Can Magnets pass by eachother without creating any drag?

I'm doing a Science Fair project for my Physics class over Magnets, their force, and if it is possible to have them pass by each other with out creating any drag inbetween. I realize that some believe that this is impossible because of the perpetual motion, but i wondered if anyone had any comments to agree or contrast the subject.

This touches on another recent thread here.  
What you would need is some way to divert or redirect the field.

Dr.D

### [Joint for pipe tower?](#)

By [Old F](#), Section [Homebrewed Electricity](#)  
Posted on Thu Dec 11th, 2003 at 07:25:24 PM [Power Systems](#)  
MST

#### Joint for pipe tower?

Has any one tryed using 1/4 inch or 3/8 steel plate to make weld on flanges to join two lengths of pipe ? Been kicking a round some tower ideas.

I know they make weld on plumbing bolt up flanges but don't know if they would be strong enough or what they would cost.  
The flange can also be used as a place to attach guy wire.

Old F

Re: Joint for pipe tower? ([none / 0](#)) ([#1](#))  
by [Hank](#) on Thu Dec 11th, 2003 at 09:26:21 PM MST  
([User Info](#))

Old F

I used 1/4" steel plate to re-enforce the welded joint of my tower. I used two sections about 2" wide and about 10" long. I then formed a semi-circle in the middle of these to fit around the pipe, clamp style (this took some work). The ends that were protruding were drilled and bolted together around the pipe for a tight fit. I then welded this to the pipe. These also are used as the connection points for my guy wires. I used a total of four pairs (also for 4 guy wires).

I did not trust a welded joint just where the pipes slide in together. To much time invested to have a failure such as this. Incidentally my tower is 44 feet high consisting of 3" pipe, 2 1/2" pipe and a small section of 2" pipe.

So far so good,  
Hank

Here is what I am thinking . It is sort of like what Hank is doing.

You set the 2 an ½ inch pipe in to the three inch and then bolt the welded flanges together

Old F

Re: Joint for pipe tower? ([none / 0](#)) (#4)  
by RobC on Sat Dec 13th, 2003 at 01:43:15 PM MST  
([User Info](#))

Just let the small pipe extend a foot or so into the other pipe. If its a very loose fit weld 3 small spacers on the bottom of the small pipe to take up slack.

If the pipe is going to break it will break at the weld on the flange on the small pipe first 3 small gussets might be good idea. Other than that I don't see how you could improve on it.  
RobC

Re: Joint for pipe tower? ([none / 0](#)) (#6)  
by Hank on Sat Dec 13th, 2003 at 06:54:07 PM MST  
([User Info](#))

Old F,

Actually this is what I did. (hope photo comes through).

Two at right angles to each other at all joints, which is also where I connect my guy wires.

Perhaps an over kill but a cheap investment. Hand CAD is faster!

[ [Parent](#) ]

Re: Joint for pipe tower? ([none / 0](#)) (#5)  
by drdongle on Sat Dec 13th, 2003 at 05:01:11 PM MST  
([User Info](#))

I was working on my "small" tower today and to attach two pieces together I slipped 12" of one into the other and drilled two 1/2" holes through the two pipes 2" from each end and will insert two 3" schedule 8 bolts through with nuts to hold it together. seems a lot simpler and more secure than the welded flanges.

I might add a third bolt 180 degrees from the others if there is any wobble.

Just my \$0.02 worth

Dr.D

## [MHD Generator?](#)

By [The MCP](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 2nd, 2003 at 12:21:36 AM MST

[Power Systems](#)

Using supermagnets, foil, and lighter to generate power?

I tried using an item #60 from Wondermagnet.com as the magnetic field source for a crude MHD generator. My experiment was simple. Simply tape two pieces of foil parallel to and about 4 mm from each other on glasses. Then place your magnet with either pole facing down the gauntlet between the pieces of foil.

Fire up a lighter between the foil pieces as a source of a precious few ions and you should get at least a few millivolts of output. Has anyone else tried this?

When I tried my experiment, I generated around 10 millivolts with a dying lighter and the plates about 6 or 7 millimeters apart. The most curious effect was when the foil was backed by glass, which resulted in the same gap generating 100+ mv with or without the magnet.

I'm very intrigued by this behavior, and a little lost as to an explanation for the foil/glass effect. Anyone want to replicate my experiment or tell me what the heck was going on?

Acronyms are so unintuitive... [\(none / 0\)](#) [\(#1\)](#)  
by [TomW](#) on Tue Dec 2nd, 2003 at 06:26:03 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

MCP;

acronyms are so unintuitive, perhaps you can just spell out what MHD means to you?

Other than that I believe you have perhaps simply created a thermocouple or some strange version of a capacitor.

Cheers.

TomW

Yep, thats MagnoHydroDynamics.

Im working with this, currently my ion stream is 5.5in in diameter, and reaches over 24inches. Im setting up a magnetic field coil for just 8inches, driven by 450amps @12.4vdc set up on a pulse width modulation schedule. the electrodes are of an un-named material for now. MHD is quite well known, and yes im using a very clean burning, Corn Burner for this. most of the previous research for this (MHD) used coal.

Re: MHD Generator? ([none / 0](#)) (#5)  
by JW on Thu Dec 4th, 2003 at 12:24:01 PM MST  
([User Info](#))

Hi iFred,

Sorry no pictures at this time, But I did find an interesting link that has some basic diagrams.  
<http://mr-roboto.me.uiuc.edu/kawka/public/coal/future.html>

Normally this process uses superconductors to generate a very strong magnetic field around the fire/ion stream, and the addition of some form of seed material to the stream, to make it more electrcally conductive.

I think MCP's sugestion is a good one, just use magnets instead, and omit the seeding part. Im using coils to help optimize configuration, then most likely will use magnets. I look at it this way, some output is better than no output, its worth a try. Besides you could always cool the magnets with water cooling and use this for heating purposes. It might be a good way to get electricty from wood without a steam engine, and generator.

Re: MHD Generator? ([none / 0](#)) ([#6](#))  
by E man on Thu Dec 4th, 2003 at 04:43:13 PM MST  
([User Info](#))

I remember being fascinated by this MHD stuff even in high school...no moving parts; simply wicked. There's another configuration that involves two squattish conical shapes back to back with the burner in the middle. I found this beast on a google search for "disc MHD":

<http://www.ihed.ras.ru/mg/MHD.htm>

I searched awhile ago and found a group using a spark plug (pulsing at a regular intervals) upstream of the combustion zone to help ionize the gasses and increase the conductivity of the gases before they blast past the magnetic field. Fun topic.

-Enjoy

E-man

[TO JERRY ABOUT THE GARBOGEN](#)

By [Homebrewed12vdc](#), Section [Homebrewed Electricity](#) [Power Systems](#)

Posted on Wed Nov 19th, 2003 at 01:02:33 PM MST

can I buy one

Jerry, I have heard of people claiming they bought a complete garbogen from you, and how well it was packed. I emailed you once about it, and got no response, so hears my last try, if you are building them and selling them, how much, and how do I buy them, If you arent then lets set the rumor straight for once and all. Thanks From Mike

P.S. I didnt see a link on the websites on the garbogen on where to buy one, or what the cost.

[TO JERRY ABOUT THE GARBOGEN](#) | 1 comment (1 topical, 0 editorial)

Re: TO JERRY ABOUT THE GARBOGEN ([none / 0](#)) ([#1](#)) by Jerry on Wed Nov 19th, 2003 at 09:48:18 PM MST ([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Mike

Sorry if I missed your e-mail. If I don't see something that I can identify in an e-mail I delete it.

I may have mistakenly done that?

I do build and sell the GARBOGEN. The curent price is \$350. I ship COD UPS. Casiers check or money order. UPS has a \$7 fee for COD shipments.

I'll only be able to build a few more GARBOGEN,s as the supply of curved neo magnets is about gone.

The curent modle has a large yaw/flage bearing that will mount to 1 1/2 inch EMT electrical conduit. Wires go down inside the mast. The unit is a 3 blade 49 incher.

I'm several weeks out in production right now.

JK TAS Jerry

## [Systems -- Fuses and Circuit Breakers](#)

### [-- where do I put them in a system?](#)

By [ADMIN](#), Section [Renewable Energy FAQ](#)

[Power Systems](#)

Posted on Mon Nov 17th, 2003 at 09:25:46 PM MST

For safety's sake, there are different places to put them, with different types of fuses and breakers required.

Your system should have BIG power cables from the batteries to the inverter. The '+' cable here should be fused with a BIG fuse--usually a Class T with a 250 or 500 amp rating. Your inverter probably came with suggested fusing information. If not, try the chart located at:

[http://www.otherpower.com/otherpower\\_systems\\_inverters.html](http://www.otherpower.com/otherpower_systems_inverters.html).

There are also big circuit breakers you can use for this, but they are extremely expensive. Just the fuse and holder will cost you \$60 -- a 500 amp DC breaker goes for \$300 and up. You can also run your DC loads through this fuse, though they should have their own smaller load breakers/fuses too.

You should also have fuses on both your DC and AC loads. Your inverter has fuses inside, but it's much better better to blow your breaker first. For the AC side, a standard, inexpensive breaker box will work. But it's made for the 220v feed into your house -- you'll have to bridge the hot side of your 2 vertical rows of breakers with a short piece of #8 wire to make the second row active--otherwise only one row of breakers will have power. Do this where the main feed wires attach to the rows of breakers.

You can also use breakers for the DC side, though standard automotive fuses will work if they are big enough for your loads. Check the specs on the breakers -- only certain kinds are rated for DC use. But we were able to find some at the local Home Depot.

You should also fuse your DC inputs from solar, wind, hydro, etc. This can again be done with a breaker box or fuses.

It's also wise to have a "big switch" on the + side of your system -- rated the same as your big inverter fuse, you can use it to completely shut down everything going in or out of your system. If sparks are still flying when you shut down with the big switch, something fell across your battery terminals! You can also combine your big fuse and big switch in one unit (about \$200). This starts to show how handy the use of buss bars can be (see [http://www.otherpower.com/otherpower\\_battery\\_wiring.html](http://www.otherpower.com/otherpower_battery_wiring.html)).

They give you more places to hook up inputs and outputs, and make it easier to make ALL your + wires go though the big switch.....and easier to make all your '-' wires go through your shunt, if you have an amp/hour meter installed.

### Residential wiring

A lot of your questions regarding residential installation of PV systems may be answered at the Sandia PV website at <http://www.sandia.gov/pv/> They have a number of articles including John Wiles' Homepower articles dealing with PV and the NEC. I also find this forum helpful in regard to the NEC requirements: <http://www.homewiringandmore.com/homewiringusa/2002/index.html>

HTH, -RussH

welding cable is not appropriate : (  
guess I won't be up to code with 2/0 wiring....  
woder why that is?

Re: Residential wiring and PV ([none / 0](#)) (#2)  
by [troy](#) on Tue Nov 25th, 2003 at 04:39:15 PM MST  
([User Info](#))

Welding cable has never been tested for this application. Basically, it's a bureacracy issue. And while Mr. Wiles is a very smart guy, he is also a nitpicking, strictly by the book kind of guy. If he designs/installs your system, you can be sure it will pass code. If he's your inspector, you can be pretty sure it won't.

Best regards,

troy

MST

Just arrived...

I just picked up the GM-90/8hp I ordered about a week ago. Was pretty excited... What a beast! I ripped open the crate like a kid at Christmas spent about 2 hours assembling, bleeding the injector pump, lines and injector.

Put a couple quarts of diesel in the tank and gave her a spin. I had a hell of a time.. couldn't get this thing through a full stroke to save my life... talk about some mean compression!!! Thinking this thing is getting a starter and feeling a bit frustrated I took a break. Looking at the distructions ( all in arabic ) I noticed a funny little gaget on one of the lifters. Hey a compression release gizmo !! Rushed back to the shop set the compression release spun it up a bit and turned the gizmo... off she went. What a sound! With a cheap pepper can muffler that came with it, it hardly makes any noise. You can hear the lifters and injector more than the exhaust... very quiet... you'd never know its a diesel. This is an 8hp unit and chugs along at 900 rpm. I plan to drive a 3kw 120/220 alternator and a GM 100 amp with it while heating about 1000 gallons of water with the exhaust and cooling system. There will also be some solar helping the heating of the water as well as my wood burner. Using the water as heat storage.

Here is a pic of the little beast ( 700 lbs little)...

I purchased this one from Mike in North Carolina.  
His email is mdmo@rfci.net . Good guy to deal with,  
at least my experience was a good one. He charges  
800.00 for the engine plus shipping of course. I paid  
155.00 to have it trucked in so I have a bit of change  
invested in it. I didn't run it very long but tried some  
vegie oil in it and it didn't seem to care a bit... time  
to hit the restaurants!

