gluing route of gluing good boards together. It works fine. A while back I found a old cabinet at a thrift store for 5 bucks. The wood caught my eye. I tore it apart to make some blades. I found out through a search that it is basswood. No knots, very light and very fine grain and you talk about something easy to carve, its like butter and it didnt splinter. The blades I carved were out of a chunk 40 inches long by 1 3/4 thick by 10 1/2 wide. I made 3 out of this section goin from 3 1/4 to 2 inches at the tips 40 inches long and they come in at 14 ounces each unpainted. I guess this wood is fairly reasonable. i saw some on ebay. I dont know how it holds up. JB

Dave, that sounds about right on the prop. I have no experience in driving a heater element and I'm not real sure how to calculate the outcome. Looks like riches comments make sense and his numbers seem to fall in place using ohms law.

Plugging in some numbers in the blade designer, it looks like you'd need to drive the alternator at a 2 to 1 ratio to achieve the output your looking for at 25 mph. Thats more of a calculated guess.

Is there a way you can adapt it to a small engine and carry the load through the rpm range the prop would be driving it. This way you can get actual output readings at a given rpm driving the load. This would give you a better idea of what will be needed in the way of a prop. Your still guessing on the efficiency unless you can get a torque reading from the stator ( pony brake set-up), but it may at least get you closer to the actual performance.

Ed & Rich

Thank you for your information and suggestions on my application. I know I can't get blood out of a rock but it looks as though I could at least pre-heat or pre-warm some water anyway with hours of wind averaging 10 mph or better and a very well insulated maybe smaller tank (20 gal ?) I need to focus on getting all this together with some guessing and your help and get it flying. I'll learn more about my next one than if I keep trying to improve what I have without flying solo yet. The numbers dont lie, I can speed things up, double up the magnets (again), squeeze down the airgap, rewind a more wire efficient stator, go with 3 phase, go bigger, bigger , bigger STOP ! It's a love/hate, I'm going to the garage to work on my tower. Just one more question, do you think more of a drag type (fixed pitch) 3 blade set for lower rpm but more torque would be a better option

Re: Ed, am I close ? (blade design) ([none / 0](#)) (#2) by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Dec 30th, 2003 at 07:06:41 AM MST ([User Info](#)) <http://www.windstuffnow.com/main>

Dave, that sounds about right on the prop. I have no experience in driving a heater element and I'm not real sure how to calculate the outcome. Looks like riches comments make sense and his numbers seem to fall in place using ohms law.

Plugging in some numbers in the blade designer, it looks like you'd need to drive the alternator at a 2 to 1 ratio to achieve the output your looking for at 25 mph. Thats more of a calculated guess.

Is there a way you can adapt it to a small engine and carry the load through the rpm range the prop would be driving it. This way you can get actual output readings at a given rpm driving the load. This would give you a better idea of what will be needed in the way of a prop. Your still guessing on the efficiency unless you can get a torque reading from the stator ( pony brake set-up), but it may at least get you closer to the actual performance.

Have Fun  
Ed

Kell is right, you won't find a magnet, electric or permanent that will have a force that you describe. If your looking for a magnet that has a large field, your looking for a ceramic magnet. I have some ring magnets that will affect a TV from 4 ft away. They are 8 inches in diameter with a 4 inch hole and are 3/4" thick. They aren't real strong in the sense a neo is but the field size is impressive.

Have Fun!  
Ed

Thats actually a unique idea! I tried to find out what type of steel they use in make them but didn't find anything. I would imagine its low carbon and then tin coated. Low carbon materials are easy to work with and much cheaper. My guess is it would be a good material for laminants although it would take alot of cans to make up a stator. The rings that add strength to the can may create a problem getting them tight together. If you have a slip roll you can flatten them out quite easy or a small hammer. Could be an interesting project none the less.

Old F

It sure seem a shame to wreck such a nice looking tower!!! Seems like you can calculate the compression loads on 2 of those tubes and come up with a suitable number for wind loading. If you know the strength of the steel your using it shouldn't be to hard to calculate this out.

Looks like your having fun! Nice Tower.

Ed

Dave,

You can usually guesstimate reasonably well if you have a tested output on your machine. I usually make a chart for the rpm range and calculated output for the alternator.

This way you have more of a calculated "guess" instead of pulling numbers out of the air and hoping for the best.

Once you know your approx alternator output at a given rpm then it makes it much easier to match a blade with that performance.

As an example say your test showed your alternator was making 12 volts at 100 rpm. The resistance of the stator was say 1 ohm to make it simple, and the charging voltage was 12 volts

$$100 \text{ rpm} / 12 = 8.33 \text{ rpm per volt}$$

So at 200 rpm we can calculate what the output might be without any losses...

$$200 \text{ rpm} / 8.33 = 24 \text{ volts open (no load)}$$

Charging to a 12V battery would yeild..

$$(24 \text{ volts open} - 12 \text{ volts charging}) / 1 \text{ ohm} = 12 \text{ amps}$$

You can chart this at any rpm, I use a spread sheet to make it simple

RPM	Open volts	Amps	Watts
200.	24	12	144
300.	36	24	288
400.	48	36	432

And so on...

Then you can easily go on to matching a prop to perform in the range of your wind from there.

Have Fun...

I have a new shipment of silicon comming in soon, I was going to pick it up but its a 5 hour drive and I didn't have the time to spend on the road. Its going to be trucked in instead. I'll have about 500 lbs of silicon available shortly and some sample rolls which I'll list in a few days...

Dave,

It's difficult to match the full torque range because of the cubed power coming through the blade at different wind speeds. It would probably be best to match the average winds in your area. For instance we have a relatively low average 6-12mph I typically set them up to perform best in that range. We quite often have higher winds in the range of 12 - 20 mph so anything extra is a bonus although they tend to drop efficiency as wind increases.

The blade designer program will work with all efficiencies, simply change the efficiency number in the efficiency box. I use an overall efficiency based on the alternator and expected blade efficiency so if your expecting say a 40% blade and a 70% alternator then the number to plug in would be (.4 x .7 = .28) 28% overall.

Have Fun  
Ed

[Question for blade experts.](#) | 7 comments (7 topical, editorial)

Re: Question for blade experts. ([none / 0](#)) ([#2](#))  
 by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Mon Dec 29th, 2003 at 08:55:36 AM MST  
 ([User Info](#)) <http://www.windstuffnow.com/main>

Hi Jerry,

The power you'll get from a given size blade pretty much remains the same regardless of angles. The angles, however, will tell you at what speed the blade will run at a given power output or wind speed. Also, each blade set runs at different efficiencies depending on the air foil. A simple formula for finding power output is...

$.00508 \times \text{blade area} \times \text{windspeed}^3 \times \text{efficiency}$

So at 25mph your 43" blade could make...

$.00508 \times 10 \times 25^3 \times .30 = 238 \text{ watts}$

That's assuming the prop is 30% efficient, it could be higher or lower.

Another thing to consider is the alternator efficiency... If your alternator is say 80% efficient attached to the 30% blades your actual output or over all efficiency would be  $.3 \times .8 = .24$  or 24% overall. So you'd end up with only 190 watts actual output not including any other losses.

A good airfoil will run in the 40-45% efficiency range.

Have Fun  
 Ed

Thank you Ed for the great info. We have a wide range of wind here in Western NY but all charts say around 12mph annual average. Sustained winds of 20+ are very common during the winter so it's tough to guess at my design for my application. If this wasn't my first one I'd have a better feel for the specs. I have no easy way to physically measure the power or torque needed under load while I'm testing, pony brake is out. I'm going by feel and guess and just wondered if I'm better off going with more torque and sacrifice some speed, I know I can't have my cake and eat it too. This is great fun, you sold me the silicon steel a while back and I may be in the market again, I'm hooked. Dave B.

Once you know your approx alternator output at a given rpm then it makes it much easier to match a blade with that performance.

As an example say your test showed your alternator was making 12 volts at 100 rpm. The resistance of the stator was say 1 ohm to make it simple, and the charging voltage was 12 volts

$$100 \text{ rpm} / 12 = 8.33 \text{ rpm per volt}$$

So at 200 rpm we can calculate what the output might be without any losses...

$$200 \text{ rpm} / 8.33 = 24 \text{ volts open (no load)}$$

Charging to a 12V battery would yeild..

$$(24 \text{ volts open} - 12 \text{ volts charging}) / 1 \text{ ohm} = 12 \text{ amps}$$

You can chart this at any rpm, I use a spread sheet to make it simple

RPM	Open volts	Amps	Watts
200.	24	12	144
300.	36	24	288
400.	48	36	432

And so on...

Then you can easily go on to matching a prop to perform in the range of your wind from

there.

Have Fun...

I have a new shipment of silicon comming in soon, I was going to pick it up but its a 5 hour drive and I didn't have the time to spend on the road. Its going to be trucked in instead.

I'll have about 500 lbs of silicon available shortly and some sample rolls which I'll list in a few days...

Ed

Hi Ed

Thanks these are the #s I was looking for. Now all I have to do is put it on a genny and wind test it in my S-10 pu. We got about a foot of snow last night so I gota wait till it melts and things warm up a bit.

Ed,

Thanks again for all the help. I'll start crunching some numbers and post my results to further narrow in on the blade design. I sure appreciate all the trial & error out there behind your experience that has saved me much time. Believe me if I had the time I would like nothing more than to help pave the way for others through experimenting. I'll keep in mind you will have the steel also, I'm already thinking about maybe bigger and better, that's what happens when you're adicted. Thanks,  
Dave B.

Hi Jerry,

The power you'll get from a given size blade pretty much remains the same regardless of angles. The angles, however, will tell you at what speed the blade will run at a given power output or wind speed. Also, each blade set runs at different efficiencies depending on the air foil. A simple formula for finding power output is...

$.00508 \times \text{blade area} \times \text{windspeed}^3 \times \text{efficiency}$

So at 25mph your 43" blade could make...

$.00508 \times 10 \times 25^3 \times .30 = 238 \text{ watts}$

Thats assuming the prop is 30% efficient, it could be higher or lower.

Another thing to consider is the alternator efficiency... If your alternator is say 80% efficient attached to the 30% blades your actual output or over all efficiency would be  $.3 \times .8 = .24$  or 24% overall. So you'd end up with only 190 watts actual output not including any other losses.

A good airfoil will run in the 40-45% efficiency range.

Have Fun  
Ed

I purchased a GM90/8 a bit ago then ordered a 5kw ST Head for it. I'm using the pulley that came with the unit and a 5VX belt to drive the head. I haven't had time to make up the mounting frame as yet but have all the materials to get it together. I'm hoping some time will free up in the next couple weeks so I can finish it up. I'll post some pics when its together and functional.

Have Fun

[Silicon steel](#) | 3 comments (3 topical, editorial)

Re: Silicon steel ([none / 0](#)) (#3)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Dec 23rd, 2003 at 03:00:01 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

If you interested in the 1/2" silicon the formula to find weight is:

$$(OD^2 - ID^2) \times .7854 \times .134 = lbs$$

This is for the 1/2" stuff, the 3/4" will have a different conversion, I'll know when I get it here.

The cost of the stuff is \$4.00 per lb. for either

You can email me with any specifics.

I'm thinking of putting it on my site but in specific size rolls instead of winding each one specific for an application. So there will most likely be 5 or 10lb rolls as a standard.

Have Fun  
Ed

Ed;

actually you can get to 110 using toes.

for every 10 on fingers curl one toe when all toes are curled its 100 then you still got the 10 fingers .

Cheers.

[Vawt or S Rotor](#) | 3 comments (3 topical, editorial)

Re: Vawt or S Rotor ([none / 0](#)) ([#3](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sat Dec 20th, 2003 at 12:45:31 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Hi Arno,

I'm not sure I'd do any betting at this point, VAWT's are still quite bulky and have their own set of problems.

Personally I like the way they look, I could sit and watch them for hours ( if I had the time ).

Basically what it boils down to is.. Each side has a drag coefficient (Cd) and the object is to get the upwind side as low as possible and the downwind side as high as possible.

On a typical Savinuous machine the downwind drag is close to 1 and the upwind side is around 0.20 , This shows that its about 80/20 collection. You also have to factor in the speed that the downwind vane is moving away from the wind as well as add the speed the upwind side is moving into the wind. Adding vanes to direct the flow works fairly well and ducting works extreemly well. The trick is to remove the upwind restrictions while enhancing the downwind torque. There are specific shapes that provide extream drag resistance for the downwind side and other shapes that help remove the resistance on the upwind side.

The shape that provides the highes drag is a "half tube" ( Like a pvc pipe split in half). This shape has a drag Cd of 2.3 with the C collecting the wind ( C < - wind direction).

Unfortunately when you turn it around ( wind direction -> C ) it still maintains a drag Cd of around 1. If you add a shape to the nose but still keep the shape inside you can reduce it considerably ( <C ). As JJ pointed out a few posts back, adding an air foil to the front of it. Since its not a complete airfoil the air breaks up behind it and creates a turbulance and adds drag. This would allow you get the Cd on the upwind side down to around 0.4 or possibly a little less. The half airfoil shape on the "Lenz Turbine" brings it down to around .2 or slightly higher but we're still collecting the higher Cd of 2 on the downwind side or slightly higer. By adding a difuser or ducting the upwind side only sees its own speed ( plus a little turbulance). So now, basically we're collecting almost all of the power in the wind. If the ducting allows for collection of the entire area ( area of the turbine - both sides ) this forms a venturi, the venturi will increase wind speed as it approaches the downwind blades. Now your collecting at a higher speed than the wind comming into the inlet which offsets the downwind blade moving away from the wind. An open Savinuous sees 12 mph wind and if the blades are moving 4 mph away from the wind then your only collecting from an 8 mph wind with the upwind side fighting 16 mph head wind. So you can see the benifits of the venturi and blocking the upwind side.<p>I think Savinuous had the right idea using the "barrel" or "S" type rotor but I think it would do far better by spacing them out and adding an airfoil shape to the nose of the barrels. Also by adding a simple drum in the center would help direct the air into the barrel and create a low pressure

to the back side of the turbine which helps carry the "barrel" farther behind the machine creating a longer torque period. Also adding 3 blades or barrels enhances the overall torque. Either, by ducting or removing the built in flaws can make a big difference in performance over the Standard methods...

Fun Subject!!  
Windstuff Ed

On a typical Savinuous machine the downwind drag is close to 1 and the upwind side is around 0.20 , This shows that its about 80/20 collection. You also have to factor in the speed that the downwind vane is moving away from the wind as well as add the speed the upwind side is moving into the wind. Adding vanes to direct the flow works fairly well and ducting works extreemly well. The trick is to remove the upwind restrictions while enhancing the downwind torque. There are specific shapes that provide extreem drag resistance for the downwind side and other shapes that help remove the resistance on the upwind side.

The shape that provides the highes drag is a "half tube" ( Like a pvc pipe split in half). This shape has a drag Cd of 2.3 with the C collecting the wind ( C < - wind direction).

Unfortunately when you turn it around ( wind direction -> C ) it still maintains a drag Cd of around 1. If you add a shape to the nose but still keep the shape inside you can reduce it considerably ( <C ). As JJ pointed out a few posts back, adding an air foil to the front of it. Since its not a complete airfoil the air breaks up behind it and creates a turbulance and adds drag. This would allow you get the Cd on the upwind side down to around 0.4 or possibly a little less. The half airfoil shape on the "Lenz Turbine" brings it down to around .2 or slightly higher but we're still collecting the higher Cd of 2 on the downwind side or slightly higer. By adding a difuser or ducting the upwind side only sees its own speed ( plus a little turbulance). So now, basically we're collecting almost all of the power in the wind. If the ducting allows for collection of the entire area ( area of the turbine - both sides ) this forms a venturi, the venturi will increase wind speed as it approaches the downwind blades. Now your collecting at a higher speed than the wind comming into the inlet which offsets the downwind blade moving away from the wind. An open Savinuous sees 12 mph wind and if the blades are moving 4 mph away from the wind then your only collecting from an 8 mph wind with the upwind side fighting 16 mph head wind. So you can see the benifits of the venturi and blocking the upwind side.<p>I think Savinuous had the right idea using the "barrel" or "S" type rotor but I think it would do far better by spacing them out and adding an airfoil shape to the nose of the barrels. Also by adding a simple drum in the center would help direct the air into the barrel and create a low pressure

to the back side of the turbine which helps carry the "barrel" farther behind the machine creating a longer torque period. Also adding 3 blades or barrels enhances the overall torque. Either, by ducting or removing the built in flaws can make a big difference in performance over the Standard methods...

Fun Subject!!

Hi JJ,

Both books are quite good. Neither of them have any specific building but the one you refer to has alot of math and covers most turbines. This includes the Darrieus, savinous, multi-blade to the modern turbines. I would recomend both if you can find them. Both are similar and each seems to have a bit of detail that the other doesn't. He also goes into some hybrids that are kind of unique.

I found them in Half.com for a reasonable price. Both have been out of print for some time now.

[Laminated Copper Coils?](#) | 8 comments (8 topical, editorial)

Re: Laminated Copper Coils? ([none / 0](#)) ([#6](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Thu Dec 18th, 2003 at 08:24:47 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've used bar stock to make some extremely powerful alternators as well as copper sheet. It is, however, very difficult to work with and you have to do some advanced planning on winding them and setting them into place.

One I experimented with was made from copper sheet, punched out the coils and soldered together to form a "slinky" style coil. You can get almost double the turns of an equivalent size but it will take a couple days on each coil. The outcome, of mine, wasn't real rewarding for the amount of work I put into it and the idea was scrapped. I believe the limit was 30 to 1 which is to say the width of the sheet can't exceed 30 times the thickness of the metal. Ribbon wire would be much better and easier to work with. I used a thin plastic sheet for insulating between the copper and I'm sure I was getting a "capacitor" or "skin" effect from the unit.

Another idea was to use a circuit board to form the coils, simply etching the coils from a copper clad board and laying them in place. This worked well but didn't make any real power, but... I believe it could be done with a thicker copper using less turns and more magnets. Yet another attempt to solder straight wires between circuit boards to create coils. The idea here was to use thicker return lines to reduce the wasted resistance on the upper and lower portion of the coil thus reducing the over all resistance of the phase. This also worked fairly well if you have the patience. If they were made on an assembly line put together by robots would have great potential... doing it by hand, and making all the wires and parts... well it took me a month to make one set of coils for a 3 phase unit... needless to say it was never finished. The phase that was finished kicked butt! Laying bar stock in slots and wiring them together using heavy wire also makes an extremely powerful "welder" or an alternator that will power a small town. Sky's the limit! Your only limited to your imagination!

That is the general idea that I had in mind. Here is a (hopefully small) picture of what I had in mind. I'm guessing (literally) that the eddy currents would be as bad with laminations as they would be with solid stock. I think that the same situation would exist with regard to eddy currents as exists with laminated stators, or thinner versus thicker wires. The thinness of the laminations would hopefully reduce the problem of "skin" conduction as it exists in very thick conductors (which sounds like a different kind of "skin" conduction than the capacitance induction that you mention in using the film as an insulator between the coil layers in your experiment.

The thought is that the coil segments could be struck from copper sheet on some kind of die, or that they could be cut in a stack on a scroll saw. Having been shaped, they could be coated with a thin film of insulation (polyester resin?) Then they could be soldered together at the top. An adhesive would be placed between the insulated layers where the magnet passes over them, and they would be compressed until the adhesive cured. The end sections of the coil would not be glued to each other so that they could be bent into the fan shape at the top of the coil to provide surface area for cooling the coil.

Andy,  
Those are driven by a small kicker circuit and are quite simple. The basic circuit was used in the "adams" and "bedini" motors. Another site that has a very simple circuit for doing just what you described is here....

<http://home.earthlink.net/~lenyr/magkick.htm>

That should get you going...

[IDEA FOR LENZ TURBINE](#) | 1 comment (1 topical, 0 editorial)

Re: IDEA FOR LENZ TURBINE ([none / 0](#)) ([#1](#))  
 by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Dec 17th, 2003 at 07:03:03 AM MST  
 ([User Info](#)) <http://www.windstuffnow.com/main>

JJ, that would work. If you keep the half tube in place on the inside and use a partial airfoil on the leading edge you'll still benefit in the lift and collect high drag on the downwind side. Keep in mind on the upwind side we want to basically offset the drag with lift to overcome the losses and possibly add some power to the machine. Once the machine reaches a TSR of 1 or higher you no longer making power from drag. (actually occurs at just below 1)  
 A drag machine produces it's best power at around a TSR of .33, anything above and up to a TSR of 1 the power starts to fall off drastically.

[Twin Rotor Question??](#) | 5 comments (5 topical, editorial)

Re: Twin Rotor Question?? (none / 0) (#3)  
 by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Dec 16th, 2003 at 06:55:20 PM MST  
 ([User Info](#)) <http://www.windstuffnow.com/main>

Hi JB,

In the past I've used an equal number of magnets to coils on the slotted stators. The drawback to this is the slots line up with the poles causing a cogging as the magnetic field changes polarity from one slot to another. If you think of the coil arrangement used in the dual rotor machines the cogging issue is solved. I've designed a progressive 3phase machine that should prove interesting... It's definately been a challenge in designing. 16 magnets over 36 slots.

Anyway if you think of a disc with say 8 magnets and wire the coils in the stator slots the same way as the dual rotor disc your done... no cogging. I have a stator that I made up a long time ago but the slots were screwed up and I did a test using 16 poles over the stator. Ran smooth as silk. The stator was set up for 12 poles and had 36 slots. This got me to thinking ( dangerous -)... a few pads of paper and some scorched brain cells I found a way to use all 36 slots and use a 16 pole disc. The current induced cogging should be reduced to a minimum also. I'll post the beast when its done. Should make for some interesting conversation... if it works

Have Fun  
 windstuff Ed

[Twin Rotor Question??](#) | 5 comments (5 topical, 0 editorial)

Re: Twin Rotor Question?? (none / 0) (#3)  
 by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Dec 16th, 2003 at 06:55:20 PM MST  
 (User Info) <http://www.windstuffnow.com/main>

Hi JB,

In the past I've used an equal number of magnets to coils on the slotted stators. The drawback to this is the slots line up with the poles causing a cogging as the magnetic field changes polarity from one slot to another. If you think of the coil arrangement used in the dual rotor machines the cogging issue is solved. I've designed a progressive 3phase machine that should prove interesting... It's definately been a challenge in designing. 16 magnets over 36 slots.

Anyway if you think of a disc with say 8 magnets and wire the coils in the stator slots the same way as the dual rotor disc your done... no cogging. I have a stator that I made up a long time ago but the slots were screwed up and I did a test using 16 poles over the stator. Ran smooth as silk. The stator was set up for 12 poles and had 36 slots. This got me to thinking ( dangerous -)... a few pads of paper and some scorched brain cells I found a way to use all 36 slots and use a 16 pole disc. The current induced cogging should be reduced to a minimum also. I'll post the beast when its done. Should make for some interesting conversation... if it works

Have Fun

Hi Hank,

I believe this is another "personal preference" type answer as well as skill and tools available. There are advantages and disadvantages to both. I prefer building them with laminants. I think there is more bang for the buck, but... there is alot more work involved in slotting the laminants and its not something that's easily accomplished without the right tools. The dual rotor system compensates for the missing laminant by using the magnets to concentrate the field through the coils but is fairly expensive depending on the magnets you choose.

Cogging is only a problem when the magnets are lined up with the slots on the laminants this is easily overcome.

Cogging, due to current following through the coils is still a consideration in either system. Single phase systems tend to hum or vibrate, the 3phase systems still have the hum but its far less distinctive. So its basically back to the personal preference, skill and tools again... decisions... decisions....

([User Info](#))

Hey Ya Ed. Can you get into a little more detail how the cogging issue is easily overcome on the single rotor with laminates. Is it the laminates on the backside like the one that Dan did here the magnets actually the laminates on the backside. Thanks JB

[Bedini questions](#) | 8 comments (8 topical, 0 editorial)

Re: Bedini questions ([none / 0](#)) ([#1](#))  
 by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Mon Dec 15th, 2003 at 10:14:21 AM MST  
 ([User Info](#)) <http://www.windstuffnow.com/main>

Hi Monte,

I haven't built a "bedini" motor per say, I've built a few based on the original "Lenz" concept which was used to prove the "Lenz law" then later went on to experimenting with the "Adams motor" which is what I believe the bedini motor principal is based on. One of my early models ran for 6 months by switch charging 2 dead 9V batteries. The coils ran about 20 degrees below ambient for the whole time. Later I went on to building some more advanced models the last one shown below... This one had dual rotors with 4 coils. Each coil had 2 windings (primary and secondary) for extracting back emf. The voltage going into the caps sometimes exceeded 1500 volts. When connected to 2 8ft flourescent bulbs, had no trouble powering them up to full light. The motor ran at 7200 rpm and ran from a 12V battery drawing about 5 amps. It never made an "over unity" output but It did come in at around 97% as long as it only ran itself and powering flourescents or recharging the secondary battery. So basically it was extremely efficient as long as it did no real work. I used a hall sensor for the timing and mosfets for powering the coils. I must have spent 2 years playing with about 40 different motors I built before I decided to move on to other things. Then built a magnetic rotary engine followed by a new hobby into the stirling engines... and on and on and still going!

Actually, You can get more coils with fewer turns between the magnets to do the same job. Thus reducing the air gap and increasing power and efficiency. The only problem with the dual rotor system is you need a certain thickness to maintain the integrity of the stator, especially under load. Over lapping doesn't mean they overlap in the gap only at the top and bottom of the coils.

I posted an idea for a stator sometime back which iFred tried doing a poured stator similar using the technique but I haven't heard anything about it since...

Here is the pic again.... Have Fun..

not trying to butt in here but this looks like a good place for these ??s. I like the diagrams and pictures they are very helpful but i want to be sure Im OK.i get confused.Give me a automatic transmission and I can probably fix that. here is what i got or plan to do. I want to make the dual rotor like Dans but with a qty of 12 1.5 by 1/4 magnets on 2 steel discs that i got that are .440 thick and 9 inch in diameter. . The overlapping coil is a little bit out of my league for right now though I have toyed with the idea in my head for quite a while. This is what I thought. Dans machines have 9 coils, 12 magnets on each rotor. I can squeeze in 15 coils by making the hole in the stator 10 inches OD . If i series coils 1-4-7-10-13 for one phase and coils 2-5-8-11-14 for another phase and coils 3-6-9-12-15 for another phase will i be allright for a 3 phase machine or is there a better way to wire it or will this work?? . I was hoping to sandwich these coils in between some lexan I got that is 1/4 thick. Thanks JB

### 3 Phase Question

By [Hank](#), Section [Homebrewed Electricity](#)

Posted on Sun Dec 14th, 2003 at 11:56:54 AM MST

[Wind](#)

Now that one is flying... Thinking about a 3 Phase

What are the benefits of a 3 Phase unit?

If I build a 3 phase genny based on the single phase I built (Volvo type). I will in essence have to reduce my coil windings to fit in the additional coils for the 3 phase so as not to increase the laminate to magnet gap.

If my single phase unit is using 40 windings of #14 wire per coil with 16 poles then I would have to decrease these windings per coil to about 20.

However the amount of coils would increase from 16 to 24 coils.

If, for arguments sake, I am getting 2 volts per coil in the single phase unit at some arbitrary rpm that will total 32 volts (16 x 2).

Now if I need to cut down the coil windings to 20 then the voltage will decrease to 1 volt per coil. The amount of coils will increase from 16 to 24 so my voltage at the same rpm will now be 24 volts rather than the original 32 volts. Or will it be less still as any one phase of the 3 phase unit will only have 8 coils (1.73 X 8 = 13.84 volts)

Would be interested in comments and advice from the 3 phase as well as single phase advocates as this sounds like an interesting project.

[3 Phase Question](#) | 6 comments (6 topical, 0 editorial)

Re: 3 Phase Question ([none / 0](#)) (#1)

by Electric Ed on Sun Dec 14th, 2003 at 01:33:55 PM MST

([User Info](#)) <http://www.electric-ed.com>

If all other factors remained unchanged, which I know is difficult to accomplish, adding two more windings (sets of coils) identical to the first, should increase the power output by 73%

Whether the voltage or the current is increased will depend on whether the three phases are connected wye or delta.

#### Twin Rotor Magnet Arrangement

### Three Phase Connections

Assume each of these symbols represents a complete phase winding, and that each is producing 10 volts, in a test setup.

For a Wye connection, connect any two Finish leads together. The voltage between the Start leads should be approximately 17.3 volts.

If the total voltage is 10 volts, interchange, and re-identify, the leads of one of the windings. The total should now be approximately 17.3 volts.

Then connect the Finish lead of the remaining phase as shown, and use the Start leads as the output line terminals. Check for 17.3 volts between any two line leads.

Make a Delta connection, by connecting the Finish of one phase to the Start of the next as shown. The voltage between lines should be 10 volts, equal to the phase voltage.

## Two examples of a Three Phase winding/magnet layout

3 phase winding - 4 coils per phase - Connected in series

Overlapped winding - requires 8 magnets

3 phase winding - 4 coils per phase - Connected in series

"One layer" winding - requires 16 magnets

### Twin Rotor Magnet Arrangement

Electric Ed

Re: 3 Phase Question ([none / 0](#)) ([#5](#))  
by Hank on Mon Dec 15th, 2003 at 08:22:47 PM MST  
([User Info](#))

Electric Ed,

Excellent graphics!

I guess "everything else being equal" is the key phrase. I would have to reduce my windings to get everything to fit in the limited realstate.

Question I have for you, in the above diagrams which would generate more power for the same rpm and coil size. The overlapping version (with fewer magnets) or the "one layer" version with more magnets.

Also, seems like twin rotors are in vogue now. Apart from not needing laminates and possibly reducing/eliminating cogging is there a real benefit to these to justify the increase magnet requirement/cost and perhaps complexity?

([User Info](#))

Question

Ed - I like the overlapping coils idea, but that would require increasing the distance between the rotors. If flux is inversly proportional to distance squared (is that correct?), which method above would be the most efficient?

The way it looks for the overlapping coils you would have to double (at least) the distance between rotors resulting in 1/4 the flux field. The alternative is to use "flat" coils and increase the number of magnets.

Anyone tried this for comparison?

I know that Ifred built an overlapping setup, but I never heard the results of his testing.

I share your excitement!! Although, my first one didn't work as well as yours, I was still quite happy and excited when it was up and it worked.

I know, now that the machine is up and running, your mind is going a hundred miles an hour and contemplating the next machine... the addiction has begun...

Have Fun as I know you are!

Ed

I share your excitement!! Although, my first one didn't work as well as yours, I was still quite happy and excited when it was up and it worked.

I know, now that the machine is up and running, your mind is going a hundred miles an hour and contemplating the next machine... the addiction has begun...

Have Fun as I know you are!

Ed

Finally producing power

After almost an year of planning, scrounging, tinkering and building it's up and producing power.

Special thanks to this board especially the Dans, Ed and Hugh who's advice and help made this possible.

It stands about 45' high supported by guy wires on a 60' radius secured to the ground using home made "duckbill" anchors.

I'm using an 8' 2 bladed rotor and it starts in winds of 8-10 mph.

It starts to furl at about 40 mph winds and time will tell how long it will last.

The most current I've measured out of it was about 36 amps at 14.5 volts into the battery banks. This was during a gust estimated to be about 30-35 mph.

Have to complete my electronics and monitoring system to get reliable data. Line loss is a killer, 500 watts into the batteries and another 1000 watts in copper/line losses.

Having a hell of a lot of fun though,  
Hank

Looks great! :-) How does it sound?

I like the colors.

Re: Up and flying ([none / 0](#)) (#3)  
by [charged](#) on Sat Dec 13th, 2003 at 11:58:04 PM MST  
([User Info](#))

Put a heavy induction booster at the genny and a large capacitor bank at the battery bank. Pulse the capacitors into the batteries.

The induction booster is very simple. They use them in small electronic equipment all the time. Just make sure that the inductor winding has a very low resistance.

You need to short the genny output into the heavy inductor with a pulse. I single high voltage, high-power transistor can do it with a simple pulse generator. Put a scope across the inductor and watch the input pulse as you gradually increase the pulse width. You should see a little ramp during the input pulse, but NO STEADY DC. If you get the pulse too wide, you'll see some DC at the top of the input pulse ramp and that much is wasted power. Just keep the pulse-width a wee bit short of that DC point.

Then you need a single heavy-duty high-voltage diode with it's cathode attached to the positive connection on the inductor.

The lines going to the house are connected to the inductor's negative negative side and the Anode of the diode.

The lines at the house are connected to the capacitor bank. The diode lead is connected to the cap negative and the other lead goes to cap positive. The very first capacitors in the parallel bank should be several small 400v electrolytics, about 1000uf total. These will absorb the highest peaks of spikes coming down the lines. Then run 2ft jumpers to the BIG cap bank. Put three car-stereo 1F super-caps in series for a 330,000uf capacitance.

Then, set up a simple discharge circuit between the big caps and the batteries. Connect the capacitor bank common negative to the battery negative. Then put a HEAVY SCR in the capacitor positive lead going to the batteries.  
Connect the Anode of a 5v ZENER DIODE to the SCR GATE.  
Connect the CATHODE of the zener to the CAPACITOR POSITIVE.

Put an analog meter on the caps so you can watch the voltage changes and then engage the genny.

You should see a fairly steady oscillation on the meter.

The caps will fill with the incoming spikes and when they reach 5v above battery voltage, the SCR will turn on and SLAM a high-current pulse into the batteries. Don't worry, the batteries will love it. No sulfating.

All your genny power will be converted to what amounts to "transient spikes" on the lines and your line losses will disappear. CEMF is almost pure voltage, almost no real current. The capacitors convert these spikes back into usable current to charge your batteries.

The engineering community mostly ignores everything Tesla patented after 1890 or so.

This is one aspect of his "radiant energy" power transfer systems.

Enjoy!

hi charged,  
i used to live in cambridge UK and know quite a few university engineers. when i tried to submit a Tesla coil as my degree project it was kicked out as fringe science. with well informed engineers like that about it is not surprizing that he is ignored. i thought it was maybe a UK thing but alas seems you have the same degree of ignorance over there as well. bit strange that someone who more or less invented most of the things we take for granted is unknown by people who should know better. opps getting on my soapbox again back to my VAWT project. Just to prove Teslacoils do exist have a look at our website WWW.HVFX.CO.UK  
end of blatant plug.

I'm off topic as well, but I have to comment on this. I've observed that those who are way above and beyond the norm, like Bruce Lee in martial arts, Einstein in physics, Jesus in religion, etc., there seems to exist a large group(the norm) that reject the truth each of these great individuals have revealed. So much so it's rather comical in a maddening sort of way. I guess if you don't understand something most would rather pretend it's not real than learn about it. LOL Many "teachers" I had seemed to be especially prone to such behavior. LOL Beam me up Scotty!!!! :-)  
Kevin(mostly self-educated, with a b.s. degree I'll sell real cheap :-)

Hi Charged,

This sounds interesting.  
Can you sketch out a schematic of this circuit or point me to where I can find one?

How would this circuit work with a charge controller when I have to divert the load. I'm thinking of using a Trace C40 charge controller.

This genny is pretty quiet, however at higher wind speeds you can hear it humming as the coils load up. The faster it goes the louder the the humming, it's single phase.

Thanks,  
Hank

by Nando on Sun Dec 28th, 2003 at 01:39:15 PM MST  
([User Info](#))

Congratulations for hte job done.

I is sad taht the industry is not realizing that to have generators producing low voltage are, lot of them, power limited by tehcabling to the battery or load.

With present technology, it would be best to have a high voltage generator with AC Voltage transmission.  
At the load a converter is installed to hav emaximumpower transfer.

In your case, I see that you could reduce the losses to about 10 % so, instead of 2/3 power transmission losses just 10 % or around 1350 watts into the battery and 150 watts into the losses, also it may be possible to charge at lower wind velocity regimes and the charger(converter) can be supplied with MPPT to maximize the power harvesting.

Regards

Nando

By laying them out the way iFred explained works well also but the field doesn't extend out as far as pushing them together. By allowing them to spread apart will match the field of the magnet. In turn open up the area of the field.

On a dual rotor system with a fairly large gap it would be better to butt them together. Where'as a laminated stator may better use the area of the magnetic field as opposed to the concentration. It all works well in the right places.

iFred tends to think outside the normal, this is usually where new things are found. I for one like unusual and creative thinking... the stranger the better! I'd like to say I think in similar terms but there are so many rules that are in the back of my head that sometimes makes it difficult.

Like a cup overflowing... there is no more room to add more... sometimes we need to empty our cup in order to get more.

More fun than my cup will hold!  
 Ed

## [How many wires can you fit in a hole...](#)

By [windstuffnow](#), Section [Diaries](#) [windstuffnow's Diary](#)

Posted on Sat Sep 20th, 2003 at 12:00:05 PM MST

Formula...

Here is a formula to find how many wires you can fit in a certain size hole:

$$(\text{hole dia} / (1.14 \times \text{wire diameter}))^2 = \text{total wires (turns)}$$

If you know how many turns you want to use but need to find out what size hole you'd need to fit them in:

$$1.14 \times \text{diameter of wire} \times \text{sqrt}(\text{Number of turns}) = \text{Hole size}$$

Its better ( more efficient use of space) to use a square or rectangular hole or slot but its easier to drill a hole as opposed to cutting slots for the home builder. I'm still looking for a square drill bit...

Back to playing in my toy box...

Have Fun  
Ed

Hi Ed,

I have to tell you, you are a veritable cornucopia of intersting formulae.

Hey you still have your ultralight???

Best regard,

troy

Re: How many wires can you fit in a hole... ([none / 0](#))  
(#2)  
by mkseps on Fri Oct 3rd, 2003 at 05:50:12 PM MST  
([User Info](#))

Hi Ed:

They do make square drills. They call them broaches and are available in many sizes.

Another approach is to have a machine shop equipped with a traveling wire machine cut the slots for the wire by EDM.

Might cost a bit but the results would be very professional.

EDM machines are programmed via CNC programming and can very accurately cut the whole stator slots and all.

Gene

Re: How many wires can you fit in a hole...

([none / 0](#)) (#3)

by [windstuffnow \(elenz@windstuffnow.com\)](mailto:elenz@windstuffnow.com) on Tue Oct 14th, 2003 at 09:40:14 PM MST

([User Info](#)) <http://www.windstuffnow.com/main>

Hey, thanks for the tip! I do use broaches for cutting key slots in my homemade hubs. Not sure how I would use them in cutting slots in the stators. I've machined them which works fairly well but its time consuming and it leaves the slots a bit wide at the surface. I've been working on a punch machine with a gear driven indexer to punch the slots one at a time as the material is wound. Still working out the gear change system to punch slots for just about any configuration. The tooling is quite expensive. Also trying to figure out a way of cutting different size slots with the least amount of tooling. I purchased the gears and materials to make the gear box and finished machining a 4 point geneva drive for the stop/punch motion all I need now is a few 36 hour days to get caught up with everything...

Have Fun

Ed

## [Draggy shapes....](#)

By [windstuffnow](#), Section [Homebrewed Electricity](#)

Posted on Thu Oct 16th, 2003 at 07:54:11 AM MST

[Wind](#)

Curious

I've been searching the web to get more information about VAWT's. There are alot of sites out there but none really get into any of the nitty gritty. There are no formula's for them, with the exception of the darrieus which relates to the lift formula's of the basic HAWT.

In particular, I'm looking for the drag coefficient of different materials and/or shapes that create lots of drag. The highest I've seen so far relates to a cup shape similar to a parachute or an anemometer which has a Cd of 1.42 on the cupped side and .38 on the curved side. Anyone seen anything like this on the web? or a higher Cd than 1.42?

Thanks and as always... Have Fun

Ed

([User Info](#)) <http://www.windstuffnow.com/main>

Never mind... After sending several emails out to some engineers, my question was answered. The reason I wanted to know was because I was using the 1.42 in my formula's and it wasn't working out on the "Lenz Turbine" compared to the output I'm getting. When proving it out I was getting a Cd number over 2 and wasn't sure this was possible. I found out the downwind side was achieving a Cd of around 2.3 and the .3 was lost from the upwind side.

Anyway, I'm still on track... Still working out some new ideas. Oh yea... I've build a difuser for the unit ( a couple different designs actually) and have achieved almost 21 watts on the output shaft in a 12.5mph wind.

Way to much fun!

Ed

hi ed,

here is a progress report on my lenz tubine. got the tower guyed up and have lifted the turbine up 6 feet! it still worried about thrashing it before its finished. have built the alternator apart from the stator. am going to try and reduce the weight a bit by using spiders on the ends instead of the 3/4 ply i am using at the moment. am taking lots of pics.

cheers  
bob

Great! Can't wait to see it! I agree on the plywood, there is alot of mass. I suppose there could be benifits from it but I still think if it responds quicker to gusts you'll end up farther ahead in the long run. I plan to build the real world version using aluminum to keep the weight down as much as possible. Its starting to "morph" into something a little different than the picture posted on my site. I believe the final version is just around the corner... still have a few more alterations to try.

Havin' Fun

trying struts made of oval shaped pvc tubing, the stuff you use for running cables along walls its about 1/2" by 1/4" only done one end of the turbine so far. the bottom end is still 3/4 ply and is bolted to the volvo hub at the moment. got lots of very cold easterly wind at the moment so a good test. will see if it is still in one piece tommorow. Went to the local scrap yard today and got them to save an old caravan for me. going back with my tin snips monday and cutting all the ally off it. just as i was leaving noticed a large pile of 6 volt 225 amp vrla batteries some with bulging cases some not some brand new, better take my meter with me as well hehehe. thinking of making the airfoil ribs from

plastic chopping boards. a good cheap source of polyethelene sheeting 12" x 8" x 3/8" thick is about 3 bux. wish it was a bit warmer..... think i will curl up and read windpower workshop which just arrived.

still having fun

bob

## Dual rotor stator ...

By [windstuffnow](#), Section [Homebrewed Electricity](#)

Posted on Thu Sep 18th, 2003 at 10:23:46 AM MST

Thoughts on making them thinner

[Alternators](#)

Here is a drawing on the idea of making the stator on a dual rotor system thinner. Basically a plastic disc with holes drilled into it for winding the coils. This would spread out the coils making them much thinner to increase efficiency/power from the unit. This would also help to keep the resistance down. After it was wound you would have to make a mold for the mounting tangs and pour the plastic around the wires. The drawing shows a 12 pole 36 slot disc.

Continuous thoughts... Have Fun... Ed

([User Info](#)) <http://www.oldf.homestead.com>

Hi ED

To make it easier to build how about a 1/4 inch thick plywood disk with 3/4 inch pine wedges glued to it. Than after winding the coils you set it in a mold and cast resin over it.

This way you could get by with hand tools.

Just a thought.

Old F

Re: Dual rotor stator ... ([none / 0](#)) ([#2](#))

([User Info](#)) <http://www.windstuffnow.com/main>

That would work. You'd have to make a jig to crush the coils down when you were done to keep the thickness down. The idea above is basically the same, you only need a drill and hack saw and probably a jig saw to cut the circle out. Also a protractor to lay it out. I think it would help contain the wires in the area the magnets are moving in. You still have to deal with the thickness of the overlapped wires on the outer and inner part of the ring but the magnetic area would still be quite thin.

I'm sure there is a better way... keep thinking.

Have Fun  
Ed

([User Info](#)) <http://www.windstuffnow.com/main>

Use lots of small magnets and simply push copper bar stock through the holes and wire it like a wave winding. End up with negative resistance.... ok not quite but pretty darn low. I built one using bar stock makes a heck of a welder ;O)

Have Fun

by JB on Thu Sep 18th, 2003 at 08:46:40 PM MST

([User Info](#))

OK ED. You got me thinking now. I have some 9 1/4 by 3/4 round delrin discs. Now here are my ???. If you knew how you were going to wire this either star or delta could you wire or actually be snaking the wire 3 slots next to one another and go over 4 slots and do the same, I think thats delta but im not sure and keep on goin without a bunch of splices so in the end you would end up with 6 wires and no splices instead of 24 wires and splices or would the wires from the other coils or other phase cancel things out as they would be going over the top of the others on the outside diameter. I was thinking of doing this on my mill with a superspacer and making a groove in the inside and outside diameter to keep all the wires tidy. I hope you understand my ???. The hub and discs are not a problem. I finally got that part figured out. Im a little slow. Thanks JB

Re: Dual rotor stator ... ([none / 0](#)) ([#9](#))

([User Info](#)) <http://www.windstuffnow.com/main>

Hi JB, I'm not sure I understand what your trying to explain... I usually wind them just like a single phase. But add two more phases in. So in the stator above you would have 12 poles, one coil for each of the poles make up one phase. So you'd start in one slot, skip two slots and finish the coil in the 4th slot. So the first coil would have 2 empty slots between it when your done. The second coil would be wound in the reverse direction as the first and so on until all 12 coils are in place. Second phase goes in the next open slot to the right wired the same as the first phase, and finally the remaining slots are filled with the same configuration. You end up with 3 starts and 3 ends of which you can wire it for star or delta or set it up for both with a switch.

I'm not real good at explaining things... sometimes pictures are much better than words and I think some time back electric Ed posted a diagram of the same winding arrangement. I'll see if I can find it...

Have Fun in any case..

Ed

[ [Parent](#) ]

by Electric Ed on Fri Sep 19th, 2003 at 10:55:28 AM MST  
(User Info) <http://www.electric-ed.com>

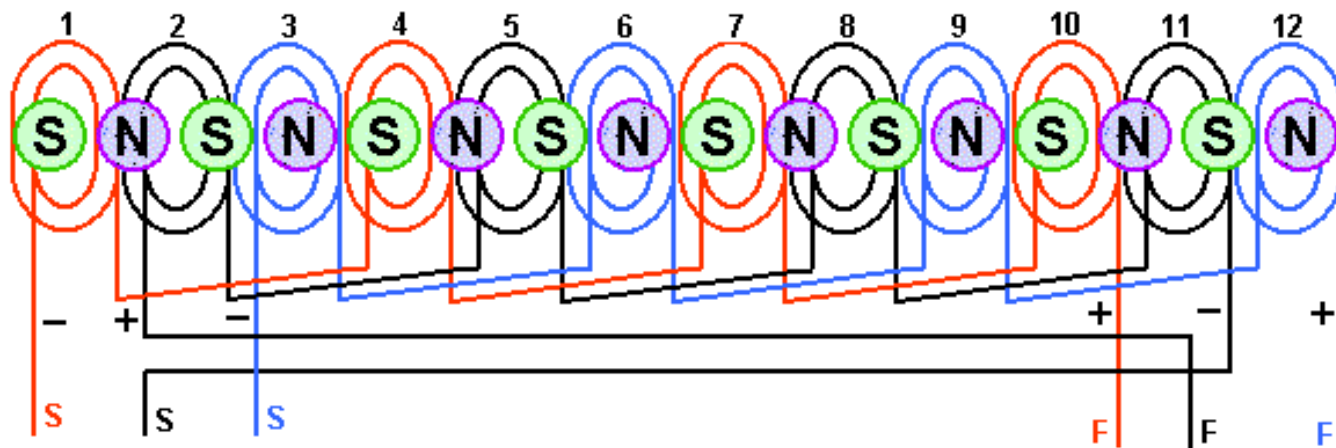

Perhaps it was this sketch Ed was referring to.

### Two examples of a Three Phase winding/magnet layout

3 phase winding - 4 coils per phase - Connected in series  
Overlapped winding - requires 8 magnets

3 phase winding - 4 coils per phase - Connected in series  
"One layer" winding - requires 16 magnets

### Twin Rotor Magnet Arrangement

Electric Ed

by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Fri Sep 19th, 2003 at 11:26:42 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Hi electric Ed,

I think its the one but it seems like you had another one that was closer. When I wind them each coil shares the same slot as the one before and after it. Seems to compact the wire better. I use 2 poles for 3 coils but the second set of 3 is partially covered by the first two magnets... I don't know if that came out right... I can see it but words don't seem to make the picture. Basically 3 legs under each magnet.

Have Fun

Ed

[ [Parent](#) ]

Re: Dual rotor stator ... ([none / 0](#)) ([#14](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Fri Sep 19th, 2003 at 12:45:54 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I made an attempt to diagram the wiring I'm talking about...

In the diagram, Red is phase 1, green phase 2 and blue phase 3. The grey represents the magnets. Each coil shares a slot with the coil before and after. This allows 6 legs positioned under each magnet or 6 coils are affected by each magnet. This allows you to pack alot of copper in small areas and allows for less turns per coil to achieve the same output of other configurations. This ultimately helps to lower resistance as well as cure other problems.

Have Fun!  
Ed

Re: Dual rotor stator ... ([none / 0](#)) ([#15](#))  
by JB on Fri Sep 19th, 2003 at 03:43:55 PM MST  
([User Info](#))

Ok Ed. I got ya covered now. Thank You. That word reverse in there through me for a loop but after about 6 times I figured it out. 36 slots that has to be. Got ya covered there also. Now my last ?? for a little bit. I got 1500 feet of 22 gauge neopreme covered door bell copper wire and 8 large neos. I realize that aint enough magnets for a non laminated dual rotor machine but im thinking that should be enough for a single rotor machine with 12 poles 3 phase. I hope im right on this. I guess I should by the book but my basic question is if I put a lot of turns of this 22 gauge would I get some good results or should I await till i get some money and buy the book and some 14 or 18 gauge. Thanks JB

([User Info](#)) <http://www.windstuffnow.com/main>

JB, using 22 wire won't make a power wagon but it will make a nice learning machine. Use 24 slots with 8 magnets or 12 slots with 4 magnets on each rotor. If you use a small diameter prop ( like 2 or 3 ft) it will run faily fast. Set it up for a TSR of about 3 or 4. A 2ft prop at a TSR of 3 will run just over 400 rpm in a 10 mph wind so you really don't need to over do the amount of turns per coil.

Have Fun  
Ed

Re: Dual rotor stator ... ([none / 0](#)) ([#18](#))  
by JB on Fri Sep 19th, 2003 at 08:25:56 PM MST  
([User Info](#))

Okie Dokie Ed. Thank You. Im still having fun. I havent messed up anything on this one Yet||\$\$\$\$\$. Ive built an induction motor and a pm motor and they worked ok through trial and error and lots of time of course. I was thinking the 8 magnets and 24 slots basically the single rotor type 3 phase but I got to do a little more thinking. The magnets are 1 1/4 by 1 1/2 by 1/4 thick. If i put 24 evenly spaced slots they wouldnt cover all 3 legs at the same time not at a 9 1/4 inch diameter anyway. I could make 24 slots in 8 bunches of 3 making them either 1 1.4 wide or 1 1/2 wide by drilling 8 evenly spaced holes on the outer edge and a hole on both sides of them to the width of the magnets so I would end up with 8 magnets over 8 of the 12 coils or I can downsize the diameter of the rotor. I really dont want to go single phase. Decisions Decisions Decisions. JB

Re: Dual rotor stator ... ([none / 0](#)) ([#21](#))  
by JB on Sat Sep 20th, 2003 at 01:00:53 PM MST  
([User Info](#))

Hello ED and others. Im thinking that my yesterdays thinking and last post was messed up. If i space 24 slots evenly and 8 magnets evenly everything should line up to one of the 3 phases. Im thinking I dont have to cover 3 legs at the same time. just one phase at the same time.I wonder If Im thinking correctly now. Thanks JB

[ [Parent](#) ]

Re: Dual rotor stator ... ([none / 0](#)) ([#22](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sat Sep 20th, 2003 at 01:23:15 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Thats right JB... As long as everything is lined up it should work. Its better to cover as much of the wire with magnets as possible but even if the magnet only covers one leg at a time it will work. More magnetic surface means more power.

Lots of fun!  
Ed

[ [Parent](#) ]

Re: Dual rotor stator ... ([none / 0](#)) (#23)  
by JB on Sat Sep 20th, 2003 at 01:59:23 PM MST  
([User Info](#))

Why Thank You Very Much Ed. I was getting a little Goofy thinking there. I was looking at the Dans triplets and then Electric Eds Diagrams and Your new stator Idea and getting foggy. Then I realized Electric Eds Diagrams are one for Dans type wiring scheme and One similar to Your wiring scheme which uses less magnets and more coils where Dans wiring uses more magnets and less coils. Thanks again. This is Very Nice of You. JB

Re: Dual rotor stator ... ([none / 0](#)) (#24)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sat Sep 20th, 2003 at 03:46:55 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

JB, you can download the instructions to my educational turbine to get an idea of how I do my windings ( as well as anyone else interested ). Maybe you already have... The little alternator uses 6 magnets and is a 3 phase system so there are 18 coils.

<http://www.windstuffnow.com/3phasekit.pdf>

It will give you a better representation of how I've been doing most of my alternators. To make it much easier for beginners I wind one large coil for each phase and its twisted into the slots. By doing it this way you end up with each coil reversed from the one before it.

If you have a large coil of 50 turns twist it and fold it in half you now have a coil of 100 turns, in half again you have 200 turns. So my little turbine basically has 6 folds or the equivalent of 300 turns of wire per phase and a total of 900 turns of wire in a tiny space.

Lots of wierd ideas that turn into something useful...

Have Fun  
Ed

Re: Dual rotor stator ... ([none / 0](#)) ([#27](#))  
by JB on Sat Sep 20th, 2003 at 07:58:04 PM MST  
([User Info](#))

Hello Ed. I just figured out Acrobat reader and downloaded it and your diagrams. I think i see what you are doin. I was going to do it wrong. I was going to fill up slots one and four and then go to slots seven and 10 but wind them in the other direction fill them and so on. The way you are doing it slot 4 will be completely filled when you are doing 4 and 7 and slot 7 will be filled when you are doin slot 7 and 10 and so on. Basically the next slot 3 over will be filled halfway and filled all the way when you are doin the next slot 3 over from it. I hope I explained this ok and that sounds right? Thank You. JB

by boomer on Fri Sep 19th, 2003 at 08:52:08 AM MST  
([User Info](#))

hi ed I am Handy Andy (post as boomer). I would like to say thanks for posting so many usefull drawings this one is awesome. For some reason this drawing cleard up how you can overlap coils and have the same amount of flux through pass through both legs of the coil. Do you have any suggestions how to deal with the big 3 coil overlap that happens on the inside and outside without loosing that nice small gap?

Handy Andy

Re: Dual rotor stator ... ([none / 0](#)) ([#12](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Fri Sep 19th, 2003 at 11:17:32 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Hello, boomer

On the outside of the rotor it really isn't a problem since the magnet rotor rides over the thin part of the stator. The problem arises within the center. This would have to be dealt with by using fairly thick magnets or at least thick enough to provide clearance between the discs and wires. The outer diameter you could make a mold to pour plastic around the wires and incorporate a mounting structure. This would allow for leaving a portion of the wires exposed for cooling and some would be enclosed in resin. I haven't built, just an idea so there is lots of room for improvements.

Another idea was to make 2 rings with wire hooks ( as posted earlier ) making the windings similar to bike spokes. This would be much harder to make the coils remain thin but wouldn't require any resin and the coils would be exposed. Also, the outer ring would serve as a mounting structure.

Lots of ideas... little time to try them all...

Have Fun  
Ed

by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Fri Sep 19th, 2003 at 09:37:04 PM MST  
([User Info](#)) <http://www.internetfred.com>

Hi Ed, That's a sweet idea. I think a simple round mould like normal, and insert wood dowels into place. I think the accuracy will be the issue, but when your working dry and slow it would be better. As long as the dowels are lubed or waxed up good you could then just slide them out when the mold is completed. Then a simple small cut with a hand saw per each center point where the dowel is and wola! done. I'm interested on how you do with this one! Good Luck!  
Fred

Re: Dual rotor stator ... ([none / 0](#)) (#20)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sat Sep 20th, 2003 at 08:18:43 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Thats a good idea iFred... Especially if you wanted to do a few of them instead of building "one offs" It would take a bit more work to lay it out and set it up but once you had it made you could make dozens of them as long as the mold lasted.

It was just an idea and I really hadn't planned on building one right away. It seems my mind wanders and ideas pop up now and then that I put down in a journal and when I have time I like to try new things. Looking back through my "idea" book sometimes what seemed like a good idea at first doesn't always work well in real life... others do... so I have to at least give them a try...

Have Fun  
Ed

Re: Dual rotor stator ... ([none / 0](#)) ([#25](#))  
by Old F on Sat Sep 20th, 2003 at 06:02:24 PM MST  
([User Info](#)) <http://www.oldf.homestead.com>

iFred

Looking at this like a foundry pattern you could use key stock glued to the bottom of the mold to form square slots in the casting.

You mite have to round the corners of the key stock a little. So that what will be the bottom of the slot of the finished stator will release from the mold this is called draft.

This would not be to hard to set up for a one of .

Old F

Re: Dual rotor stator ... ([none / 0](#)) ([#26](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sat Sep 20th, 2003 at 06:18:59 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

OldF, thats actualy a great idea. You could really pack it with alot of wire either turns or wire size depending on what you wanted out of it. Could almost make a corrugated type structure. This is getting better every minute.  
I take it you used to work in a foundry or still do?

Have Fun! Keep thinking!  
Ed

Re: Dual rotor stator ... ([none / 0](#)) ([#29](#))  
by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Sat Sep 20th, 2003 at 10:36:10 PM MST  
([User Info](#)) <http://www.internetfred.com>

Yes, that sounds about right! A single mold could be reusable if made properly. You know, you could have a slot on the dowel that is raised and ends in the bottom of the mold so that your cut is even made for you. Very cool!! I wonder what OLD F is thinking???? ummmm.. casting and foundry.. Very Cool!!!

Fred.

Re: Dual rotor stator ... ([none / 0](#)) (#31)

by Old F on Sun Sep 21st, 2003 at 07:47:48 AM MST

([User Info](#)) <http://www.oldf.homestead.com>

Here some thing that could work.

It is a split mold . When you lay out your mold you would drill holes the dia of your slot cores on the edge of the mold and the center mold core this will give you slots to place the key stock cores and hold them in place

This will all so give you some thing to get a hold of when it comes time to remove the cores from the stator.

You would have to coat the cores with melted wax so you can get them out.  
And I am thinking you could use a hair dryer to heat the cores soften the wax if need be.

Sorry about the ruff drawing all I have and know how to use is paint.

What do you get when you combine a Darrieus, Savonius with other ideas...?

About a year ago I became intrigued by a couple patents dated in the mid 80's. They were basically the venturi effect type mills. After building each and testing them, I felt there was some real potential but they still lacked in efficiency, although, they did performed much better than the Savinious. I found after building them in varrious arrangements some were real duds and others seemed to work extreemly well and converted in the 30% range. The picture below shows a 2ft by 2ft turbine. This incorporates all that I've learned from building a dozen or more test units not including the darrieus and savonius units I built for learning and experimenting with...

This unit makes 17 watts in a 12.5mph wind and runs at 240 rpm. Its kind of frayed and was built in about 3 hours using simple materials (plywood and aluminum flashing) but definately shows it is possible to get very close to the efficiency of a Horizontal unit using a drag/lift type Vertical. It will start turning in a 4mph wind although it doesn't start charging until around 6mph.

It has a "fat" wing design similar to the savonius as well as leaving part of the wing uncovered, also similar to the savonius but the blades are angled differently. The "fat" wing creates really good lift but has a tendency to create more drag. The drum in the center helps to alter the direction of the incomming wind which adds lift on the

upwind side. The original conception, as some of you may remember, was the "700 rpm coffee can". Unfortunately when I built a larger one using a 5 gal bucket it didn't work at all. After putting a small round can inside it started spinning on its own although not very well. This idea was changed and rebuilt several times before I finally realized what was going on. I believe I posted another one sometime ago but I can't seem to find any pictures of it. It worked very well but I wasn't completely satisfied with it. Once the "venturi effect" was embedded in my brain I started playing with different configurations of the coffee can design in larger 5 gal sizes. I found if you leave the inside wing flat instead of the original forming a wing on both sides it runs and starts much better. Adding a smaller drum in the center increased the power considerably. All the variables from all the designs are incorporated into this design in some way can you see them all in the diagram below?

Any thoughts or ideas?

Just having fun as usual...

Ed

([User Info](#))

VAWT (vertical axis wind turbines) have always bugged me a bit...

but that's awesome Ed! I'm starting to feel tempted to try one! Thankyou so much for sharing.

Re: Yet another VAWT ([none / 0](#)) ([#2](#))  
by hvirtane on Wed Sep 3rd, 2003 at 02:18:40 PM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Really nice.

Thank you very much for sharing this design.

Can you give any book references about the 'Venturi effect'?

Which kind of generator are you using?

Are you going to build bigger ones using the same design?

What happens if you've got more blades and a corresponding middle part?

What happens if you make it tall and narrow?

What about fat and short?

RPM change only or different efficiency?

What about different blade shapes?

- Hannu

Hannu,

The alternator is an axial design ( of course) but its only a single phase unit. I built this up primarily for testing these things.

"Are you going to build bigger ones using the same design?"

I plan to build a 4ft dia x 6ft tall for practical testing, hopefully this year still but time is running short to get it up.

"What happens if you've got more blades and a corresponding middle part?"

I think it would increase drag and not allow the air to flow properly around the wings and drum.

"What happens if you make it tall and narrow?"

What about fat and short?

RPM change only or different efficiency?"

Since I've only been making models at this point I don't know the outcome of changing the aspect ratio.

I believe building it identical only taller shouldn't hurt the efficiency and the rpm's should remain similar, larger diameters would of course move much slower. This one runs at a TSR of about 1.3 loaded and just over 2 with no load.

I've also tried a bunch of different shapes for blades but these seem to have the best ( so far) bang for the buck. I'm sure there are some others that may improve it. The position of the triangular drum makes a major difference in its performance also which could be put on a centrifugal control system and control rpm for overspeed situations. Keeping it simple for now though....

Have Fun  
Ed

Re: Yet another VAWT ([none / 0](#)) ([#3](#))  
by Norm on Wed Sep 3rd, 2003 at 03:18:15 PM MST  
([User Info](#))

Beautiful Ed...an idea popped into my head the second I saw it ...the drum in the middle gives enough room inside of it for a very large diameter rigid pole that could be buried deep enough or with a wide supporting platform so there would be no need for any other support. (by the way that drum reminds me of a Wankel rotor!) still Havin Fun in NE Ohio please send some wind...I'm only gettin about 1-5 mph according to my homebrew anemometer 6.5" center of cup to axis figure 60rpm is 2.3 mph (about right?)Norm.

Re: Yet another VAWT ([none / 0](#)) ([#4](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Sep 3rd, 2003 at 04:51:53 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Norm,Those were my thoughts exactly! I thought of using a pillow block bearing for the top support and 3 wheels around the pole at the bottom. It would be quite easy building the alternator inside the drum also but may present a maintenance problem.

I'm favoring the tower someone posted some time ago that pivots in the center... should be a fun project...

([User Info](#))

Very nice work Ed. I was planning to build a darrieus out of two old snowboards, but I can't find em for cheap. I think now I'll try my hand at one of your new-fangled VAWTs. How about "The Venturinator"? :-) One thing about VAWTs that's always puzzled me is when "lift" is produced it seems like the force would simply be directed in line with the axis and not produce any torque. I guess it's a resultant vector force thingy, but I can never quite figure out how the darn things work. Thanks again for the great info, Ed.

E-man

([User Info](#)) <http://www.windstuffnow.com/main>

Eman,

It is kind of mind boggling until you really get into the thick of it. Actually, I owe a bit of thanks to Hugh once again for helping me with the formula's for the wing angles.

If you take this thing apart and only use the drum it will spin but not much in the way of power.

If you remove the drum and only use the wings once again there isn't much there. The two combined at the correct angles and Zooom off she goes.

The Darrieus is sort of like that, it may start and it may spin but until it gets hit with the right air flow thats all it will do. Unless you give it a helping push to get it past the stall zone. Its like an engine with fouled plugs until they clear then its like a turbo kicked in. The force on the darrieus is very close to the center so you really don't get the full potential of the torque produced by the lift.

This design, I think so far, has the best of both worlds with start ability, low wind torque and reasonable rpms. It also produces good torque even loaded down to a TSR of .5 so matching the alternator isn't quite as critical as Horizontals although still a contributing factor for efficiency.

Time will tell...

([User Info](#))

Nice work, some of the features were used on the "Cory Jib Windmill", a 'soft sailed' machine designed by Will Cory in the late 60's or Early 70's. Will's design furled to self-regulate using centrifical force and a series of weights and springs. But he also pulled power both with drag and lift.

The gaps and airfoil shapes will be an interesting design problem. And one will also be able to pull power off the "rim" using it as a pully and driving a high speed alternator, if desired.

Ron

details for calculating the drum,wing, etc.  
([none / 0](#)) ([#12](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Thu  
Sep 4th, 2003 at 06:36:13 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

If anyone would like to build one to experiment with the formula's below will size things up. These dimensions were what I've calculated to work the best so far although I'm still working on some others...

Wing width or leading edge circle = diameter of the machine you wish to build x .14

Wing chord = circumference x .09 ( not to be confused by diameter)

Center drum radius = diameter x .28

The triangle drums points are set to point directly in line with the trailing edge. If you vary it more than a few degrees you loose efficiency. The top portion of the leading edge circle and the circle line up with the radius and creates a negative angle of attack. Its a very simple machine and takes very little time to put it together.

dimensions ([none / 0](#)) (#13)

by hvirtane on Fri Sep 5th, 2003 at 12:26:49 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Ed told:

"If anyone would like to build one to experiment with the formula's below will size things up. These dimensions were what I've calculated to work the best so far although I'm still working on some others..."

Excellent.

This can lead to a development of a very good new style wind turbine.

I will introduce this idea of Ed to some people here capable of building wind turbines.

---

I've many times suggested in various places that somebody should start a movement to create freely available drawings for renewable energy things. In the style of the well-known GPL licence for 'free software'. I've several times written to the highest guru of the free software movement, RMS (Richard Stallmann) about this idea.

Please see:

<http://www.gnu.org>  
about the GPL licence.

Database of airfoils....

Those of you that like to experiment with different airfoils for the blades may find it interesting to download a program that shows the profile of many different airfoils. The program is free and can be downloaded from...

<http://aerolab.virtualave.net/airfoil/index.html>

I've used the program for quite a few years and its very interesting. I typically print the profile and design the blade from there.

If you don't want to mess with the program but would like to look at the profiles of different airfoils you can click on the link at the top to get to a database of over 1500 airfoil designs in gif format.

Have Fun  
Ed

Hi Ed,

It's a nice program especially considered the price...In my ongoing quest I found another program with a lot more features. It has a builtin virtual wind tunnel inside! Unfortunately its only free for five days. It's called DesignFOIL and you can find it here: [DesignFOIL](#)

DesignFOIL is based on the former program SNACK. DreesCode Software isn't selling it anymore, but if you search with Google you can find it still somewhere. It's a shareware program and you are allowed to use it for 30 days. It also has the virtual wind tunnel inside. You can even find a crack for it.