Still looking for people that want the Lister Clone...  
basically the same thing only without the water  
pump. I want another one for the shop but need to  
order a minimum of 10 to get the price.

Yep, still having fun

Ed

([User Info](#)) <http://www.windstuffnow.com/main>

No, not by itself, well it probably would over time.  
I've calculated about 40,000 BTU in waste (exhaust  
and water) per hour run if its loaded to 8hp... less  
with vegie oil so it would take some time to get the  
water up to temp. I plan to add some solar as well  
as an add in for my wood stove. 1000 gallons at 140  
degrees would heat my house for 1 full day if I did  
my math correctly...not to mention cut my hot water  
costs.

Long day...  
Ed

Well, at this point it's still only some thoughts but...  
I was thinking of 2 main tubes with smaller tubes  
interconnecting the two. This would be submerged in  
water. It would look like a radiator but working in  
reverse. Like I say its only an idea at this point but I  
think it would work fairly well. My first thoughts  
were to wrap the pipe in copper tube and circulate  
water through the copper but I'm not sure it would  
fully disapate the heat that way, although it would be  
much easier. Still tossing ideas around...

Too many projects... I'm pooped

It has a 4.5" bore x 5.5" stroke, I believe this and the listers are identical between the 6 and 8hp models. I'm thinking the only difference is the rpm their set to run at ( 6hp at 750 and 8hp at 900 - everything else is identical

Open a valve ([none / 0](#)) (#10)  
by wdyasq on Mon Nov 10th, 2003 at 05:44:29 PM MST  
([User Info](#))

Ed - and all,

I can't remember if Lister opens an exhaust valve or the intake. It has been a while since I played with them. But, what happens is one opens a valve, gets those massive flywheels turning and then drops the valve - presto, instant compression, the energy from the compression is converted to heat, the injector does its job, a couple of strokes of white smoke, then smooth running.

If you care to use cooking oil BE SURE to purge the cooking oil from the injector and pump before shutting the engine down. It is extremely difficult to crank a cold diesel on -heavy- oil.

Compression Ignition engines are an interesting thing - keep clean fuel, oil and air to it and it will last a long time.

Ron

Another quote came in...

Slow returns but this one is for the Lister Clone 6hp diesel engine. These have roller bearings on the crank but still a thermosyphon colling system and splash oiler for the rods. The quote was 360.00 each including shipping to the Seattle port. From there there would have to be some distribution set up for delivering them to their final destination.

I wouldn't mind trying one out if there is enough interest to purchase 10 or more of them. If so is there anyone in the Seattle port area that wouldn't mind handling the distribution of them? For a free engine or someone with some trucking connections?

Just some thoughts...Let me know

Ed

micro power generation

I am trying to build a 100 to 200-Watt 12 to 24-V power source from commercially available model airplane engines and miniature permanent magnet electric generators and power electronics. Can someone give me tips on the generator? Specifically, I would like to know the names of commercial sources.

([User Info](#))

I have a .46 CID Magnum XL airplane engine puts out 1.43 hp and has "useable power" between 2000 and 12,800 rpms. I haven't found a torque curve for it. The fuel is quite expensive, and unless it could be coaxed into running on diesel, I do not think it would be worth the trouble. I'd be happy to sell the engine for 30 USD, plus shipping. I bought it used from the owner of a hobby shop for \$40, for a project which I never got around to building, and have not used it. New they go for well above \$80.

Demetri

Probably would be better (cheaper, easier) to use a weed wacker engine. They use those in model planes too...small...cheap...and runs on pump gas.

a couple quotes are in...

I recieved a couple quotes today from about a dozen I sent in. These are for the Lister clones not the GM-90 engine and are for the 6hp units. One quote was for the bushing engine at 390.00 each plus shipping the second was for the roller bearing engine at 400.00 each plus shipping. I don't imagine shipping on those would be cheap and I still don't know what other costs would be involved with importing. Just guessing at a shipping cost of about 100 bux each plus possibly 50 bux in other unknown costs would put the engines at around 550 each.

I know little to nothing about these engines and it seems each company has a little different version. Someone that know's the engines better could chime in with some knowledge of the goods and bads. The GM-90's seem to be a breed of their own. After emailing several info/quote requests for the GM-90 I've recieved nothing in return.

I contacted Mike in NC who sells the GM-90's and decided to gamble on one of his 8hp units. I'm not sure if would be worth the gamble ordering from unknown sources as I'm a bit leary of sending funds to a place where there may be no recourse to retrieve the funds if something went bad for what ever reason. I certainly wouldn't feel right about taking someones money and not being able to produce a product. So for about 300.00 more and no headach/worry you can get one in the states from either Mike in NC or George at utterpower.com . At this point I don't plan to pursue the importing idea.

Anyone interested in the GM-90's you can email Mike at [mdmo@rfci.net](mailto:mdmo@rfci.net)

Have Fun  
Ed

### [3 phase to single phase inductive conversion](#)

By [propel7](#), Section [Weird Science](#)

[Power Systems](#)

Posted on Mon Nov 3rd, 2003 at 09:04:11 PM MST

**3 phase induction motor as generator used in single phase application by using capacitors**

I am wanting to use a 3 phase induction motor (27 HP) as a generator on a 30 ft. DI wind turbine to tie directly with the grid in a single phase application where there is not a 3 phase grid available. I have been told that capacitors can be configured to a 3 phase motor to accomplish this. Is this the truth? If so, how do I do it and what are the specifics? A response would be deeply appreciated. THANKS, Devon Drake

[3 phase to single phase inductive conversion](#) | 6 comments (6 topical, 0 editorial)

Re: 3 phase to single phase inductive conversion ([none / 0](#)) (#1)

by [drdongle](#) on Tue Nov 4th, 2003 at 06:00:24 AM MST ([User Info](#))

Capacitors are used when wanting to run a 3 phase motor off a 1 phase supply not the other way. You may be thinking of the use of a capacitor wired parallel to a motor coil to "self excite" when used as an alternator by running it at higher than rated speed. I know of no simple way to convert the 3 phase out put to single phase. Perhaps if you gave more info regarding you application we could be more helpfull.

Dr.D

I want to produce power with an induction motor by driving it at a higher than rated speed in a wind turbine application in a grid intertie situation. I was told that a 3 phase motor could be used when only a single phase is available from the power grid from the utility. Capacitors are somehow connected to accomplish this.

It is probably the same situation as what you stated with the 3 phase motor being run by a single phase by using caps. How is this done and how do I determine the values of the caps? Thank you very much for your help. I hope that I may have explained this a little better. I just want to basically run a 3 phase motor with a single phase. THANKS again,  
Devon Drake

([User Info](#))

I have experience with an induction grid tied homebuilt wind turbine 25' diam. and also with building phase converters. I used a single phase motor on the wind turbine.

I believe a 3 phase machine will work fine, generating into a single phase line at reduced capacity by just ignoring the third leg.

To get higher power capacity a cap( be sure to use motor run, oil type, capacitors) can be connected from the 3rd leg to one of the other legs , which one determines direction of rotation. You can experiment by trying to run the motor on single phase with the cap connected, you may need to start it with a rope ( pull the rope, then throw switch). the direction it wants to run is the direction you want to turn it. The size of the cap will probably be a compromise, to small will not add enough power capacity at high load and to large will lower efficiency at low load.

Make the wind fun!

Victor

[\(User Info\)](#)

interesting,

looks like simple payback period is about 15 years (at todays fuel prices)

Wonder what the expected lifetime is? Upkeep?

By the way, anyone have a comparison of energy costs for U.S. vs G.B.?

They say that it saves more energy when used in larger houses- sounds like a good fit for the "typical" U.S. household.

at least another company sees efficiency as paramount!

regards,

darren

## [Terbium and Dysprosium Metal, possible power generation](#)

By [wooferhound](#), Section [Homebrewed Electricity](#) [Power Systems](#)

Posted on Sun Nov 2nd, 2003 at 07:02:18 PM MST

**Metal that changes shape when electrical voltages are applied**

I found these two articals about making speakers from Terbium and Dysprosium, metals that change shape when Electrical power is applied.

<http://www.fortune.com/fortune/smallbusiness/technology/articles/0,15114,534705,00.html>

<http://radio.weblogs.com/0105910/2003/11/02.html>

Normally when this type of thing is possible, then the reverse is possible. Change the shape of the metal and electrical energy is created.

Personally I've never heard of these metals . . .

by [JW](#) on Mon Nov 3rd, 2003 at 10:28:36 AM MST ([User Info](#))

Hi Woof,

Ya, I stubled across the original inventor(company) of this product some time ago. these guys are doing quite well with this material in the transducer market. I suspect you may be correct, and voltage may be produced with this. But it is unclear to me at this time. from what Ive gathered about these new materials is that they are the next generation of "muscle wires" or "memory wires" .

While memory wires can be controlled using electricity, it is the heat from the wire's resistance and not the electricity itself that changes the size or shape. I don't think you can reverse the process to get out electricity from them.

I haven't heard specifically about these new ones so they could be different.

Martin.

Yes I thought about peizo effects too but, peizo material that I know of isn't metal and quite brittle, the motion obtained from peizo is more microscopic in nature and not much useful for moving things, getting power from peizo materials is usually very high voltage in short bursts.

Very Nice Ed!

A while back I was doing some playing around with a solar trough experiment - never really finished it past a prototype (no time you know!). I was using a automotive heater core as a heat exchanger. I got a new one for a 1990 Chevy Caprice from the auto parts store for \$40. According to my Moog auto heating/cooling tech manual these are supposed to reject 6 to 10,000 BTU depending on size. Might be a good choice - 5 / 8 " and 3 / 4 " hose fittings - the one I got is mostly brass!

Now it looks like you're having "Christmas came early" Fun!

Ted.

by troy on Wed Nov 12th, 2003 at 11:57:44 AM MST  
([User Info](#))

Lovely machine!

I thought of running the exhaust through a gas water heater. That's what they were designed to do, and come with an overheat/overpressure safety valve built in, plus all the easy hookups for the water. If the flue length is too short, you could run two in series. Unsure of what to do with the condensate...

Have fun with the new toy.

Still interested in the 6 hp if there is a way to make it work.

Good luck and have fun,

troy

Making contacts...

I've sent numerous emails out to different companies in India trying to find out a cost for these things. Still waiting on the prices. Most of them are the Lister clones and only one company sells the GM-90 version. The difference between them are the GM-90's have pressure oil on the connecting rod and a water pump. The lister clones have splash oiling and thermosyphon cooling. Seems like the more parts you have the more likely they could fail.

There is a guy in NC selling the GM-90's but only has the higher HP units available. 8hp and up. He sells the 8's for 800 bux plus shipping.

I should have some numbers for the others soon. Is there any "duty" costs for importing goods into the US. I know when I send stuff to Canada they get hit with brokerage fees and duty costs which I think is rediculous... anyone have any idea on what costs we may run into?

Have Fun

No idea on the import cost/hassle factor. But on a completely different note, here's three nice links concerning the care and maint. of Lister diesels, along with some great stories about the Australian farm experience:

- <http://www.steamengine.com.au/ic/faq/tipstrix.html>
- <http://www.steamengine.com.au/ic/history/48hours/index.html>
- <http://www.steamengine.com.au/ic/history/bushpowerlister/index.html>

Best regards,

troy

Re: GM-90 diesel update ([none / 0](#)) (#2)  
by DonG on Fri Oct 31st, 2003 at 06:19:48 PM MST  
([User Info](#))

I checked into importing the Lister diesel clones. I was going to have to import a minimum of fifteen to get a price from them. If I could have got it down to five I might have considered it.

[kill a watt load meter vs power cost controller](#)

By [gameman](#), Section [Homebrewed Electricity](#) [Power Systems](#)

Posted on Mon Oct 27th, 2003 at 08:42:18 PM MST

which is better .. kill a watt load meter or power cost controller

you can plug an appliance into these units, and plug the unit into the wall. The controller will monitor the power usage of the appliance in watts..

but which is the best to get ?? i have heard that you can't use the kill a watt one with a gen ..any one know if you can use the power cost controller (La Crosse Technology 3362U Power Cost Controller )with a gen ??

also wheres the cheapest place to get one ?  
thanks terry

gameman;

someone on here told me ( about a year ago )that there's brunt up when they used with there gen ....

Well, not to put too fine a point on it we have a few folks that post here that, quite frankly, are experts in their own minds only. Especially with a "it blew up" type comment its hard to know if it was the device the powersupply or user error just too many variables

Beware of any free advice and realize that just because its written someplace [newspaper, magazine and especially the internet] does NOT mean it is either true or sound advice. Not to point any fingers just a fact.