Moreover DreesCode has also a primer on aerodynamics: [primer](#)

[Multi-Disc again](#)

By [windstuffnow](#), Section [Homebrewed Electricity](#)  
 Posted on Thu Jun 12th, 2003 at 04:38:35 PM MST  
 Still disappointed in the results...

[Alternators](#)

Well I'm going to write this one in as a learning experience. Although it performs fairly well, it doesn't do what I need it to do. It's going to go on another project sometime in the future. Voltage is a bit lower than I wanted and the amps aren't comming close in the rpm range I wanted. Maybe I expected to much from those tiny magnets. Connected to a 5hp honda connected through 4 100 amp auto rectifiers it was making about 165 amps at just over 700 rpm. I didn't hold it at that speed very long because my battery bank voltage was reaching close to 15 volts. I've built better single disc units... alot less work too! So I'm going to build a single disc unit for the one needed for my ongoing project. I must admit it was a fun project.

Back to the drawing board.

Always having fun...

Ed

Hi Ed.

Did I notice that in your picture you had 2 magnet rotors and 4 stators? is that right? I seem to remember hearing somewhere that dividing magnet disks up with 2 stators on either side divides up the magnetic field and murders the efficiency... I wasn't going to say anything, since I also noticed you had magnets on both sides of each rotor, but maybe the thing to try (when you have time in the future) is to have two rotors with a single stator between each set of 2 magnet disks on either side.

Something like this (poor excuse for a) diagram shows:

What do you think? It would be expensive, to use all those magnets, but the wire losses should not be too great, and the cogging issue should not be a problem...

Regards,

Xeroid

Re: Multi-Disc again ([none / 0](#)) (#5)  
by Bach On on Fri Jun 13th, 2003 at 08:20:16 AM MST  
([User Info](#)) [change AT: bach\\_on AT hotmail.com](mailto:bach_on@hotmail.com)

Ed,

If I'm following you, you're saying the problem is that the thing is not producing enough voltage at low RPMs? You said you're getting 165 amps at 700 RPMs. Can you go with fewer turns per coil to increase the voltage? Sounds like you're getting lots of amps, though you didn't tell us how it does for voltage or amps at lower RPMs.

Several questions:

1. How many coils per stator?
2. How many magnets per rotor?
3. I think you said the gap between rotor stator was .05 inches. Was that right?
4. How many magnets are actually placed close enough to excite each coil at any particular time?
5. What voltage/amperage readings do you get at various RPMs?

You had said there was an initial wiring screw-up (the coils on one stator were not alternated). Was that right? Did you correct this?

I'm just trying to understand the "internal" details. That's where the devils often lie in wait to screw us up.

Bach On

Re: Multi-Disc again ([none / 0](#)) (#7)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Fri Jun 13th, 2003 at 08:47:45 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Hi Bach On,

Here are the reading I got while testing...

100. rpm 8.78Vopen  
200. rpm 17.57Vopen 18.5 amps  
300. rpm 26.3Vopen 47.9 amps  
400. rpm 35.1Vopen 77 amps  
500. rpm 43.9Vopen 106 amps  
600. rpm 52.7Vopen 135 amps  
700. rpm 61.5Vopen 165 amps

Battery bank voltage varried from 12.6 to 15 where I stopped. Actually after I learned it wouldn't make 1000 watts at around 250 rpm the test seemed irrelevant but I continued to see what it would do. I didn't do any efficiency testing on the unit but it may be an interesting test just to see where it leads. I'm sure there are some hidden factors that havent been looked into as yet.

Actually it would need more turns to get the voltage up and this would change the resistance which would lower the oveall output to some degree.

Other data as per your question...

There are 120 coils per stator: 3 sets of 40

40 magnets per side on the disc's

The air gap ended up being about .045 thats magnet to coil. The over all gap from magnet to core is .105

In a 3 phase set up there are 2 phases excited at any given time. I guess the answer to #4 would be all 40 magnets will excite 80 coils at any given time per stator.

The wiring problem was cured by reversing the phase's on stators 2 and 4.

Interesting learning...

Have Fun  
Ed

([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

Sorry the new prototype didn't meet your expectations. Those output figures are, you must admit, nothing shabby. Many of us would soil our pants if our generators even began to hit figures approaching these - especially at such low RPMs.

Not sure of your sources for magnets, but you must have a substantial amount invested in those. I can understand your hesitation to add extra rotors. But I'd be willing to bet (with your money) extra rotors would increase the output to something more like what you wanted.

Is the voltage produced on all stators pretty much the same?

I suspect the gap from the magnets to the extra coils is causing losses. Too, the first set of coils may be creating something like eddy currents to block the other set of coils from getting the full amount of available flux. But, what do I know?

Bach On

P.S. Were these magnets placed in at an angle or laid out flat?

Re: Multi-Disc again ([none / 0](#)) (#6)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Fri Jun 13th, 2003 at 08:25:39 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Thanks all for the kind words. I really don't need the 165 amps for what I'm doing but I wanted a 1000 watt load at around 225 to 250 rpm max and it doesn't make 1000 watts until around 400 rpm. It performs far less than I've calculated it should. I measured .55 tesla in the air gap and calculated the output from this but going back over the output data its only achieving about .3 saturation. Or something else is going on I'm not realizing as yet. Xeroid may have a good point with the losses in a multidisc unit. I've built a single disc 2 stator unit that performed very well and exceptionally close to my calc's so I assumed ( a dangerous word - assumed) adding another set would do the same. Also, the center stators are separated by the width of the plywood...seems the losses of transferring flux between the stator cores would be minimul, although I never measured flux loss between the cores. DanB's idea of doubling the magnets may cure the problem but thats alot of magnets. I may just use it as is on another project.

Thanks for your kind words TomW and BillF and 80 amps is nothing to be ashamed of thats a nice machine. Some of my early machines I was tickled pink to see 30 amps... I never had a wonderful board like this to learn from.

Here is a question that I have about magnets and maybe someone has run into a site or book with some data about it... Is there a limit to the amount of amps a magnet will produce given a size and strength of the magnetic field. Since the magnets I used are very small ( 1" x .5 x .125) possibly the amount of power they can produce is much lower than my actual calculations. Just another thought.

Have Fun  
Ed

([User Info](#))

Hi Ed,

I think your prototype is an important and successfull step. And in my prior experience (not just in alternators), the first prototype barely works at all, the second one shows that it's possible but never really makes it and the third one actually meets most of the original design criterion. So if this is your first multi-rotor/multi-stator multi-phase prototype, you're way ahead of where I would be on the first prototype.

I hope my next "failure" is as good as yours.

On the separate question of the limiting factor for max watts out of a given size magnet, one of the neo mag sites I read said that total flux for a single magnet was linearly proportional to mag volume. So I'm guessing that with your small magnets, the flux density is adequate right in the middle of the face of the magnet, but limited in it's area. ie it falls off rapidly as you leave the magnetic epicenter of the small neo. Or perhaps I am just showing my love for large expensive magnets...

Best Regards as always,

troy

Thanks for the input troy,

This isn't my first multi stator unit but it is the first one with multi disc/ multi stator units. It seems they are pretty much isolated from each other and should perform about the same. There could be other things going on I'm not seeing as yet. I don't consider it to be a failure, it simply failed to perform to my expectations. I needed 36 ft lbs at 250 rpm for a load and it just doesn't quite make the load. That assumes I can get 75% efficiency through the alternator. At this point I'd say the efficiency is pretty poor on the multi unit (this one anyway)... I have another one in mind...

Have Fun  
Ed

Re: Multi-Disc again ([none / 0](#)) ([#13](#))  
by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Sat Jun 14th, 2003 at 11:08:59 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

If you have stators on both sides of the magnet disk, then you need twice as much magnetic force to create the same flux as a single sided version. You will need to double the thickness of your magnets to overcome the double air gap.

A case of not getting something for nothing.

If you want to get the most possible output from a given weight of magnets and coils, then multidisk (stacked up) machines are not the best way to go. You would do better if every coil saw the flux from every magnet in each revolution, so you should put all the magnets on one disk, and then increase the diameter of the rotor to as large as possible. I know this may not be practical but it can work at low speed.

Looking at the data you have given, it appears that the alternator may already be past its best by the time you get 1000 watts. You could probably get 1000 watts at lower rpm by reducing the number of turns per coil and going for a higher cut-in speed but steeper output curve.

I do wonder what you can use to drive this beast other than an engine though and how long it would last before overheating? I estimate you may be using 8kW of drive power to produce 2kW of output.

Hugh Piggott <http://www.scoraigwind.co.uk>

by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sat Jun 14th, 2003 at 06:51:47 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I believe your quite right, I was driving it with a 5hp honda engine and when it was making about 2400 watts the engine was pulling hard to maintain. The efficiency is really poor as my results have shown and I'm guessing at around 50% at low speed and diving to around 30% as the load increases. Definatly not one of my better ideas. It would be difficult to reduce the turns per coil since they are all one turn. I may try doubling the magnets just for the test and learning but doubt I'll use this one. Its actually 10lbs over what I wanted also... back to the drawing board...

Having fun!  
Ed

" You would do better if every coil saw the flux from every magnet in each revolution, so you should put all the magnets on one disk, and then increase the diameter of the rotor to as large as possible. I know this may not be practical but it can work at low speed."

I think that the above comment is very true.

Of course you will get the best power at slow speeds, if your magnetic flux is as strong as possible and it changes as fast as possible.

a)  
With the disc layout.  
It is easiest to achieve this using a big disc for the magnets, because then they are moving fast past the coils.

b)  
But on the other hand your magnets must be near each other to get the magnetic flux changing fast...

These two points a) and b) are demanding a bit different layouts?

I think that you are doing the best if you first make your disc that big only that the magnets can be laid next to each other only a couple of mm between them.

And then make as many discs as needed to fulfill that task?

I think that a multi disc layout is an important development, because that way alternators can be made scalable.

But:  
I think that better alternators could be done by using a steel cylinder and putting the magnets inside that; making the laminated core of a plastic cylinder coiled with thin steel wires and gluing copper coils on the top... so that the laminated coil core can be fitted inside the magnet cylinder...

The magnet cylinder should be as big as possible for

magnets so that there is only little space between them to achieve the alternator to reach its peak efficiency at slow speeds?

Some modern motorcycle alternators are using this kind of layout.

Re: Multi-Disc again ([none / 0](#)) ([#17](#))  
by [Wolfe1](#) on Tue Jun 17th, 2003 at 06:12:31 AM MST  
([User Info](#))

But your logic breaks down on this part: -

I think that you are doing the best if you first make your disc that big only that the magnets can be laid next to each other only a couple of mm between them.

And then make as many discs as needed to fulfill that task?

If you are going to make more discs, you are going to use more magnets. You could make the single disc bigger and use those other magnets here as well. Wouldn't that produce more power than two discs at the original size?

There are obvious limitations on size of these discs and the glue that will hold these magnets down but we are talking theoretical here not practical.

Martin.

[quote]But on the other hand your magnets must be near each other to get the magnetic flux changing fast...[quote]

The statement quoted above is not accurate.

Some flux is actually wasted if the magnets are spaced closer than the optimum spacing, which is always equal to the coil "span".

## Magnet / Coil Spacing

In order to connect coils in series or parallel, so that the voltages, (or currents in parallel) will add instead of cancelling, the voltages induced in the coils must be "in phase" with each other.

The only way to ensure that the coil voltages are in phase is by accurate magnet / coil spacing.

Magnet center-to-center spacing should equal the coil "span".

The objective is to have the leading edge of a NORTH pole reach one side of the coil - -

- - just as the leading edge of a SOUTH pole reaches the other side of the same coil.

Both leakage flux and voltage cancellation can occur if the magnets are too close together.

It is not a "fast change" in magnetic polarity that increases voltage. Voltage is determined by the number of magnetic flux lines cut (by the conductors) per second.  
 $100,000,000 \text{ lines-per-second} = 1 \text{ volt.}$

The voltage generated per coil can be increased by increasing any of the following:-

1. Total flux cutting (linking) coil.
2. Length of conductor in coil influenced by the flux lines
3. Linear speed of motion.

I like the dual-rotor for an efficient magnetic circuit.

**Problems with air-core (no iron) stator**

**Laminated "Core" and wider magnet spacing**

**2 - BETTER**

**Dual rotors with wider magnet spacing**

**3 - BEST**

Electric Ed

If you are going to make more discs,  
you are going to use more magnets.  
You could make the single disc bigger  
and use those other magnets here as well.  
Wouldn't that produce more power  
than two discs at the original size?

There are obvious limitations on size of  
these discs  
and the glue that will hold these magnets  
down  
but we are talking theoretical here not  
practical.

Martin.

Yes, you are right.

I was just thinking that it would be usable to  
develop 'a scalable generator' such a way that  
for a given set of magnets we first developed  
a best possible disc layout. And then could scale  
the generator up by just adding more similar discs.  
No need to redesign the whole thing again.

I agree that better power probably would be got by  
making a new design with a bigger disc if we add  
more magnets. But then we have again got the  
all the same design problems?

There are so many things, which have to be considered.  
Cf. below.

-----  
-----

[quote]But on the other hand your magnets  
must be near each other to get the magnetic  
flux changing fast...[quote]

The statement quoted above is not accurate.

Some flux is actually wasted if the magnets  
are spaced closer than the optimum spacing,  
which is always equal to the coil "span".

I agree.  
The coils must be taken into consideration as well.

But basically I think that the magnets  
should be as near to  
each other as 'possible'.  
(If there is empty space between them  
there is very little magnetic flux starting  
from that 'empty area'?)  
If we could get coils to fit to the arrangement  
of putting magnets near to each other  
it would be good?

I think that by using round disc magnets  
it is not possible to  
make really 'ideal' alternators.  
The coil shape cannot be  
made really ideal?

Maybe sectors, which Ed is often using are quite a lot  
better?

And on the other hand I think that  
if the coils would be long  
and narrow, it would make better alternators?

That could be possible, if the layout would be something  
like Hugh's 'brakedrum alternator'.

- Hannu

By [windstuffnow](#), Section [Homebrewed Electricity](#)  
Posted on Wed Jun 11th, 2003 at 12:10:16 PM MST  
I screwed this one up...

[Alternators](#)

Well I finally found time to complete the unit... Shown below...

After getting it together and was looking at, things for some reason didn't look right. It dawned on me that although I offset the phasing to connect them all together I wound the stators in the same direction... So the 1st and 3rd stators are the only ones that were done correctly. I'm glad I caught it before I started wiring it or went any farther...

Needless to say its 40 pounds of junk as is... goes to show you if your busy doing other things you tend not to think things through completely. I should know better to try and build anything for myself when other projects are in my mind. I'll go back to it when things are caught up...

Still Fun though... you learn the most from the things you screw up..

Ed

I was just pondering the delemma and came to the same conclusion. I would basically have to designate the 3rd phase of the second stator as the first phase. I scraped a couple wires and did some quick voltage tests and it seems to work. So basically I have to reverse the phase's on the 2nd and 4th stator.

That should save some time... very short of at this point.

Having Fun again...

Ed

Yeaaaaa, thatsssss nice! I was thinking the same thing this week, multi-rotor. Cool that you built it! And yes the mind does have a way of wondering around doesn't it.... Always wants more, and the more you give it the more it wants...confusing. Anyway, I think you have now set the boundary line for next generation gennys. Multi-rotor designs have many advantages. But core is still somewhat a problem. The metal strapping works good, also i found out that the more narrow the cuts into it the better. Wider cuts means cogging it seems. How's the cog or resistance on this machine?

Re: Multi Disc alternator... ([none / 0](#)) ([#4](#))

([User Info](#)) <http://www.windstuffnow.com/main>

I still haven't completed it for any real tests. I did do a quick wire on one phase to check the voltage and amps and its quite impressive. Dead short turning by hand showed 8 amps. I have a key slot in the shaft to line up the magnetic rotors and it was torquing into my hand so I didn't push it. There is no noticeable cogging and it turns very smooth and easy. Open voltage on 1 phase was just over 8 at about 60 rpm. That should get me about 13+ volts wired in star at 60 rpm. After confusion, dissatisfaction in my wiring and kicking myself in the butt several hundred times I calmed down enough to think it through and switched the first with the 3rd phase all turned out well.

It has a couple bugs I don't like and I'm going to disassemble it tonight and try to fine tune it a bit. One rotor has a very slight wobble so I want to put it back in the lathe and surface the hub and

I think I made one to many spacers for the end plate because the air gap on the rear stator is at about .05 the others came in correct at .03 go figure... To much of a hurry in the short time spans I had to play with it... lesson learned.

Picture of the rotors before installed...

Having fun

([User Info](#))

Incredible Ed...  
Curious... what are the physical dimensions of this, Im having a hard time picturing its size.

Is it for a wind turbine?

Wonderful thing about alternators and wind turbines... most of that stuff isnt junk! Even if you have to do a bit of rewinding it's not the end of the world...

Good luck and have fun!

Re: Multi Disc alternator... ([none / 0](#)) ([#9](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Thu Jun 12th, 2003  
at 08:39:58 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

The physical dimensions of the unit are 5.75" wide (board to board) and 11" square. The discs are 10" diameter. Weight is 45 lbs. The shaft is 12 inches.

Basically a test bed for wind power applications, although, I have some real strange idea's for a concept motor that will require a heavy load. For the most part it was designed around the free wing concept.

I had no intentions of throwing in the towel on this. I was frustrated because of time limits and wanted to move forward with the project. With the thoughts of rewinding the two stators would have pushed the project farther into the future because of other work comming in. So in my mind it was junk until I had time to get back to it.

But, if all goes well I should have some numbers on it by this weekend... Seems like I've been saying this for a few weekends now... Anyway all is still a go and no matter what the project will go forward.

Have Fun!  
Ed

I had to make some rubber gaskets to pour the plastic over the iron and wood. You can see the plastic poured in place before it hardened...

After the plastic hardened the slots were machined in the plastic... super smooth cuts and it went quite quickly.

Here shows the stator wired and waiting for the bearing holes.

There is 1 turn per coil, 40 magnets on each side of the disc. There will be 4 stators altogether utilizing 160 magnets (they are small - 1" x .5" x 1/8"). All the stators will be wired in series. This is a 3phase unit and the resistance per phase is .03 ohms. It should come out to about .3 ohms wired in star or close. My calculations show it should make just over 2000 watts at 500 rpm but I don't plan to run it over 300 rpm so it should lug along making just over 1000 watts quite nicely. The air gap will be one wire thickness (.064) plus the clearance gap of about .020+ . It should make 12V at around 60 rpm but like all calculations there is a difference between calculated and reality because of all the variables. This is the first time I've tried the plastic as a wire retainer so I don't know how it will hold up. It seems to be fine at 200 degrees and at about 250 you can push your thumbnail into it. I don't think it will run this hot so it should work out... we'll see. I'm hoping to see it ready for tests this coming weekend... barring any other interruptions...

Having Fun as usual...  
Ed

Ha ha you have a keen eye... your right they are. I never in my wildest dreams thought anyone would notice that... I noticed along time ago when using rectangular magnets over triangular shaped coils that the lower edge of the magnet is going in as the other side is comming out... canceling basically. By setting them slightly on an angle the full side of the magnet goes into the coil and only a very tiny tip of the trailing corner is in the field. Basically lining up the entry edge of the magnet with the entry of the coil.

Good catch troy... can't keep any secrets from you ;o)

Have Fun  
Ed

Jun 8th, 2003 at 04:50:52 PM MST  
([User Info](#))  
<http://www.scoraigwind.co.uk>

Hmm, Ed

I am not convinced that you will gain anything by angling the slots, because it will put the other side of the coil just as far 'off line' as it put the leading edge on the desired line.

In the end, the voltage is induced by the rate at which flux through the coil as a whole changes.

You will get the most flux by laying the coil legs radially along the centres of the magnets. That way they will both peak at once, and both hit zero at once. No fighting each other.

Of course you can't put all the wires there. Also, there is a small tradeoff in making the coil narrower so as to reduce the length of wire (resistance).

That's how I see it anyway :-). We all have our own mental map.

hey ed your stator is looking good.but what are you doing to the 49 panel. have owned to old deliveries a 58 ford and 57 chevy. cleaned them up put new motor and complete interiors used them to haul furniture to be reupholstered.now i only do cars and truck coustome interior, and read about new ground being broke here on this board...staples

Old cars... ([none / 0](#)) (#8)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Thu Jun 5th, 2003 at 01:54:03 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

The 49 is the last of my restoration projects. This one was sitting for a very long time and was used as a billboard. Basically moved out in the summer and back in in the winter. It has 8,000 acutal miles on it. I did it as a favor for a friend that I restored a 56 2drHt. I retired from building streetrods and restorations about 10 years ago... just got burned out, seemed everyone wanted their car/truck done and I just started loosing interest. So basically all I do now is R&D work and design.

Have Fun  
Ed

## Odd Idea...

By [windstuffnow](#), Section [Homebrewed Electricity](#)

 Thinking of the gravity motor idea...

I've always been intrigued with these types of motors ( or any motor for that matter). After calculating out the potential of a gravity motor I started thinking of ways to power it. I'm looking for the cheapest method to move weights and by cheap I mean the least amount of power or the least loss between energy transfere.

Some of the methods that I've pondered are:

compressed air:

- driving a cylinder to move the weights  
 (drawback: not very efficient energy transfere and high volumn of air necessary)

Solar:

- using the expansion or contraction of soft metals or other material with better expansion rates. ( drawback: High maintenance with fatigue)
- hybrid stirling displacer to drive the cylinders.

The stirling idea seems about the best for the purpose but also has its drawbacks.

Any ideas out there to move the weights? This is just an idea at this point and was spawned from the Pelton wheel as well as Techstuf's version.

I built a small solar gravity motor many years ago using 2 paper cups, cut strips of black garbage bag plastic and some tape, a pencil and pins. You stretch the plastic and place strips around the cups. The cups have a hole in the bottoms in the center and are placed on the pencil bottom to bottom with a small space between them. Pins are used for a frictionless surface to rotate. There were about 10 strips of plastic around the outer edge of the cups taped in place. When placed in a window the sun would heat the plastic, shrinking it a bit and pull the cups off balance. It took a little while but it would actually find a speed with the heat given and would run about 10 rpm. Fun to watch but no practical use for it.

All in good fun!

Ed

I picked up a book called "Perpetual Motion, history of an obsession" a while back and it puts me to sleep on those few nights I need help.

In about the middle of the book is a chapter on a fellow who used changes in atmospheric pressure (think big barometer) to wind a clock spring. While it was a clunky looking thing, it all fit into a grandfather clock case and lo and behold, it actually worked for many years. In a climate with a decent amount of weather, this could be the ticket for keeping those gravity motors going. What is a clock anyway but a gravity motor (pendulum).

Could be just the thing. :o)

Chuck

PS, nice little solar motor idea. Could be a good classroom project.  
Chuck

Class Room Project ([none / 0](#)) (#2)

([User Info](#)) <http://www.windstuffnow.com/main>

Nope JCP this one would require power to drive the weights... I wasn't sure what category to put it under and figured since its a strange idea I'd put it under the FE area even though its not.

Trying to find ways to alleviate one or two steps in energy transference.... Seems like we're always defeating ourselves.. Wind blades to alternator to wire to batteries to inverter whew... lucky there is anything left in the end. Or, Gasoline in a car... 3/4 of the energy in a gallon of gas is wasted... engines aren't good converters.

Here is another crazy idea.... instead of using a gas engine or electric motor to drive a pump to compress air, why not simply inject the tank with a preset amount of oxygen and gas mixture and ignite it... instant 160 psi...or BOOM!... assuming you get the mixture right of course... that would have to be an underground experiment to find the correct mixture, going in small increments.

Anyway, you get my point... reduce the amount of steps to get what we want from the stored source...

Having Fun... must be the pain killers

hard way ([none / 0](#)) (#4)  
by Johnny Cool Pants on Tue Jun 3rd, 2003 at  
04:26:18 AM MST  
([User Info](#))

Okay Ed, I'm gonna tell you how to do it the hard way, since none of you believe it can be done the easy way.

Gas is lighter than water, but water gas increases in volume, weighing the same or not.

Have a huge iron wheel, each spoke is hollow and has (some) water in it.

As the wheel turns, the spokes on the way up have their water flash steamed, making it a gas for a moment.

Or, on the way down, if you have a vacuum in the spoke and the spoke is a long piston. Then hydrogenate it on the way down, sending out the long extended iron spoke piston (leverage for the way down.

The vacuum sucks it back in again on it's way up the other side of the wheel. Might end up with left over electricity, never know.

Or use hydraulics, try beeswax with Bill if you can find him. I intended to try it with memory metal, but then I forgot. I need more iron in my diet.

I'll work on anything at this point. That's the problem with free juice, once you figure it out, you have no project anymore.

JCP

### [More on coils...](#)

By [windstuffnow](#), Section [Homebrewed Electricity](#)  
Posted on Wed May 14th, 2003 at 07:29:31 PM MST [Alternators](#)  
Need more wire in a small space?...

You can pack more of the same size wire in the same space by using ribbon wire. For instance using a slotted stator with a slot of .25 wide by .25 deep. If say your using #15 wire which is .062 diameter with the coating you can only get 16 turns of wire in the slot. In order to increase the number of turns you either need to open up the slot or go with smaller wire. Well, If you use ribbon wire that is .012 wide x .25 tall you can increase the amount of turns to 21 thus increasing voltage at a given rpm. Square wire also helps to fill the lost area from circular wire and can increase the output considerably. If you used square wire that was .062 square you'd still only get 16 turns in the slots but would be the equivalent of #14 wire instead of #15. So if you needed 6 inches per turn x 16 turns = 96 inches (8ft) of wire per coil the resistance would go from #15 wire .026 ohm to #14 wire .020 per coil. Say a set of 16 coils means going from .416 ohms down to .32... thats quite a boost of power at a given rpm.

DanB shows a concern in the wasted wire on the top and bottom loops... I too went there and came up with some pretty strange configurations that worked well but were difficult to build. Imagine cutting sections of wire for the slots on both ends a perf board for the wires to go into.

On the perf board are plates that match up the turns of wire. Each of the plates are large enough to be considered 0 resistance or so low the resistance is irrelevant so the current flows freely through the top and bottom. Difficult to build but the output is astronomical. Another way is to use stamped plates with the top and bottom very wide while the area through the slots are sized proportionately.

The plates are stacked and each has an attachment slot and assembled such as a slinky. This also works very well with the exception of the wide area of copper showing in the magnetic field. I was able to actually double the amount of turns in a slot with 1/2 the resistance of the wire replaced using this theme. The drawback... Because of the wide area of copper showing in the slots created much more drag ( lenz's law ) and produced alot of heat.

There are many ways to overcome geometry problems some good and some well not so good but it can be done.

This is just my experience with these things and for those who want to take it to another level. I'm still waiting for the room temp super conductors to play with... Although I believe I can come up with a configuration that will come very close to the output of such a wire...

My quest for the holy grail in wind power goes on... It seems I'm always at the beginning.

So much fun... so little time

Ed

Interesting site.... ([none / 0](#)) (#4)

by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Thu May 15th, 2003 at 07:47:11 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

It seems I've read somewhere that the ratio in elongation has a maximum of 30:1 or 30x the width. If you go smaller than that then the "skin" effect of AC takes over.

I've tried alot of different methods, sizes, shapes etc. I've even built an alternator with bar stock... very difficult to bend copper bar stock. The resistance is so low that my meters couldn't make an accurate ohm measurement so I never knew what it really came out to. It required a large amount of power input once it reached charging voltage. The unit would make 12V at 80 rpm and at 85 rpm It was making 12V charging at about 700 amps... Not practical for most applications but makes a very strong welder if you have an engine to drive it.

I'm designing a similar unit with 2 discs with 50 magnets on each side of the discs and using 4 stators. A single phase all in series to make 12V charging at 30 rpm. The resistance of the coils will be .2 ohm or less (in series from all 4 stators. I'm using very small magnets in this project and its meant for a VAWT with a large diameter (slow turning) maintaining a constant force on the turbine... The size of the unit will be approx 11" tall and about 6" deep and weigh about 30 pounds (end result may vary)...just need to find some time to build the unit.

Have Fun!  
Ed

## [More fun with Magnets and Coils...](#)

[2?](#)

By [windstuffnow](#), Section [Homebrewed Electricity](#) [Alternators](#)

Posted on Wed May 14th, 2003 at 12:17:26 PM MST

Not sure how to post pics in a reply so I've revised the topic...

Here is a picture of what I'm trying to explain..

Each leg of each coil is shared... sorry about the poor quality of the picture. This one actually exceeds my 1/4 width theory but works very well. This is the one I use for testing small turbines. There are 30 turns per coil giving 60 wires at each junction point which matches the magnets center point. There is no gap between the magnets shown in the picture below...

Definitely a waste of magnets for a small output alternator. This is a simple single phase unit also. It makes 130 watts at 500 rpm and about 325 watts at 1000 rpm. Anyway it shows the coils I'm trying to explain.

Have Fun  
Ed

I see... ([none / 0](#)) ([#1](#))  
by DanB on Wed May 14th, 2003 at 02:13:15 PM MST  
([User Info](#))

that makes perfect sense..

I guess perhaps with coils that long, and maybe a bit more "slack" at the ends you could stack them to achieve 3 phase without compromising the airgap too much.

It seems similar to my "coil#1" - with basically a bigger hole in the middle so that you could get more wire in the right spots and perhaps have room for another phase or two... ? I wonder if you'd shape them slightly differently if you were dealing with disc magnets instead.

I tried another one this afternoon.. which was suggested to me via email. I'll post about that one shortly.

I'd leave them the same ... ([none / 0](#)) ([#2](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed May 14th, 2003 at 03:00:28 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I don't see any reason to change them because of the disc magnets. For that matter I wouldn't change the style for rectangular types either. This seems to be the best from all I've tested... so far...

Always open to new suggestions and ideas though...

Have Fun  
Ed

[ [Parent](#) ]

coil shapes. ([none / 0](#)) ([#4](#))  
by DanB on Wed May 14th, 2003 at 04:10:46 PM MST  
([User Info](#))

Part of me thinks, if the sharp corners were rounded off (so they were rounded instead of square)... there'd be less wire in there so less resistance.

The rest of me sees that it makes sense to be right dead center between the poles like you are, and more room in the middle for the wire/coils of extra phases.

Thankyou for the pictures and discussion on this... it's enlightening!

[ [Parent](#) ]

VAWT ([none / 0](#)) ([#5](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com))  
on Wed May 14th, 2003 at 05:32:09 PM MST  
([User Info](#))  
<http://www.windstuffnow.com/main>

Thats actually one of many failed test subjects of the "VAWT free wing" that became parts for others. It's actually fairly small standing about 3ft tall and 3 ft in diameter. There are 4 wings that make it up, 2 on each side and pivot in the center on the main shaft. Had alot of fun building them but was dissappointed in the overall results. Learned alot about VAWT's in the process but its time to move on. The HAWT "free wing" is still in the works though.

Lots of Fun!  
Ed

## Fun Stuff

By [windstuffnow](#), Section [Homebrewed Electricity](#)

Posted on Fri May 2nd, 2003 at 02:46:09 PM MST

[Wind](#)

I've made and wrecked many wings so there had to be a way to make them quicker and easier...

I've been reusing parts as possible but making wings ( or blades for that matter) can be time consuming and tedious. This was sort of a spin off from the 1 hour blades and a bit quicker actually.

First off my son is an aspiring movie maker and works with lots of different materials for making props. One that caught my eye was liquid rubber for making molds and liquid plastic's for making the actual model. Anyway I figured I'd try it for making small parts. This stuff is amazing to say the least. You simply make the first part, make a mold with the rubber then make as many parts as you want out of plastic.

The above picture shows the ribs made from plastic for the wings of the free wing turbines. One large hole for the spar and the other two holes for the controls and rods. It takes 15 minutes to pour and demold the parts... quite fast.

The above picture shows the ribs on the main spar ( 1" dia 6061 T6 x .058" aluminum tube). One nice thing about making them is they all come out identical... So if you get the first part right they're all right.

The above photo shows the trailing edge of the wing covered in aluminum. These can be built from start to finish in about a half hour. These make up a total of a 64 inch wing section ( or 2 32" wings).

The materials used was purchased from <http://www.smooth-on.com>

They are a bit expensive for making only one or two parts but if your making lots of them its actually quite cheap on the per part cost.

All in good fun as always....

Ed

[Fun Stuff](#) | 4 comments (4 topical, 0 editorial)

really nice! ([none / 0](#)) (#1)  
by hvirtane on Tue May 6th, 2003 at 10:45:38 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

A great project.

That stuff seems to be working really well.

Maybe one good way to start a kind of mass-production of blades... Covered with plastic cloth...

If you would make a ready set of ribs for three blades for 5 m in dia prop... How much do you think it would cost?

I mean only the profile pieces, not tubes and the cover.

- Hannu

Costs ??? ([none / 0](#)) (#2)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue May 6th, 2003 at 11:53:40 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

These are small ones, only 9 inches for the blade width... you talking about a large prop. What size tubing are you using for the main spar? They would have to be spaced about 8 to 12 inches appart so there would be a need for lots of them. The small ones I'm making use about 2 oz of material so the cost to make lots of them is minimul. This is a symetric airfoil and better used for Verticals but a standard airfoil wouldn't be any problem to fabricate using the same material. The strength qualities are quite good in the plastic also, they remain somewhat bendable and I believe the sheet said it had a psi of 375 lbs. I don't believe any one section would ever see this kind of wind pressure ( short of a major storm ).