Cheers.

([User Info](#))

Dave, my first Kill-O-Watt meter came with instructions stating that it should not be used with a generator or inverter. I did try it out on a generator & it seemed to be OK. But after several hours the input resistor FRIED.

I bought a new K-O-W in order to identify that resistor. The old resistor was a 5w of unreadable value. The new KOW had a 10ohm 10watt resistor. That will probably solve the problem of using it with a generator. But I don't know since I haven't tried it. There may be thousands of the old design out there.....

([User Info](#))

Ed,

The Listers and clones - I think Lister quit building the things in the late 1960's, are one of the most reliable engines ever built. I think India must have more than 20 companies building engines near identical to the original. Pakistan might have half a dozen companies making them and the Petter. There are some options that may be worthwhile. There is a compression changing device that will allow the engine to crank in colder weather. Some offer the option of roller bearings on the crank and pressure oiling. There may also be a radiator option.

If you get one with roller bearings, pressure oiling and the radiator, your great grandchildren might need to rebuild it if you run it all the time. (provided you keep clean fuel and oil in it)

If one could get a group together, the engines might be bought for a REAL good price. If I could afford to buy a container full and market them, I might try it.

Ron

Ron,

Sounds like its a fairly good machine then. I talked with George that runs the site utterpower.com and he seems to think their quite amazing. I saw a new GM-90/6 on ebay but didn't bid on it. It may be interesting to order a bunch of them through a group of people to get a better price... how many would be interested? Anyone?

I noticed some have the pushrods external and some internal... seems like the external ones would be high maintenance... well a glob of grease now and then isn't "high" maintenance but messy.

Any other comments on them?....

Ed

by RobD on Tue Oct 28th, 2003 at 04:54:30 AM MST  
([User Info](#))

I did a quick look and they seem to run 550 lbs. for the 90-6. Where do you get them?  
Anyone have a price?  
RobD

Re: GM-90 diesel ([none / 0](#)) (#8)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Oct 28th, 2003 at 07:13:13 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've seen them for about \$750.00 ( plus shipping ). These things are quite heavy. If there were enough of us, we could possibly get them cheaper buying them direct and having them imported.

I've drawn up some ideas, since I burn diesel to heat the house anyway, why not turn it into house heat, hot water and electric. Instead of simply using it for singular use and wasting it. It would be quite easy to build an axial flux alternator running direct drive on the engine for battery charging. A radiator, and exhaust heat exchanger to do the rest. I hear they perform well with biodiesel as well.

There is a guy in NC that sells the GM-90's if I can find his address again I'll contact him and let you all know, unless you would like to pursue the possibility of getting them cheaper from India...

Have Fun  
Ed

Re: GM-90 diesel ([none / 0](#)) (#9)  
by RobD on Tue Oct 28th, 2003 at 07:33:28 AM MST  
([User Info](#))

Hi Ed,  
I burn diesel here too. I like the idea. The weight seems to be about 255 Kgms, just under 600 lbs for the 90-6. I'm wondering how much more oil the 90-8 uses? I'll bet not much.  
I'd like to run it inside the basement with an outside exhaust or just use the cooling water to supplement my heat.  
Let me know what you find maybe we can get a bunch straight from India.  
How are they on parts? Will we have to be making our own?

RobD

[ [Parent](#) ]

Re: GM-90 diesel ([none / 0](#)) (#11)

Rob,

It looks like the 6 and 8 are the same engine... Both identical in bore x stroke and weights. One runs at 750 rpm the other at 900. So it appears to be the same engine running faster. The slow rpm is the part that intrigues me the most... much quieter than a briggs or other engine screaming at 3600 rpm ( although the honda's are quite quiet ).

Having fun  
Ed

Re: GM-90 diesel ([none / 0](#)) ([#10](#))  
by monte350c on Tue Oct 28th, 2003 at 07:56:13 AM MST  
([User Info](#))

Hi Guys,

Very interesting! I've been thinking about bio-diesel and generation too...

A while ago I found this on a message board:

Dear Sirs,

I know you name and address from alibaba.com. I'm writing you in hope of establishing business relations between us.If you need small diesel engine,you can touch us.

'XINHUAN' brand diesel engines are the main products of company which are quality product and very low price ,its are becoming more and more popular.

The company have 2HP-6HP air-cooled and water-cooled two series of engines,its excellent in quality and quotation is attractive.

Please inform us as to any further information you may require.

= = = = =

It's our price list and main specifications:

MODEL FOB NINGBO PORT CHINA (US DOLLAR)  
Z165F 83.00 (2.7HP ; kw/rpm/min 2.00/2600)  
165. F 84.50 (3.3HP ; kw/rpm/min 2.43/2600)  
170. F 85.00 (4HP ; kw/rpm/min 2.94/2600 ; Specific fuel consumption g/kw.h 289.7)  
175. F 94.00 (5HP ; kw/rpm/min 3.68/2600)  
ZR165 90.00 (3HP ; kw/rpa/min 2.21/2600 )  
ZR170 92.00 (3.7HP ; kw/rpa/min 2.72/2600 ; Specific fuel consumption g/kw.h 299.2)  
R175 100.00 (6HP ; kw/rpm/min 4.4/2600 )  
R175A 110.00 (6HP ; kw/rpm/min 4.4/2600)

COMPANY:CIXI XINHUAN POWER MACHINERY CO.,LTD.CHINA  
CONTACT:MR JEASON XAO  
ADD:Economic Development Area CIXI ZHEJIANG CHINA  
TEL:086-574-63284816 63289202  
FAX:086-574-63289065  
EMAIL:enginesupply@sina.com

After a bit of futzing around, I found their Web site which gives more specs on the engines:  
"http://www.new-circle.com/DIESEL.htm">http://www.new-circle.com/DIESEL.htm

You occasionally find these motors (which seem to be the same as the Yanmar brand) on E-Bay for greatly inflated prices compared with the FOB China pricing.

Also this address with more specs but no prices for 90/6:  
<http://www.satyaheet.com/de2.htm>

Seems reasonable if an order for a dozen or so of any of these was put together the

prices would be really good.

Ted.

Re: GM-90 diesel ([none / 0](#)) (#12)  
by josephcrawley on Tue Oct 28th, 2003 at 09:13:28 AM MST  
([User Info](#))

I've been interested in getting lister diesel engine for some time now. Depending on the price I would be willing to go in on some sort of group purchase.

thanks  
Joseph

Fuel Consumption ([none / 0](#)) (#13)  
by wdyasq on Tue Oct 28th, 2003 at 03:44:31 PM MST  
([User Info](#))

Diesel engines get ~ 18-21 HP/Gal/hr. That means if we burn a gallon of diesel, there have been about 15kW of power produced. One will need to back out the losses in the power conversion and one of these old crude but elegant engines will burn just about any oil that one can make flow. A modern engine MIGHT be 15-20% more efficient but, that will be about all one can do to improve fuel consumption.

The Chinese engines are/were and old German design except for the "new" air-cooled ones which are Yanmar "Clones" - or, at least all I have seen and/or read about are.

Like many I have dreamed of the small diesel powerplant supplementing a renewable energy home. Mine would have a "heat pump". I would hope I could use most of the "reject heat" for heating my home in the Winter. In the Summer I might have an airconditioner and use the heat for distillation of water if there were no other use.

Ron

BTW - the cost of the engine FOB (Free On Board) India was less than \$300 for a plain-bearing 650 RPM engine when I checked them out. I think a small container load was about 25 of them. BUT, that is old memory and about 2 year old information.

Re: GM-90 diesel ([none / 0](#)) (#14)  
by zmoz on Tue Oct 28th, 2003 at 06:57:51 PM MST  
([User Info](#))

Here's one of the foreign manufacturers:

<http://www.vibha.com/diesel.html>

How long would one of these really last running 24/7? I'm thinking if I could make diesel cheap enough I could be generating power 24/7 and feeding it back into the grid...even if it was only a few cents an hour I think it would be pretty cool just to have one of these things...:)

Re: GM-90 diesel ([none / 0](#)) ([#15](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Oct 28th, 2003 at 07:33:08 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've heard they would run for 100,000 hours, others have said they would outlive the owner, and that your kids kids would have to rebuild it. It's all hear say though, but within some of the hearsay there may be some truth as well as some exaduration... but... I've yet to hear anything bad about them.

Have Fun  
Ed

[ [Parent](#) ]

Re: GM-90 diesel ([none / 0](#)) ([#21](#))  
by troy on Thu Oct 30th, 2003 at 06:00:36 PM MST  
([User Info](#))

I'd be interested in going in on a container of Listers, pressure oiled, roller bearings, water cooled to make for easy cogeneration.

Coincidentally, my brother-in-law spent a year in Africa, giving technical support to a bunch of missionaries. They had a couple of Listers for gennies. He assured me they can take a lot of abuse and still perform. He did comment that they were pretty noisy, not from the exhaust, but from the combustion noise. But they were the air cooled model I think, so I would expect that to be much less from the water cooled version.

Best regards,

troy

[ [Parent](#) ]

Sell it back -NOT ([none / 0](#)) ([#16](#))  
by wdyasq on Tue Oct 28th, 2003 at 07:35:37 PM MST  
([User Info](#))

Zmoz,

If one could get 15kW of sellable product with \$1.50 a gallon fuel, the fuel cost will be \$0.10 kWh. Buy back rates are about half that. And, one hasn't paid for oil-changes, disposal of the used oil(it can be filtered and used as fuel if mixed with the diesel) or the rebuild after the 100,000 hours (over 11 years, 24/7) or so life of the engine. With my math, I still haven't taken into account you won't get but about 10 kW or less out of the 15 kW produced by the engine due to energy change losses.

I also think if one sells electricity, they are bound by the rules of a new generation plant as it pertains to airpollution and such. I know in Texas, the folks with gas wells can't sell electricity generated by fuel from those wells without going through a bunch of hoops.

IMO, the only thing that makes sense is to use one as a backup to renewable sources or as a main power source if the grid is not close (or one is just plain obstinate).

Ron

Re: Sell it back -NOT ([none / 0](#)) ([#18](#))  
by zmoz on Tue Oct 28th, 2003 at 07:43:10 PM MST  
([User Info](#))

wdyasq - yes, with diesel fuel from the gas station it would be nothing more than a good backup generator. However, biodiesel is much, much cheaper...I haven't looked into it in a while, but I think it could be had for well under \$0.50 a gallon. If only producing 10kwh from that gallon of fuel, that would be 5 cents a kwh. Around here, the power company is required to buy back the power at the wholesale rate, which I would guess is at least 5 cents a KWH. They are also required install a meter for that free of charge. As for using fossil fuel to generate that power, I don't know what the laws are, but I don't think they ask how you generate that electricity. :) As I said, it wouldn't be much of a money maker, but after a few years I might be able to have one of these cool engines for free...

Re: GM-90 diesel ([none / 0](#)) ([#17](#))  
by zmoz on Tue Oct 28th, 2003 at 07:35:56 PM MST  
([User Info](#))

Another thing I've heard about is pre-heating diesel fuel to increase it's volume, therefore creating more fuel to burn. I don't know how well the concept works, but it seems like it would to me. One could probably rig up some sort of heat exchanger with the exhaust to heat up the fuel...

Re: GM-90 diesel ([none / 0](#)) ([#19](#))  
by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Tue Oct 28th, 2003 at 11:53:45 PM MST  
([User Info](#))

I dunno about heating the diesel before burning. I'm sure it would make more fuel on a volume basis, but there'd be no more energy in the 120 gallons of heated fuel than there was in the 100 gallons of unheated fuel. Sure, the expanded fuel would last longer, but the engine would have less power. I guess if a person wasn't using the full output of the engine anyway.....

Demetri

Re: GM-90 diesel ([none / 0](#)) (#20)  
by wdyasq on Wed Oct 29th, 2003 at 04:44:01 AM MST  
([User Info](#))

I guess if a person wasn't using the full output of the engine anyway.....

As matter of fact, the governer on the engine would adjust the fuel flow to match the load. Running an engine at the proper temperature might be the best option to increase the power from a given amount of fuel and to allow the engine to live as long as possible.

I'm in my mid 50's. I have been playing with diesel engines for over 40 years. At one time, I was factory certified on 8 different brands of engine and one company thought enough of me to employ me as an instructor and trouble-shooter.

All sorts of magic devices have been marketed to make engines more efficient, your wife more amorous and your children smarter. Personally, the best I have seen only lighten your wallet. BUT, your mileage may vary.

I don't know how much bio-diesel costs to produce. I think one needs to calculate the cost of the equipment and their own time, including the disposal of the wastes, in determining the TRUE costs of a product.

Ron

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

If using a diesel engine,  
why not using 'producer gas' or biogas to run it?

For a diesel engine  
you need a bit oil as well if using gas,  
but that is a really small amount, it can be biodiesel.

I thought I'd add to this thread. I run a small low rpm Kubota diesel engine with a 12v 100amp alternator attached. This engine is the same one that they use for the 'road side' signs that go blink blink here in the states.

The Kubota gets about 9 hours to a gallon of diesel (yes 9+ hours), and I usuall charge my batteries at between 50 and 70 amps till they hit about 15.0v.

This unit has been a real workhorse especially in the winter when solar is non-existant and darkness settles around 3:00pm. Had it now I think 8 years.

I really like this setup (Generating at 12V). So many people I know buy these HUGE generators are unhappy with the noise, expense and smell. They all have inverters, and for the most part just run battery chargers off of them anyway.

Just thoughts to consider.

How exactly does electric current work . . .

---

Hello Everyone,

I would like to once and for all get to the bottom of how electricity performs.

When one's car battery quits working and the car is running, the lights will shine as bright as when the battery was good and the car was not running. So this means that the lights are now being run solely from the alternator. Presumably the alternator is producing, or is able to produce more current than the lights actually need. So my question is why do the lights only take as much as they need to work properly and not burn up from too much current?

Along this same line of questioning is how and why does a battery being charged able to convert for example, a 100 volt 15 amp input to 12 volts @ 125 amp charge? But if you plug 12-volt bulbs into a 24-volt current, they burn out?

Say hypothetically you have a pmg alternator being turned and operated by a constant running stream and rather than having it connected to batteries you just have this alternator connected directly to an inverter. Would any appliances and lights be able to work with this system as long as the wattage needed didn't exceed the wattage being produced by the alternator? In other words, would one's appliances perform correctly like the lights on the running car with a bad or no battery?

What if one had a very large DC current coming in, say 1000 volts @ 100 amps, would you be able to connect this current directly to an inverter and all your appliances and lights just grasp what they need to operate properly? Or would the inverter burn up if enough was not being consumed?

Sorry if these questions are too elementary. I am just trying to grasp the entire overview.

All the best,

Billy Baty

Hi Billy,

"When one's car battery quits working and the car is running, the lights will shine as bright as when the battery was good and the car was not running. So this means that the lights are now being run solely from the alternator. Presumably the alternator is producing, or is able to produce more current than the lights actually need. So my question is why do the lights only take as much as they need to work properly and not burn up from too much current?"

The light or any load, has resistance and the current it draws is not related to the power capability but the resistance of the bulb filament. The formula is

$E(\text{voltage}) = I(\text{current}) \times R(\text{resistance})$ . A lamp inside your house is plugged into a wall socket that can supply much more power than the lamp needs but the lamp only 'draws' what it needs.

"Along this same line of questioning is how and why does a battery being charged able to convert for example, a 100 volt 15 amp input to 12 volts @ 125 amp charge? But if you plug 12-volt bulbs into a 24-volt current, they burn out?"

The battery acts as a load to the power coming in and it has very low resistance that would draw much more power than the supply can handle so the supply in this case, drops to the voltage of the battery. This is just the opposite of the condition above, now the battery controls the voltage but the same formula applies,  $E = IR$ .

The 24v source would apply twice the voltage to the bulb at the same resistance so from our formula you can see that the current through the bulb is twice what it would be at 12v and would most likely burn out.

"Say hypothetically you have a pmg alternator being turned and operated by a constant running stream and rather than having it connected to batteries you just have this alternator connected directly to an inverter. Would any appliances and lights be able to work with this system as long as the wattage needed didn't exceed the wattage being produced by the alternator? In other words, would one's appliances perform correctly like the lights on the running car with a bad or no battery?"

No, because the battery acts as a regulator for the generator and keeps its voltage at the 12v maximum. Without the battery the alternator would over drive the inverter and it would either shut down or blow out.

"What if one had a very large DC current coming in, say 1000 volts @ 100 amps, would you be able to connect this current directly to an inverter and all your appliances and lights just grasp what they need to operate properly? Or would the inverter burn up if enough was not being consumed?"

Inverters are designed to work with specific voltages, say 12 or 24 volts. You don't want to apply more voltage to them. If an inverter was capable of running at high power say 2500 watts it would be able to 'carry' any appliance that didn't consume more than that 2500 watts. The formula for watts is:

$P(\text{power}) = E(\text{voltage}) \times I(\text{current})$ . The appliances in your home will tell you on the back how much power they consume. You don't want to put more appliances on the line than the inverter will take.

resistance heaters ([none / 0](#)) (#3)  
by JeffC on Sat Nov 22nd, 2003 at 10:05:34 AM  
MST  
([User Info](#))

I am also new to this arena and have a somewhat similar question.

I'm wondering if it would be possible to build a brake disk mill and run the 3-phase AC directly into my baseboard resistance heaters. I posed this question before and was told that it may work if I "get the loads" right. Could a mill produce the kind of power needed to produce any heat from a baseboard resistance heater, and if so, how would I figure the loads?

Thanks very much,

Jeff

Is this a hard thing to do?

I've got a 10kw gen. Short and sweet. Can anyone tell me how complicated it is to back feed the big high dollar grid in the USA. I am real new to this.

([User Info](#))

All these years you've been giving them your money now you want to give them your electricity? From what I've read on this post it's complicated and expensive and 10KW isn't near enough. The electric company doesn't want your electricity they want your money! (:>) Norm.

Re: spin the meter backwards ([none / 0](#)) ([#2](#))  
by kmitchel on Sun Oct 26th, 2003 at 04:46:38 PM MST  
([User Info](#))

u need a synchronous power inverter. the utility company must buy your electricity, but depending on your area, they may be reluctant, or try to make it impossible 4 u. ur equipment will need to be inspected and be on the up and up.

A lot of regulation ([none / 0](#)) ([#3](#))  
by wdyasq on Sun Oct 26th, 2003 at 04:46:43 PM MST  
([User Info](#))

There are many hoops, loops and expenses to hook-up a generator to "the grid". Homepower magazine has many articles on those doing it "on the sly".

I don't like dealing with the "nice folks".

Ron

by zmoz on Sun Oct 26th, 2003 at 06:07:03 PM MST  
([User Info](#))

I've looked into this before, around here they have to buy it back at the wholesale power rate, and the power company has to pay for the new meter and installation. Depending on how that generator of yours is powered, however, it would probably cost more to run than the electricity they would buy back.

Re: spin the meter backwards ([none / 0](#)) (#5)  
by DanB on Sun Oct 26th, 2003 at 08:06:52 PM MST  
([User Info](#))

Not only is it complicated....

but Id argue your stance on "high dollar grid". The power grid in the US is (in my opinion) somewhat govt subsidized... and it's dirt cheap. Around here we pay about \$0.10/kwh. You can't compete with that with a diesel generator. Even if they payed you retail for it all I think the cost of fuel alone would probably be about break even, if not a slightly losing deal... not to mention maintenance and wear and tear.

Now.. last fall, when wholesale in CA was over \$1.00/KWH I think you maybe coulda made some \$\$ !

Re: spin the meter backwards ([none / 0](#)) (#6)  
by troy on Thu Oct 30th, 2003 at 02:11:31 PM MST  
([User Info](#))

Also keep in mind, the phase of your electricity MUST be totally, perfectly in step with the phase of the utility power, or bad things will happen, like fires, destroyed generators, things like that. A normal gas or diesel gennie has no provision for matching the phase properly.

Sorry...

troy

Re: spin the meter backwards ([none / 0](#)) (#7)  
by BrianK on Fri Oct 31st, 2003 at 06:10:26 AM MST  
([User Info](#))

I also have a 30kw that has parallel abilities adjustable freq.timing lights and all could that gen be able to do this task easier?

Re: spin the meter backwards ([none / 0](#)) ([#8](#))  
by troy on Sat Nov 1st, 2003 at 06:59:42 AM MST  
([User Info](#))

Nope, not unless it's specifically designed to intertie with the grid. Good frequency control is one thing, and matching the utility frequency and phase is something completely different.

Sorry again...

troy

## [Calculating Potential Voltage from a Ferrite cored Coil](#)

By [jcertain](#), Section [Homebrewed Electricity](#)

[Power Systems](#)

Posted on Thu Oct 16th, 2003 at 01:06:16 PM MST

I am experimenting with getting AC from a ferrite cored coil.

I am experimenting with getting AC from a ferrite cored coil. I have 10 layers each with 80 windings making a total of 800 windings. I am using 32ga wire. I am using the magnets in the link with an "n40" grade. What other information do I need to figure out my voltage based on a variable turn speed?

[http://www.rare-earth-magnets.com/images/arc\\_750\\_625\\_90\\_750\\_N.jpg](http://www.rare-earth-magnets.com/images/arc_750_625_90_750_N.jpg)

[Calculating Potential Voltage from a Ferrite cored Coil](#) | 2 comments (2 topical, 0 editorial)

Re: Calculating Potential Voltage from a Ferrite c ([none / 0](#)) (#1) by [RobD](#) on Fri Oct 17th, 2003 at 04:01:11 PM MST ([User Info](#))

I think there are to many variables. You will have to do it by empirical testing. The power of the magnets , the distance from the cores, the permeability of the cores, just to much stuff.

Re: Calculating Potential Voltage from a Ferrite c ([none / 0](#)) (#2) by [TomW](#) on Fri Oct 17th, 2003 at 06:10:02 PM MST ([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Folks;

I have to whole heartedly agree with RobD on this.

I am somewhat puzzled by this recent need by people to be able to calculate these things out. While it is possible to run the math on lots of these things and get viable numbers it is just not practical.

Don't get me wrong, math is the language we must use to describe these things but it is simply a way to get in the ballpark and the only way to really know is empirical testing and measurement.

There is so much "windage" in these devices that there is simply no way you will calculate out values and arrive at those values in the completed unit. A much more sane approach is to follow the basics in the designs others have built and read everything you can on your intended subject then add in your own "windage".

Just my opinion and likely not shared by everyone, especially the mathematicians in the world.

Cheers.

TomW

by Old F on Sun Sep 28th, 2003 at 07:30:58 AM MST ([User Info](#)) <http://www.olf.homestead.com>

Hi DR.D

If you are talking about changing a compressor based refrigerator to a heat driven ammonia cycle the short answer is no. About the only thing you would be able to salvage is the refrigerators insulated shell.

If you do a web search on the Crosley Icy ball. You will find some interesting reading. And you will see what I mean  
Hope this helps

Old F

Re: Converting a refrigerator to Ammonia cycle? ([none / 0](#)) ([#2](#))

by wdyasq on Sun Sep 28th, 2003 at 07:48:43 AM MST ([User Info](#))

I'll agree with Old F. I will also state I wouldn't want to try and cram the gear necessary for the ammonia cycle into a "Premade Box".

Ron

I pritty much new that one would only reuse the insulated box and perhaps the inside cooling coils and that you would end up with a "built in" system, which in many respects might be an advantage as the external heat exchanger could be mounted outside and reduce heat re introduced into the home.  
Dr.D

by Norm on Mon Sep 29th, 2003 at 06:33:20 AM MST  
([User Info](#))

Evidently this is how a gas 'Servel' refrigerator works? I think for the most part it would be easier to either buy or convert one to run on 12 volts, plug it in to an inverter even! Probably would be fun to convert one to Ammonia cycle if your talent lies in that direction. Way back we used to just put the stuff down in the well...or hang out the 'ice card' for more ice! ..that was before frozen foods tho' (:>) Norm.

## [Is a big engine going to use more gas than a small engine with a small load?](#)

[Power Systems](#)

By [zmoz](#), Section [Homebrewed Electricity](#)

Posted on Tue Sep 23rd, 2003 at 07:10:20 PM MST

**V6 powered generator inefficient with a small load?**

I'm thinking of setting up an air compressor/generator/welder with a small fuel injected V6 engine. If I was just running the generator portion of that (~10kw) off of a large engine...is that going use up more gas per hour than something like an 18hp briggs engine? I mean, the briggs engine would probably be running at full load at top RPM...while the big engine would have a very small load and could run at ~1500-2000 RPMs.

[Is a big engine going to use more gas than a small engine with a small load?](#) | 14 comments (14 topical, 0 editorial)

Re: Is a big engine going to use more ..... ([none / 0](#)) (#1)

by Norm on Tue Sep 23rd, 2003 at 09:53:52 PM MST ([User Info](#))

This is just an opinion but fuel injected computer monitored engines should win over an air-cooled engine that was never touted for fuel economy. When's the last time you've seen a claim for fuel economy on a lawnmower engine? Also I think a water-cooled engine is more efficient than an air-cooled one. Norm.