Have Fun!  
Ed

The rough idea ([none / 0](#)) (#3)  
by hvirtane on Wed May 7th, 2003 at 03:00:25 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

You say:

"What size tubing are you using for the main spar?  
They would have to be spaced  
about 8 to 12 inches apart  
so there would be a need for lots of them."

-

The tubes I purchased for a 'tube wire project' are  
2,5 m long and 4 cm diameter (made of steel).

-

You say:

"but a standard airfoil wouldn't be any problem  
to fabricate using the same material."

-

My idea has been to use no twist and no taper.  
5 degree pitch all the way. The airfoil maybe NACA 412  
or something similar. (See my post on the old board  
'big tube wire blades') The width of the airfoil 20 cm.  
What do you think about that?

I checked the resellers of the product you are  
using. It is not available here. We probably could  
make similar things quite easily of polyurethane, but as  
far as I know, nobody has done it yet.

If you have time and a suitable turbine available, maybe  
you could have a try, if it makes better blades than  
carving of wood. Maybe a good product for mass  
production.

If you can make cheaply ribs described above I would  
buy them, if the price would be suitable.

My Indian friends would probably be interested in this  
development, too. Please see the post and the website  
by Mr. Desai on the old board.

[Vertical Free Wing...](#)

By [windstuffnow](#), Section [Homebrewed Electricity](#)

Posted on Fri May 2nd, 2003 at 01:28:39 PM MST

[Wind](#)

Here goes another one...

This is the last and final attempt on the Vertical type free wing. After about 9 or 10 of these things I've decided that the Vertical unit is unreachable. The numbers look good but the problems involved make it such that its not a real reliable machine as well as the complexity. So this version of the free wing has ended. However, I've learned alot about the Verticals and believe there is still considerable hope for such units. I have one more idea to follow through on the Vertical free wing before its over completely but the path I've been following has ended. The horizontal free wing, however, has shown considerable advances since my last post. With very minor changes I've reached 55% efficiency. The most noticable item to mention about this unit is when standing behind the prop there is very little wind. Measuring windspeed in front of the unit I get readings of 12.83 mph and behind the unit reads 5.1 mph. The vertical comes close but the highest efficiency reading was 45%. Onward and upward... new ideas that clutter my mind need to be free'd

Have Fun  
Ed

## [Magnetic bearings](#)

By [windstuffnow](#), Section [Magnets & Magnetism](#)

Posted on Thu May 1st, 2003 at 06:41:39 PM MST

[Magnetism](#)

Has anyone dabbled in magnetic bearings?

I've searched the web and only find reference to electromagnetic bearings, these have no interest to me.

I'd like to build a passive magnetic bearing system using magnets only... anyone have any info on these?

Thanks in advance

Ed

Not as such, but... ([none / 0](#)) ([#1](#))

by [Don](#) on Fri May 2nd, 2003 at 07:35:01 AM MST  
([User Info](#))

Howdy, Ed,

Well, I've worked with magnetic bearings, and haven't had any reason to look into them (optically or theoretically), but it's one of those things that, I, too, find fascinating, ever since I first heard of them.

I'm guessing that the bearing design would have to be similar to an old car's wheel bearing, because you're going to have to have it "thrust" away from some point to maintain equilibrium. Earnshaw's theorem is going to get in the way, otherwise. It may end up being similar to a spherical roller bearing, allowing thrust in two different directions.

Regarding radial generators, they should line up at magnetic center when spinning, due to Lenz's law. I think the bearings on those should be more protected from induced currents, rather than for friction. I'm not saying that lubrication is unnecessary, just that there won't be much stress on the bearings when the rotor is spinning.

On the axial generators mostly being made here, then you'll have the load (weight), thrust (Lenz's law, except on dual-rotor designs), and currents to fend against. A magnetic bearing would need some type of friction-reducing mechanism while coming up to speed, at which time the Lenz effect can take over.

I'm just "thinking out loud" here, but it is a subject I've thought about for quite some time. I'd be interested in any design ideas you have, including pointing out fallacies I've convinced myself are true, in my ponderings.

Regards,  
Don

magnetic bearings ([none / 0](#)) (#6)  
by rlortie on Fri May 9th, 2003 at 10:51:52 PM MST  
([User Info](#))

Don, I made a test bed some years back of a vertical shaft model with a 14" inch rotor weighing aprox 13 pounds. I was intended to be a scale replica of a GE 80 megawatt hydro generator. The unit has been suspended for over four years now and has not decreased in clearance or magnet weakening. The magnetic suspension is acheived using speaker doughnut magnets, bottom of rotor is opposing base while there are two sets above, first or upper is attracting second set is opposing. Unit has noticable vibration at low speeds but smooths out at higher rpm. although rotor is complete with exciter magnets I never got the stator coils installed as I got sidetracked into magnetic motor ideas, so lenz law has not been tested. The above description handles thrust with no problem, but I still need a little work on guide bearings. I do not believe that this is much of a problem. It is nice to think that no grease or lubricant is required as there is no bearing friction. A little twist of the wrist and this thing will spin for an extended coffee break.

Magnetic bearings ([none / 0](#)) (#2)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Fri May 2nd, 2003 at 09:19:33 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Hi Don,

Thanks for your input! This is simply an experiment and there won't be any loads on it for the most part with the exception of gravity holding the load of the flywheel. I've always been curious about the set up, A friend brought back one of those floating thingies from Hong Kong and of course the first thing I did was tear it appart to see how it was set up. Its interesting because you can spin it up to around 500 rpm and it will continue spinning for over an hour.

Anyway, I sort of have the basics of how to set it up but would like to see some that have been completed and/or some tech data on them. This would save time in experimenting and building different set ups to find a proper solution. Also I'm limited to magnet sections (stuff I have on hand)and would like to know if there are any problems I will run into by using these. I think balancing will be quite critical both radially and axially since it will be literally floating in the air gap... could get mighty scarry above 5000 rpm's.

Lots of fun!  
Ed

mag bearings ([none / 0](#)) (#3)  
by troy on Fri May 2nd, 2003 at 11:57:31 AM MST  
([User Info](#))

Hi Ed,

Magnetic bearings are a very cool piece of work. My understanding of industrial sized magnetic bearings (which is basically nerd gossip) is that they need conventional bearings to support/align things until the rotational mass reaches the full stable RPM.

There are lots of interesting web sites on the Levitron magnetically levitated top which was quite popular.

A significant number of these websites dealt with the physics and may point you in the right direction for a more scientifically rigorous understanding of what's going on. Too much heavy slogging for me though.

If you get one to work I'd love to hear more about it.

Best wishes

troy

Hi Ed ([none / 0](#)) (#4)  
by Anonymous Hero on Mon May 5th, 2003 at 07:26:07 AM MST

I was playing with these when I was working on a special pendulum. It showed to be more complex than it first appeared. One thing I noticed is that you have to balance both sides of the shaft AND you will need some ball bearings to stabilize the shaft, at last that's what I found. Regards, RobD

[Horizontal Free wing...](#)

By [windstuffnow](#), Section [Homebrewed Electricity](#)  
Posted on Sun Apr 20th, 2003 at 02:11:36 PM MST

[Wind](#)

Here is a glimps of the Free wing turbine...

The picture doesn't show exactly how the wings operate but just imagine the wing has full freedom of movement caused by the wind ... kind of a balancing act caused by the wind and movement...

[Horizontal Free wing...](#) | 7 comments (7 topical, 0 editorial)

Pretty neat! ([none / 0](#)) ([#1](#))  
by TomW on Sun Apr 20th, 2003 at 03:21:00 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Ed;

You come up with some of the most interesting concepts and ideas. I am ready for details.

I wish my R&D [Rough n Dirty] samples had anything near the elegance yours have. Proof of concept stuff is rarely pretty or refined but it draws us down the road.

Oh, and when you finally chronicle all this in a book i want one of the first copies, signed of course.

Thanks for sharing, Ed.

Cheers.

TomW

Free wing... ([none / 0](#)) (#3)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sun Apr 20th, 2003 at 08:29:10 PM  
MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Thanks for the kind words Tom. Its actually rather ragedy and under built and would be scarry in any kind of wind other than low winds.

I found by making some minor changes brought it up to over 50% efficiency. Here is some other data to ponder...

Wing area is 3x the area of a 403 but the unit is 1/2 the sq ft frontal area making the same amount of watts a 403 makes in the same wind. It has 2 wings. It runs at 328 rpm loaded and 480 no load.

When shorted, won't stop it... the wings go to an extreemly deep angle and it keeps running.

The vertical unit performs about the same but I'm stumbling over some of the bugs with this model. The biggest problem I'm having with this one is the reversal of the downwind wing, the angle changes drastically for the downwind side to continue creating lift. It will be worked out this summer.

Lots of fun... and challenges..

Ed

free wing ([none / 0](#)) (#6)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Apr 22nd, 2003 at 07:17:50 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

The wings air foil is basically an E168. This is a symmetrical wing and quite possibly not the best choice for the horizontal free wing. These wings were used with the Vertical version and instead of building new wings I used these. Although they perform exceptionally well in the application.

I'm not going into any detail on the actual working of the wing as yet but soon. I'm basically trying to prove the concept at this point. Details will come later.

Thanks for the kind words about my site...

Ed

OK I will wait for it ([none / 0](#)) (#7)  
by hvirtane on Tue Apr 22nd, 2003 at 02:29:34 PM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

'I'm not going into any detail on the actual working of the wing as yet but soon.'

OK. I will stay tuned.

I've had regular talks with my friends on the idea that people will probably still invent much better windmachines than we have got at present.

For example with horizontal axis wind turbines the parts of the blades near the axle are almost useless. Almost all the work is done by the last third parts of the blade near the tips. Maybe your free wings will solve this problem.

Hannu Virtanen  
hvirtane@cc.jyu.fi

The alternator shown in the picture ([none / 0](#)) (#1) by [windstuffnow](#) ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sat Mar 29th, 2003 at 03:30:10 PM MST ([User Info](#)) <http://www.windstuffnow.com/main>

This alternator was wound with 1 ( yes one) coil. The single phase shown is 50 turns around a 9.5 inch disc then twisted into place to form the 6 coils of the first phase. Its similar to Rob's wave windings using both ends. Have Fun

Interesting... ([none / 0](#)) (#2) by [DanB](#) on Sat Mar 29th, 2003 at 06:34:02 PM MST ([User Info](#))

Hi Ed -thanks for testing the new board! It is a "complicated sucker" - powerful though, and I guess it'll have it's pros and cons.

Regarding your strange winding here...  
What is the diameter of the unit pictured? This looks like the 1st winding (set of windings) for a 3 phase machine.  
The thing that makes me wonder... and maybe I'm not understanding something, is that it \*seems\* like the ratio of wire parallel to the moving magnetic field vs that which is perpendicular to the moving field may not be kind of high - vs small individual coils. Is that right? - or am I missing something. Seems like the resistance would be higher winding coils like that.

If you measure it out the length of wire is exactly the same as winding individual coils. This is a small unit so the wires are small and this wouldn't work very well winding larger units with heavy wire in them. There is no difference in resistance either way. Yes it is a 3 phase unit with one phase in place... or as is a single phase unit. Have Fun Ed

Re: formatted re-post of more on ferrous cores... ([none / 0](#)) (#6)  
by charged on Fri Jan 2nd, 2004 at 10:26:45 AM MST  
([User Info](#))

Get a roll of soft-steel MIG welding wire or just plain 'ol mechanics wire from the hardware store. Wrap the mechanics wire right along with the copper wire as you make your winding. Start winding on a 3/8" dowel and work your way out. This integrates the ferrous material right into the coil and virtually zeros out the eddy-current losses.

Note: You may cloak yourself from appearing here in your Display Preferences.

Better do this with a coil that you don't value very highly. There will be voltage induced into the iron wire, and if the turns are not insulated from each other, short circuits will exist where adjacent turns come in contact.

Current will flow in these "shorted" coils, producing hot spots, similar to what happens in a motor winding that has partially shorted coils.

Electric Ed

([User Info](#))  
<http://www.dplusv.com/Photo-03.html>

Ok guys now you've went a done it again. And just when I thought i had to many ideas and projects you go and add another one. This board is addictive and dangerus. OK so heres my next progect idea. My brother use to work for Mead paper Corp. you know those folks that make spieral note books and stuff like that. He use to bring me large carboard tubes. We make sub woofer inclosers at the car stereo store. Some of these tubes still had a very nice varnish coated soft steel wire they used to make the spiroll spring things. However its nice and straight on these big rolls. I still have a few 100 feet. Magnets realy like this stuff. So I'm going to wind some coils with copper and this stuff in perelell. I have a zilion speaker magnets so I'll wind the coils same size and shape as the speaker magnets. This will get the magnets very close to the laminations (Mead wire) and copper coils at the same time. Very small gap. Thanks so much for this idea. I guess better get ahold of Mead or = to see about more of the soft and candy coated steel wire? JK TAS  
Jerry

([User Info](#))

I would have to agree with Ed on this one. The steel wire will make an inductor, not unlike your copper wire does. This steel inductor will have voltage induced on it, so it must be insulated from itself just as the copper magnet wire is. If you could wind a full layer of the steel wire and bond it to itself so that it did not form an inductor, then I think you would get it to work. Otherwise it should be insulated steel wire. You may be able to wind the coil so that the copper insulated wire always keeps the steel wire separated, but you would need to put a layer of insulating material between each winding layer... Just my thoughts, Bill

Hi OldF,

Here's a page that helped me a bit, it's pretty basic but explains the concepts!

<http://www.asme.org/education/precollege/esp/act5sr1.htm>

Hope this helps,

Ted.

Re: Guitar string ([none / 0](#)) ([#4](#))  
by monte350c on Tue Dec 30th, 2003 at 07:38:57 AM MST  
([User Info](#))

Hi Norm,

I spent "some" time in the past couple of months fiddling around with hot wire cutters and now I've got a good reliable unit that really works well.

I started with plans from the net that used a Rad Shack xformer and a regular light dimmer which lasted about 1 hour, then the transformer smoked.

So I got another heavier transformer, and kept on truckin' but went through about 6 fuses.

My final configuration that really works well is as follows:

Hammond PH100JG transformer - 100 VA, 120 volt primary, 24 volt secondary (about \$35 from a local electronic supply place)

I use a Leviton fan speed control on the 120 volt side of the transformer. This looks just like a light dimmer but seems to hold up for this use. (less than \$10 Home Depot)

Then on the hot wire side of the transformer, I use 2 of those old ceramic ballast resistors they used to use in a lot of Chrysler cars in series with the wire.

For the wire I use 20 guage stainless wire which is available at Home Depot in 20 foot rolls for about \$3

I turn the unit on and set the fan speed controller to its lowest setting. Then slowly increase the setting until the wire is warm enough to melt the foam. I found a lot better results by just heating the wire barely enough to melt the foam. If the wire gets red-hot it will lose its tension and sag a lot in the middle.

The bow I made up out of 3 / 4 " copper pipe with a pair of 90 degree elbows. I use a couple of pieces of wood dowel in the ends of the pipe legs to insulate the wire from the bow. And a couple of small turnbuckles attached to the dowels to hold and tension the wire.

I found nicer cuts when the temperature of the wire is just hot enough to cut the foam, with a lot of tension on the wire. This way if the bow jerks a bit during the cut, it won't leave bumps in the cut.

If you need some pics of this setup let me know and I'll come back and post them!

Having fun!

Ted.

Hi OldF,

That's going to be a very neat tower! I like the design...

Here's a possibly easier and maybe safer suggestion - if you're just looking to find the buckling strength, you could support the tower in a horizontal orientation (like on strong sawhorses or something similar) at each end.

Then put a couple of empty barrels on top, in the center of the tower. Add measured amounts of water to the barrels until she buckles. Water is 1 kilogram per liter (or 8.34 pounds per gallon). So if you had a 50 gallon drum full it would put 417 pounds plus the weight of the barrel on it. Two or three barrels would probably do it. Or if you had an old oil furnace tank...

At least when it fails, the most danger will be from having a barrel land on you, or getting wet!

Good luck and keep us posted!

Ted.

Garage Heat ([none / 0](#)) ([#1](#))  
by monte350c on Thu Dec 25th, 2003 at 09:50:35 PM  
MST  
([User Info](#))

Hi zmoz,

My guess would be that just for straight heating, probably it would be cheaper and more efficient just to use propane. Unless you need the electricity for something of course...

Every conversion of energy from one form to another always seems to involve some kind of loss.

Picture running the Briggs on propane, driving the alternator vs. just burning the propane to make heat. I think the burning would necessarily be more efficient.

But it would be cool to have the Briggs churning away in the garage!

Ted.

([User Info](#))

Hi Ed,

Looks really interesting!

I can appreciate the problem with the smallest windings at peak speeds. How about a power resistor switched into the small winding's circuit at a certain point?

Or you could always try one of those capacitive discharge circuits Charged has been posting about, might solve the current problem...

Good luck with this Ed, it's important research, and looks like a lot of fun!

Ted.

Hi All,

Charged is right on the money with this one but perhaps a little pessimistic about the amount of KWH available.

Check out this site:

[http://www.focus-solar.com/insolation\\_levels\\_us.htm](http://www.focus-solar.com/insolation_levels_us.htm) It gives the amount of power, in KWH, available in a square meter in various locations, in different seasons throughout the year.

I made a small parabolic trough about a year ago which was able to heat water quite quickly to an impressive temperature. Like boiling.

If it's mainly heating you're after, there really is a lot to recommend this approach.

Here's another page that illustrates the main kinds of "solar concentrate"

[http://www.eere.energy.gov/csp/csp\\_tech.html](http://www.eere.energy.gov/csp/csp_tech.html)

Have fun!

Ted.

Hi Sibirsk,

If you're not too concerned about 60 hz but just want the 110-120 volts check this out. There's a plan for a regulator there too:

<http://www.qsl.net/ns8o/welcome.html>

Have fun!

Ted.

Re: Auto Alternator Conversion ([none / 0](#)) ([#2](#))  
by Harry Luubovv on Wed Dec 31st, 2003 at 09:38:49 PM MST  
([User Info](#))

Actually, it is a piece of cake if the secret is spoken out loud ! Basically there is no such a thing as "12 Volt" or whatever other volts for that matter with a car type alternator. The voltage is held by the regulator alone, the regulator determines the voltage available in other words. If you defunct the regulator and remove the diode group from the inside of an automobile alt. GM or not, (Which is easy, but leave the brushes there) Then you will let the engine idle up to higher speed and watch the volt meter which is hooked to the output of the alternator, keep the engine speed steady when you see 120 Volt. There bingo, you have an instant 120 Volt "Generator" from a GM set !!!

Ciao !  
Luubovv.

### [Auto Alternator Conversion](#)

By [sibirsk](#), Section [Homebrewed Electricity](#)  
Posted on Mon Dec 15th, 2003 at 08:34:00 PM MST [Alternators](#)  
Need a regulator schematic.

I am converting a 12 volt Delco-Remy alternator to produce 110 volts.  
I was wondering if anyone knew of a good schematic to follow for a regulator.  
Simple is good. An explanation of how she works is also a plus.  
Thanks. Sibirsk.

Hi Charged,

Is there a practical limit to paralleling caps to increase capacity? Say each phase of a wind generator has an open circuit voltage of around 40 VAC, any suggestions for cap sizes at the generator, and at the battery end?

Thanks - learning lots!

Ted.

You got me. I've never used them.  
Electrolytics are what you want for pulse-charging systems. You can scavenge them from old TV's and monitors pretty easy.  
Or, you can hit some of the electronic surplus places on the net.  
Last, you can shop at digikey.com and get everything that's shiny and new!

Later...

Re: What size and voltage ([none / 0](#)) (#3)  
by [bob golding](#) ([yubba at clara dot net](#)) on Mon Dec 15th, 2003 at 05:08:17 PM MST  
([User Info](#))

hi charged what voltage caps will i get away with on the pulse charging circuit you talked about the other day? i notice 1 F audio grade at 25 volts are 180 bucks apiece. 3 of those would buy a lot of batteries. the memory back up 1f ones are much cheaper. they are rated at 5 volts so would say 2 banks of 3 in parralell work ok? that should be 330,000uF at 30 volts i think?

bob

Hi Bob

I've metioned here B-4 that I will sell you guys car stereo stuff cheaper. This is easy for me since I've owned and operated my own store since 1986. I started as an installer in 1976 I've been involved with audio & electronics since 1958.

Now that I've patted myself on the back heres the deal. That \$180 1 farrad cap you mentioned. I'll sell that to my wind freinds here for \$75 + shipping & hadling.

Plus I have I have a 1000 or 2 of caps with voltages and UFs all over the map. Many of these start at \$5 depending on UF and voltage rating. All or computer grade, many are take outs.

JK TAS Jerry

What is the physical size of a high voltage 300uf? for this 4 bolt bicycle charger I have one in a 700 watt microwave(found in the junk but works good enough to reheat my coffee out in the shed.) I think the capacitor is about the size of a toilet paper tube... will that work(if it would I'll be coming back in the house to reheat my coffee)? I don't think I need those \$180 ones that Bob Golding mentioned???? .....(as Lil' Abner used to say 'Amoozin' but confuzin ' ) (:>) Norm.

Those capacitors on lawnmower engines are very low capacitance. They wouldn't be of much use.

DS

Re: What size and voltage ([none / 0](#)) (#8)  
by charged on Tue Dec 16th, 2003 at 06:09:06 AM MST  
([User Info](#))

Whoa! Lots of questions!

Ok, here's how to set it up.

HV inductive spikes need someplace to "land" that can tolerate their peak voltage.

For this reason, RIGHT ON the genny winding (or right beside it), mount the HV capacitor. A 300v or so electrolytic should more than suffice. Next, build a bank of LARGE low voltage caps. I'd build for a 50v nominal rating, minimum. Run a couple of feet of heavy twin lead between the genny mounted cap and the large cap bank.

This capacitor bank is the HEART of your battery charging system. DO NOT SKIMP if you can help it. It will be serving as the mediator between ALL your various generators and the battery bank. The more capacitance, the better. That's the rule.

You never want HV spikes hitting the low voltage caps. It'll pop the dielectrics inside and you're out the cash.

You might want to build an overvoltage bleeder to put on the large cap bank so that if it goes over peak, a few heavy parallel power transistors can bleed the excess before any damage takes place.

If you build your cap bank with enough capacitance, it

shouldn't ever be a problem.

When you have sufficient capacitance, your bank voltage will float just over the battery voltage (whatever it may be).

Makes sense?

[More speed? or more wire?](#) | 14 comments (14 topical, editorial)

Re: More speed? or more wire? ([none / 0](#)) ([#14](#))  
by monte350c on Fri Dec 12th, 2003 at 09:58:31 PM MST  
([User Info](#))

Hi Charged,

So... let me see if I've got this straight. The timing thing is mainly to discharge the cap - but that should happen when there's no interaction with any of the coil(s)?

If that's the right answer - could I skip the belt and timing disk and add a hall effect sensor in between the magnets on the main flywheel and achieve the same result? Say discharge the cap once per revolution.

Looked over the sketches on the link you sent, and it doesn't look too difficult to build. Very cool in fact. Out of curiosity how long does your motor run on 1 or 2 9 volt batteries?

Ted.

[ [Parent](#) ]

Re: More speed? or more wire? ([none / 0](#)) ([#15](#))  
by charged on Sat Dec 13th, 2003 at 09:21:44 AM MST  
([User Info](#))

Depends on how you build the motor. There is no "one" answer. Look at the video clip at [www.keelynet.com/bedmot/bedmot.htm](http://www.keelynet.com/bedmot/bedmot.htm) and read the text about what's happening. You'll have your answer.

I don't want to be rude and continue blabbing about that device in this particular thread. Just toss any other questions on the Bedini system over to this message thread.

<http://www.fieldlines.com/story/2003/11/12/8365/3048>

See ya there!

Hi Charged,

So... let me see if I've got this straight. The timing thing is mainly to discharge the cap - but that should happen when there's no interaction with any of the coil(s)?

If that's the right answer - could I skip the belt and timing disk and add a hall effect sensor in between the magnets on the main flywheel and achieve the same result? Say discharge the cap once per revolution.

Looked over the sketches on the link you sent, and it doesn't look too difficult to build. Very cool in fact. Out of curiosity how long does your motor run on 1 or 2 9 volt batteries?

Ted.

## [More speed? or more wire?](#)

By [Norm](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 9th, 2003 at 05:21:07 PM MST

[Alternators](#)

Oh & ^ %&%\* &% !!! 100 turns around a 1/2 inch bolt...<br>

needed some more wire for 200 turns...no problem scrape the coating off and splice some more wiring....hmmm...that bare wire is silvery Gahh...aluminum wire!  
Went to Google and was checking out properties of aluminum wire and found out that aluminum is not as conductive as copper so would need larger wire versus copper and also and at the bottom...it says One last note on aluminum magnetic wire. The polyester insulating varnish commonly used on a motor's magnetic wire has a copper hue. This makes it almost impossible to distinguish the material used in the motor windings. So I guess ...maybe just a higher ratio so it spins faster?Fun...fun..fun! Norm.

I'm quoting 'Charged'in a reply to 60 amp altenator won't work.

Forget using alternators. They're junk. You already have a high velocity spinning surface, the wheel. Make use of that.

Go to Radio Shack and get \$10 worth of those LARGE high power ceramic magnets that they sell (part #64-1879). They're something like 1"x1 3/4" or so. Remove the tire and stick the 10 magnets around the outside of the rim, evenly spaced. Make sure all the magnets have the SAME POLE facing out. Use glass-fiber packing tape to wrap around the magnet and rim. Plastic tapes tend to flex and release the magnets like bullets when you're really cranking, Centrifugal projectile launcher. Nasty.

Get four 1/2"x 4" bolts, 8 large washers, 8 nuts, and a piece of 2x6 lumber. Cut the curvature of the wheel into one edge of the 2x6 so you can mount it under the wheel. Wrap about 200 turns of #14 wire onto the first 1 1/2" of the bolt by positioning the two washers with one at the head of bolt and the other one held in place by one nut. All the windings go between the two washers.

Drill 4 holes into the curved piece of lumber so that the bolts can be mounted so that they're heads all line up with 4 of the ceramic magnets at the same time.

Wire the 4 coils in series and put a single diode on the output, feeding a high voltage capacitor of at least 300uf.

Take your power off the capacitor directly.

and so I'm halfway thru winding the first bolt will it work? I'm shooting for 35-45 watts.....(:>) Norm.

Re: More speed? or more wire? ([none / 0](#)) (#6)  
by DanB on Wed Dec 10th, 2003 at 06:44:42 AM MST  
([User Info](#))

35-40 watts is not much to ask - I suspect it could work if you wind it right...

But its not an ideal design. Youll have significant eddy current losses in the bolts/washers (laminates, or even small soft steel rods instead of bolts would probably work better I think) - so I dont think it would be very efficient.

I think it will also cog pretty badly - perhaps not a big deal once you get it running, but it might be. The cogging will make it a bit hard to start and once it does start it will vibrate.

Im not sure why wed have the same pole pointing out around the rotor...

I think iit would work, but I think it would not be very efficient. I'd do some things differently...

If you throw enough magnets at it (and you can - because again - 35 watts is not a lot to ask) - then you could forget about using any steel/iron inside, or behind the coils alltogether, and wind very flat coils that run very close to the magnets. This would eliminate the cogging, and the eddy current losses in the bolts - but you'd need more magnets to get the same result I think.

[ [Parent](#) ]

Re: More speed? or more wire? ([none / 0](#)) (#8)  
by charged on Wed Dec 10th, 2003 at 07:49:56 AM MST  
([User Info](#))

Eddy currents will be more than offset by the lack of hysteresis loss from pole reversal in the cores. Also, the flat washers will only be swept by the fields edge-on. I learned a lot about eddy currents in various metal structures when I worked at an MRI magnet facility a few years ago. Different shapes handle the field-lines in different ways.

Ever get to play with a 3 Tesla, steady-state superconductive magnetic field? Very cool. I highly recommend it.

That's so strong that it slows down the water flow in your inner ear if you turn your head too fast inside the field. Also very cool. I highly recommend it.

I could drag a flat 1/4" thick aluminum plate into that field edge-on. But, I could literally dangle in mid-air from that same plate when I tried to pull it down face-on into the field. Very strange to see yourself hanging there from a plate that's stuck in a bunch of "nothing" about 4 feet off the ground. Tremendously cool. Recommendation goes without saying.

In any case, the monopole rotor will produce a spike/ramp waveform to charge the capacitor(s). This is a magneto, not an alternator, in the truest sense.

Since most folks have never even bothered to build something like this, they make assumptions that don't really reflect what the device can do. "Wasted flux" means nothing. Efficiency can be very very high with simple components.

You can also space your stator cores so that there is a continual imbalance of PM forces to prevent cogging. But, this will require that all the windings share a common ground to the capacitor's negative terminal. Also, each winding will need a single diode between the other lead and the capacitor positive. That's one diode for EACH winding so that they can't feed back on eachother. You'll have a multi-phase "machine-gun" pulsation going to the capacitor.

OR you can put a single diode AND a single capacitor on EACH WINDING. Then just wire each of those capacitors in series and draw you power (higher voltage) off the top (positive) and bottom (negative) capacitors.

The single diode also causes an inductive kick effect since it "chops" the sine-wave into individual "upward" voltage ramps that are the peak to peak voltage difference in the sine-wave. If your winding is producing, let's say 10vac, then the diode turns that into 20v spikes.

Your individual capacitor's floating voltage would be 20v.

Low resistance, and lots of turns, 200+ on each stator.

You can also use a much larger capacitance either way. 300uf is about the minimum for my tastes though. Bigger is always better for filtering purposes.

The velocity of your magnets, the field strength and the number of turns on each stator will determine your peak voltage. The system resistance will determine your max current.

Of course, impulse current from your capacitor bank can be much higher and can produce some interesting effects in loads, especially lighting, since the capacitor has no significant internal resistance.

40 watts is nothing. A "standard" human (is there such a thing?) can do about 500 watts for a pretty fair duration.

Re: More speed? or more wire? ([none / 0](#)) ([#10](#))  
by Norm on Wed Dec 10th, 2003 at 06:06:38 PM MST  
([User Info](#))

OK First things first...the wheel rim I suppose an old 10 speed would be about right....(got it for \$2.50 the tires are rotten anyways) the magnets go lengthways in the rim? ...and some strapping tape to hold them in. Some JB Weld on the edges..Maybe? As far as the 200 turns of aluminum goes ...if it doesn't work good enough can always add more or rewind with copper wire. Well that's about it for now your comment has been very enlightening and encouraging...and fun...thanks (:>) Norm.

[ [Parent](#) ]

Re: More speed? or more wire? ([none / 0](#)) (#13)  
by charged on Fri Dec 12th, 2003 at 02:02:36 PM MST  
([User Info](#))

Ok, you can use the aluminum with great success.... IF.....

IF you set it up so the capacitor discharges ONLY when there are NO PM INTERACTIONS WITH ANY OF THE STATOR WINDINGS.

In other words, separate the two current loops in your system.

Go ahead, scratch your head. It's ok. Nobody ever does this. Well, some people do. But, they probably keep it some sort of "trade secret". Ha! Not anymore, whoever you may be.

Actually, the idea's been out there a long time. But, the generator industry seems to be stuck in a sine-wave rut for some reason. Yek. Tesla's post 1890 "impulse" or "radiant" patents work MUCH better than AC systems. He said so himself, AFTER his AC designs were already running most of the industrial world. But, that's another story. Go read his autobiography.

You ONLY need commutation for the capacitor DISCHARGE, nothing else.

If you're doing the "imbalanced fields" thing to eliminate cogging, try this...

Let's say you put 8 pm's around the outside of the wheel. Now, remove 2 of them, from opposite sides. Now you have 6 magnets in two sets of three on either side of a center-line. Got it? Ok....

Set up your stators so that they all fit inside that "blank" area of the wheel without interacting with any magnets. In other words, let's say you have about 30 degrees of arc on either side where there aren't any magnets. Make the stator windings line up in less than that 30 degrees of arc. This will produce 2 "blank" periods per rotation where the stators do nothing.

This doesn't "waste" anything since the guy peddling is just storing a little flywheel inertia that will be collected by the next set of pulses. Got it? Ok.

Set up a commutator on the wheel near the hub. It should make contact with two brushes that are in series with the cap, to discharge it. That commutator should only make contact with the brushes at the MID-POINT of the blank space, while the stators are doing nothing.

So, what you will get on each rotation is a little tat-tat-tat-tat, pause, SNAP! , pause, tat-tat-tat-tat, pause, SNAP!, pause, etc.....ad nauseum.

Why are we doing this? Well, your wire has a specific impedance and your load also has IT'S OWN impedance. The windings and your load will never come close to matching impedance, even on the best of days. Impedance mismatch is loss. Aluminum may be RESISTIVE but since it's wound into an inductor there is also an INDUCTIVE field-collapse component in this particular application. The inductive "spike" component of the output is a "radiant" (ala Tesla) component, or PURE VOLTAGE with little or no associated electrons. Therefore it easily bypasses the resistance of the aluminum windings and fills the capacitor virtually losslessly. Don't worry if you don't understand it. You don't absolutely need to. It will work based on the laws of physics, not on your belief patterns. heh. Below a certain voltage coming from the windings (RMS), it IS electron current and must fight the wire resistance. So, you have BOTH of these components supplying charge to the capacitor.

Along comes this capacitor. To be quick about it, it will "match" itself to any other impedance, in this particular application.

First, the cap charges at the source and reaches peak voltage. The it floats away and dumps it's charge into the load. Then it disconnects from the load and floats back over to the source for more charge. It's an impedance translator.