Re: Is a big engine going to use more gas ([none / 0](#)) (#2)

by zmoz on Tue Sep 23rd, 2003 at 10:51:25 PM MST ([User Info](#))

I know small engines in general aren't very efficient, especially compared to a water cooled fuel injected engine, but when only running a small load (very small for a car engine) is it going to use less gas per hour? I mean, we are talking ~4 liter engine compared to a ~1/10th of a liter engine...

Danged subject too long ([none / 0](#)) (#3)

I'm fairly certain that a fuel injected v-6 that can (probably) move a 3200 lb car up, over, and through mountain passes while maintaining 24 mpg would get considerably better fuel economy than an 18 hp carb'd engine screaming all out. I'm sure the calculations can be done to figure it mathmatically, but I think you'd do better than the B&S. Pully ratio would be extremely important.

If you have the v-6 already, or are getting one for free, or at considerable discount, etc., go for it. If you have yet to procure an engine.....I would suggest a four cylinder engine, as one would probably pull the load just fine, get even better economy, and are far more common and inexpensive. A diesel engine would be great for increased longevity, efficiency, and easy use of biodiesel. Good luck with whatever, and let us know what you decide on.

this reminds me of a story ([none / 0](#)) (#5)  
by RobD on Wed Sep 24th, 2003 at 06:53:39 AM  
MST  
([User Info](#))

Once upon a time (around 1973) when gas became a problem I decided to find the smallest cheapest engine for my VW bug. I finally found and old 1100 or 1200 cc engine, blue printed it and put it in the car. It couldn't even go up hills and I always had my foot to the floor. Worse yet, the mileage was only about 30 mpg. Finally I got so fed up I put in a 1600 cc engine with twin Weber carbs. It flew! Better yet was that I got just about the same MPG. My girl friend said, "Gee, glad to see you finally tuned the car!"

([User Info](#))

zmoz,

I use a single cylinder Kubota oil burner. It's a EL-300-E rated at 4.5 with surge to 5 HP water cooled. I drive a big 100 amp Mopar externally regulated alternator, and a 2.8KW AC gen. Of course I can't load both power sources to their max at the same time, but I can put 20 amps into the battery bank while running any tool or appliance off the AC side. This engine gets about 1.25 PINTS of diesel (sp) per hour under full load (or as much load as I care to put on it).

This isn't a cheap engine, but with total maintaince and operating cost to date I'm still WAY under what the grid bills would be. I buy off-road fuel (without the road taxes) 50 gals at a time and have a semi tank that holds 109 gals. I useually buy fuel twice a year. I'm adding other power sources as time and money will allow. But the Kubota has been a really good investment.

Now all I need to do is figure out how to make bio-diesel.

RogerAS

Id think the V6 is too big...

Lots of bits reciporating - lots more friction, I'd vote for the 18hp briggs... or a nice old wisconsin or something. They are not that inefficient!

Better would be find something a bit oversized and run it slow (1800 rpm or less) for peace and quiet.

The V6 is probably a 160-200hp engine, and you'd be asking for so little from it, I think you'd be using most of your fuel just to keep the engine running.

I don't think air vs water cooled really enters into efficiency. Flat heads, and low compression do to some degree, but I think efficiency is not a big factor in 4 cycle gas engine.... they are all similar I think. One cool thing about a briggs, or other air cooled engines - once hot, they will run nicely on kerosene or light diesel! (wont start that way...) If you run on that, you'll go through almost half the fuel and they'll run a bit more smoothly. Funny how that works out - but Ive run lots of small battery chargers with little aircooled motors on diesel or kerosene and found it to be quite economical.

A few years back I took a 4 cyl volvo engine (and old B-18 90hp) and tied it to a welder (probably about a 10KW generator) and it ran 1800 rpm (direct drive). Worked great... it wasnt fuel injected, but I used an FI manifold and put a motorcycle carb on it - it was running clean, and fairly efficiently I think. But... it was a gas hog.

Your case might be even worse. A briggs, or a wisconsin or something along those lines is reasonably efficient, light weight - a good one will last a long time, they are cheap and easy to fix. If you can get one large enough to run at lower rpm that'd be better. I think you'd do OK, like

someone else said.. to find a small 4 cyl car engine perhaps, but I'd look for real small one.

Or.. a larger engine off a motorcycle might be nice!

([User Info](#))

HI Dan,  
I knew that B18 engine and it was a real work horse. The 544's ran them.  
I don't know how true this is but one of my friends said he gets relatively good efficiency on his lawn tractor. I told him mine was a hog and he said the overhead valve engines are much more efficient. My little Honda lawn mower with overhead valves is quite good and my 2 cycle mopeds get about 125 mpgs. Not bad for a horse and a half to two horse power. I think the most efficient is the diesel in the long run.  
RobD

Re: Is a big engine going to use more gas than a s ([none / 0](#)) ([#10](#))  
by DanB on Wed Sep 24th, 2003 at 01:54:11 PM MST  
([User Info](#))

yes.. the B-18 is a tough little motor so long as you keep oil in it! I've had 544's... lotsa fun!

I think "efficiency" - as far as the engine itself is concerned (not the fuel system) largely boils down to compression. Overhead valve engines generally have higher compression ratios simply because there is less volume in the head. Flatheads usually have low compression because the valves have to sit beside the cylinder - and the airflow is not so smooth.

But I think it's a fairly small factor really in small engines... (my model A gets good milage with a flat head!).

I dont think air, or water cooled enters into it. My honda generator (with overhead valves) definitely does well on gas, surely a bit better than it would with an old briggs&stratton or something. I do like the simplicity of a flat head though and I think they are not bad.

(#8)  
by N9WOS on Wed Sep 24th, 2003 at 01:37:56 PM MST  
([User Info](#))

If it is a 3L engine, it would top out at about 150HP  
at 5100RPM or so.  
At 1800RPM, it's rated HP will be around 50HP or so.

A 3L engine would make a good match to a 25KW or 30KW  
1800RPM generator.

If your are going to run a welder/10KW  
generator/compressor  
off of it, I would say the engine would be a good match  
at 1800RPM operating speed.

Make sure the O2, map/mas, TPS, and engine temp sensor  
is working properly, so that the ECU will be in a closed loop  
operating mode, otherwise the fuel usage will suck.

Starting on diesel(yes the subject was too long)  
([none / 0](#)) (#11)  
by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Wed Sep  
24th, 2003 at 10:55:01 PM MST  
([User Info](#))

Dan, it's possible to start a B&S when it's running diesel. I  
turn on my propane torch all the way, but I don't light it,  
and hold it near the air intake so that propane vapor can  
be "inhaled". It smokes an awful lot until the engine warms  
up, but it does work. Also good for starting an engine in  
stone-cold weather, though I have never tried starting one  
burning diesel in stone-cold weather. I'll have to try that  
when things start cooling down here in Oregon. 91F  
today....

Demetri

(#12)  
by zmoz on Wed Sep 24th, 2003 at 11:23:29 PM MST  
([User Info](#))

Now you've done it...you've got me interested in a diesel  
powered lawnmower engine! :D I have never heard that  
before. So you're saying once it's warmed up, it burns it  
just fine?? Does it smoke alot? (I do have close neighbors!)  
How exactly would one "switch over" from gas to diesel  
while it's running?

Anyone else having problems with the subject?

([none / 0](#)) ([#13](#))

by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Thu Sep 25th, 2003 at 10:09:30 AM MST

([User Info](#))

Once it's warmed up, it doesn't smoke (any more than usual, hehe), except upon a change in engine speed or under heavy load, and then only a little bit. When starting on diesel with propane, like above, it'll billow white smoke for a minute or two. The easiest way to make the switch over is to have just enough gasoline in the fuel tank to warm the engine up when you start it. When the engine is warm, fill up with diesel. You'll have to adjust the carb settings as it runs and diesel makes it's way into the system; the gasoline settings will be horribly rich for diesel. The biggest drawback I've found is that the oil change interval is shortened a bit. But with the cost of offroad diesel vs. gasoline and a quart of oil being 99 cents, it works out just fine. HTH.

Demetri

### Grid Tie Question

I have watched this page for sometime, and I have learned quite a bit. There are definitely many people on the this page that know ALOT! I started messing with windpower this winter, and within 2-3 wks I hope to have my 42' tower up. At that point I will do alittle more testing on my motor/rotor combo, and then proceed from there. I do not have an inverter or battery bank yet. I have 2 deep cycle batteries for now just to have a battery source at the bottom (on my 12' test tower that I've been messing with).

I have read some on net metering laws and such, and from what I understand, Nebraska is not one that will credit you back retail for every KWH you put into the grid. They will pay you wholesale, not retail. I could be wrong, it happened one other time.

Lets say the local utility company says on the local level, they will keep good on their goal to work customer relations, and they will credit me back retail what goes into the grid. If my main goal is just to cut the electric bill alittle every month, could I go directly out to the grid? I know its not just a plug and play situation, but could I, or would I want to? Could it save me doing some rewiring in my house? Could I get by with a smaller battery bank? Everytime I have a full battery bank I could discharge into the grid, therefore never having to bury power through a regulated discharge?

I'm sure there are alot more components to this scenario that I am aware of, but its a question I've been wanting to go to the utilities about. I need to be more knowledgeable of what is involved before I go to them, so I dont sound like an idiot.

If I'm all wet on some of my ways of thinking, feel free to set me straight.

Thanks, Bruce

Re: Connecting to the Grid ([none / 0](#)) ([#1](#))  
by [drdongle](#) on Tue Sep 16th, 2003 at 09:25:41 PM MST  
([User Info](#))

Connecting to the grid requires a special synchronus inverter and the utility always buys at a rate advantages to them, so I wouldn't bother, use any power for your own and reduce your dependance on the utility.

Dr.D

Re: Connecting to the Grid ([none / 0](#)) (#3)  
by troy on Wed Sep 17th, 2003 at 11:58:53 AM MST  
([User Info](#))

Intertie inverters have multiple redundant safety features and produce beautiful sine wave juice, better than the utility, and it's also designed to stay precisely in phase with utility power so things don't blow up, catch on fire, etc. If the grid goes down, you automatically go down also.

Intertie inverters cannot work independant of the grid.

They are pretty expensive and your utility may also want you to have two seperate meters. Then they will typically charge you twice the monthly base rate because now they have to "read" two meters.

Occasionally, you'll find a utility that's not such a jerk to work with, but that's rare.

Best regards,

troy

Re: Connecting to the Grid ([none / 0](#)) (#4)  
by bruce on Wed Sep 17th, 2003 at 08:15:26 PM MST  
([User Info](#))

Thanks for the inputs all. The utility guy I talked to once did mention about a second meter, so that right there would probly just add more costs to it.

It appears separating some outdoor lighting will be what I will strive for at first. I have alot to figure out being a newbie, so you will be seeing more postings from me.

Thanks, Bruce

Bruce;

I have to chime in here on the side of just use it yourself.

Back a couple years ago when I got bit by the RE bug I investigated grid tie. Seemed to be the way to go and no batteries to maintain . I discovered several things that led me to my current system:

- Payback on the investment was going to be beyond my lifetime
- If the grid goes down so do you [generally].
- You get less than you pay for your power while charging a premium for "green" power to other users.
- Mandatory onsite inspections by the electric company at their discretion.
- More hoops to jump through than a dog and pony show.
- Uncooperative "cooperative" electric company.

Just to name a few reasons I decided to go with a stand alone system.

In my case I have my RE setup for my garage / office / workshop area. What I did was pull 2 of the cables out of the breaker box and put heavy duty plugs on the romex that feeds those 2 circuits to the building. I have an outlet near my inverters and I can plug those circuits into one of my inverters or the grid very easily. This works very well and is pretty straight forward and foolproof. I run most of my garage area off of the solar most of the year. I generally just flip on an inverter when I am actually out there doing things which is about 5 hours a day on average running computers tv stereo lights maybe the drill press or other tools as needed. In January or other times when I am low on stored power I just plug into the outlet to use the grid. I do not run our freezer or well from the solar yet but thats because for those things the grid is lots easier and more reliable and relatively cheap here and my system is not big enough to do it reliably.

Let me make one major point in regards Alternative energy systems and use:

It is a lot easier to reduce your consumption by a few kilowatthours than to produce a few KWH.

Best of luck in your search for energy independence.

Cheers.

TomW

Lots of differing opinions...

Batteries are one of the most expensive parts of a RE system. The cost of batteries alone, broken down over their average lifespan can easily cost more than all the power you'd have got from them had you bought it off the grid! (this depends some on where you live and where you buy your grid power). The power grid is actually a pretty neat thing, in that it allows areas with excess power to share with areas that need more power! It doesn't rely on batteries...