The generator always floats up to peak voltage and the load ALWAYS gets the maximum available generator power. Given, it's in microbursts. But, you CAN put a filter cap across the load.

You might even see some "strange" effects that you weren't expecting.

This is a GREAT way to run resistive heating elements.

After you see the weirdness at the commutator and you're no longer fascinated by it, you'll probably want to step up some high-power solid-state switching components and a little slotted photo-coupler.

This system also works well for homemade wind generators.

Once you have determined your maximum generator voltage, place enough batteries in series to come up just short of that voltage without going over it.

Fire your capacitor discharges into this series stack to recharge them.

Hmmm....Why is it so easy to peddle this thing?

Enjoy!

by monte350c on Wed Dec 10th, 2003 at 07:35:25 PM MST  
([User Info](#))

Hi Charged,

Do you have any idea if it's possible to actually build a small version of that Bedini motor 2 battery thing I keep seeing on the web? I think it would be pretty cool to have one of those spinning on my desk...

I've seen a few sketches and schematics but none were complete enough to send me to Radio Shack, I'm looking for some fairly straightforward drawings. If you've seen any I'd appreciate a drawing or link! Thanks!

Could be fun...

Ted.

Re: More speed? or more wire? ([none / 0](#)) ([#12](#))  
by charged on Fri Dec 12th, 2003 at 01:13:42 PM MST  
([User Info](#))

The motor is REALLY simple. There is not a "fixed" set of plans, per se.

Almost any configuration conceivable will work.

In a nutshell, the CIRCUITS and the basic layout are here. Build the stator winding just like the diagram shows. I use 1/2" ID cpvc with a couple of plastic ends to make a spool. Wind a triplet of #24 wire (trifilar winding) about 500 turns and that's about it.

Magnets can be just about any kind. If your wheel isn't metal, use high-power ceramic magnets. If you have a non-magnetic metal rotor, use neodymiums. Using the neo's with a light rotor makes a disturbing rumbling sound as it spins.

[www.keelynet.com/bedmot/bedmot.htm](http://www.keelynet.com/bedmot/bedmot.htm)

The circuits are actually more critical than the rotor and timing wheel designs.

A good TIP3055 transistor is all you need. Just check the gain on the transistor with a meter and make sure that it exceeds 80. You might have to go through a bunch in order to find one that high. It WILL run with a lower gain. But, it runs optimally with higher gain.

If you stick with 1/4" steel rod for the axles, you can use a set of hole-saws to cut all your wheels from whatever material you like. Just make sure the rotor has some mass to it since this is pulse driven. It's not much different from an IC engine in this respect. It needs the flywheel mass to run smooth.

I use string for the belt. Just tie the string in a snug loop around the big pulley and the axle. Then start the motor and rub silicone rubber into the string while the motor is running. It will dry in about 20 minutes and then the rpm's will go up a little.

A couple of brass strips for brushes and a chunk of brass glued to the side of the commutator wheel and let'r rip!

Hope this helps!

by monte350c on Tue Dec 9th, 2003 at 09:07:36 PM MST  
([User Info](#))

Hi Norm,

Sounds like a conundrum...

I'm now using exclusively new magnet wire - I went to a local shop that rewinds motors and they will sell wire by the pound really reasonably. I got a roll of 18 AWG that I used in my very first alternator project:

It's got 18 coils in it of 70 turns each, plus I've used the wire for another couple of projects and experiments too - total cost was about \$20 - and I still can't see the bottom of the reel!

At least with the new stuff you know what you've got - just check your local yellow pages under electric motor service - bet you'll find a local source pretty reasonable. Saves all that cussing!!

Ted.

Re: More speed? or more wire? ([none / 0](#)) (#4)  
by Jerry on Tue Dec 9th, 2003 at 10:04:46 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Norm

Thats right. You'll find aluminum wire in ac motors. I've found this in the garbage disposal motors in the 1/3, 1/2, 5/8 and 3/4 hp. The 1 hp has copper but out of the 300 or 400 motors I've collected 3 have been 1 hp. They are rare. The aluminum dose work but not as good. It has higher resistance and less amperage. It is prety though, just like the copper? But who needs prety just give me AMPS.

JK TAS Jerry

[Magnet Strength vs Thickness](#) | 26 comments (26 topical, editorial)

Re: Magnet Strength vs Thickness ([none / 0](#)) (#1)  
by monte350c on Fri Dec 12th, 2003 at 01:39:43 PM MST  
([User Info](#))

Hi Dave,

Here is a site I found extremely useful for this kind of thing:

<http://www.magnetsales.com/Design/Tools1.htm#disc>

You can just punch in magnet thickness, size, type (ie. Neo 35) and the distance from the magnet, or between them if they're on a dual disk and it will return the gauss at that point.

It really illustrates that small air gaps are good - a small magnet on a small air gap can give the same results as a much bigger magnet with a corresponding big air gap. So I think you can save money on magnets to some degree if you up the diameter and close the air gap down... Just my two cents worth!

Have fun,

Ted.

That's really a handy tool! Thanks for the link!

One thing it learnt me (that's proper English in my dialect) was that paying for the Neo 48s is probably not worth the price difference over the Neo 35s.

Another thing is that a 1/8" air gap is probably a worthwhile target.

(If I ever get around to building one.)

I was real excited about the site with magnetic gauss calculator, but then I hit a feature that has me concerned about accuracy of equations used by the calculator. If you use:

[http://www.magnetsales.com/Design/Calc\\_files/FluxDensityRectYoke.asp](http://www.magnetsales.com/Design/Calc_files/FluxDensityRectYoke.asp)

(supposed to calculate gauss at the center between 2 rectangular magnets in a steel yoke) and put in 3 by 3 by 1/4 neo N45's with .75 gap between magnets, it calculates about 4149 Gauss... Increase the size of the magnets to 5 by 5, with everything else remaining constant, and the Gauss calculation decreases to 3606!?! I cannot think of a reason how that could be correct. What am I missing here?? Sure wish I had access to the formulas they're using...

dbert,

It's true. The wider magnet causes a demagnetizing force on the center point.

You can verify this with a flux meter.

Flux lines repel each other and cannot cross but there all "trying "to get to the same place. The more the crowding the higher the reluctance.

Make the wind fun!

([User Info](#))

Hi Dave,

Here is a site I found extremely useful for this kind of thing:

<http://www.magnetsales.com/Design/Tools1.htm#disc>

You can just punch in magnet thickness, size, type (ie. Neo 35) and the distance from the magnet, or between them if they're on a dual disk and it will return the gauss at that point.

It really illustrates that small air gaps are good - a small magnet on a small air gap can give the same results as a much bigger magnet with a corresponding big air gap. So I think you can save money on magnets to some degree if you up the diameter and close the air gap down... Just my two cents worth!

Have fun,

Ted.

Hi Charged,

Wow some pretty neat ideas. Here's a ?:

What kind of waveform would I get if I had 2 caps wired to a transformer - one discharges + , then the next discharges - , into the primary of the transformer. The pulses would be timed so they're 180 degrees apart.

Would this give a sort of quare wave output? Or some kind of sine wave? You're making me very curious....

Have fun!

Ted.

[\(User Info\)](#)

Is this a single rotor setup, or dual? And is the air gap the distance between the face of the magnet and the face of the coil?

Thanks,

troy

Its a dual disk. I started with the smallest air gap that I could get, then increased the air gap without moving the coil. The coil at this point was not centered in the air gap at the wider gaps. The test is the open ac voltage of a single coil. I think that I will test to see if coil centering in the air gap makes a difference. Keep an eye open for these results. I can do this later today. The air gap is the distance between the magnet faces.

Troy,  
I missed your question, The air gap is the distance between the magnets.  
I have also completed a test to see if the coil voltage varies with position of the coil in the air gap. The air gap is .660", the coil is .160" thick. With the coil up to the right side disk the voltage was 5.75 @ 500rpm. When the coil is centered in the air gap the voltage was 5.54 @ 500rpm. When the coil was to the left side disk the voltage was 5.70 @ 500rpm. I had about 1/32" gap between the coil and magnet in the above side test.

by [charged](#) on Fri Dec 12th, 2003 at 11:01:11 AM MST  
([User Info](#))

That's an excellent test you've set up.

Just wondering, is that an AC voltage measurement with no rectification?

Here's something you can try if you like.

Tighten up that air gap as much as you can. Put a single diode on one lead from the coil and charge a 500uf (or more) electrolytic capacitor that's rated for at least 50v.

Connect a pair of leads to the capacitor and put a momentary contact switch on one lead.

Hook up a battery and a small analog ammeter in series with it. Start tapping the switch with very sharp pulses and watch the battery voltage with another meter.

If you want to get really fancy, replace the switch with a commutator on the generator's rotor shaft. Set it so that the commutator only dumps the capacitor IN BETWEEN the times when the magnet is passing your winding.

You'll love this.

The capacitor will "float" at a minimum of the battery's voltage. The generator will only be topping off the capacitor and will never be directly interacting with the battery. The capacitor acts as an impedance "translator" between the genny and the battery. It's much more efficient to charge this way.

Watch what happens at the commutator. It can be a real freakshow.

I'm planning on building a sealed commutator box and flooding it with Argon to prevent oxidation of the contacts. The commutator shaft has a small magnetic gear on one end (inside the box) and it's coupled to a magnetic gear OUTSIDE the sealed box that's mounted to the genny axle. It's kinda like a magnetic clutch-plate.

Oops. I've gone off on one of those little technobabbles again.... my bad.

(puts on bunny ears and walks off into the crowd).....

Hi Charged

I would guess there would be some arching between swiching cicles. Both at the battery end and the coil end. It neat that the coil and the battery never meet electricaly. The coil hands the power to the cap and the cap takes the power to the battery. The cap charges more easily than the battery and dumps a large reseve of amperage onto the battery. Man I'm liken this.

We've had problems with swich arching on our 156 volt dc system. We've cured this by placing 2 UF caps accross the swiches.

I think this might help here if arching problems are incountered and the small value of this cap should not interfear with the large caps storage and power transfer function.

If the dose not work then maybe soild state swithing with SCRs.

I've built CDI ignition systems and they work on a simular princapal.

The CDIs have a 200 to 300 volt suplly that chargese a 2 UF cap that is then dicharged accross the ignition coil. An SCR is use as the electronic switch that discharges the cap accross the ign. coil. No arching.

An electronic trigering lobe on the alt shaft would act just like the points in a cars ignition to triger the SCR. Heck take an old distributer and hook it to the alt shaft.

I know caps are very powerfull. Some of our lit on the 1 Farrad caps state that when a 1 Farrad cap is charged to 12 volts that at the instant of dead short discharge 4000 amps of current is released.

This Idea may be the next greeneration. I have zilions of caps so I like it.

JK TAS Jerry

([User Info](#))

IGBT's (insulated gate bipolar transistors) used in ignitions have built-in protection in the form of avalanche diodes to clamp overvoltage spikes, and unlike SCR's they turn off when you release the gate. The gate on an IGBT acts just like a MOSFET gate.

They're a good alternative to mechanical switching. You can use a hall effect sensor and a magnet attached to a shaft or flywheel, or use a shutter disc that interrupts the field of a stationary magnet.

Re: Test Results ([none / 0](#)) ([#11](#))  
by [charged](#) on Sat Dec 13th, 2003 at 09:17:49 AM MST  
([User Info](#))

This guy's as sharp as a tack. :)

First, SCR's definitely not the best way, in THIS application. They can float "on" longer than the commutator signal and cause genny-capacitor-load connection overlaps.

You can use mosfets, bipolar transistors, IGBT's, etc., as long as the reverse voltage tolerance is high enough. I've destroyed many transistors that were rated too low for this system.

It's pretty strange to see a 25v capacitor discharge into a 12v battery pop the guts out of a 150v transistor. 200v rating is about minimum. Make sure the "on" state resistance of your transistor is very low.

Anyone not familiar with paralleling semiconductors to lower switching resistance and increasing amp tolerance should dig around the web a little and learn how to do it.

Capacitive discharge is much more "kinetic" than a

sinewave system. It's also MUCH more effective for battery charging.

Imagine, all of Tesla's patent designs on "radiant" energy had to be done with purely mechanical switching. What could he produce with access to today's semiconductors?

I suspect that the problems you describe with blowing transistors was more of a problem with a limited current handling ability than with voltage.

Dr.D

Re: Test Results ([none / 0](#)) ([#15](#))  
by charged on Mon Dec 15th, 2003 at  
04:13:12 PM MST  
([User Info](#))

Nope. The voltage peaks when breaking the circuit were popping them. I solved it when I went to higher voltage rated components.

Current is easy. That's just a matter of wiring a suitable number of parallel transistors. They were still popping. That's what threw me a little at first. I was building WAY over the wattage required and still frying the parts.

Breaking the current flow off has some strange (and useful) effects.

[ [Parent](#) ]

Re: Test Results ([none / 0](#))  
([#16](#))  
by drdongle on Sun Dec 21st,  
2003 at 07:18:33 AM MST  
([User Info](#))

Were you able to observe these "transients" that blew the transistors? Your comment leads me to think that it was inductive "kick" that produced them. If so it would be a simple matter to add a limiting circuit ( zeners, and or a triac) to clip these spikes to a safe level.

Dr.D

Re: Test Results ([none / 0](#)) ([#12](#))  
by kell on Sat Dec 13th, 2003 at 04:49:43 PM MST  
([User Info](#))

I looked at one website where a guy made a tesla coil using MOSFETs. He did it so that the MOSFETs would turn on and off when they weren't conducting. Very efficient.

People burn up transistors all the time in inductive applications... That's why IGBT's are so useful. They are designed expressly for firing a coil (automotive). When I converted my old bike over from points to a homebrew solid-state setup, I ordered my IGBT's and hall effect sensors from Newark.com. I mounted a shutter disc on a bushing and slid it down over the points cam, with a set screw to hold it. I put little quarter inch neos pressed into holes in an aluminum plate above the disc, and mounted the hall sensors on the plate the points used to be on. The usual wiring scheme is to have a pull-up resistor to bias the transistor or transistors ON. When the shutter disc spins it intermittently allows the hall unit to see the magnetic field and, when it does, the hall unit shunts current to ground, turning off the transistor... shutting off current to the coil. This is when the spark fires. I think you could use a related setup for this charging circuit you're talking about. You could also wire in a voltage regulation circuit to turn the transistor off when necessary. Might even be able to work out a way to use a voltage regulator from a car alternator so you don't have to do a lot of circuit building. Instead of regulating voltage at the output of a charging system, they are designed to turn on and off the field coils (depending on the voltage measured across the battery), so you could just use it instead to control the transistor.

You don't have to use the hall effect units if it feels to complicated. A mechanical switch to turn the transistor on and off would work fine without arcing because the gate

current is truly negligible with MOSFETs and IGBTs.

[More speed? or more wire?](#) | 14 comments (14 topical, editorial)

Re: More speed? or more wire? ([none / 0](#)) ([#11](#))  
by monte350c on Wed Dec 10th, 2003 at 07:35:25 PM MST  
([User Info](#))

Hi Charged,

Do you have any idea if it's possible to actually build a small version of that Bedini motor 2 battery thing I keep seeing on the web? I think it would be pretty cool to have one of those spinning on my desk...

I've seen a few sketches and schematics but none were complete enough to send me to Radio Shack, I'm looking for some fairly straightforward drawings. If you've seen any I'd appreciate a drawing or link! Thanks!

Could be fun...

Ted.

[ [Parent](#) ]

Re: More speed? or more wire? ([none / 0](#)) ([#12](#))  
by charged on Fri Dec 12th, 2003 at 01:13:42 PM MST  
([User Info](#))

The motor is REALLY simple. There is not a "fixed" set of plans, per se.

Almost any configuration conceivable will work.

In a nutshell, the CIRCUITS and the basic layout are here. Build the stator winding just like the diagram shows. I use 1/2" ID cpvc with a couple of plastic ends to make a spool. Wind a triplet of #24 wire (trifilar winding) about 500 turns and that's about it.

Magnets can be just about any kind. If your wheel isn't metal, use high-power ceramic magnets. If you have a non-magnetic metal rotor, use neodymiums. Using the neo's with a light rotor makes a disturbing rumbling sound as it spins.

[www.keelynet.com/bedmot/bedmot.htm](http://www.keelynet.com/bedmot/bedmot.htm)

The circuits are actually more critical than the rotor and timing wheel designs.

A good TIP3055 transistor is all you need. Just check the gain on the transistor with a meter and make sure that it exceeds 80. You might have to go through a bunch in order to find one that high. It WILL run with a lower gain. But, it runs optimally with higher gain.

If you stick with 1/4" steel rod for the axles, you can use a set of hole-saws to cut all your wheels from whatever material you like. Just make sure the rotor has some mass to it since this is pulse driven. It's not much different from an IC engine in this respect. It needs the flywheel mass to run smooth.

I use string for the belt. Just tie the string in a snug loop around the

5 minute interval.  
Note: You may cloak yourself from appearing here in your Display Preferences.

big pulley and the axle. Then start the motor and rub silicone rubber into the string while the motor is running. It will dry in about 20 minutes and then the rpm's will go up a little.

A couple of brass strips for brushes and a chunk of brass glued to the side of the commutator wheel and let'r rip!

Hope this helps!

Re: More speed? or more wire? ([none / 0](#)) ([#14](#))  
by monte350c on Fri Dec 12th, 2003 at 09:58:31 PM MST  
([User Info](#))

Hi Charged,

So... let me see if I've got this straight. The timing thing is mainly to discharge the cap - but that should happen when there's no interaction with any of the coil(s)?

If that's the right answer - could I skip the belt and timing disk and add a hall effect sensor in between the magnets on the main flywheel and achieve the same result? Say discharge the cap once per revolution.

Looked over the sketches on the link you sent, and it doesn't look too difficult to build. Very cool in fact. Out of curiosity how long does your motor run on 1 or 2 9 volt batteries?

Ted.

Re: More speed? or more wire? ([none / 0](#)) ([#15](#))  
by charged on Sat Dec 13th, 2003 at 09:21:44 AM MST  
([User Info](#))

Depends on how you build the motor. There is no "one" answer. Look at the video clip at [www.keelynet.com/bedmot/bedmot.htm](http://www.keelynet.com/bedmot/bedmot.htm) and read the text about what's happening. You'll have your answer.

I don't want to be rude and continue blabbing about that device in this particular system thread. Just toss any other questions on the Bedini system over to this message thread.

<http://www.fieldlines.com/story/2003/11/12/8365/3048>

See ya there!

Hi Johnjach,

As Windstuffnow said, it's pretty much up to the individual. I got into this whole wind and energy thing about 6 months ago and ended up building an axial flux machine. It wasn't all that tough once I got started. DanB has posted a whole bunch of really good photos that are an excellent step by step guide to this sort of thing. I don't have a machine shop - so I just farmed out the cutting of the disks. I used a new trailer axle and hub since they're quite cheap. I had the machine shop weld it to an X shaped base too. The whole machine shop bill came to about \$100. The rest can mainly be done with regular home shop tools - ie. jigsaw, drill etc. It was pretty cool to see the light bulbs come on during the first test!

Jerry's garbogen also seems to get pretty good results at low windspeeds. From what I've read those and the axial machines are good in the low speed regime - and if you honestly look at it I would say it's probably better to have a machine that really performs well in a 15 mph wind than one that's only good in 25 mph. Just my \$.02!

Have fun!

Ted.

Hi Johnjach,

As Windstuffnow said, it's pretty much up to the individual. I got into this whole wind and energy thing about 6 months ago and ended up building an axial flux machine. It wasn't all that tough once I got started. DanB has posted a whole bunch of really good photos that are an excellent step by step guide to this sort of thing. I don't have a machine shop - so I just farmed out the cutting of the disks. I used a new trailer axle and hub since they're quite cheap. I had the machine shop weld it to an X shaped base too. The whole machine shop bill came to about \$100. The rest can mainly be done with regular home shop tools - ie. jigsaw, drill etc. It was pretty cool to see the light bulbs come on during the first test!

Jerry's garbogen also seems to get pretty good results at low windspeeds. From what I've read those and the axial machines are good in the low speed regime - and if you honestly look at it I would say it's probably better to have a machine that really performs well in a 15 mph wind than one that's only good in 25 mph. Just my \$.02!

Have fun!

Ted.

Which would work best if I don't want to attempt building a PMA from scratch?

If I don't want to build a PMA from scratch, which is best? (disregard cost and labor)

An auto alternator refitted with thinner stator wires, new neos on the rotor, and direct drive to the prop.

An unmodified auto alternator geared down to the prop with a belt or chain drive.

A "garbogen", or AC induction motor with a ground-down rotor, new neos attached, and a direct drive to the prop.

JJ, I think this question would be opinion based... The simplest is to get a PM motor, blades and a pole... instant wind generator.

There are some that are more inclined to build the gen's from motors and those of us who build them from scratch. We all have a nitch in what we do. Personally I feel more inclined to build them from scratch, but that's me.

I think it's got to be pretty overwhelming for someone starting out in wind power and finding this site. There is a ton of information all leading in different directions... When I started out there was no internet and I learned by experimenting and blowing things up... found things that worked and things that didn't... Its all quite easy now except deciding which direction to follow... what the heck build them all!!!

Have Fun  
Ed

Hi Guys

I am new to this discussion board, this is my first post. About six months ago I wanted to build a wind turbine as we have moved into a mobile home which is not near an electricity supply. I have only simple tools and no previous experience. While looking for advice I came across Otherpower.com. I read about all of their experiments and decided to give it a go. I have had a few problems and made several mistakes but I now have a very useful wind generator.

I found the of building the alternator is one of the easier parts of the project and apart from the magnets the materials are not expensive.

Ali

Hi Jerry,

Nice looking unit! Enjoyed your other posts and your approach to using lots of small units to add up to very respectable power levels. That really makes sense. Also that's a pretty cool battery bank - what's the scoop on those aircraft batteries? Are they 24 or more volts?

Anyhow, I am also working on a couple of laminate / coil alternators at the moment. I did a post a while back (<http://www.fieldlines.com/story/2003/11/25/202715/52>) and got a reply from Charged with an interesting looking setup using an "E" from transformer cores and 3 magnets rotating past them. When I saw the alt. you posted here, I wondered what would happen if the "E" part of the transformers were facing the rotor, and the magnets charged drew were arranged to pass over the "E" - sort of like charged's picture but laid down flat. I did a very unscientific experiment and laid down 3 magnets (N - S - N) on a piece of steel then waved it over a transformer "E" section, then compared that with the same magnets laid out N - N - N. The first way there was a lot less cog.

Lots of fun wish I had a lot more time to play with this stuff!

Ted.

Hi Ted

You and Charged are responsible for my trying this. After seeing your posts. I have a few hundred of these little transformers. They are audio isolatin trans. with a 1 to 1 ratio. When both coils are siriessed it measures 2 ohm,s DC. I cut the laminations so there are a "T". I place the top of the "T" in the round slot where normally a circle of lamination matereal would go. This alowed the "T" part to almost tuch. I filled the small void between each "T" with JB Weld. It has steel in it so it bridged the magnetic gap between transformers. The cogging was bad until rpm was up.

## [Small Disc Alt](#)

By [Jerry](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 9th, 2003 at 11:14:59 PM MST [Alternators](#)

First disc alt.

This is my first attempt at a disc alt. I'm using 12 little transformers. It cogs real bad and out put is low. I'll change it to regular laminations and coils. The disc is not shown its a 5 inch with 12 small neos 1X1/2X1/8 in. There is a 1/4 pice of pleaxy holding the coils/transformers in place.

Jerry

Here is a inductor coil I found at a Ham swap meet I got 32 of them at 50 cents each.

The guy that I got them from said they were for speaker cross overs.

I tested one with eight neos 3/4 by3/4 by1/4 on the 6 inch face plate on my lathe.

I got 3.4 voltes at 138 rpm with a 1/4 inch air gap. This is as slow as the lathe would go.

Cogging has been my main worry for not going any farther than this the tool post that I had clamped the coil in had some play in it and shook like the devil.

Keep them flying

Old F

MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Old F

Yes these are subwoofer crossover coils. We don't use these at our stereo shop because you loose 36 watts out of 100 watts in this coil. We do use them as part of a hipass xover for midrange speakers some times however. I have these also.

Dan B did an experimnt with a simular coil arrangement befor he discovered the disc alt. I think preformance was poor however so the idea was not persude.

I'm getting the same voltage from the small disc alt no load per coil but very low amperage. In thirory it should have worked but in reality I'm moveing on to the normal laminations and coils. I am however going to use small gage wire and do a diode bridge for each coil.

Its that large # of small things working together?

JK TAS Jerry

Hi Johnjach,

If you're looking to find out about the realistic power available from a certain amount of wind, there's a lot of info out there. That link I posted the other day to Dr. Johnson's book has several examples and a lot of math to back it up. But basically, for verticals, if you have a look at Chapter 1, page 16, he gives an example of a unit built by Kansas State U. It has 4 savonius rotors, each one measuring 3m high x 1.75 diameter. That unit is rated at 5 KW in a 12 m / s wind ( about 26 mph)

I found a wealth of info in his book, in fact I printed it and put it in a binder. It's really readable and I spent quite a few nights perusing this book. It makes for easy reading, but has all the tech info when you get to the stage to need it.

You'll also find lots of practical (and tested) info on Hugh Piggott's web site ( <http://homepages.enterprise.net/hugh0piggott/> )

Good luck and keep having fun!

Ted.

## [SURPLUS PERMANENT MAGNET DC MOTORS](#)

By [johnjach](#), Section [Homebrewed Electricity](#)

[Wind](#)

Posted on Tue Dec 9th, 2003 at 01:44:33 PM MST

What kind of output can be expected from permanent magnet DC motors?

Almost every day, E-Bay has permanent magnet DC motors for sale at reasonable prices.

Dan B. said himself on this site that they make adequate generators for someone just starting out in this DIY jenny hobby. What would be the best one to purchase since they range from 20 vdc to 72 vdc. I'm not an electrician -- how do these voltages convert to amps or watts per wind speed or propeller diameter or swept area or whatever?

Again, thanks for your help and input.

([User Info](#)) <http://www.windstuffnow.com/main>

Multiply the rated amps by the charging voltage it will be used for. For example if its rated at 10 amps and your charging a 12V battery bank then you'll get 120 watts from it or at 14V 140 watts. If it runs beyond its Amp rating it could possibly burn up, its best to set up a furling system for them so they won't go over the rated amps. It would probably be fine going over for short bursts but not for prolonged periods.

Look at rpm its rated to run. If it's rated at 12V 10 amps at 5000 rpm then chances are you'll never get it to produce any power from a wind machine. The lower the rpm the better. If you take the rpm and divide it by the volts you'll find an RPM per volt ratio ( 5000 / 12 = 416 rpm per volt ).

So if the 72 volt unit was rated at 1250rpm then you would have 17.3 rpm/volt and it would make 12volts at about 208 rpm. This is just a ball park figure but will get you close for designing blades to run it.

Have Fun  
Ed

I think this is the easiest way to get started. A 40V Ametek tape drive motor off of Ebay is what I used. I get up to 150 watts into 4 golf cart batteries at 12V. Put 2 Jerry blades with mike mods and a tail and your set. Total cost about \$60 - \$80. I've got 2 running now. I don't furl mine and they have been in a blizzard this fall with 50 - 60 mph winds with no problem. I don't think there is an easier way to build your own. I used a chevy waterpump mounting flange for a shaft hub and then a piece of 1/8" x 1 1/2" flat steel to mount the blades. Twist it to 23 degrees. I learned alot building and flying these tape drive mills.

Scott

To back up what Scott said. This is a very easy and cheap way to get started.

And just think you could spend \$400 or \$500 on a 100 watt solar panel that dose not work at night or with low output in the winter, when you need the power or make a wind genny for under a 100 bux and make 100 watts plus 24/7 depending on the wind?

I'm using a 50 volt Ametek 4"X7" with 2 Jerry blades. This thing makes an amp or 2 at 5 mph and I've seen a peak of 364 watts. Real cheap and easy go for it.

BTW \$10 each on unmodifide Jerry blades and \$15 each for Mike mod Jerry blades.

JK TAS Jerry

Hi Johnjach,

If you're looking to find out about the realistic power available from a certain amount of wind, there's a lot of info out there. That link I posted the other day to Dr. Johnson's book has several examples and a lot of math to back it up. But basically, for verticals, if you have a look at Chapter 1, page 16, he gives an example of a unit built by Kansas State U. It has 4 savonius rotors, each one measuring 3m high x 1.75 diameter. That unit is rated at 5 KW in a 12 m / s wind ( about 26 mph)

I found a wealth of info in his book, in fact I printed it and put it in a binder. It's really readable and I spent quite a few nights perusing this book. It makes for easy reading, but has all the tech info when you get to the stage to need it.

You'll also find lots of practical (and tested) info on Hugh Piggott's web site (

<http://homepages.enterprise.net/hugh0piggott/> )

Good luck and keep having fun!

Ted.

Hi Norm,

Sounds like a conundrum...

I'm now using exclusively new magnet wire - I went to a local shop that rewinds motors and they will sell wire by the pound really reasonably. I got a roll of 18 AWG that I used in my very first alternator project:

It's got 18 coils in it of 70 turns each, plus I've used the wire for another couple of projects and experiments too - total cost was about \$20 - and I still can't see the bottom of the reel!

At least with the new stuff you know what you've got - just check your local yellow pages under electric motor service - bet you'll find a local source pretty reasonable. Saves all that cussing!!

Ted.

[DARRIEUS BLADE AIRFOILS](#) | 5 comments (5 topical, editorial)

Re: DARRIEUS BLADE AIRFOILS ([none / 0](#)) ([#1](#))  
 by monte350c on Fri Dec 5th, 2003 at 10:07:06 PM MST  
[\(User Info\)](#)

Hi Johnjach,

There is a lot of info out there about VAWT's and research into blades. I've switched to a HAWT project, but would still like to try a VAWT at some time in the future. The main problems I saw with the VAWT / H-Bar proejct I have been working on all center around centrifugal force and the complexity of dealing with an appropriate furling / protection system for the generator. Centrifugal loads get pretty spectacular when the rpms go up - and it becomes obvious pretty quickly that dealing with those potential runaway scenarios should be the main preoccupation when designing a VAWT. Having said that - I'm still hopeful about the VAWT thing. I found Dr. Gary Johnson's book particulary helpful. You can download it for free here:

<http://www.eece.ksu.edu/~gjohnson/>

Also if you haven't already found it there's a very good resource for VAWT's at Sandia Labs site:

[http://www.sandia.gov/Renewable\\_Energy/wind\\_energy/topical.htm](http://www.sandia.gov/Renewable_Energy/wind_energy/topical.htm)

If you scroll down you'll come to a section titled "VAWT archives"

There's good reading in:

"Final Project Report: High-Energy Rotor, Development, Test and Evaluation"

"Aerodynamic Characteristics of Seven Symmetrical Airfoil Sections Through 180-Degree Angle of Attack For Use In Aerodynamic Analysis of Vertical Axis Wind Turbines"

"Aerodynamic Performance of a 5-Metre-Diameter Darrieus Turbine with Extruded NACA-0015 Blades"

"Free-Air Performance Tests of a 5-Metre-Diameter Darrieus Turbine"

Good luck with you project, and keep us posted!

It is a lot of fun in any case

Ted.

## DARRIEUS BLADE AIRFOILS

By [johnjach](#), Section [Homebrewed Electricity](#)

Posted on Fri Dec 5th, 2003 at 09:51:18 PM MST

[Wind](#)

What type of airfoils should be used for a Darries VAWT?

If I were to build a straight-bladed, H-rotor type Darrieus turbine, what would be the optimal number of blades and the best type of airfoil to be used if I wanted the unit to be self-starting? If the machine were to have a swept area of about 16 square feet (a 4 x 4 machine), what I've garnered from reading so far is that I would be better off with a thicker, more bulbous shape airfoil and 3-4 blades. Is this correct?

I got this idea from looking at the Solwind turbine at [www.solwind.co.nz](http://www.solwind.co.nz). This machine is said to self-start in low winds and the photos show the blades to be wider than most Darrieus blades.

by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sun Dec 7th, 2003  
at 08:35:38 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've found the 3 blade unit to be the best for reliable self starting. 2 blades will sometimes "bobble" back and forth until either a gust hits it or some turbulent air forces it past the point of no return.

The same will happen with a 4 blade arrangement although more reliable than simply 2.

The "fat" wing will start quicker than the thin blades but there are advantages and disadvantages to either. The fat wing has more drag ( especially on the downwind side ) and will tend to run slower than the thin aerodynamic foils but will produce power at lower wind speeds. Also, the fat wing has a better tendency to stay "in check" for overspeeding because of the extra drag. The thin blades are impressive and a bit more efficient but If you've ever built a small one, the rpm gets quite scary fast. If you've ever noticed the standard HAWT air foil has a start up sound and when it reaches its designed TSR it sounds like a turbo kicked in... the same happens to a properly designed darrieus wing. It's hard to explain unless you've actually experienced it. As long as the wings are stalled to some degree it will spin but the output is considerably low, but once it reaches its designed TSR the whole tone of the machine changes, its making power... and it sounds like it!!!

Build one of each ( small ones to experiment with) Take note of the differences... I prefer the "fat" wing design, although not as efficient in high winds its not as scary as the fater moving thin wing.

Have Fun!  
Ed

Hi Ed;  
Should the airfoil shape of a darrieus blade flat on one side or both sides curved??  
RayW

[ [Parent](#) ]

Re: DARRIEUS BLADE AIRFOILS ([none / 0](#)) ([#5](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sun  
Dec 7th, 2003 at 12:06:28 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

The standard blade is symmetrical, that is to say it has an airfoil on both sides. The "flat on one side" will work with a lesser degree of torque depending on the design.