Batteries are a drag. They are expensive, toxic, heavy... they require lots of special care. Battery factories are horrible places - lead, acid.. etc.

Unfortunately folks who live off the grid have to deal with them. (I don't mind too much, but it is my LEAST favorite part of the system!).

If you have interest in RE, and have the grid right there, I'd seriously consider staying hooked up. You can keep a small battery bank which might get you by in the occasional blackout, and you can run your grid-tie inverter off it - and tie your system to the power grid. Most states have Net metering, which means that whatever you generate will come off the top (power that you WILL NOT have to pay for). So that power you generate comes off your utility bill directly and you don't have to pay for the huge battery bank that would've otherwise been required. If you ever generate more than you use - they may pay you retail, they may pay you wholesale... or they may pay you nothing at all. It doesn't matter a great deal though until you generate more than you need and that's probably unlikely.

It depends a lot on resources and what you really have in mind I think. Grid tie inverters are pretty expensive... but once done, it would be a neat system and I think the savings on batteries, bad backs... etc might make it all well worth it. I suspect as time goes on, more options will come along and prices for grid tie equipment will go down.

The "ideal" system (big scale) in my mind... would be if everybody could take from, and feed into the power grid and NOT use batteries. This would make us all less dependant on big coal fired power plants and probably make the power grid a bit more stable. I suspect that's a ways off yet, but the technology is definitely getting there. Solar panels and inverters are getting cheaper and better all the time.

Agreed... they're not cheap either! (getting better though)  
But the panels may last a lifetime, batteries need to be replaced every 5-15 years (depending on their quality and how they're cared for). I bet if you boil it down over the "life of a system" - batteries are the most expensive thing.

# The Homepage of Timothy Mark Mitchell

**Huntsville Alabama**

Hello there, I'm 46 years old and I've lived in [Huntsville Alabama](#) since 1964. I have some hobbies and work at companies that may be of interest to some of you. At sometime in my life I have been very involved in the following subjects . . .

- Electronics, Electronic Graphics
- Computers, Programming
- Sound, Lighting and Video
- Photography, Animation, Darkroom
- Pyrotechnics
- Model Rocketry
- Construction

As you can see I have done just a little bit of everything in the entertainment business, however I consider myself best at Sound and Lighting. In fact I have a sound and lighting company called "[Woofers Hound](#)", with sound systems as big as 5000watts, and up to 60 stage lights.

Here is a little more information about some of my interests . . .

**[Photo Gallery](#)**

**[My Wife Svetlana](#)**

**[Mutt Lee my puppy](#)**

## BBS Bulletin Board Systems

## Sound and Lighting

## Some old Doodles

## My Favorite Links

Feel free to E-Mail me at the address below, if you share similar interests . . .

[Main Page](#) / [My Wife](#) / [Photo Gallery](#) / [My Dog](#) / [Sound and Lights](#) / [Doodles](#) / [BBSes](#) / [Favorite Links](#)

[generating electricity using Earth's magnetic field?](#) | 2 comments (2 topical, 0 editorial)

using Earth's magnetic field? ([none / 0](#)) ([#1](#))  
by drdongle on Sat Jan 3rd, 2004 at 09:41:23 PM MST  
([User Info](#))

It works but the trick is the motion, that is finding a way to move the coil continuously through the natural magnet field and as that field is very weak producing enough power to be usefull.

Dr.D

It's easier to build a giant compass, with the pointer connected to a gearing system that drives a generator. You have a couple of "Wings' or "Fins" built to capture the wind so that each time the wind blows on the wings, it turns the comass body away from megnet north, the pointer moves southwards of course correspondingly, and so the gearing underneath registers the movement, converting the movement into generated power. Simple and straight ! Heck it, cancel that wings satuff, you just move the compass body by your own hands, it is just a science project anyway, we don't need wind in this case !

Love, not hate  
Luubovv.

[Perpetual motion or science - have a look](#)

By [Reno](#), Section [Weird Science](#) [Free Energy](#)  
Posted on Thu Jan 1st, 2004 at 09:07:01 AM MST  
none

Anyone here who is interested in perpetual motion or free energy might want to take a look at these guys. This apparatus is a hydrogen machine. I think the company is canadian. From what I gather there is already quite a story here. <http://www.xogen.ca/>  
<http://www.xogen.ca/tests.php> If you do a search on the company name you will find all kinds of links (makes for some good entertainment.) They even have a video!!!!!!!!!!!!!!(in this case a picture isn't worth a 1000 words) I originally came across this about a year ago while looking for info on wind turbines. On one of the Alt energy pages there was news releases published and this company had news that wind and sloar energy would be used to drive this machine.

Hydrogen Experiments ([none / 0](#)) (#1)  
by [pexring](#) on Thu Jan 1st, 2004 at 11:34:44 AM MST  
([User Info](#))

Over Christmas vacation I started reading a lot more about hydrogen. Someday hydrogen will replace the oil fields. Is anyone out there experimenting with hydrogen?

Mark

Re: Hydrogen Experiments ([none / 0](#)) (#3)  
by [drdongle](#) on Thu Jan 1st, 2004 at 04:48:39 PM MST  
([User Info](#))

It won't unless some one comes up with a more efficient way to extract it from water. Currently it requires more energy to extract hydrogen that is liberated by burning it or using it in a fuel cell. If the article is accurate then just maybe some one has, only time will tell.

Dr.D

Re: Perpetual motion or science - have a look ([none / 0](#)) (#2)  
by kell on Thu Jan 1st, 2004 at 03:53:47 PM MST  
([User Info](#))

They don't make claims of perpetual motion. They do claim to get more gas with less current than predicted by theory that no one has questioned for more than a hundred years or examined narrowly in this particular experimental context insofar as I am aware... and the empirical trumps the theoretical. If you're a scientist.

Also, even if they were to claim that the hydrolyzer would run on its own heat output (which they don't), that's still not "perpetual motion". It isn't a closed system.

Re: Perpetual motion or science - have a look ([none / 0](#)) (#4)  
by Reno on Thu Jan 1st, 2004 at 05:09:28 PM MST  
([User Info](#))

The way I read it is this system is for stationary uses. Along with the use of solar and or wind as the power source. Being a stationary device then the solar or wind energy being used directly wuld be more effecient. Even though there is no claim of free energy the fact that these systems are stationary would imply a benefit to converting the energy source. If the hydrogen was stored and used off site then it might make sense. This is the way I see it.

Re: Perpetual motion or science - have a look ([none / 0](#)) (#5)  
by Tom in NH on Thu Jan 1st, 2004 at 10:30:16 PM MST  
([User Info](#))

Hydrogen production with straight DC is pretty straightforward, but when you get into AC and pulsed DC strange things appear to happen and there is debate as to what it is. With AC electrolysis, you have hydrogen and oxygen bubbles forming at the same electrode, a very explosive mix. Some people report that heating takes place which is unaccounted for with the electrical energy going into the water. Some suggest that the hydrogen and oxygen reform into water and give off heat in the process. Others think it may be a form of cold fusion. Whatever is happening, it needs more investigation. Here's a link to an interesting site. Look for the article about the "boiler cells." That's something I want to try to replicate.  
[http://www.geocities.com/mj\\_17870/myideas.html](http://www.geocities.com/mj_17870/myideas.html) In reference to home energy production, Hydrogen should be thought of as being a storage medium, like batteries. When the sun shines or the wind blows, you make H2 and burn it later. --Tom

([User Info](#))

That's what I've been reading, that hydrogen makes great storage for alternative energy products.

Countries around the world are spending millions on hydrogen research, so something has to break.

Have also been reading about adding different catalysts to accelerate the the hydrogen reaction.

Then there's the plans on the internet for building a simple hydrogen gadget that will increase your car mileage. It makes hydrogen and pumps it directly into the motor. So if that's the case, why can't that be upscaled to make enough hydrogen to totally run the car without the need for other fuels? So long gas stations!

Have any of you read the book, "They Hydrogen Economy?" Now available in any bookstore.

Interesting info in that book.

Mark

I myself like the SOFC fuel cells can run on many hydrogen containing fuels. They produce electricity and heat at around 800C. As for hydrogen as a fuel in automobiles I believe the winning idea in all this is the internal combustion engine. BMW has had a fleet of vehicles on tour for some time. (do not know if they are still out there)got to BMW.com and search Hydrogen. BMW has stated the only thing missing is the supply chain. If hydrogen is to be used in a stationary device it makes no sense to me to make electricity convert it to hydrogen then to power. That is where the SOFC cells have an advantage, they can take natural gas in a house or gasoline in a car to run. BMW used SOFC cells as the electrical source in their hydrogen vehicle.

A more efficient hydrogen production method uses sodium hydroxide. The NaOH is heated to liberate the oxygen, leaving NaH. Solar concentrators can do a great job of this. The NaH is then sealed in ping-pong-ball-like spheres of plastic and carried in the car's "fuel" tank. The balls are split open into a sealed container of water where H<sub>2</sub> is liberated and sent to power the engine.

<http://www.powerball.net/> What you're left with is essentially a container full of "draino" solution that only needs to be heated and re-packaged to repeat the process.

Can anyone tell me how aluminum, Zinc, and motor oil can produce heat???

Ad claims chemical reaction between Aluminum container, zinc rod in center, filled with motor oil will produce heat. Is this remotely possible? Me thinks "To Good To Be True!

Wild Idea from Wildbill

Bill

I am no chemist but off the top of my head the only way you would get heat with this set up is to set the oil on fire.

Where did find the add?

Old F

I don't even remember the website. It sounded absurd to me too. BUT they claim it will produce heat and won't consume the oil. I had prettymuch forgotten about it but I figured that the folks here seem to try almost anything, and a few years ago I never would have imaged getting to very volital substances out of a non volitle substance (water) but you can. Or spinning magnets near a peice of aluminum will produce heat. I know the old saying "If that were possible then everybody would be doing it." Well from what I have learned here and elsewhere, If all these things were possible none of us would be paying outragous prices to get electricity and fuel to heat our homes. But most of the world is still coughing up \$\$\$\$\$ to do just that. :)

Seems like this may be possible(I've forgotten a lot). However, it's not going to make a lot of heat or work for very long or it'd be a lot more popular, unless it's just been developed. You can experiment using a beer can(aluminum container) and a galvanized nail(zinc plated) to see for yourself. Btw, you can make heat by simply turning something in a container of oil, but not much unless you're really putting a lot of energy into it.

A transmission is a good example of this.

Kevin

Maybe it consumes the metals... somebody came up with an engine that runs by oxidizing aluminum. The aluminum sits in a container of water, and there's some way they use the energy released by oxidizing the aluminum to hydrolyze the water, then burn the hydrogen to run the engine. After a while you have a bucket of aluminum oxide sludge. As you may know, refining (reducing) aluminum takes huge amounts of energy, so there's a lot of energy in an aluminum ingot -- I think twenty pounds drives a car 500 miles, or something like that.

([User Info](#))

go to [www.radiantec.com](http://www.radiantec.com) they have plans for such a system i just installed one in my own home in the summer all the domestic water runs thru the slab to help cool it and it also preheats it for the water heater.

Re: Using cold tap water to cool home ([none / 0](#)) (#3)  
by [DDT77](#) on Thu Dec 18th, 2003 at 06:47:22 AM MST  
([User Info](#))

Hi,

Just wondering if anyone has had condensation problems in relation to the loop in the slab?

Has anyone tried to replace / avoid using a central air system with a loop of pipe in the ground tied to a coil in the duct (as in a typical central air system) in which water or other fluid is circulated? Similar to ground source heat pump, without the heat pump part.

Would seem that the benefits would be low electricity (pumping) costs, as power hungry compressor would not be needed, but limit to cooling would be the ability for the ground to sink the heat from the house.

thanks,

I knew it must have existed already, I will probably build my system from scratch unless the radiantec units make it alot easier and arent very cost prohibitive. I'd love to hear a more indepth opinoin on how you feel about the system, and the kind of performance gains you seen on your water heating.

([User Info](#))

I read an article the other day (can't remember where off hand, though) where a guy had done it this way.

On the supply line from the city water supply, he put a valve which would run the water directly to his water lines in the house or through a heat exchanger made from a heater core from a big van. When he is watering his lawn (the water is running then) he turns the valve to divert the water through the heat exchanger before going to the supply lines in the house. The cold water (if your pipes are deep enough it will be about 60 degrees) runs through the exchanger, where he has a solar-powered fan blowing air through the exchanger.

This is "free" cooling. You are already running water to water the grass anyway, and the water is warmed when it hits the lawn, so why not use the cooling "before" it hits the lawn. . . And the fan is powered by solar (you probably wouldn't be watering the lawn on a cloudy day) panels so the electricity don't cost you anything and you don't even have to pump the water!

Doug

ground temperature ([none / 0](#)) (#5)

by wdyasq on Thu Dec 18th, 2003 at 04:48:05 PM  
MST

([User Info](#))

These procedures depend on the ground temperature and the water temperature coming into the house. The two areas I know are Central Ohio - 57 degree water in the Summer and North Central Texas, where 85 to 90 degree water is normal.

Obviously, Ohio might be a "possible" with a 15 degree delta to reach 72 degrees. Of course the Texas water has a 15 to 20 degree delta too - it is just in the wrong direction.

The only reason I mention this is because a little research will save one a lot of trouble. I would consider a 15 degree delta marginal for trying this.

Different climates will take completely different approaches to cooling and heating. Most solutions that are addressed can work if liberal amounts of energy are applied. Minimal power consumption requires different thoughts and processes.

([User Info](#)) [www.ecoforums.com](http://www.ecoforums.com)

well I believe that could be two things, usually well water (at the tap) isnt much colder then 60degrees anywere. (not usually) maybe the high 50's but it realy depends on were your at (have you measured the temp?) I live in northern indiana and my tap water is seldom below 60f but it feels ICE cold in the summer time because well. its hot :) So it might just be a perception thing. Also the water is comming from deep underground were it could be even colder. that is a possibility too.

by RogerAS ([rogeras@cei.net](mailto:rogeras@cei.net)) on Fri Dec 19th, 2003 at 11:15:44 AM MST  
([User Info](#))

Hi,

I live in Stone County Arkansas and there is a place called Blanchard Springs nearby. The water coming out of a cave there is so cold one cannot stand the water for more than a few minutes, far too cold. Most of the wells in our area also produce water so cold it hurts ones head if it is drank too fast, like ice cream headace!

I plan on dilling our well this spring, and if I get the same cool water I'm going to try this.

RogerAS

Roger...just to satisfy our curiosity after you drill your well take a thermometer and let us know how cold the water actually is! Back in Illinois I remember the water from our well used to be cold enough that a tin pitcher would 'sweat' on the outside, used to lower milk and stuff down in the well to keep it cool....power outages back then only meant you had to get out the kerosene lamp when it got dark. (:>) Norm.

Re: Using cold tap water to cool home ([none / 0](#)) ([#9](#))  
by charged on Sat Dec 20th, 2003 at 03:29:17 PM MST  
([User Info](#))

Get a basic window mounted AC unit.

Build a sealed enclosure around both hot and cold side exchangers with a water inlet on one face at the top, and the outlet on the opposite face on the bottom.

Mount the evaporator thermostat to the outer surface of the evaporator box.

Put a small flow-control valve on the hot-side outlet. Feed the hot-side with your cold-water source and route the heated water to your hot-water tank heat exchanger. You won't need to open the flow valve very much since the water absorbs heat MUCH FASTER than blown air, even when the water is seemingly already "hot" to your touch.

Run a separate liquid flow loop through cold-side (evaporator) box and use a simple manifold valve system to send the cold water anywhere you want in the house.

By sealing this inside an insulated enclosure, and building a flow switching manifold, you can adjust the hot and cold side flows to either COOL or HEAT the house, depending on the season.

Seal both hot and cold-side loops and circulate 50:50 antifreeze solution in both. Then, disconnect the evaporator thermostat and rewire the compressor control to the house thermostat. The evaporator won't ever ice up since R22 boils at about -40 and the antifreeze is good down to about -60.

Your outdoor heatexchanger should be a LONG flow path inside a metal pipe. You can run it anywhere you want. Got a fence? As long as the fluid returning to the house from the loop has reached ambient outdoor temps the system efficiency will be through the roof.

The greater the total exchanger space access (longer flow path) the higher the efficiency will be.

and there is + and - to show the polarity of where the wires are attached. Does anyone know a way or have a link to a way I could make this work?

[ [Parent](#) ]

Re: The motor ([none / 0](#)) (#4)  
by Hank on Tue Dec 16th, 2003 at 06:53:52  
PM MST  
([User Info](#))

Static,

Sounds as what you have is a mass produced PM DC motor. These are used in many toys and other battery driven gadgets.

Just spin it and it will generate electricity. Not a whole lot but it will generate DC voltage with some current. If you spin it the other way the polarity reverses.

The + and - leads are probably there to ensure whoever assembled these as a nail dryer would have the fan going the right direction.

These motors will probably generate enough power to light a flash light bulb but generally need to be spun pretty fast.

Have fun,  
Hank

### [Perpetual motion questions](#)

By [CrookedScepter](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 16th, 2003 at 08:49:37 AM MST

[Free Energy](#)

Just a couple things...

I heard from someone at work how a guy showed his "perpetual motion" machine on the Johnny Carson show. Obviously if it was legit, I'd be seeing variations of that machine on this website and others, I'm wondering what was it exactly and who was he?

Lets say someone actually pulls it off and creates a PM machine that works and they tried to get a patent for it, what would happen? Would the gov't still laugh at the person, or would they apply for the patent only for that person to mysteriously "dissappear" into the desert along with the patent app?

Please indulge me, Thanx :)

[Perpetual motion questions](#) | 12 comments (12 topical, 0 editorial)

Re: Perpetual motion questions ([none / 0](#)) ([#1](#))  
by [charged](#) on Tue Dec 16th, 2003 at 09:36:43 AM MST  
([User Info](#))

First, there are no "closed energy systems" in the known universe. So, anything that appears to be "perpetual motion" must be drawing it's power from somewhere.

Every machine that we use relies on nature's constantly cycling energy flows. We simply "tap" those flows in the most convenient ways we can.

A windmill isn't perpetual motion since the energy to turn the blades AND the extra energy to generate power all comes from the wind. But, once the system is installed and running, the power is "free energy" with respect to US.

Trees are essentially free "fire energy" since it costs less in btu's to cut one apart than what you get out of it when you burn it.

There are already quite a few machine patents that claim a smaller USER ENERGY INPUT than the total energy the system COLLECTS from the ambient sources. Heat-pumps are good example. They are rated in "coefficient of performance". That's a nice term that they came up with so that they don't have to exceed 100% efficiency numbers. A C.O.P. of 6 would really be 600% efficient, by old standards. There is no

theoretical upper limit of C.O.P. in any heatpump systems since ANY air temperature that is higher than the boiling point of the refrigerant WILL boil that refrigerant given enough time.

A "free lunch" for US is ALWAYS paid for by NATURE at some point in the chain.

Perpetual motion does not exist. Nor does it need to.

It's just a question of how big you draw your boxes.

I have a page you should look at

<http://www.lhup.edu/~dsimanek/museum/unwork.htm>

I'm still working on the gravity machines in conjunction with the adams type motor. I believe that Newton was correct. I also believe that a permanent magnet perpetual motion device (the magnets) will fail after 5000 years. thus satisfying that bastards theory.

Nice Ed!

I would like to share a quote with you folks that I have found that has done nothing more than to excite me and increase my will to achieve PM.

"He has survived an attempt on his life by an individual affiliated with the New Zealand Secret Intelligence Service and the Central Intelligence Agency, direct suppression of his invention by former (and recently deceased) Prime Minister of New Zealand, Robert Muldoon, the giant British electronics company, Lucus Industries, as well as numerous other insurmountable difficulties that have been placed in his path. ALL BECAUSE HIS INVENTION WORKED. And not only that, it is so simple, any electronics manufacturer or skilled backyard-home-scientist could build one."

From

<http://www.geocities.com/CapeCanaveral/Lab/1287/adams/adamsall.htm>

Keep the faith.

As long as they re-charge themselves!  
;-)

Nice point though.

As well as the Magnets failing with the pyramids the batteries will certainly fail within a birds life. Newton never said anything about maintenance. This seems alot like my wind generator problem, Ie.. I have to apply energy to an auto alternator to allow it to produce energy. Thats almost as silly as an adams motor needing a battery bank.

Actually, unless the inventor can make someone really understand EXACTLY HOW any device works, the device is usually ignored.

IF any device APPEARS to go against what "scholarly" people consider the "known laws" of thermodynamics, they immediately begin vitriolic assaults on the inventor, his "bogus" device, his family, his friends, even his pets.

The logic of thinking you'd see "variations" of these devices on boards "like this" is a bit flawed.

It could be that you are ALREADY seeing variations without realizing what they are. Every machine that manipulates part of nature's energy flows has an analog that manipulates a DIFFERENT KIND of energy flow, using comparable force application.

A heat-pump IS a "free energy" device. With a SMALL application of USER INPUT, the device collects and concentrates a MUCH LARGER AMOUNT of ENVIRONMENTAL ENERGY. The larger the surface area of the "cold side" of the heat-pump, the greater the system efficiency.

A large concentrating mirror array does the same thing.

The same goes for wind machines. You build it once (hopefully) and it extracts mostly useless mechanical energy from the wind, concentrating it onto an axle and transforming it into USEFUL ENERGY for YOU. Free energy, after initial expenditures.

Here's a toy you can build.

Applying this to permanent-magnet fields. Build a "ramp" of fields in a loop (spiral). Put a single permanent magnet on a rotor, inside the spiral so that IT's field opposes the ramp field.

Move it into the tight end of the spiral and let go. You'll have torque on the axle until the rotor magnet reaches the end where the two spiral ends meet. Then it just stops there. Sounds useless, right? Wrong.

Place a single stator winding at the tight end of the ramp so that the rotor magnet is attracted to it and locks in position over it after it rotates through the spiral.

Apply a battery to the winding and determine the polarity that causes a "push" on the rotor, forcing it away.

Wire a set of points on the axle so that when the rotor comes into line with the stator, the winding receives a current pulse and jams the rotor back into the tight end of the spiral. Now you have a simple spiral pulse motor.

Connet the cathode of a rectifier diode to the positive coil terminal. Connect the anode to the negative of a large electrolytic capacitor. Connect the positive cap terminal to the other coil lead.

Now, every time the stator gets a pulse, the emf from the field collapse is collected.

Set up a charge dumping circuit and pulse a second battery with that capacitor.

Your capacitor discharge rate, capacitor voltage (minus battery voltage) and total capacitance will tell you just how much power is being recovered from the emf with each pulse.

Sounds like a waste of time and money. 1001 neodymium magnets???????

Anyway, just start reading here:

<http://cheniere.org/mission.html>

This is real physics applied to real energies to get real results.

Free energy flows are all around you. But, there is no such thing as "perpetual motion".

That particular term is commonly used as a derogatory remark and also used as an "intellect clamping device" to quickly shut the doors on useful innovations before they've been given a fair review.

Yes, I believe that "free energy" exists, with respect to MY energy needs. The environment provides it. All I have to do is engineer the devices the collect it, concentrated it, and store it. Then I can use it for my benefit.

which should I use?

[Free Energy](#)

I live in North East Texas. I liked the idea of a wind gennie but after 30secs of research on the net, i realize i'm not in an optimal area. ...Poor wind fields here and the pines are rather tall. I live close to a river but alas I have no moving water on my property,...unless i can tap into the city water pipes with a hydro gennie, but i don't think they would think to kindly of that. I've looked at solar but it appears to be outside of any kind of financial budget I could think of. So I'm left at drawing a blank. Hmmm what resources do i have here. I live on 7ac. of mostly cleared land but surrounded by tall pines on all sides. I raise redbone coonhounds, rabbits, and goats. I do have alot of rabbit poop. is that a resource or just a pile of crap? The rabbit poop does do wonders for my vegetable garden. I have 3 children ages 3,2, and 3months. They seem to possess an internal battery that never need recharging and might be look upon as a bonifide perpetual motion mechanism. I thought about that, but you try to harness that resource. lol  
my goal is to find an energy source to provide power to my barn. barn has 8 60watt light bulbs, and my wood shop tools. I don't expect to beable to run a table saw or planer, but being able to provide lights and maybe power a power drill or dremal tool would be great. any suggestions guys.

Thanks Ron.

thanks for the response guys. BTU's outta the rabbits butts. How do I tap that resource to convert the energy to something i can use? I might just take your advice elvin1949 and experiment verticle. Has anyone ever developed a way to pull static electricity from the air. From what I've seen around here about Tesla, he could of probably done it, but he did transmissions. I figure they're quiet a bit of static charge around these power lines.

thanks again guys

([User Info](#))

Build a heliostat. Direct sunlight will give you about 1kw per square meter.

A single 4'x8' panel with 1'x1' square mirrors all focused on the same point would give you a 32x concentrator yeilding a usable 2.4kw of energy in a 1'x1' square spot. That spot has a peak potential temp around 700 degrees F.