If your depending on developing power from strictly lift then the symmetrical blade is what you want. If your building a combination of lift and drag there are many different variations that will work quite well. Lift and drag versions attempt to offset any upwind forces that robs power from the downwind side.

Althought there are "standard" ways to build specific machines the world is still open for unique and untried versions. There is always a better way!

Ed

Hi Norm,

Yeah, it's pretty unbelievable what people expect out of their small engine products. If you took a car, only used it at full throttle, stored it for 6 months at a time, and never changed the oil or otherwise maintained it, I suspect it wouldn't last half as well as most Briggs last.

Hats off to the Briggs company - where else can you buy a brand new source of 3.75 hp for \$60?

Ted.

by Norm on Sat Dec 6th, 2003 at 06:58:26 AM MST  
([User Info](#))

Full throttle? One guy even mentioned to me one time the secret of cutting grass... 'You don't really need a sharp blade ...the speed is what does it! ....then another person says 'Yeah you know you shorten that little spring on the carbuerator and you get a lot more power!... (Oh Wow!) Next year ....those very same people were asking me if I could fix their mowers! They didn't even have a clue! Big mystery! Norm.

Hi Norm,

Yeah, it's pretty unbelievable what people expect out of their small engine products. If you took a car, only used it at full throttle, stored it for 6 months at a time, and never changed the oil or otherwise maintained it, I suspect it wouldn't last half as well as most Briggs last.

Hats off to the Briggs company - where else can you buy a brand new source of 3.75 hp for \$60?

Ted.

Hi Norm!

Woo - hoo!! (as Homer would say!)

That's a great tip and may very well come in useful some day.

I got a free lawnmower last week with a Briggs 3.5 Classic on it. I was looking for something to load test alternators - and this just showed up. Took the head off and decarbonized it and the piston top - no scores in the bore. The old owner complained it was hard to start and wouldn't rev up. The choke plate was completely missing from the carb (!), and the control cable was all jammed up. Fixed the control cable, got a new choke plate from our local small engine shop, put in a new carb diaphragm while I was at it, and now this thing runs like new. Total: \$10

Here are another couple of small engine links I've found useful:

For good exploded views of engines, plus part numbers and prices (haven't actually ordered anything from here yet):

<http://www.partsandservice.com/index.html#home>

and a good general forum for small engines:

<http://forums2.gardenweb.com/forums/lmower/nph-ind.cgi?n=60>

Both links probably good for folks looking for generator engine parts or troubleshooting tips.

Lots of fun!

Ted.

by Norm on Fri Dec 5th, 2003 at 09:04:02 PM MST  
([User Info](#))

Yeah I used to get them all the time one time one was so bad it lost compression got a chunk of carbon lodged under the exhaust...now that's carbon!

Another time saw this lawnmower in the junk...looked like new after taking it home wouldn't turn over...took the head off the cylinder wall had a deep gouge in it about 1/8" deep the owner tipped it over to check the blade gas from the carb had washed all the oil from the cylinder wall. ...still I had a lot of like new parts. Lot of fun almost unbelievable what some people do to lawnmowers. Norm.

Hi Norm,

Makes me wonder just how long those 3,600 rpm generators will really last. Seems to me it might be better to use a larger engine and make it 4-pole to run at 1,800 rpm instead. 3,600 is really honking for most stock 1 cyl. engines.

Ted

A couple of transformer questions!

---

Hi All,

Was 'lucky' enough to pick up this junked transformer. No idea what it's from!

A couple of questions -

I'm trying to take it apart - it seems to be welded or fused together. There's 2 small depressions like grooves across the laminations at both ends. If I take my disk grinder and grind through those will that damage the laminates from heat etc?

Is there any "better" transformers to watch for? Our local scrap metal dealer has lots of this sort of thing.

And finally - does anyone know where to get and how expensive new transformer 'E' and 'I' laminations are?

I want to try out a couple of coil on laminate alternator configurations like the ones posted by Electric Ed and Charged in response to another post I made

This company, Lamination Specialties Corp, has many sizes of lamination sets. I didn't see any prices on their website, but they may be there somewhere.

<http://www.laminationpecialties.com/TOC/products.htm>

Example - This is their EI-100 size.

**GRAIN DIRECTION**

**APPROXIMATE WEIGHTS**

GAGE	THICKNESS	PER 1000 SETS	SETS PER POUND
29	.014	35.25	28.4
26	.0185	47.26	21.2
24	.025	64.09	15.6

hi ted, taken dozens of transformers apart. for small ones i dont think it is worth the hassle as lams for small transformers are quite cheap anyway. differant story when you get to multi kva ones. dont let that stop you. just think the time would be better spent on working out your design.

bob

## What would happen if

By [monte350c](#), Section [Homebrewed Electricity](#)

Posted on Tue Nov 25th, 2003 at 08:27:15 PM MST

[Wind](#)

a PM alternator was designed with only north poles?

Hi All,

This may seem like a really dumb question but here goes - what would happen if a permanent magnet alternator was assembled with only one direction of flux like this:

Would there be any generating going on? Would it produce a wierd type of AC with the sine wave displaced up of the normal axis? Or....

Just curious!

Have fun!

Ted.

[What would happen if](#) | 10 comments (10 topical, 0 editorial)

Re: What would happen if ([none / 0](#)) ([#1](#))

by Electric Ed on Tue Nov 25th, 2003 at 09:19:37 PM MST

([User Info](#)) <http://www.electric-ed.com>

You would get normal AC. Because magnetic flux lines form closed loops, each line returns to the magnet it started from, and "consequent poles" will develop in the iron rotor disc, between the "salient" (actual) poles.

You will have twice as many poles as actual magnets, but the flux will be weakened, due to the wider air gap at the consequent poles.

Also, the pole spacing will not be optimum, unless the consequent poles are considered when spacing the magnets.

Electric Ed

Thanks Ed,

Actually I was trying to figure out if it would be possible to have an alternator that would operate at 60hz, 2400 rpm. I have pretty much always seen multiples of 2 when it comes to poles - so I guess if you had 3 poles arranged as above, spinning at 2400 rpm it would give 60hz?

Thanks for your thoughts!

Having fun,

Ted.

[ [Parent](#) ]

Re: What would happen if ([none / 0](#)) (#3)  
by charged on Wed Nov 26th, 2003 at 07:13:49 AM MST  
([User Info](#))

Here's a configuration that works quite well. It maintains full flux-usage but never "flips" the core back through it's hysteresis loss zone.

Sorry the drawing is so crude. Using a scavenged transformer core and three sets of magnets spaced 120 degrees apart around the outside of the rotor, at 2400 rpm this would produce 120 full cycles per second.

It would make more sense to put a single rectifier diode on each winding, output those current pulses to a large electrolytic capacitor. Then use a power mosfet (or IGBT) to pulse the capacitor into a heavy 1:1 transformer with 50% duty-cycle 60hz pulses to get your desired AC frequency out of the secondary winding. It's just a simple chopper-inverter circuit.

Hope this helps.

### Low hysteresis PM Dynamo Generator

Re: What would happen if (none / 0) (#4)  
by monte350c on Wed Nov 26th, 2003 at 08:57:14 AM MST  
([User Info](#))

Hi Charged,

That's a pretty interesting idea! I'd love to give it a try.

My goal for this particular project is to make up a small alternator. I'd like 60 hz at 2400 rpm - I could do a 4 pole for 1800 rpm without much problem but I was interested to see if 2400 is a do-able number. This unit needs to be very simple without electronics.

A 2 pole unit will lead to 3600 rpm operation - too high for this application.

I gathered that the formula for frequency is (number of poles x rpm) / 120 but every textbook example of alternators I've seen so far always has poles in multiples of 2.

This made me curious about odd numbers of poles - ie. 3, 5, 7 etc. to tune rpm more exactly. Possible or not - I'm really kind of past the limit of my electro-magnetic knowledge at this point!!

But it's definitely a lot of fun - learning a lot.

Ted.

by RobD on Thu Nov 27th, 2003 at 08:46:11 AM MST  
([User Info](#))

I think you could run the magnets at an angle on this and cut down the cogging somewhat. I like the idea.

RobD

Re: What would happen if ([none / 0](#)) ([#10](#))  
by charged on Sun Nov 30th, 2003 at 01:16:37 PM MST  
([User Info](#))

If you are applying the low hysteresis method without inverting the stator poles, getting rid of the cogging is easy.

There is no limit to the number of magnets or stators you can "stack" on the axle. It is not limited to just three poles. You can make as many layers to the stack as you want and then just add more transformer cores that are in parallel with the axle shaft. Like my cruddy ascii drawing here.

```
E ||
E ||
E ||
E ||
```

Around the circumference of the rotor, use and EVEN number of stator sets and an ODD number of rotor magnets. Each set or "stack" of stator poles is wired in series with a single rectifier diode and it feeds an electrolytic capacitor.

Then just wire it up like so and shuttle your power around to wherever you like.

The two switches represent two heavy-current transistors or mosfets rated for at least 200v.

Each of the three capacitors on the left of figure 1 is wired to it's respective alternator as shown in figure 2.

for simulation of alternators etc

[Wind](#)

Hi all,

As I post this I'm downloading a program that promises to be really interesting!

[http://www.ansoft.com/about/academics/simplorer\\_sv/index.cfm](http://www.ansoft.com/about/academics/simplorer_sv/index.cfm)

It's for simulating design of all sorts of electrical components (like alternators for example)

The student version is available free at the above link. Suggested to have a high-speed connection - it's about 36 mb.

I'll run the program tomorrow and post the results. If you look at their web site this certainly sounds interesting.

Anyone else looked at this one before?

Sure would be nice to know if that new design you're thinking about would actually work or not!!

Ted.

Ted, I ran into the Maxwell 3D back when I was involved with stirling engines. I had run into it while surfing the NASA web on their stirling projects. I never downloaded it, but it sounds quite interesting... keep us posted on your findings if you download it!

Have Fun  
Ed

Re: Wow - good software download ([none / 0](#)) (#2)  
by [monte350c](#) on Mon Nov 24th, 2003 at 08:21:33 PM MST  
([User Info](#))

Hi Ed,

Downloaded both Ansoft's Simplorer and Maxwell programs last night. Just installed them but haven't started the learning curve with them yet. There's a program on their site called RMXprt which is for rotating electro-magnetic machines both motors and generators. Unfortunately, I found a price for this on another reseller's site (only \$36K!!). Oh well. At least pencils are cheap!

<http://www.ansoft.com/products/em/rmxprt/>

I'll post anything useful I can get out of the software I downloaded. Fun!

Ted.

[ [Parent](#) ]

Re: Wow - good software download ([none / 0](#)) (#3)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Nov 25th, 2003 at 06:40:33 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Yikes... 36k?? We can make alot of mistakes and still come out with money in our pockets as well as at least one successful turbine for far less than that... I'll stick with my calculator and multiple pads of paper for the design work... it does sound interesting though ... wish I knew some one who had the program and could look over their shoulder...

Have Fun  
Ed

Re: Wow - good software download ([none / 0](#)) (#4)  
by monte350c on Tue Nov 25th, 2003 at 07:23:18 AM MST  
([User Info](#))

Hi Ed,

My mistake - I think the \$36K is for the whole suite. RMXprt is available for (only!) \$9,400. I too wish there was someone around here who had this so I could try it out without the major investment!

I could build about 8 wind turbines for the price of that software....

I found another piece of software too for magnetic field analysis - femm 3.3 - I'll plug away at both of these as time permits. If there's anything good to be seen I'll post the results.

At least the price is right for these programs.

Am having fun!

Ted.

## [HAWT blade question](#)

By [monte350c](#), Section [Homebrewed Electricity](#)

Posted on Sat Nov 15th, 2003 at 06:39:34 PM MST

[Wind](#)

about the forces present on the blades...

Hi All,

I'm just finishing up a set of 3 blades for my downwind HAWT. I've been immersed in math and Excel for the past three days, and after reading Hugh Piggot's article on how to make blades about 100 times I think the various concepts have finally sunk in! By the way thanks Hugh for the formulas (off your Web page) I did the chord calculations as you suggested and the Reynolds number for each "slice" comes out pretty much exactly the same - it's nice to arrive at the same numbers by two different methods. Let's me know I probably didn't do anything wrong.

I'm using a TSR of 6.5 for this set of blades which will see them (hopefully) spinning at about 235 rpm in a wind of 18 mph.

Here's the question: It seems logical that the force of the wind acting on the 3 blades will try to push them downwind. (blade area x .00256 x V<sup>2</sup> (mph))

Is there anything else pushing or pulling them downwind? Does the lift being generated by the downwind section of the blade pretty much all get used up in rotating the blades, or is there part of that force pulling the blades downwind too?

I'd like to try to figure out the safety margin for the blade hub, and also the balance arrangement for furling.

Thanks again - still having fun!

Ted.

Ted,

"Here's the question: It seems logical that the force of the wind acting on the 3 blades will try to push them downwind. (blade area x .00256 x V<sup>2</sup> (mph))

Is there anything else pushing or pulling them downwind? Does the lift being generated by the downwind section of the blade pretty much all get used up in rotating the blades, or is there part of that force pulling the blades downwind too?"

The forces on the blade are lift and drag. they are aligned parallel to and at right angles to the direction of the wind that actually hits the blades as they spin.

If the speed ratio is high, then drag is almost in the plane of the blades. It slows them down but it does not push them downwind in the sense of the background windspeed.

Or maybe just slightly but not significantly. Drag has to be quite small or it will not have got up to that speed. So we are talking about a small fraction of very little.

Lift on the other hand is pushing the blades back quite hard (and slowing the wind at the same time - action/reaction).

Lift will have a small component driving the blades (or they would not be spinning) but most of it is backwards.

This is the dominant aerodynamic force on the machine.

There will also be centrifugal forces on the blades, and gyro forces when it yaw suddenly.

Hugh Piggott <http://www.scoraigwind.co.uk>

Thanks Hugh,

The calculation for thrust - I'm reading page 6 of the PDF file I got from your web site - (drag not considered)

$CL * (\rho / 2) * BC \Delta r * (tsr * V * (r / R) / \cos(\phi))^2$  gives a nice way to calculate thrust for a certain segment of the blade.

Is there a way (or formula) to calculate thrust for the whole blade?

The thrust, if metric units are used in the formula, that's in kg?

For example the blades I'm working on:

Diameter: 14 ft (4.26 m) (three blades)  
TSR: 6.5  
CL: .748  
Radius: 7 ft (2.13 m)  
Blade begins at 1 ft (.3 m) from the hub centre so the length of the actual blade is 6 ft (1.83 m)  
The chord at the root is 16" (.4 m) and at the tip is 3.7" (.094 m)

I'm not too sure about my calculations at this point! I'm coming up with a number of about 180 kg of thrust if the wind speed was 12 metres per second. (Trust me it will be furled long before that!)

Does that thrust number sound reasonable? Is there a formula I can plug into Excel for future reference? I really like putting formulae into Excel, it's so easy to play around with the variables.

Thanks again Hugh, learned a lot from your Web and hope to attend one of your workshop sessions.

Ted.

([User Info](#))

Hi Hugh,

(Again!!)

I should read more and type less!!!!

On the same page where I got the formula for the last post, I noticed:

$$(4/9) * \rho * A * V^2$$

I suppose in a perfect world that will give the thrust on the whole rotor, just divide by the number of blades to get the thrust on each blade.

Sorry about all the questions - one more - what units result from that formula if I use 1.29 kg m<sup>3</sup> for density of air, square metres for area, and meters per second for wind speed?

I'd like to boil it down to kg or lb.

Thanks again Hugh,

Ted.

by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk))  
on Mon Nov 17th, 2003 at 04:15:24 PM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

Ted,

Yes you have found the right formula for the total thrust.

$$(4/9) * \rho * A * V^2$$

I use 1.2 for rho.

In metric units, it boils down to Diameter<sup>2</sup> \* windspeed<sup>2</sup> / 24

giving the answer in kg force.

if blade diameter is 4 metres and wind is 10 m/s (22 mph) then the thrust would be about (4x4)x(10x10)/24= 67 kg or 146 lb.

Re: HAWT blade question ([none / 0](#)) (#6)  
by monte350c on Mon Nov 17th, 2003  
at 08:16:30 PM MST  
([User Info](#))

Thanks Hugh!

That now makes sense and I can get back to designing a safe hub for this blade set. They are going to be a foam core with fibreglass cloth and an outer layer of carbon fibre with epoxy resin (it doesn't smell and has a bit of 'give' when cured). I'll give the whole thing a coat of polyurethane 2 stage clear coat for UV protection.

Other than cutting the templates this system is quite easy, accurate, light, and strong. I use a hotwire on the templates to cut the cores. I've tried a bit of wood carving and I guess I just don't have the knack. I'll post some pictures when they're done.

Thanks again for the help Hugh - it's nice to learn from others - I won't live long enough to make all the mistakes myself!

Ted.

It's only 48 kb but works great to print your wing profiles...

Hi all,

I've been using Xfoil to work with wing profiles, and it's a great program that lets you take an airfoil, make changes, and see what the results are to flow, as well as the mechanical strength of the wing. But it's really obtuse to print from.

Found this:

<http://www.aae.uiuc.edu/m-selig/ads/register/AIRFOIL1.EXE>

which basically loads the profile, displays it on the screen. You can make some minor changes like scaling it up or down. Then it will print a good quality profile to your PC printer. Two good things, it solves a problem, and it's free.

More fun than before!

Ted.

### [Plans for Gauss Meter?](#)

By [monte350c](#), Section [Homebrewed Electricity](#)  
Posted on Fri Nov 7th, 2003 at 10:39:07 PM MST [Wind](#)

**Anyone know of plans for a home-built Gauss Meter?**

Hi All,

After my first alternator, (and looking towards building some more) and reading many posts here on the board, it seems like gauss in the airgap is a very important subject. BUT - I've pretty much been flying blind. I'd love to be able to build something as a stand alone meter or something that would attach to my Fluke 85 to measure gauss in the airgap...

Ted.

2800 Watts @ IDLE ([none / 0](#)) (#1)  
by [wdyasq](#) on Sun Nov 2nd, 2003 at 07:23:14 AM MST  
([User Info](#))

WOW, they are talking some serious power 200 amps at 14V for today's cars. If one were using the new 42 Volt system we would be talking 8.4 kW at idle and 14.7 kW at 6000 RPM with a peak of 525A making over 22 kW - I guess that is for 20 seconds or the magic smoke appears, whichever comes first.

I'll be combing the wrecking yards looking at all the wrecked, junk Maybachs I'm sure are there for give-a-way prices. Does the color of the vehicle matter? If not, I'll take the one the Easter Bunny drove.

Ron

Sounds interesting though were still talking auto engine speeds of 6000 RPM, I'd like to know if the technology will be applicable to lower speed wind applications, 600 RPM and lower.

The technical description is as usual is vague, though it sounds like there using some form of synchronous rectification. This could enhance power delivered by reducing losses in conventional rectifiers. considering the typical alternator with two rectifiers in circuit at all time a voltage drop of 1.2 volts at 50 amps works out to 60 watts of power lost ( $P$  or  $W=VxA$ ). Perhaps one of us needs to explore synchronous rectification for use in PMA's.

Dr.D

Re: HMMM anybody good with a soldering iron?

([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

From what I understand is that FETs have less losses, so they are hooking them up in a bridge rectifier layout, and turning them on and off at zero crossing on the waveform. sounds like it would be very easy to make electronic relay/rectifiers.

>=- W o o f -=<

Re: HMMM anybody good with a soldering iron?  
([none / 0](#)) (#4)  
by RobD on Sun Nov 2nd, 2003 at 09:44:24 AM MST  
([User Info](#))

I did not look at the circuit but I imagine this is synchronous rectification where the diodes are replaced by low  $r_{ds(on)}$  FETs. For those of you who don't understand, this is not an alternator that IR has developed as far as I can see. It is a way to replace the diodes in the alternator which allows very high current to be developed at low losses.

RobD

Re: HMMM anybody good with a soldering iron?  
([none / 0](#)) (#5)  
by monte350c on Sun Nov 2nd, 2003 at 01:18:43 PM MST  
([User Info](#))

Hi All,

I guess that's what got me so excited about this idea - if you're putting out 600 watts and you have a chance to increase that by 25% in the recifier stage by changing from diode to mosfet - it's certainly worth a try.

It sounds like the hi-amp project they're talking about is more or less another claw-pole alternator. That of course is interesting too, but how 'bout using this technology on a PMA? Especially on the smaller mills it could really shine.

Ted.

Re: HMMM anybody good with a soldering iron?  
([none / 0](#)) ([#6](#))  
by RobD on Sun Nov 2nd, 2003 at 09:59:35 PM MST  
([User Info](#))

Ted,  
You might want to look up synchronous rectification on google and see what you get. The technology has been around awhile but it sure is nice to have it in a pre-made package.  
RobD

Re: HMMM anybody good with a soldering iron? ([none / 0](#)) ([#7](#))  
by monte350c on Mon Nov 3rd, 2003 at 08:09:58 PM MST  
([User Info](#))

Thanks RobD,

Actually I've spent quite a bit of time looking for a MOSFET synchronous bridge rectifier circuit without much success I'm afraid. Maybe there hasn't been too much of this because of the low current capabilities of the older MOSFETs compared to the units mentioned in that IR article. I did another post about bridge rectifiers that links to an interesting site - it lets you play with the firing angle for a controlled bridge rectifier and see the output that results.

Anyhow - if you come across a circuit for this MOSFET bridge rectifier thing please post! I'm going back to cutting some NACA0015 foam cores for my Darrieus!

Ted.

[Wind](#)

They have to be spun too fast....

Hi all,

This probably falls into the hare-brained scheme category but here goes:

What would happen if the field on a Delco or other automotive alternator was fed on a diet of carefully phase controlled AC? Anybody think it would be possible to fool the stator into thinking there's more poles going by? It'd reduce rpm but really not sure if such a thing is even practical?

Ted.

Having fun & asking lots of questions!

[Delco alternators](#) | 3 comments (3 topical, 0 editorial)

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Ted

Don't know about the ac thing. I recently posted on some modifications to a GM alt to reduce rpm requierments. I prefure to replace the rotor with NEO magnets. This way no power is wasted energizing this coil. I think your first 50 watts gose to just make this electromagnet work.

However I did an expiriment with a tape drive/servo motor wind genny and a GM alt. The small tape drive wind genny supplied power to the rotor coil in the GM alt. The GM alt wind genny had its own set of blades. These 2 machines worked as a team.

4 amps from the tape drive genny was connected directly to the GM alt rotor no other connection to these 2. 4 amps was all that was needed to energize the GM alt rotor. However the tape drive can do an easy 10 amps and peak out around 27 amps.

Also made some mods to the GM alt wire scheam. There was a post about this last week or so.

Hey TomW help could you post that post here or tell us where it is. The bottom line was, getting about 30 amps at 30 mph from the GM alt with direct mounted blades.

Thanks

JK TAS Jerry

([User Info](#))

Hi Jerry,

Thanks for the info - I think this is the post you were talking about?

<http://www.fieldlines.com/story/2003/10/3/2301/87723>

That's very interesting, and when you tried your blades on the GM alternator with the tape drive powering the field of the alternator, did you get any performance specs in lower winds - like 18-20? The reason I ask is it seems there is always a lot of wind around where I live, especially in the winter, but always from 15-20 mph. A lot of the commercial units (usually rated at 28 mph) would only be sort of putting along at those speeds - and the net effect is a rather large lightening of the wallet without much "amps" to back it up! So I'm always interested in hearing about what's going on below 20 mph. I'm beginning to see the brilliance in your idea of a bunch of smaller machines too. Couple of questions -

1. Have you tried anything with the smaller squirrel-cage motors as induction generators - or have they all got PM cores?
2. Any bigger versions of those blades available?

Thanks again Jerry!

Ted.

[ [Parent](#) ]

Re: Delco alternators ([none / 0](#)) (#3)  
by Jerry on Fri Oct 31st, 2003 at 11:55:05 PM  
MST  
([User Info](#))  
<http://www.dplusv.com/Photo-03.html>

Hi Ted

At 20 mph I was seeing 10 amps and at 30 mph the meter was reading 22 amps. The neo magnet version of the GM alt did 25 amps at 30 mph.

I have not tried a small or any size ac motor as an induction generator yet. Although the idea is tugging at me.

In the beginning it was tape drive motors but most have been ac motor converted to pma,s.

As an example the GARBOGEN with a 4 blade 49 inch plastic prop does around 15 amps at 20 mph and 40 amps at 30 mph. Also see a few amps at 5 mph. This thing smokes my lazy 403. The GARBOGEN is a 1 hp converted garbage disposal motor. It uses 4 \$5.50 curved neo magnets. The blades are 22 3/4 inches long. You can use extensions. But so far I've had best luck under 50 inches. I've built a couple 62 inch but get better results around 50 inch. I've also seen 80 amps at

45 mph and I've wind tested them to 68 mph.  
This was the limits of the cuntry road and my  
S-10 pu. The blades held up fine.

JK TAS Jerry

## [D-OH!](#)

By [monte350c](#), Section [Homebrewed Electricity](#)

Posted on Tue Oct 28th, 2003 at 08:13:35 AM MST

[Wind](#)

Miscalculation on my part for RPM and resulting VAWT confusion!

Oh Brother!!

Somehow my addled brain was using frequency = (poles x rpm)60 to calculate rpm. I was measuring the frequency with a Fluke meter and working backwards to get rpm. I read recently in another post about having to account for the south poles, and have since checked in several reference books and the correct formula is:

frequency = (poles x rpm) (2 x 60)

The highest consistent frequency I measured from my 24 pole alternator was 50 hz, and on that day I was getting wind gusting from 16 to 19 mph. Guess that means the Savonius blades were doing 250 rpm?? So the TSR on those 18" diameter blades was in the .8 to .9 range? There was a small load on the alternator too consisting of 3 x 25 watt (120 volt) light bulbs, one on each phase.

If it was totally unloaded, and I'm sorry I didn't test it that way, I wonder if the TSR would have gotten to 1 or... maybe better?

Interesting - time for more testing! Ed, you mentioned that this type of rotor likes to be loaded down to about 1/3 of its free rotation speed to extract the most from it. So I would have had to load it to about 80 rpm that day?

Still learning (obviously) and having a lot of fun!

Ted.

[D-OH!](#) | 2 comments (2 topical, 0 editorial)

Re: D-OH! ([none / 0](#)) ([#1](#))

by [monte350c](#) on Tue Oct 28th, 2003 at 08:16:38 AM MST

[\(User Info\)](#)

Those formulas somehow dropped the "/" when I posted - this is what I meant:

I was using frequency = (poles x rpm) divided by 60

The corrected formula should read: frequency = (poles x rpm) divided by (2 x 60)

Ted.

Hi Monte, There is a formula to calculate the savonius, or any drag type turbine which you can find the "optimum" output of the machine...

$.5 \times .00492 \times \text{Area} \times (\text{Windspeed} - \text{Rotor speed})^2 \times \text{Cd} =$   
pounds of pressure on the rotor wing

Area = Area of either the downwind or upwind side in square ft

Windspeed = MPH

Rotor speed = MPH

Cd = drag coefficient

Savonius has a drag coefficient of around 1 on the downwind side and about 0.2 on the upwind side.

When calculating the upwind side remember to add the rotor speed to the windspeed.

Optimum extraction is at around a TSR of .33

You can convert the pounds on the blade to HP then HP to watts...

$\text{lbs on the blade} \times \text{Radius} \times \text{rpm} / 5252 = \text{HP}$

Then of course  $\text{HP} \times 746 = \text{watts}$

The "torque", you'll notice, from a locked rotor drops drastically as rotor speed picks up. You can calculate your start up torque by leaving out the rotor speed in the formula (locked rotor readings)... the start torque is quite high depending on the wind. My savinious will start rotating in a 3-4 mph wind although very slowly... its usually the only one spinning on calm days.

Lots of Fun!!!

Ed

More Volvo parts, less custom fab work...

Hi DanB,

Ever since I read your first post on using Volvo stuff I really liked the idea, the less custom fab work the better. But I wanted larger diameter than a brake disk so my first alternator uses custom water-jet cut pieces. OK but expensive, and fairly heavy rotating mass. Last night I came up with this idea: Cut 2 circles out of 3/8" plate, the ID maybe 1" smaller than the OD of the Volvo disk, and the OD the size you want for the new alternator. Put one of these on top of the Volvo disk and the other on the bottom. Drill through both and the Volvo disk and sandwich the three pieces together. Something like this:

Then there's just one rotating item, in a stock location on the hub. There could be spacers between the disk and the steel circles if more room is needed for the stator. I will be giving this a try for my next alternator.

Re: For DanB idea for big Volvo based alternator ([none / 0](#)) ([#1](#))  
by DanB on Mon Oct 27th, 2003 at 08:47:07 AM MST  
([User Info](#))

Funny you bring that up... I've thought a lot lately about exactly the same thing!

The problem with the Volvo disk... is limited diameter. 2" tall magnets are the max we can use - and of course, the circumference is an issue too. I think they are adequate for pretty big alternators, but... I've got this urge to try something a bit larger.

Anyhow - I thought about it, and it may well be the best way to go. As it turns out... I've decided to not use brake disks in the next larger one and instead I've cutout some 14" diameter disks from 3/8" steel, and I'll be biting the bullet and doing a bit of extra fabricating I guess..

But yes, you're right - that would work quite well I'm sure and it may be the simpler way to go, hard to say...

Seems like... the more fun we have the more power tools we need!

Re: For DanB idea for big Volvo based alternator ([none / 0](#)) ([#2](#))  
by JB on Mon Oct 27th, 2003 at 10:29:44 AM MST

power tools? dream on. after spending days filing out a volvo disk i bit the bullet and paid someone to turn the hub down for me. at least doing it this way i can use any volvo disk without having to pay out for machining twice. had a dream about finding an abandoned machine shop full of lathes and milling machines and folders and stuff. oh by the way i filed out the wrong disk just to rub it in.

having as much fun as you have with a battery drill and a jig saw and a 300 watt inverter.

bob

I have a 19-20" diam. thick steel disk I got from "Agri-Supply" years ago to make a disk plow out of. It's got about a 2" diam. hole in the middle. Anyway, it was cheap from what I remember and I think there's different sizes, if you're interested.

Already have an 8-bolt idler hub awaiting disks to build such a 'sandwich'...

Re: For DanB idea for big Volvo based alternator ([none / 0](#)) ([#5](#))  
by wdyasq on Mon Oct 27th, 2003 at 03:53:42 PM MST  
([User Info](#))

As one built larger diameter rotors, some interesting weight reduction ideas could be incorporated. Also, with the proper design, the rotor plates might become a sandwich. The magnets could be in pockets. There would be little need to glue the magnets on and all the magnets would be properly located if the parts were done properly.

BTW - I think wooden templates could be made to locate -centers- and a drill press might be used to bore rather large holes with the proper - and not real expensive, tools.

Ron

Re: For DanB idea for big Volvo based alternator ([none / 0](#)) ([#6](#))  
by DanB on Mon Oct 27th, 2003 at 05:04:53 PM MST  
([User Info](#))

yes, we could make a sandwich... the rotors could ultimately wind up as one piece so they never had to be seperated, and if the stator is made in two parts it could slip into the slot on both sides. I think, once the magnetic forces get so strong this could have advantages and be a good bit safer.

Re: For DanB idea for big Volvo based alternator ([none / 0](#)) ([#7](#))  
by monte350c on Mon Oct 27th, 2003 at 07:13:12 PM MST  
([User Info](#))

Hi DanB,

Good idea, I was thinking about making a mold out of polyethelene or another plastic that doesn't stick to fiberglass (test it with acetone). The mold would hold three coils only. It will have small holes drilled in through the outer edge to pass the wires out through. Plus a tapered 'core plug' to go in each coil center (ventilation!). The mold will be sort of pie-shaped and on the two cut edges of the pie there will be plastic pins that will go into the fiberglass and hold each coil to its neighbour.

I figure by casting them in 3's the mold will be quite small, so it'll be easier to make it exactly a certain size (ie. to fit between the two rotor plates) and keep a close air gap. Each pie-shaped piece will have two small holes on the outer edge that will mount to a stator ring supported on the alternator frame. So the rotors never have to come apart and the whole thing ends up being quite strong. Also easy to change one or more stator coils. It IS fun!!

Ted.

([User Info](#))

I have just completed assy of my 1st alternator and had problem with disc diameter being too small,so i decided to just remove them completely.

I then machined 2 new discs,drilled and tapped 5 more holes in hub to hold discs.

5 studs go from rear of back disc to front of blades,other 5 screw into hub and bolt front disc on.

If you do this just remember to thread discs so a jacking plate can be made for seperation.

if i build a another one i would do it the same way.

hope this helps

Check this out

Maybe you will get some ideas. Just a reminder that the forces that the magnets can put on the disk may be big so make the disk assembly strong!

Just came across this site.....

Hi All,

As usual while looking for something on the web I came across this site which was totally unrelated to what I was looking for!

<http://www.goldenmotor.com/frame22-hubx.htm>

There's a couple of low RPM brushless DC hub motors that look interesting, and the prices listed at the bottom of the page seem fairly reasonable too.

Looks to me if you combined a couple of those plastic pipe blades posted by zubbly and one (or more) of these little motors you might have a good cheap source for 400 to 500 watts.

Ted.

looks like theyre made in china. Pretty neat though - and the prices are great. As they are wound, they are not 12 volts, and the rpm are pretty low. So I suspect they might make for good small 12 volt windmills... better might be 24 volts. They all seem to be 24, or 36 volts and the rpm are real low, so I think they might not be quite right for your average HAWT. Hard to say though - itd sure be fun to experment with one.

## [Number of blades 3 or 4?](#)

By [monte350c](#), Section [Homebrewed Electricity](#)

Posted on Sun Oct 12th, 2003 at 06:47:35 PM MST

[Wind](#)

About to launch into a Darrieus experiment...

and I have thought of a good, strong, and mechanically simple method of dealing with 4 blades instead of 3. Are there any factors I should be aware of that differ from a horizontal turbine for blade number calculations?

I'm aiming for a solidity of around .24 with 4 blades. The planned unit will be 10' diameter, 6' high wings. Planned rotational speed of 150 to 200 rpm.

Have done a lot of other calculations for Re, centrifugal force, tip speed etc.

Is there any reason I have never seen a 4 bladed Darrieus?

[Number of blades 3 or 4?](#) | 8 comments (8 topical, 0 editorial)

Re: Number of blades 3 or 4? ([none / 0](#)) ([#1](#))  
by [johnjach](#) on Mon Oct 13th, 2003 at 08:53:37 AM MST  
([User Info](#))

Go the the net at [www.windharvest.com](#). This is a commercial outfit that has made four-bladed Darrieus turbines for years and actually has them in operation. They're obviously too big for residential application but the photos are great and should give you a few ideas if not inspiration.

Also, go to the U.S. Patent office at [www.uspto.gov](#) and search for Darrieus patents. There are a lot of them and they're a lot of fun looking at the various ideas. If you have any trouble searching patents, do another posting on the board and I'll give you specifics on how to search.

One more resource: use your search engine and look for Sandia Laboratories. They also have volumes on VAWTs.

Re: Number of blades 3 or 4? ([none / 0](#)) ([#2](#))  
by [monte350c](#) on Mon Oct 13th, 2003 at 10:42:56 AM MST  
([User Info](#))

Hi - and thanks for the windharvest link. I've been (extensively) looking at the VAWT archives at Sandia, there is a lot of good reading there, and as you pointed out at the USPO.

Looking around at the [windharvest.com](#) site answered another question - looks like a 4 blade unit will be self-starting.

Thanks again for the info! Now back to having fun!

by johnjach on Mon Oct 13th, 2003 at 01:44:40 PM MST  
([User Info](#))

Forgot to tell you this in my first comment: I also am intending to build a Darrieus turbine and I bought the NACA 0012 aluminum airfoils from MTM Scientific . They sell it at \$7.00 per foot and that's pretty good for something professionally extruded. As of today, they only have about forty feet left so move quickly if you want some ([www.mtmscientific.com](http://www.mtmscientific.com)). I intend to do some experimenting using the piece I bought to make a mold and then make duplicates from fiberglass resin strengthend with carbon fiber rods--hope they withstand the centrifugal forces.

If you're interested in VAWTs, also check out [www.ropatec.com](http://www.ropatec.com). This is a unique machine which appears to be sort of a "Darrieus-Venturi" concept. Ed Lenz of this discussion board made one similar to this. Check out the "Lenz Turbine" on [www.windstuffnow.com](http://www.windstuffnow.com). If you want the proportions of the Ropatec machine, again go to [www.uspto.gov](http://www.uspto.gov) and check out patent no. 4490623. For the "Darrieus-Venturi" concept, check out patent no. 4537559.

I'm starting construction on mine soon and I'll keep the board posted.  
Good luck.

this vawt stuff is really addictive hehehe doing a crash course in aerodynamicns. found this site very useful.  
<http://www.dreeseencode.com/> they do a 30 day free demo. i can almost work out what a NACA 0012 is now. was thinking if we work out the best shape for the airfoil i will see if it is possible to get someone to make one with a standard metal folder then use that as a mold. wonder if aluminium filled with that expanding foam used for fixing gaps in window frames would work to stiffen it up?

having lots of fun

bob

Hi Guys!

You're right about the VAWT's. I can't stop thinking about this - though I know very well if I just put a HAWT prop on it my gen would be flying a lot sooner!!

About the best program I've found so far for playing around with airfoils is "X-Foil". The great part is that it's free, takes endless custom settings, and comes with a huge database for many different NACA and other profiles. Based on what I've read at Sandia, I think the NACA0015 is a pretty good starting point.

You can download the X-foil program at this link:

<http://raphael.mit.edu/xfoil/>

There is a pretty good read-me attached, and with a bit of prodding the program will save a file to the hard disk in Adobe Acrobat format. Then you can use your printer software to scale and print it. When the program loads, type NACA0015 (enter) then ppar and (enter) and it will plot the foil on screen. That's if you want to use the NACA0015 profile - there's lots of others to play with too.

The program works in a DOS window, I run W2000 and it works fine. Not a demo or time limited offer either, it's the full program.

I've decided on a 4 blade approach since it's mechanically simpler - with 4 x NACA0015 profiles about 6 to 8" chord (watch the rpm, rcf, tip speed, and Re number!)

All factors = compromise in one way or another.

I have done 1 test wing in foam core, laminated with 2 layers of epoxy fiberglass and vacuum bagged. I am amazed by the strength and light weight.

Seems every step of the way you have to invent something to continue. But that's the fun part, and as we say I am definitely having fun!

[ [Parent](#) ]

Re: Number of blades 3 or 4? ([none / 0](#)) ([#6](#))  
by monte350c on Tue Oct 14th, 2003 at 08:21:11 PM MST  
([User Info](#))

Here's a screen shot of the X-Foil program with a NACA0015:

And here is the same thing, but output from the program to a PDF file (actually PS but who's counting!)

From the screen shot you can see the plot points, you can modify those and see the results. Also the program will give you lots of info about the foil, such as bending moments, and airflow.

Re: Number of blades 3 or 4? ([none / 0](#)) (#7)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Oct 15th, 2003 at 08:03:35 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've made them using rubber molds and pouring a 2 part plastic mix in the mold. Makes nice ribs for the darrieus wings. The Main spar is aluminum and to stiffen them up for higher rpm and/or longer spans to a support you can add 2 3/4 inch thinwall tubes.

The first one is made from plywood, the rubber is poured over the plywood and cured. Once the mold is done you can make as many as you want. The rubber and plastic is from [www.smoothon.com](http://www.smoothon.com) and part for part ( as well as the ease to use it) is quite inexpensive. Each rib costs about 40 cents to make. I cover them in aluminum using contact cement then add rivets in key locations. These could be stiffened up by doing an expanded foam fill. A 3 ft wing comes in at around 18 ounces using 1" .083 wall aluminum tubing.

Fun stuff ;o)  
Ed

## [Alternator output vs. rpm](#)

By [monte350c](#), Section [Homebrewed Electricity](#)

Posted on Tue Oct 7th, 2003 at 08:34:22 PM MST

[Wind](#)

Question about the relationship between output and speed...

Hi All,

Sorry in advance if this has already been dealt with!

What's the relationship between the voltage and rpm for a pm alternator??

I have been able to fairly accurately measure open voltage of 27.5 VAC at 100 RPM and 40 hz on my first alternator. I took the measurement on one of the three phases.

Does the voltage vary in a linear way with rpm?

Also how does one go about doing actual output testing - let's say I can attach my alternator to a gas motor (geared down for a range between 75 to 300 rpm). Keep adding load until... what should I be watching for? I've got a Fluke 85 and that's about it for instrumentation!

The specs on the alt.:

Resistance for 1 phase: 2.8 ohms

# coils: 18 (80 turns of 18 AWG ea.)

# magnets: 24 x 2 dual rotor

diameter @ magnet centerline: 15.25"

Thanks in advance for any help!!

[Alternator output vs. rpm](#) | 9 comments (9 topical, 0 editorial)

by [wpowokal](#) on Tue Oct 7th, 2003 at 11:51:13 PM MST  
([User Info](#))

Ok my two bobs worth,

Output unloaded will be aproximatly linear, usefull for determining cut in speed, oh remembering to convert AC back to DC volts.

As to testing on a motor the most important parameter I would monitor is current output as one could easily overheat the stator. Resistance of 2.8 ohm/phase at 5 amps/phase =  $5 \times 5 \times 2.8 = 70$  watts of heat/phase.

With a single metre, if it has a DC current measuring capacity I would measure one phase output. Remembering multimeters are only short term rated so dont leave the metre in the circuit for lengthy periods.

Once connected to a load the output voltage will depend on the load as it would if connected to batteries. ie output

voltage is "somewhat" stabilised at load voltage, subsequent increases in speed will result in more current.

If your load/s have known watt values at a given volts you could use the metre to monitor volts whilst adding load, because knowing watts gives amps (voltsXamps = watts), always remembering not to melt the stator.

hope this helps more than confuses  
regards Allan

Hi -

"What's the relationship between the voltage and rpm for a pm alternator??"

- it's linear, so double the rpm and the voltage doubles.

"Resistance for 1 phase: 2.8 ohms"

That's quite a lot unless you're goal is fairly high voltage.

What voltage are you planning to charge at? If it was 12 or 24 volts, I'd consider rewiring the coils so that you have a higher cutin rpm and lower resistance.

"# coils: 18 (80 turns of 18 AWG ea.)"

So do you have 6 coils in series for each phase?

How big are the magnets? Sounds like a heck of an alternator! Love to see some pictures.

Re: Alternator output vs. rpm ([none / 0](#)) (#3)  
by monte350c on Wed Oct 8th, 2003 at 12:42:12 PM MST  
([User Info](#))

Hi Dan,

Thanks for the answers. The plan is to leave the voltage fairly high, send the AC to the house, then rectify it. Figured there might be some savings in wire this way - it's about 200 feet to the base of the pole.

Yes, there are 6 coils in series for each phase.

The magnets are teeny by comparison to your Volvo projects! Actually since I'm fairly new at this, I looked all over near where I live, and ended up buying the magnets at Lee Valley, they were the biggest they carry. They are 1" diameter, and 1/8" thick neos.

So with my magnets in hand, I thought about a dual rotor machine, with 24 magnets per rotor. I ended up making the rotors to suit the magnets. There's a 15.25" diameter around the magnet mounting circle.

( $15.25 \times 3.14159 = 47.9$ ) which gives about a 1" space between each magnet. Since I'm not too good with the protractor and compass (!) I did up a couple of charts in Excel - one for the magnets:

and one for the coils:

Then printed them out, after a bit of fiddling around got the magnet chart to 15.25" diameter. My printer has a poster printing feature - it prints a piece on several sheets, then you just tape them together for a full size chart.

I took this pic to the machine shop:

In addition to the four holes to mount it to the trailer hub, I drilled 2 more 3/8" holes and tapped them. I can screw 3/8" bolts in those extra holes, the bolts push the rotor up off the hub for removal (and less exciting installations!)

The coils are 1/4" thick, and I put down 2 layers of fiberglass cloth in the mold, then the coils, then filled it with resin, then 2 more layers of cloth. The lid went on plus lots of weight. When the stator came out it's exactly 3/8" thick and very flat, so I was able to hold an airgap of about 1mm between the magnets and the stator.

Here's the finished unit:

The base is a 2" square box tubing with 1/4" wall.

At this point I have been playing around with different blades - tried a small Savonius set on it. I wrote more details about that in an earlier posting. It's under the title "I promised a few pics".

Next up I plan to put a fair size set of Darrieus wings on it. The wings are 10' long and 6" chord. They're foam core with epoxy fiberglass coverings. Light and strong. There's some more detail in that other post.

Of course if that doesn't work out then I'll try some 3 bladed horizontal designs.

Really glad to have come across this board, and in particular I owe you a big thank-you for all the help on how to do stators. This really is a lot of fun!

([User Info](#))

hi all been thinking about this speed thing a bit and it seems to me that to get an idea of the probable voltage all other things being equal, which i know they aren't, what is needed is the formula for time taken for one magnet to pass over one coil. this will depend on the size of the magnet and the diameter of the rotor. so the actual rpm is not as important as the transition time of one magnet over one coil. can someone with a better memory than me tell me the formula for working this out please. i did know it from building rotary spark gaps for tesla coils but can't remember it for the life of me. i think it is called the dwell time.

still havin fun

bob

Re: Alternator output vs. rpm ([none / 0](#)) (#5)  
by troy on Thu Oct 9th, 2003 at 12:37:26 PM MST  
([User Info](#))

I don't think dwell time alone will predict relative voltage very well. A better criterion would be to calculate the speed of coil vs magnet, which is easy:

$(\text{rpm}) (\pi * \text{diameter in inches}) / 12 = \text{linear feet per minute}$

if you double the linear feet per minute, either by increasing rpm or by increasing diameter, you pretty much double the voltage, until the stator starts heating up and losing efficiency due to increased resistance. We can't make any absolute predictions about voltage without knowing a bunch of other variables like magnet strength, coil turns, resistance, airgap, magnetic circuit efficiency (difficult to quantify), temperature and so on.

Good luck and have fun,

troy

Re: Alternator output vs. rpm ([none / 0](#)) (#6)  
by deezl on Thu Oct 9th, 2003 at 03:36:30 PM MST  
([User Info](#))

Hi, you could try this one

$N * A * R * B * P = \text{voltage}$  N= #of wire turns in coil. A= area of 1 magnet in square meters (square " \* .000645). R= R.P.S. (rpm/60). B= tesla in air gap (gaoss/1000). P= # of magnet poles.

Could re arrange to find missing #'s.

Deezl

Re: Alternator output vs. rpm ([none / 0](#)) (#7)  
by monte350c on Thu Oct 9th, 2003 at 09:06:23 PM MST  
([User Info](#))

HMMMM!!

About the only thing I really don't know for sure is the tesla in the air gap - but I do know it makes 27.5 volts @ 100 rpm so...

$$80 * .00051 * 1.67 * 16.81 * 24 = 27.48$$

So for a slightly larger version of this alternator, assuming I leave all other things the same, but just increase the number of magnets to 32 (24 coils) with a 20" magnet mounting circle instead of 15.25" and change the rpm (to 112.5)-

$$80 * .00051 * 1.875 * 16.81 * 32 = 41.15$$

If I could find a nice transformer with a 3:1 secondary:primary ratio I could have some nice 123/60hz ac voltage.

Does that make any sense?

Re: Alternator output vs. rpm ([none / 0](#)) (#8)  
by yossarian on Fri Oct 10th, 2003 at 11:57:27 AM MST  
([User Info](#))

Here's a link to some equations.

<http://icosym-nt.cvut.cz/course/node53.html>

As I understand them, the voltage is dependent on the radius \* angular velocity \* cosine of the angular velocity. I find that a little surprising, as I would have guessed it would be directly dependent on the linear velocity (pi \* diameter \* angular velocity). Hope that helps.

Re: Alternator output vs. rpm ([none / 0](#)) (#9)  
by bob golding ([yubba at clara dot net](#)) on Fri Oct 10th, 2003 at 01:18:16 PM MST  
([User Info](#))

thanks for all the equations guys. should keep me quiet until my Volvo hub is machined. As i have to pay for the machining getting the hub turned down to fit the brake rotor, rather than the other way round. means i can try differant rotors on the same hub. yes angular velocity is the one i was having trouble remembering. its going well should start on the stator this weekend.

still having lots of fun

bob

Here are a few pics of my home made electricity adventure so far...

Hi all,

Thanks for the replies about the stall question I posted last night. I'm trying to find out if stall regulation of speed is worthwhile considering or not.

I built a 15.25" diameter alt. with 18 coils - 18 AWG, 70 turns ea. with 24 neo mags 1" x 1/8" round on each rotor. The rotors I had made at a local machine shop for about \$75 total. They are made out of 3/8" steel plate. I had 4 cutouts put in each one to cut down the weight a bit. The rotors ride on a 4 bolt trailer hub/axle, which is welded to an X-shaped frame made out of 2" box tube, 1/4" wall.

I wound the coils using the usual sort of former - 2 pieces of 3/8" plywood, but I used a 1/4" dowel in each of the 4 corners of the coils, with a spacer in between of about 1/4" thickness. I cast the rotor with 2 layers of fibreglass cloth on both sides for strength. The overall thickness of the rotor is 3/8". The airgap on each side between the stator and magnets is a little under 1 mm (sorry about the mixed units!).

The first place this alt. ended up was on the bottom of a Savonius rotor assembly:

- [More on Wind](#)
- [Also by monte350c](#)

One day last week when the wind was at around 16 mph, this thing was turning at 125 RPM. The load was one 25 watt light bulb on each phase (48 ohms ea.) I measured the voltage on one of the phases by taking out the light bulb. The Fluke reported a peak of 34.5 VAC/50hz.

I hate to say it but I am undecided what will be flying on this alternator - Darrieus wings, or a conventional prop! Now that I've tried a small Savonius, I kind of get the idea that a big one would work - but there are problems with scaling these up. So now I'm making some foam core/fibreglass covered Darrieus wings to try on it. BTW it's EPOXY resin - not the normal styrene based stuff you get at the Auto Zone. I tried that and it melts the foam quite effectively!

I cut out some NACA0015 profiles using a home-made hot wire setup, and profiles from the excellent X-Foil program which you can download for free at <http://raphael.mit.edu/xfoil/> With a little prodding the program will create a ps file, which can be opened in Acrobat, then scaled as desired. It's pretty easy to make a vacuum bagging setup:

That's an old frig compressor - and the switch is from a water pressure pump - with a vacuum advance unit from a GM HEI distributor pulling on it...

Here's a pic of the first wing in the vac bag:

I'm aiming for 200 RPM or so with this test setup. It will be mounted to horizontal struts on the same frame where the Savonius now resides. About those wings - they do have to be strong, and light, due to centrifugal forces. At 200 RPM, and a 54" diameter on this test unit, the force involved will be about 30G! So if the wing weighs in at 2 lb. it will weigh 60 lb at speed. There's a nice mechanical brake on the top rotor with a long piece of rope attached if things don't work out!

Sorry for being so long winded! I'll post results of the Darrieus wings as soon as they are mounted. Again my sincere thanks to all you guys - I've learned a lot in a short period of time. And got a new hobby/obsession!

Fantastic stuff i gotta hand it to you, like the blades in fact i like the whole thing. have tested to see what wind speed the drag blades start up and when the alternator hits charging voltage? Something i havent tried on a large scale yet and thats a drag type vawt so im courious as to any data you may have on it.....sean

Re: I promised a few pics... ([none / 0](#)) ([#3](#))  
by monte350c on Fri Oct 3rd, 2003 at 02:22:05 PM MST  
([User Info](#))

Hi Sean,

The unloaded blades will start to rotate in about 7 mph worth of breeze. The alternator hits 12 volts AC at 40 RPM. The fastest I have seen this particular unit spin was at 125 RPM in a really stiff breeze of 16-20 MPH. The output at that point was around 35 volts AC. That day it had a load of one 25 watt/120 volt bulb on each phase. To measure the voltage I unscrewed one of the bulbs - this was at night, and I would say the bulbs were at about 1/3 to 1/2 their rated brightness. If it was more highly loaded, of course it would slow down. The blades are 18" wide and the stack of 4 is 56" high. For the next couple of days I'll be continuing to work on the foam core Darrieus blades. I'll mount them, probably removing a few of the Savonius sections and see what happens!

Re: Vawt's get a bad rap... ([none / 0](#)) ([#4](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Fri Oct 3rd, 2003 at 07:07:50 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

You really have to load the Savinous to about 33% of free speed rpm to achieve full power out of them. So if it runs no load at say 100 rpm's in a given wind then the best power extraction will be at around 33 rpm for that wind speed.

I think the VAWT's get a bad rap because the blades really extract power quite efficiently. They simply have alot of built in design flaws. You figure at any given time only half of the machine is extracting power, the other half is simply robbing the power. You calculate the entire area of the machine when in reality your only collecting from 1/2. Then consider what the downwind blade is doing... its moving away from the wind. This means your really collecting 1/2 of the machine and from a slower windspeed. So if the wind is 12 mph and the blade is running at 4mph your collecting from an 8mph wind. This also means the upwind blade is being held back by a 16mph wind. If you calculate exactly what the downwind blade is doing you'll find its collecting at over 50% efficiency.

Analyzing a 2ft x 2ft unit (4 sq ft total) in a 12.5 mph wind. Free

speed is 175 rpm so the optimum rotor speed would be around 58 rpm. The total watts available in that area would be around 39. The down wind blade makes about 3.23 watts but the up wind blades steals 1.12 watts leaving 2.1 watts harvested... pretty poor indeed.

Lets say your only collecting from the downwind side and the upwind is blocked off. That leaves you with only 2sq ft of collection area but your getting the 3.23 watts well geeze thats much better. Total available watts in 2sq ft at 12.5 mph is around 19 that jumped the machine up to 17% efficiency. But wait !! The blade is moving away from the wind so in reality we're only collecting from a 8.5 mph wind. There's only 6.2 watts available in that wind and we are getting 3.2 of that... (  $3.2/6.2 = .51$  ) Yes thats 51% efficient on the downwind blade. Getting very close to the Betz theory. So basically the machine gets a bad rap but the blade is quite efficient, It simply needs a bit of redesigning... without all the flaws.

Have Fun  
Ed

Hi Ed,

Yep - I kinda favor verticals too - that's why the emphasis so far has been with this configuration. I think there will be a way to do this - so even if it's going over ground previously covered I feel sort of compelled to keep trying (and of course having fun at it!). I liked your venturi ideas and this may be a good way to combine D & S styles to produce something good.

The trailer axle & hub I used for this alternator I feel will be able to accept quite a bit of loading. I am considering using a schedule-40 pipe with a flange welded to it that bolts under the hub bolts, about 6' long, with no top bearing.

The alternator is a fairly large diameter so it can develop some power at lower RPM's. I think for these power levels a gearbox or rpm step-up devices are not going to be to efficient.

Current plans will see a couple of different things attached to this. The first will be an upscaled Darrieus with NACA0015 wings. Big. (inspiration: [http://infoserve.library.sandia.gov/sand\\_doc/1977/771063.pdf](http://infoserve.library.sandia.gov/sand_doc/1977/771063.pdf)) The wings will be 10' high, the dia. 17'. Perhaps by eliminating the smaller diameter regions of the trop. shape, and using struts instead, good things will happen. The wings for this will have an aircraft type stainless control cable in them, running back through the struts and bolted to the torque tube for containment just in case...

I am working out moveable aerodynamic devices for the struts, rather than the wings themselves. Downwind deployment for startup, and deployment on all three sides for speed control (with a mechanical governor friction brake as backup, and a hydraulic caliper with master cylinder a long way from the tower as a backup for that!). This I suppose could be called an H-Bar D. setup. I like the idea of large diameter, since that way rpm and therefore RCF can be held to a reasonable level. If things go well I will be winding a bigger alternator.

The experiments I have been working on with vac bagging foam core wings look very promising. The first one out of the bag is a NACA0015 with a 7" chord - 5' long. Last night I

placed it on 2 chair backs and put a box of books in the middle that weighs about 60 lb. There was no deflection at all. These things are really strong, and very light. Boy am I long winded!

I'll post more as this develops!

[Wind](#)

Question about stall speed for turbine wings

Hi All - after doing lots of reading on this board, I've got a question. This is easily the most informative board I've seen for wind topics! I've really enjoyed Dan B's work on the triplets, and have had a good read through Hugh P.'s site too.

Using some of the things I learned here, I have built a dual rotor axial flux PM alternator. The diameter is 15.25", and each rotor uses 24 magnets. There are 18 coils in the stator. Testing gives 12 volts at 40 rpm, and 27.5 at 100 rpm unloaded. It's wired 3-phase star at the moment, but I'll probably change to delta. I'll post some pics within the next day or two. I digress...

The question I have, (possibly for Hugh P.) - I've read through most of the stuff about blades - and I can see the basics about profile, twist, taper - but is there a way to calculate at what rpm a particular profile will stall?

I do a little flying too, so from that experience we were taught that a wing will always stall at the same angle of attack regardless of speed etc.

Does the angle of attack relate to the apparent wind for wind turbine blades? And is there a way to ballpark the stall speed?

[New user - Stall speed question](#) | 2 comments (2 topical, 0 editorial)

Re: New user - Stall speed question ([none / 0](#)) ([#1](#))  
by [wdyasq](#) on Thu Oct 2nd, 2003 at 03:34:21 AM MST  
([User Info](#))

If one looks at the angles of attack, they should come to the conclusion too much power, rather than stalling, might be a problem with a turbine blade. The outboard part of the blade is stalled when stopped. As soon as any significant speed is attained, the tips "start flying" and are in a whole new set of conditions. These conditions, in my opinion, are created by the machine itself and stall angles become far less than critical.

The attach angle of the tips is low. With an 8:1 tip speed to wind speed ratio, it would be difficult, if not impossible, to stall the blade by increasing wind speed.

Ron

Monte why go to a delta? Stay a star and try paralleling some of the phases.

In NE Ohio we have wind but at the low end of the spectrum. With this in mind.

For what I'm working on is kind of in the same lines here. Building a twin axial. 10.5" brake rotors and rear hub off a Chrysler k frame car. I'm using 24(12 off my PMA for now) .5 x 1" squares N38?s. Each of the rotors has 12 equally space magnets and air gaps which fits fairly well in the middle of the braking pad surface. Was going with a 12 pole six paralleled star stator 3 phase but stator, but with thickness of this stator of 36 coils I believe will play a big facture in affecting flux strength. I've downsize it to a 6 pole stator with 18 coils two layers of nine coils. Thinking later could sandwich another 6 pole stator inline later on. The coils are wound in a wedge shape for parallel flux cuts. The wire size 22ga.at 90 turns each, which has a 3/8 thick footprint cutting the flux.

As for each coil the maxim current will be 3 amps (wire ampere little over). 90 turns for voltage. Now with 18 coils to play with my first attempt will be hooking up into a 6 pole 6 parallel star. Used the star over the delta config for greater voltage, and parallels for max current. From there I should have a reference point to start with.

Genentor wired in star 18 coils.

Phase 1 in parallel coils # 1,4,7,10,13,16

Phase 2 in parallel coils # 2,5,8,11,14,17

Phase 3 in parallel coils # 3,6,9,12,15,18

That's my start.

Don't have any graphics software to draw this, maybe some could here. For pictures I guess taking the some photos to Walmart to may then digital.

Bob

([User Info](#))

Let me try a guess,  
In 60 mph winds using a suitable sized rotor with a TSR of 8 I would guess about 500 watts. Cut in speed for charging batteries will be in the order of 600 rpm meaning about 25 mph winds for that prop.

Let us know what you test out at.

Re: PM motor ? ([none / 0](#)) ([#2](#))

Hi Hank  
Well it took me 2 days but I got the 200 lb genny in the test truck.  
That was a scary addventure?

Charging started at 10 mph at 5 amps, at 15 it hit 10 amps at 25 mph the amp meter was showing 20 amps.

The blade was a littel out of balance so i'm going to try a diferant blade.  
This blade was my plastic blades at 5 1/2 ft tip to tip.

I'm going to try a smaller blade. One of my 49 inches. Thanks for your help I'll keep working on it.

JK TAS Jerry

Sounds great,

Boy, my guess was off by a bit. Do you know what rpm you were getting at the various speeds?

Have fun and be carefull,

Hank

Yes that's more like it. NOT like the bottom one it's too large. Also I think you might want to make the legs a bit longer so the whole magnet can be seen thru the hole in the center of the coil.

Magnets passing parallel with the coil windings don't produce power. This is a waste of potential power.

The coils don't have to be perfectly rectangular, you may want to make them a bit trapezoidal to sort of fit to the shape of your magnets. Perhaps similar to the pic I have above in an earlier thread.

You may want to make your coils look more like Ed showed, sort of rectangular. You want the magnets crossing the wire at a right angles (90 deg.) not parallel. So the hole in the center should be larger then your magnets are wide and the magnets should just cross the legs of the coil.

Yeah, Itried rectangular before, but somehow the circular one gave more output :). But I guess it was my first "flat" coil. So, if I understand correctly, it should be like this? (or more like the bottom coil?).

With one magnet per pole, it's easier to be sure than with these HD magnets :) So.. just checking :) (And I think there are more people looking for answers like these in the future too :-) !)

I think thats close... the best bet is experiment I suppose. Id try the coils slightly larger. If it were me, If you're not going to break the magnets, then Id try to run them close together so the poles are as equally spaced as possible.

Jeremy,

Low carbon steel is probably the cheapest steel. Probably used in making cars. You may also find it in a Auto Body supply shop. It's soft and easy to work. You can also call a steel supply shop and ask about it. Key here is "low carbon" and that's what I would reccommend as being the most cost effective.

The strips are concentric rings insulated from each other. I used masking tape on one side for the insulation.

The pic here shows my stator. If you look carefully behind the coils in the center you will see the laminates. The width of all the laminates should be at least the size of your magnets and they serve the purpose of focusing and completing the magnetic circuit.

This greatly enhances the power capabilities of the genny.

Have fun,  
Hank

[4 component load control system](#) | 25 comments (25 topical, editorial)

Re: 4 component load control system ([none / 0](#)) ([#7](#))  
by Hank on Sun Dec 21st, 2003 at 09:06:08 AM MST  
([User Info](#))

I'm no wiz on electronics either but I think current is the limiting factor and not necessarily voltage. For instance you have those small glass fuses which, for arguments sake, are rated at 10 amps but 250 volts. They will fry at 10 amps even at 12 volts. I believe it's the internal resistance of the component that limits its current carrying capacity.

I guess another example would be using #14 wire to carry 1200 watts. In one case using 120 volts and 10 amps, in another case 12 volts and 100 amps. Both are 1200 watts but the wire will fry in the case of 12 volts and 100 amps.

But what the hell we will have fun trying and I hope someone else chimes in on this one.

By the way what type of genny do you have? Do you know what voltage it puts out and at what rpm, also your internal resistance of the coils?

[ [Parent](#) ]

Re: 4 component load control system ([none / 0](#)) ([#8](#))  
by charged on Sun Dec 21st, 2003 at 09:21:40 AM MST  
([User Info](#))

For the record, this can be "souped up" by using the triac to trigger a mosfet.

This difference will be that you need TWO mosfets and TWO triacs to control the mosfet gate to drive it positive.

OR, even simpler, put a FULL-WAVE rectifier across the generator AC and then use the single triac/transistor circuit to control the pulsed DC signal.

It's the same basic circuit you can use to discharge a capacitor bank. Bipolar transistors work better than mosfets for this application.

I see what you're saying, makes sense to me.

The genny I've been talking about has a 10 ft rotor and a 3-phase alternator. At around 1000rpms it makes 129volts, but I've only seen 52 volts with the 10 ft rotor driving it. The resistance of all the coils that make up each phase is 1.5ohms.  
Kevin

Great information and thank you for your replys. Once I get a chance to work with this I'll keep you up to date on how it's all working out. It sounds as if I should be able to get the circuit working, all I need is some more time. I can't wait to get this up and flying, with the weather we have had lately and I'm still working out the details of my tilt up tower it looks like Spring will be a realistic target. This is a great group and I'm having alot of fun. Any other suggestions or modifications to the control circuit as you guys out there work with it would be great to see posted. Thanks again,

Dave B.

## [Untraditional Magnet/Coil Shape/Spacing](#)

By [wooferhound](#), Section [Homebrewed Electricity](#)

Posted on Sun Dec 7th, 2003 at 10:52:57 PM MST

[Wind](#)

**But the coils are Not shaped like the Magnets**

I've got my wire and I'm winding coils now. I am making a Dual rotor machine with 6 magnets on each rotor. The Magnets are Large 2" x 2" x 1/2" Ferrite magnets, quite strong. However the rotors are too small at 9 inches in diameter.

So winding the coils has been a little bit of a problem. If I wind the coil properly (square to fit the magnet, hole size slightly smaller than the magnet) then the wire gets bunched up toward the hub of the rotor and limits the size that the coils can be wound.

I have seen genny designs here that use 2 magnets per coil, so that a South is crossing one Leg of a coil, as a North is crossing the other Leg of the coil. By making my coils triangular I was able get a Lot more wire in there, and achieve the arrangement of the second design with opposite poles on opposite legs.

This picture is not to scale and the real unit is much better constructed. Has anybody else tried this design where a single coil shares half of 2 separate magnets to get opposite poles on the two different Legs ?

I'm winding my coils from 19 ga magnet wire, 125 turns, 85 feet per coil, soon to be 6 coils. The triangular coils are giving me 5 volts at 240 rpm, loaded with a 6 volt 9 watt bulb. I will wind 3 coils in series, and then the other 3 in series. Two sets in parallel charging a 12 volt system.

Well , of course I would have to use the PVC Props (Zubblades).  
Probably a 4 blade, 5 foot Diameter. My machine will only be about 100 watts,  
give or take.

Your triangular coils will work much better as well as utilizing the space for more  
copper more efficiently. Are you building a single phase unit? Looks quite nice so  
far!!!

Have Fun  
Ed

Re: Untraditional Magnet/Coil Shape/Spacing ([none / 0](#)) (#4)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Mon Dec 8th, 2003 at  
01:12:03 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

It's 6 coils in all, at any instant, 3 of the coils will have North crossing them,  
these will be wired in series. At the same instant the other 3 coils will have  
South crossing them, This set will also be wired in series.

I will end up with 2 sets of 3 coils that are out of phase with each other. My  
thinking is that, at low wind speeds I will have all 6 coils switched in series to  
maximize the voltage, and past a certain wind speed switch the 2 sets to  
parallel, which will halve the voltage and double the current. Here in Alabama  
the wind isn't very good so I imagine it will spend most of it's time wired all  
6 in series...

[Wind](#)

I've been cutting PVC pipe again

I mentioned making PVC Savinous blades on Chat recently. I have them hanging on my front porch and they spin almost constantly. My camera doesn't work well with moving objects, but I finally found a calm enough moment to snap some pics . . .

It's a super simple design, basidy you just cut the pipe in half (lengthwise), almost all the way to the hub, and cut away the opposing faces. I made three of these and bolted them all together with Threaded Rod. I thought about plugging up the airway through the Hub but WindStuffNow suggested that it would be better to duct the air through to the other side. . . <http://www.fieldlines.com/comments/2003/11/22/7365/5340/7#7>  
So I'm letting the air flow freely through the middle.

Sorry I don't have any data of any kind on these blades, except. Comparing to the Zubblades that I have been cutting, it starts

Woof!

Just looking the first thing I thought was they need half an "elbow" out on the ends to keep air from spilling off the end of the half tube.

Just my first thought. Kinda nice use of discard pvc hunks.

My pal in the plumbing business has a few pieces of scrap he is dropping off tomorrow. 10, 14 and 22 inch diameter short cutoffs I think he said. This gives me some options I hadn't thought of to experiment with.

Thanks for sharing.

Cheers.

TomW

Hey Woof,

I've built many different types of VAWT's and some pretty odd, you've definately hit on one that is quite unique. I think tom made a good point to help increase efficiency though.

The half cylinder shape is one of the best for drag coefficient on the downwind side ( 2.3 ) but it also claims 1.2 on the up wind side which is quite high. If you added a wing shape to the front of each tube you could get this down to around 0.4 quite easy and retain a 1.9 Cd on the downwind side... If your looking to make some power with it. I have some old PVC pipe sections and might give it a shot if you don't mind me copying your design... can't help myself just gotta' tinker.

Lots of Fun!!!

Ed

([User Info](#))

I'd like to see what they do under load. I like verticals for ease of building them but I think they are poor performers. I'd love to see these come close to horizontals though. I might try them with the thin drainage tubes just for fun.

RobD

Re: PVC Savinous Props ([none / 0](#)) (#4)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Tue Dec 2nd, 2003 at 10:31:39 AM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

I made the above Savinous blades from 3 inch thin sewer pipe. I really just wanted to see if it would spin. I thought the rounded tips would work better coming into the air on the upwind side, but I can see how some properly modified Elboes would work better.

I thought the coolest part was that these could be stacked up as high as you wanted. They don't look too bad. With a larger number of these blades stacked at 120 degree angles (as pictured above), It would make a pretty moving spiral pattern while spinning.

I got some PVC pipe from the building where I work. It is Grey and labled "Rigid Non-Metalic Electrical Conduit, underground". I cut a horizontal blade from that stuff. This is the strongest PVC pipe I've seen , Ever. Rigid is a good description.

### [Four Blade PVC Prop](#)

By [wooferhound](#), Section [Homebrewed Electricity](#)

Posted on Wed Oct 29th, 2003 at 05:01:44 PM MST

[Wind](#)

I figured out a way to combine 2 PVC props to make a 4 blade version

I decided to try to make an experimental PVC prop out of some small 1 1/4" PVC pipe following the last diagram that I suggested to Zubby...

I made one of them and it was working great in front of a box fan set on low speed. I kept looking at this prop and spinning it by hand and saw a way that I could combine 2 of them together to make a 4 blade prop...

So I cut another Identical prop with minor modifications and bolt them together...

Well it looks good, and has about twice the torque as the 2 blade version in front of the box fan.

While it's working wonderfully, I can see that the second blade is much weaker than the front blade because a large portion is cut out from the center where the strength needs to be. So the 2 sets of blades need to be further glued and/or bolted together. This is working much better than I thought it would. Making these props from 6 or 8 inch pipe would be way higher torque and much easier to make.

Thanks for the Ideas Zubby . . .

([User Info](#)) <http://homepage.ntlworld.com/s.amesbury/homepage.htm>

Im really impressed with the way these pvc props have been cut, i have been making props from buckets and plastic barrells and bins for about 2 yrs now and put any twist to them by using heat and holding the end of each blade until the desired twist is acheived. I gotta say though using the cutting techinque you use and also Zubby this has got to be a better way of doing the same job. I will certainly cut my props in a different way in the future, thanks for the tip guys.....sean

hello Woof. the only thing i can say is " I LOVE IT !!!!! "

would like to add one thing though. the thought came to me right away. Don't weaken the one blade by cutting it to fit the other. instead, cut a short, fully round piece of the same diamater pipe and round one end and concave the other end. put it between the two blades then put your bolt through it. result, one very strong blade. also, you could make a six blader with two of the spacers, but one of the spacerwould have to have one end cut ofset to the other end so you would get even spacing in the circumference.

amazing how one thing can lead to the other isn't it.

happy you are enjoying this----zubbly

Hey the 4 blade prop seems to be working real good just made one today used 4 in. sch.40 pvc its up and spinnin so fast looks like a blur LOL. I think the prop design is pretty good.

Re: Four Blade PVC Prop ([none / 0](#)) (#4)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Thu Oct 30th, 2003 at 07:30:10 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

While I was home for lunch today I mounted the 4 blader pictured above onto the top of a piece of pipe (without any kind of load) and set it outside where the wind goes around the house. I was surprised that it started when the wind blew the least little bit, and in the 10mph gusts, it was spinnin' so fast you could'nt see it. Now I'm look at all the construction sites for bigger pipe.

Re: Four Blade PVC Prop ([none / 0](#)) (#5)  
by Jerry on Thu Oct 30th, 2003 at 09:48:37 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

I think much of the good response from these blades has to do with the cup shape that the pipe offers.

This cup shape would be rather difficult to make in a wood blade.

My plastic blades have a slight cup and I believe in part this is why at only 49 inches total tip to tip I've seen 1200 watts from these blades.

Here are the good attributes. 23 degrees at the root to almost flat at the tip and a tapering cup from root to tip. There is also a slight rise in the trailing edge from the root and peaking about 1/3 towards the tip at this point this rise and the cup flatten out towards the tip.

I had one of these blades on a GARBOGEN on a 3 foot stand today in my parking lot. In a 10 mph breeze the blades were a blur.

JK TAS Jerry

Magnet inside a 60hz field

I have been playing with magnets inside of a 60hz magnetic field. A large coil of about 750 turns of 22gauge wire is what I'm using, with a 7 volt AC transformer. The 1/4 x 1/4 rod magnet is sitting on top of the coil. But as soon as I apply the power the magnet becomes Balistic. It's unbelievable.

These are N40 magnets and it's even better if there are 2 magnets attracting together and bouncing around inside the glass (1/4 x 1/2)

## [Coil Sizing Revisited](#)

By [wooferhound](#), Section [Homebrewed Electricity](#)

Posted on Sat Aug 30th, 2003 at 02:28:27 PM MST

[Alternators](#)

I am realizing that I need to include a picture of the machine if I'm going to ask about Coil Sizes

Thank you guys so much for the answers about Coil and Magnet sizes. I have realized that there are more variables in the design that just the size relationships. So I have decided to include a picture of my machine at it's halfway point. As soon as the slow setting epoxy sets I'll be assembling the rotors and start testing some coils that I have already wound.

Being so concerned about the extra friction of 100 feet of pipe, I decided to split the flow into into 2 pipes through

Y connections so the flow would decrease to Half in these areas. If you want to follow the flow in the picture, the input to the heater is the pipe crossing to the right closest to the camera, and the output is the lefthand pipe at the open 90 degree fitting.

After constructing the unit I placed it on top of a metal shed that is adjacent to the pool. The shed is silver so any sunlight that passes through is reflected to the underside of the pipes to increase efficiency. This is not a great picture but you can find the heater on the shed because a bird is sitting on it.

I figure that in the hottest part of the year I won't need the heat so I have installed a coupla valves that will allow

Good evening !!

Not very close to Ystad i am afraid.... about 15 km from Linköping wich makes it about 427 km from here to there (according to "viamichelin"). I think You are the only Swede i have seen around here..... nice not to be alone (and also not alone using km, °C etc etc - excuse me everybody !!).

My things are coming together, i will make some kind of posting when results are here...

Good evening

Lars A

Hej du.. Small but "tall" this country !

My turbine is being made according to Hugh Piggotts blade carving instructions (2,3 m diameter) and will have a Volvo kind of PMG (i have Volvo parts and magnets but turbine or PMG does not build themselves). Because of where and how i live today it will only be a experiment or training for future living not in a village (it will need "building permit" when bigger than 2 m diameter). Between neighbours houses, trees and probably low fascination i will not call it a device making power from the wind but just a experiment. It will keep some batteries charged wich via a old UPS unit will be a backup for my wood pellets fired boiler when grid power is out (happends about ten minutes every third year !!). When i live in a more suitable place i plan (!!) to have at least two turbines, one for higher voltage feeding some kind of water heater in a storage tank (parallell with solar heating) for hot water and heating the house and one for charging batteries..... (UPS or real inverter..).

Thats all, i am planning and doing some work on it.... very slow.

How are You going to use Your power from the windmill ?? Not just a experiment i hope ??

([User Info](#))

Good evening :)

Well that sounds nice with your experiment :) And yes building permit is not nice at all i was planing on buliding any way my home is on the cauntryside so i hope it will blend in ??? I will absulutly find out if it dosent lol

I se that you are in need of grid power to the wood pellets boiler and a inverter is a nice solution when power i out :)

I build a induction generator if the grid fails and it contains only old parts from my bacyard exopt for the capacitors the are old scrap and the wrong volt but it works pefekt 50Hz and about 4kw of power and it kan start a big load on 2 phases its drawbac is the 8hp gasoline motor not economic to use fore longer time but thats note a problem for my Tea time :)

[http://www.otherpower.com/images/scimages/412/Min\\_induktionsgenerator01.jpg](http://www.otherpower.com/images/scimages/412/Min_induktionsgenerator01.jpg)

Well i dont know if the power i god for any bigger loads from my trubine but i am working on a 4 relay load regulator and i hopfully dont ned any thing else :)

Putte from Sweden :)

([User Info](#))

Hmmmm nice device..... Do You need it often ?? meaning do You loose the grid more often than i do (it is almost never here in the village) ??

I am not sure about the need for building permits ón the countryside but i think it is connected to if the area is in a "detail plan" if not the rules gives You much more freedom than in a city or village..... The good thing with my plan to get out on the countryside is that the horses will move close to my home but the most important thing is to get rid of "disturbing" neighbours and their houses trees and such plus the longer distance to the officials at the building authorities....!!

Your "four relay device"..... how are You going to build or construct it...?? My plan (always plans seldom any real things) is to use the kind of shunt regulator shown at "HomePower", i am drawing the PCB for it so i will be ready when i live in the right place.....

Good evening Lars

Good evening :)

Well that sounds nice with your experiment :) And yes building permit is not nice at all i was planing on buliding any way my home is on the cauntryside so i hope it will blend in ??? I will absulutly find out if it dosent lol

I se that you are in need of grid power to the wood pellets boiler and a inverter is a nice solution when power i out :)

I build a induction generator if the grid fails and it contains only old parts from my bacyard exsept for the capacitors the are old scrap and the wrong volt but it works pefekt 50Hz and about 4kw of power and it kan start a big load on 2 phases its drawbac is the 8hp gasoline motor not economic to use fore longer time but thats note a problem for my Tea time :)

[http://www.otherpower.com/images/scimages/412/Min\\_induktionsgenerator01.jpg](http://www.otherpower.com/images/scimages/412/Min_induktionsgenerator01.jpg)

Well i dont know if the power i god for any bigger loads from my trubine but i am working on a 4 relay load regulater and i hopfully dont ned any thing else :)

Putte from Sweden :)

Hmmmm nice device..... Do You need it often ?? meaning do You loose the grid more often than i do (it is almost never here in the village) ??

I am not sure about the need for building permits ón the countryside but i think it is connected to if the area is in a "detail plan" if not the rules gives You much more freedom than in a city or village..... The good thing with my plan to get out on the countryside is that the horses will move close to my home but the most important thing is to get rid of "disturbing" neighbours and their houses trees and such plus the longer distance to the officials at the building authorities.....!!

Your "four relay device"..... how are You going to build or construct it...?? My plan (always plans seldom any real things) is to use the kind of shunt regulator shown at "HomePower", i am drawing the PCB for it so i will be ready when i live in the right place.....

Good evening Lars

Re: Important tip boys and girls! ([none / 0](#)) (#8)  
by troy on Mon Oct 6th, 2003 at 02:20:04 PM MST  
([User Info](#))

Direction of rotation generally doesn't matter, but I  
gather that his blades are set up for one direction  
and the hub for the other direction. If he mates  
those together he'll end up with no rotation at all.

Good luck and keep having fun,

troy

[Alternators](#)

good for PMA

I was at the local flea market last weekend and saw a new GE 1/6 HP 850 RPM 120 volt induction motor for \$35.00 I think that figures out to 8 poles. I would like to find a 1 HP 120/240, 850 RPM, that would be about perfect.

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Dr.D Harbor Freight has some good buys on 1 hp motors. Most of my conversions have been 4 pole. I've done 6 pole and 2 pole also. I prefer the garbage disposal motor. Most of these are 4 pole. There are a few brush type and PM type also. The PMs have 2 big ceramic magnets about 4 to 6 inches long depending on hp (1/3 or 1/2 hp). most 4 pole are 1/2 hp there are a few 3/4 hp and out of 300 I've collected I've found 3 1 hp. I've gotten 80 amps from the 1 hp and see 5 amps at 5 mph. JK TAS Jerry

To resume Dr.D. The pm motors also have a nice little fullwave bridge diode inside. Get these motors from your plumer cause he's just gona toss them anyway. The ac garbage disposal motor has several good atribuits. It has an unusual large bore. Larger then its equal in a standard motor. This makes for higher magnet speed passing the coils. Its built a little loose so wire reassignment is easy. Heres what I'm talking about. Lets use the 1 hp as the example. Its specs are 120 volts, 10 amps , 1725 rpm, 1 PH. This motor has 4 run windings (this is the 10 amp part) and 4 start windings. The 4 run windings are in sories. We could then say we have four 30 volt 10 amp coils in sories this equals 120 volts at 10 amps. If we wire the run windings in perelell we could now say we have a 30 volt motor at 40 amps. When converting this motor into an alt. and charging 12 volts. 30 volts is closer to 12 than 120 volts and 40 amps is a hole bunch better than 10 amps. Now another plus. We can do the same thing with the start windigs and add half again as much power. The run and the starts must have seperate bridge rectifiers. They are mechanically and electricly out of phase. They also have resistance and voltage diferances. However the dc output of there seperate diode bridge can be combined. This is then a 2 ph. alternator. This makes it work well at low rpm. We start to see carging at 5 mph, around 450 watts at 30 mph and have seen 80amps/15 volts at 40 mph. This was all done with a 49 inch prop with 4 plastic blades. Oh sorry got carried away. I think to many words this might not post? JK TAS Jerry

O- Scopes

I want to pass on the URL for a device that those who want to use a PC or Laptop as a scope should consider. It is an adapter that connects to your computer, with it's own software and allow for a "real" O-scope with out the the inherent problems of the "sound card scope" previously covered.

[www.picotech.com/scope100](http://www.picotech.com/scope100)

magnets how to remove?

I was wondering if any one had any tips on how to remove magnets from PM motors, I have one that has them glued in and I don't want to wreck them trying to take them out. I'm sure there must be something I can use as a solvent to do this. I could experiment for the next week finding the right product but why reinvent the wheel?

Dr.D

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Dr. D;

I had good luck with the heat gun and vise.

Put the case in the vise so one end of the case is against a vise jaw and a board presses against the end of a magnet and other vise jaw crank the vise snug heat [I used a hot air gun] the outside of the case where the magnet is glued. Pretty quick the glue lets go and the magnet slides. Once the glue bond breaks its an easy thing to slide the mags out.

Be aware too much heat can demagnetize a magnet. It did not take much heat to loosen the ones i did on the tape drive motors.

Cheers.

No vise needed really.. ([none / 0](#)) (#4)  
by TomW on Fri Aug 22nd, 2003 at 07:49:29  
PM MST  
([User Info](#))  
<http://oneota.net/~earthsourcepowr/>

Dr. D;

You could set it on a bench or the ground and just press down on a board by hand as you thermally excite it too. The vise just made it easier.

Cheers.

TomW

Re: Magnets, how to remove? ([none / 0](#)) (#3)  
by JW on Fri Aug 22nd, 2003 at 07:48:55 PM MST  
([User Info](#))

It seems to me I once used paint thinner to remove some ceramic magnets from a electric radiator fan motor, for a car. They had a nice shape for the project that I was working with at the time. I'm pretty sure I put the whole thing in a bowl (outside, always outside!!!) and let it sit over night. please bear in mind I used virgin Lacqur Thinner which is dangerous to let stand in a bowl in a closed room. Since you may enter at a later time flip on the light switch and well, nevermind. It seems to me that it was very hard to get the solvent to penetrate the glue. And I did end up using a torch to heat the glue and break it down. I tried the torch on both treated with solvent and without. seems that the treated with solvent housing's came apart faster, easier, and with less incident. But I'm pretty sure I had to use the torch anyway. But when I was done with the whole affair, the magnets seemed strong enough. Worked for what I was doing and that was the end of it. Hope this helps.

([User Info](#))

Cool, pun intended.

On a related note, the latest issue of Homepower magazine (www.homepower.com, free for the downloading 8-) ) had a discussion of a recent high tech efficient housing competition.

Almost as an afterthought, they mentioned that one of the teams used an air conditioning system that did not depend on compressors with freon type refrigerants. What they did instead was use a fairly large amount of dessicant (eg silica gel) to suck all the humidity out of the air. In many cases, that would be enough right there. 80 is pretty comfortable if the humidity is low.

If that wasn't enough, they added evaporative cooling. This even works in humid areas since they have already pre-dried the air.

There were not many details, but I can envision a solar cooker/dryer arrangement to drive off all the absorbed humidity on day one. That dried (and now cooled overnight)batch of silica gel goes into the ductwork on day 2, while the "wet" batch of used silica gel goes out in the cooker, thus repeating the cycle.

Silica gel has basically an unlimited lifespan, and the only moving parts in the system are changing the silica gel canister and a fan.

Best regards,

troy

Hey,

It gets 110 here, and I just start to sweat. We have no humidity!!! We need humidifiers running 24/7 here. As for cooling, I saw a neat post here a while ago saying that if you use deep well water (which is generally pretty cold) and run it through a radiator with a fan blowing on it, and then return it to the deep well, this can cool pretty effiecently only using the water pump and the fan motors. I don't have a deep well, but this cooled my house down over 10 degrees using a couple of gallons of Icewater in the basement. (The ice water eventually warmed up a couple of hours later, but it was dark, so that was cool.)

## Shaft coupler for tape motor

By [drdongle](#), Section [Homebrewed Electricity](#)

Posted on Sat Aug 16th, 2003 at 02:05:03 PM MST

[Wind](#)

Shaft coupler for tape motor

I worked on my small tape drive motor/ generator yesterday and when I took the old tape hub off I discovered that I don't think the stock shaft is long enough to attach a set of blades to, which means that I need a shaft coupler with keyway to extend the shaft out from the motor face and the metal plate every thing is mounted to. This gives me cause for concern as I know that the angular forces involved are considerable and I can imagine the whole thing coming apart and pieces flying all over ( my wife would never forgive me if it killed one of her goats). Has any one else dealt with this problem and do you have any recommendations ?

As usual any help appreciated

Dr.D

[Shaft coupler for tape motor](#) | 4 comments (4 topical, 0 editorial)

by [JB](#) on Sat Aug 16th, 2003 at 05:29:23 PM MST  
([User Info](#))

you might be able to make a hub and shaft that runs in a pillowblock. It would be a little more drag but should solve the problem . JB

Re: Shaft coupler for tape motor ([none / 0](#)) (#2)  
by [DanB](#) on Sat Aug 16th, 2003 at 06:58:55 PM MST  
([User Info](#))

Lots of the tape drive motors I've seen have pretty short shafts, and I've seen a few blades fall off them. You might use the shaft, be sure you have a key in there though and really tight set screws - a good fit, and a light weight well balanced prop.

Another problem with the tape drive motors is the front bearing, I've definitely seen a few of those fail. To solve the whole problem, get a couple pillow block bearings with a shaft. The love-joy couplers work pretty well and it's a nice way to adapt different size shafts together. The love joy coupler has a steel piece on each side that fits the shaft with "fingers" poking towards each other, and then a rubber spider fits in between. That'll make the windmill longer, the motor might wind up behind the yaw bearing, but it works out well and makes for a stronger machine.

I thought of a pillow block though I will probably need two so as avoid the turbine blades drooping, and I know about love-joy couplers. Damn more stuff to buy.

([User Info](#))

You can also use short lengths of rubber hose instead of lovejoy couplings. Use even numbers of hose clamps on each end, and make sure the screws are opposite each other, to help with balance. You can put several sizes of hose together, one inside the other, for more strength. Cheaper than lovejoys, but require more service. Good luck.

Demetri

Hard to say ([none / 0](#)) (#1)

by TomW on Mon Aug 11th, 2003 at 11:55:31 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Dr D.;

I kind of wondered myself why you didn't get a response.

I think it might be multiple reasons for no response not having anything to do with you personally. First it has been discussed at some length several different times here and on the old board. Second I think it is one of those things that needs to be decided on a case by case basis. Third I don't think everyone agrees what is the holy grail on the conversion parameters.

Personally, I never did one but have read everything that has been posted here and on the old board over the past couple years and I can tell you at least 2 and possibly an even number up to as many as will fit. Probably good to have the magnets approximately the width of the legs of the coils but I am not sure and certainly no expert.

Just some thoughts.

Cheers.

TomW

I don't think that it is anything you said.

Probably you only need so specific advice that nobody was able to tell it shorthand.

I'm not an expert in this conversion work.

a)

I think that you might first do a search for all the discussions on motor conversions.

b)

Then see the web-pages of the people, who have done it.

I think that iFred has done one...

It is here. His discussion is great:

<http://www.internetfred.com/induction-mot.html>

Ed Elenz is a really great engineer, who has done almost all stuff, which anybody has done.

<http://www.windstuffnow.com>

There are for sure others.

Please see as well the main page of the otherpower.com.

c)

Then make a decision, which way to go.

I think that if you start doing it and publish some data about your results here, many people will comment.

It is one of the works I wanted to do quite shortly myself at least.

DrD

It is very difficult to say exactly how many magnets to use in an induction motor conversion, without seeing the motor. The number will depend on -

1. the diameter of the rotor,
2. the "span" of the stator winding coils,
3. the width of the magnets

A few observations-

[quote]"Motor two is 120 VAC single phase and 1/4 HP at 1150 RPM"

If this motor is a capacitor start type, it would have 6 poles. The 36 stator "teeth" are not poles.

Some basic principles for a single phase machine-

## Magnet / Coil Spacing

In order to connect coils in series or parallel, so that the voltages, (or currents in parallel) will add instead of cancelling, the voltages induced in the coils must be "in phase" with each other.

The only way to ensure that the coil voltages are in phase is by accurate magnet / coil spacing.

Magnet center-to-center spacing should equal the coil "span".

The objective is to have the leading edge of a NORTH pole reach one side of the coil - -

- - just as the leading edge of a SOUTH pole reaches the other side of the same coil.

Electric Ed

([User Info](#))

Now we're cooking I obviously didn't understand the relationship between coils and poles and that it is "flexable". I have done some searching of the archives and while it has been helpfull it's also been annoying for the lack of specifics in not all but many instances.

So Ed in you openion how may magnets should I have (in theory)? It would seem from the above illustration that I need 6

Dr.D

Is there any way that you could post a sketch or photo of the stator windings.

I am having trouble with your description. You said - "two windings what appears to be #20 wire, and a third much shorter winding with what appears to be #22,"

If it really is a capacitor start, 1150 (1200) RPM motor, the run winding should have six poles.

That would ideally require twelve magnets, but, unfortunately, there is no way to achieve the optimum magnet/coil spacing/arrangement with this winding in it's stock configuration.

Electric Ed

Re: Guys is it something I said? ([none / 0](#)) (#6)  
by drdongle on Tue Aug 12th, 2003 at 04:05:04 PM MST  
([User Info](#))

OK some more fuel for thought the rotor has a iron core 1.6 inches long and a diameter of 3.75 inches. Based on your description of the pole and coil relationship it does infact have 6 "poles". Each pole consists of two windings one surrounded by a second and seperated by a set of stator "teeth". There is also a second set of windings behind the first (closest to the rotor).

The third set of windings consists of just a few turns at various locations on the stator, this I would think is the starter winding, I have not metered it out as of yet.

Based on the info on the case and what I have doped out from the wiring it's a combo 120/240 unit.

Perhaps rewinding for 3 phase might give better results?

thanks Dr.D

Re: Guys is it something I said? ([none / 0](#)) (#8)  
by DanB on Wed Aug 13th, 2003 at 08:58:29 AM MST  
([User Info](#))

I've not messed with these in a couple years now... but I think you would get good results with 6 magnets, though 12 might work better - I never tried that. 6 magnets around the armature N S N S N S. My experience in doing that - if the magnets are of reasonable size almost always gives 12 volts at 1/10 the rated rpm in a 120 volt motor and they seem to run reasonably efficiently up to their rated current (about 10 amps or so for a 1hp motor).

They cog some, but they work OK. So in this case - you might expect 12 volts @ 120 rpm if the coils are wired in the "120 volt" configuration... and you might run well up to the rated current for 120 volts - and inefficiently above that. For lower rpm you could wire it in the 240 volt configuration and expect 12 volts at about 60 rpm.

You could rewire it I suppose, but I think you'd be in for more work than building an alternator from scratch. I never tried that... I'd probably look for a 3 phase motor before I tried rewinding a single phase.

## [Choice of motor for alternator mod?](#)

### [Pt 2](#)

By [drdongle](#), Section [Homebrewed Electricity](#) [Alternators](#)

Posted on Sat Aug 9th, 2003 at 10:32:05 AM MST  
motor mods?

I got around to checking out motor #2 this morning and found that it runs

(always a good sign) I opened up the case and found the following, 36 poles with two windings what appears to be #20 wire, and a third much shorter winding with what appears to be #22, I would think that this is the motor start winding.

Turns out that this is a capacitor start motor with the cap and starting cut out switch inside one of the end bells.

According to the hookup info on the side and the schematic I made of the connections and coils it's a 120/240 volt unit.

It seems to me that at 300 RPM I should be able to get 60 volts at 3 amps ( 180 watts or approximetly 1/4 HP)when done converting it to a PMA.

What I need to know is how many magnets I need to install on the rotor to achive the desired output.

Thanks

Dr.D

### [Choice of motor for alternator mod?](#)

By [drdongle](#), Section [Homebrewed Electricity](#)  
Posted on Wed Aug 6th, 2003 at 08:23:40 PM MST [Alternators](#)  
**Choice of motor for Alternator mod?**

I just picked up 2 different AC induction motors as possible prospects for conversion to alternators.  
Motor one ( which is currently frozen) is a combo 110/220 VAC 3 phase and 2 HP at 3450 RPM.  
Motor two is 120 VAC single phase and 1/4 HP at 1150 RPM ( and turns freely)

Both are approximately the same size and weight.

My goal in conversion is a target speed of approximately 300 RPM and an output of about 60 volts ( for a 48 volt battery bank)either single or 3 phase is OK.

Based on my still incomplete understanding of such motors and the following formula I found elsewhere at otherpower ( 60Hz= N poles X RPM/120) I think motor one has 48 poles and motor two has 12 poles. I have not yet opened either one. I am currently soaking the shaft on # one with liquid wrench and just got # two to day.

I believe that if I rewind #one and change the rotor to 12 neo magnets I should be able to get 55 volts at 350 RPM. If there are any glaring errors in my figures please point me to the straight and true.  
While I have been in the electronics business for many years I have very little experience with motor building /rewinding etc and only the most basic knowledge of the subject.

As usual any input is appreciated

Dr.D

I would take another look at the nameplates of these motors. It would be unusual for a 2 HP and a 1/4 HP motor to be the same size and weight.

If motor #1 really is a 110/220 volt, three phase motor, it must be very old.  
It is a two pole motor.

POLES = Hz x 120/RPM(synchronous speed)  
POLES = 60 x 120/3600

Motor #2 is an six pole motor. It would be more suitable for your project, if you are not going to rewind the stator.

Electric Ed

Re: Choice of motor for alternator mod? ([none / 0](#)) (#2)  
by drdongle on Thu Aug 7th, 2003 at 08:28:00 PM MST  
([User Info](#))

Went out and looked at motor #2 again and even though the ID plate said it's 120 V  
A small wiring diagram in the side suggests that it is infact a 120/240 unit which I believe makes this one look even better as a PMA. The diagram showed leads for two windings in parallel and was labled "low voltage". This suggests to me that wiring it as 240 and running it at 300 RPM would produce 60 volts. Does any one have any suggestions regarding how many magnets I will need (as many as I can cram in?).  
As all ways any input appreciated.  
Dr.D

New with a question

[Wind](#)

Hello I'm new to the group, though I have been lurking for several months. I have had an interist in Alternative energy for many years, and recently decided i'd like to try my hand at making a small wind gennerator. I have several 24V Ametek tape drive motors I picked up a hamfest several years a go,that I want to try. I am having no luck locating any of the large "muffler clams" that I have seen some of you use to mounting generators like the one used in the Garbogen. If any one could clue me in where to buy these it would greatly appricated.

Thanks Chris snyder

Re: Hello I'm new and have a question ([none / 0](#))  
(#6)  
by Jerry on Wed Jul 30th, 2003 at 11:43:44 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

I use a fan blade and shaft hub from Johnstone Supply. Most large city's have these supply houses if not they are on line.

Use there part #s W88-972 \$20.66 and a 5/8 shaft hub adaptor part # W69-124 \$5.99 each. I use 2 of the fans to make a double hub for stringth. I drill the rivets out and remove the aluminumblades and cut them down to match the plastic Jerry blades. I then use stainless steal scews, nut, flate washers and lock nuts to sandich the hole thing together.

The hubs are called CCW and they match the plastic blades perfict for angle and since there 4 blade you can make the either 2 or 4 blade. 23 degrees at the root to almost flate at the tip.

The shaft hub addaptors are availible 1/4,5/16,3/8,1/2,5/8 or 3/4 and I've even bored the 3/4 a little larger to match a car alt.

Go to [www.dplusv.com](http://www.dplusv.com) and click on airheads to see how they go together.

The most power I've ever got was from this 4 blade set up (80 amps). The most power I ever got from a tape drive motor was with a 2 blade version 26 amps.

Ps I'm working on a nice aluminum hub. Its a 3 blade, maybe this winter?

JK TAS Jerry

[Tower math ?](#) | 5 comments (5 topical, 0 editorial)

Re: Tower math ? ([none / 0](#)) ([#1](#))  
 by kell on Wed Dec 31st, 2003 at 06:15:12 PM MST  
[\(User Info\)](#)

The tower in the example has attachment point(s) 10 feet from the axis of pivoting. Yours has an attachment point 5.196 feet from the axis of pivoting, if I did the geometry correctly. Now if in the example dividing by 10 gives you the total lifting force at the attachment point(s), then for your own tower, dividing by 5.196 will give the total lifting force at the attachment point. But one point (the triangle vertex) will take all the force. The example tower has two feet attached to the ground, or a ten foot connecting rod attached to the ground or however it's built. And I hope your load figures are in foot-pounds, so that when you divide by feet, the final result comes in pounds, which are a unit of force. Only way it would make sense. Foot pounds are a measure of torque. Like if you apply 50 lbs force to a lever at a point 30 feet from the fulcrum you get 1500 ft lbs of torque. If the lever sticks out 10 feet on the far side of the fulcrum you get 1500 ft lbs divided by 10 feet = 150 pounds force at the far end of the lever. Why can't I get carriage returns on this posting?

[\(User Info\)](#)

The tower in the example has attachment point(s) 10 feet from the axis of pivoting. Yours has an attachment point 5.196 feet from the axis of pivoting, if I did the geometry correctly. Now if in the example dividing by 10 gives you the total lifting force at the attachment point(s), then for your own tower, dividing by 5.196 will give the total lifting force at the attachment point. But one point (the triangle vertex) will take all the force. The example tower has two feet attached to the ground, or a ten foot connecting rod attached to the ground or however it's built. And I hope your load figures are in foot-pounds, so that when you divide by feet, the final result comes in pounds, which are a unit of force. Only way it would make sense. Foot pounds are a measure of torque. Like if you apply 50 lbs force to a lever at a point 30 feet from the fulcrum you get 1500 ft lbs of torque. If the lever sticks out 10 feet on the far side of the fulcrum you get 1500 ft lbs divided by 10 feet = 150 pounds force at the far end of the lever. Why can't I get carriage returns on this posting?

Re: Tower math ? ([none / 0](#)) ([#2](#))

Kell;  
 You asked:  
 Why can't I get carriage returns on this posting?

The answer is because you need to set your comment posting format preferences to "auto format" and you likely have it set to "html formatted".

In case your not sure where that is it is between the Preview and Post buttons just below the text entry window. You can also set it in your user preferences. Cheers.

TomW

Thanks Kell

The force is measured in foot pounds. Should have said that in the first post.

With that snag out of the way things are starting to make sense.

And the numbers are falling in to place better than I expected.

Tho I will add an extra 15 or 20 % as a safety factor.

Looks like I am well on my way of meeting my goal

A 30 foot tower and from the of looks things now a free stander

Rated for an 8 foot diameter blade set in a 60 mph wind an supporting up to 200 pound of machinery.

Now off to gather some more data on strength of materials

Kell many thanks till your better paid

Old F

Riding the learning curve and loving it : )