That's a pretty cheap construction project considering the energy yield.

Build it like you love it.

Hi All,

Charged is right on the money with this one but perhaps a little pessimistic about the amount of KWH available.

Check out this site:

[http://www.focus-solar.com/insolation\\_levels\\_us.htm](http://www.focus-solar.com/insolation_levels_us.htm) It gives the amount of power, in KWH, available in a square meter in various locations, in different seasons throughout the year.

I made a small parabolic trough about a year ago which was able to heat water quite quickly to an impressive temperature. Like boiling.

If it's mainly heating you're after, there really is a lot to recommend this approach.

Here's another page that illustrates the main kinds of "solar concentrate"

[http://www.eere.energy.gov/csp/csp\\_tech.html](http://www.eere.energy.gov/csp/csp_tech.html)

Have fun!

Ted.

## [What project should I take on??](#)

### [I've got alot of stuff](#)

By [slecaïn](#), Section [Homebrewed Electricity](#) [Free Energy](#)

Posted on Sun Dec 14th, 2003 at 06:07:01 PM MST

**What project should I take on?? I've got alot of stuff**

Hello All,

I've put up a couple of post tonight and its my first time on your board.

I can see from reading over the past several wweks that this board is filled with many smart people with the same passion in free energy that I have.

Thus I post my 3rd (and final tonight I Promise) question. Please be advised I'm not trying to sell anything here. I just advise on what to do with it all.

----What project should I take on?? Off The Grid-----

I'm looking for ideas and suggestions as to what to do with all my stuff. I desire to get as far off the grid as possible.

A Brief Background, I have a degree in electronics engineering from 15years ago and have forgotten almost everything but the value is of a silicon diode. I am currently a Network engineer for Novell and the other Devil

Heres what I have

An APC UPS 1000 XLS and 9 - 24volt battery packs connected. About 36hrs of 500 watts off the grid (a good guess) - Psyched - got them for nothing and they work.

-I have an ONAN generator in a 1975 RV that needs almost a complete overhaul (350lbs and I can't get it out).

-Several of the 3.2watt 12v VW solar chargers you see on ebay every day and a couple of the amorphous ones.

-Two homemade Gennies that don't do a thing but hold up in tough weather. I've put up another post and am still confident I'm gomma solve this one.

-Every hand tool known to man.

-No Patience - Duct tape and a glue gun are in my daily tool kit. (just being honest)

-I live on a lake and have alot of wind all the time I think 7mph average.

-I believe I have a good southerly exposure but I live in New England (Go Pats)

-Lots of free time to put in to this.

-an Air-303 24v on the way.

-2 - 8ft wind towers, you know the \$30 jobs on ebay, I think they hold up fantastically.

-Coleman 1200watt / 2400 peak 12vdc/110vac inverter.

-No name 400 watt / 600 watt peak 12vdc/110vac inverter.

-Oscilloscope.

-Multi meters.

-20 - 3mm Neo cube Magnets.

-8 working RC cars

-Tons of computer scrap.

([User Info](#)) <http://www.oldf.homestead.com>

Steve

Seeing how your hooked and there is no 12 step program  
: )

The only thing I can pass on is you are not alone in having more project than you can shake a stick at. Ask any one here : )

You will have to focus on one and take it one step at a time.

If you go with let say a wind generator. There is a lot of different ways to go.  
Pick the one that is the best fit for the tools an toys you have to work with.

Have fun

Old F

Having so much fun it should be illegal

PS

When it come to duct tape all I can say is

If the women don't find you hansom at lest let them find you handy : )

Re: What project should I take on?? ([none](#) / [0](#)) ([#2](#))

([User Info](#))

Well as I said earlier don't through out you treasure yet,  
BTW that 1000LXS UPS sounds like a keeper.  
I would suggest taking one of your existing turbines and  
installing a TDM generator If that is feasible. As for the  
tools, looks like your in high cotton.  
The computer power supplies are great for caps, rectifiers,  
inductors and hook up wire.

Dr.D

Duct Tape ( always want to call it Duck Tape)  
Handy it is, I'm lovin the glue gun, no need for a  
welder if your ready to watch yout creations fall apart  
as they start working.

Yes I picked peices of the Gennie proto from 30 feet  
away after last nights 40mph gusts. Still see two  
blades attached and still spinning .

As for the UPS' Yes I'm very happy about them. I'm  
going to hire an electrician to wire them into my  
panel. Yes I could do it but.....  
They are very cool, They are what got me back into  
this.

I used to fry eggs on cars in the middle of the  
summer and all that other silly stuff like the drinking  
bird and parabolic (death star )solar concentrators.  
Sun concentration is where its at, but the expense of  
a tracker make it untouchable.

Any way.  
What about the bicycle dynamo's, worth pursueing?  
Trickle charge maybe?  
Dr. Whats a TDM? I'm sure I could figure it out but  
the family is upsatairs wondering where I am.

Whats up with these Woodstove fans for \$150? just A  
stirling engine from what I see.

And back to my true love, Wind. How about the  
Ametek motors.

My last prototype was on the top of a minkota trolling  
motor and it worked but couldn't get it to put  
anything out below 15mph.

Blah, Blah, Blah,  
Gotta go.  
See you tomorrow.  
Thanks  
Steve

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Filiberto  
I don't use regulators or charge controllers on any of my RE systems.

I let the load of the batteries do that. If I see to much charging or voltage in a system I add batteries. If there is more power available I like to collect it.

I may do some diversion process latter but I'm not to that point yet. If I lived in an area of strong constant wind I'm sure I'd have to deal with excessive power some how but thats not the case where I'm located.

JK TAS Jerry

[Free Energy](#)

Hi! My friends.

I recieved a very good motor from texas, it is permanent ceramic magnet 120 vcc 6 amp 0.96 hp, i rotate whith full drill i dont know revolutions per minutes readings: 60 volts cc 7.5 amp, at 120 rpm readings, 4 volts cc 1 amp, i did buy a 4 blades around 36" but the question is how to control the charging battery at low and high winds?

how to accumulate low voltages? how to transform high voltages to 13.5 volts? exists some like that?.

Thank for help

by Seth on Mon Dec 8th, 2003 at 04:44:00 PM MST ([User Info](#))

120V CC ???

Well id say something like a MPPT like this mabey... if its actually 120V OC (open circuit) then this might work... [http://www.thesolar.biz/OutBack\\_MX60\\_Charge\\_Controller.htm](http://www.thesolar.biz/OutBack_MX60_Charge_Controller.htm) I bought one... and i use a 60A@35Vdc military genset on it... when i need a boost after a couple of weeks of no sun.

So far it performs exactly as rated... witch means my pannels are below rateing( bumper huh tom & mech) ... i get 97% effecincy at 40A, just like it was rated.. so am i happy.. well i guess not... but its not the MPPT fault.

OH.. yea... forgot... this is what i would use if that PM motor dosent exceed the MAX rateing of the mppt at say 1200rpm, if it does-- well then i dont know .... u really need to get that tested ... i have a 90V TDM(Tape Drive Motor) im planning testing soon.

## [Cold Electricity](#)

By [pexring](#), Section [Homebrewed Electricity](#)  
 Posted on Fri Dec 5th, 2003 at 10:14:45 PM MST [Free Energy](#)  
 Is this for real, or a hoax?

I stumbled upon some article in Google referring to Cold Electricity. Can't seem to find out how it works, but you can certainly order a video for \$30. Is this a hoax? They talk of a fuelless motor, which is a red flag in my book.

Here's one such article:  
<http://www.free-energy.cc/radiant.html>

Cold Electricity is something that Nicola Tesla experimented with. While it's claimed by Tesla fans to work it is very technical and has to do with very very high voltage. This guy got off on wireless transmission of power through the atmosphere and other amazing things. Look up Tesla on your search engine, if nothing else it makes for fascinating reading. Tesla helped Westinghouse discover AC power and was instrumental in the development of Niagra Falls Hydro and the AC motor. It seems as though he kind of dropped out of the picture when he started talking about free power for everyone. How can the government and big business make any money on that? Some very shady stuff. I read somewhere that some of the things we consider science fiction was science fact in 1901, thanks largely to Nicola Tesla. Example of wireless power: Supposedly at his lab in Colorado he lit-up a 10KW bank of lightbulbs from 26 miles (if my memory serves correctly) away with his power transmitter!! It really is some interesting reading.

As far as the fuelless motor, supposedly there are working models, however I've never actually seen one. It's based roughly on a wheel with magnets placed around 1/2 of

the wheel at very precise angles a counter balance weight then placed on the other side to compensate for the weight of the magnets. A single magnet is then placed on a mount very close to the rim of the wheel. If you start the wheel by giving it a spin and you have done all your math correctly it should keep spinning forever. If you search around long enough you can find free plans for the same thing.

([User Info](#))

Better reread your Tesla stuff Bill,

Tesla - without Westinghouse developed "poly-phase" electricity. Westinghouse bought Tesla's patent rights for \$1 a horsepower for every motor or generator produced under the patent. Westinghouse then went belly-up, the patent rights were acquired by a new investment group that Westinghouse was involved in. Tesla lost his patent.

Tesla also described the radio Marconi built. The US government used one of Tesla's presentations to avoid paying royalties to Marconi in WWI. While Marconi was playing with spark gap transmissions, Tesla was operating a radio-controlled boat in Long Island Sound and transmitting the power to it.

Some of Tesla's work is still classified by the military.

Wellll I was trying to be diplomatic, guess I didn't word things correctly. I do think Tesla was amazing. I know he got the short end of the stick. He was a visionary and a scientist not a businessman. I used the term AC because it is easily recognized if not for poly-phase we might not have AC. Sorry I gave Westinghouse so much credit in my statement. I am sometimes a bit angry when I think of where we might be today if more of Tesla's inventions were available to the general masses instead of being kept such a secret "classified" as you worded it. In lew of the comments rules I'll stop there. :):)

by charged on Sat Dec 6th, 2003 at 10:06:44 AM MST  
([User Info](#))

The "fuelless motor" is actually Ed Gray's capacitive-discharge engine. It runs on a passive-timing high-voltage discharge from a bank of capacitors. There are other deeper details involved. But, that's the basic principle.

The "cold electricity" is also referred to as "radiant energy". There is no "scam" involved. The website that the original post shows pretty much puts all the basic patent details right on the site for you to read. The video and book bring it all together.

"Free energy" systems are all around you, especially here in the otherpower forums.

If you have built a machine that collects some form of ambient energy and re-orders it for your use, you have built a "free energy" system. This is how everything works.

Energy is all around you already. It doesn't need to be "produced", just transformed. There is no "perpetual

motion", only energy transformation. Remember THAT whenever you run across someone saying they've found a new "source" of energy, it really just means they've discovered another way to tap into nature's pre-existing processes and flows.

Radiant energy is, apparently, the primary, pre-existing flow that is the foundation of all the others. At least that's what everyone involved in that research currently believes.

Look up "Ed Gray" and "Tube" in the same google search. You'll get buried in links.

Re: Cold Electricity ([none / 0](#)) ([#4](#))  
by pexring on Sat Dec 6th, 2003 at 11:57:40 AM MST  
([User Info](#))

I've learned not to have much faith in reading patents. Lots of patents out there for things that don't work -- like Frenette's friction heater.

Hi,

I've been thinking of something similar.

My headache point about all this is the circulation pump. I've considered using a water pump from a big block V-8. Bolt plates on the inlet & outlet with pipes welded into those (before attachment!). Then put a much smaller pulley on the pump than normally would be used. Drive this with a small motor that has a big pulley, like a 3 to 1 ratio (all that assembled on a steel plate mounting system). Any time the system needed flow the motor could cycle for a few minutes. With a DC motor and a speed controller one could "tune" the circulation, avoid the need for a sophisticated expensive water pump, and adjust the flow to match either the need or supply of hot water. On the inside of the house a small 4 cylinder car radiator in a cute little box could be the heater, even use the electric fan with another speed controller. I think this could be done for very few bucks. (if one has a source for salvage parts).

If you have the water pump and the time that would probably make a reasonable set up. If you don't have the components on hand it could be more expensive than a simple "Taco" pump. You can purchase these for around 55.00 from Grainger and probably less somewhere else.

If you do have the pump and the time you could actually let the engine drive the pump and install a ball valve to regulate the flow. Once you have the flow dialed in you wouldn't have to mess with the valve anymore. Sounds like a fun and challenging project...

Re: Heat Catcher for the Generator ([none / 0](#)) (#4)  
by troy on Wed Nov 26th, 2003 at 02:04:41 PM MST  
([User Info](#))

I have in mind to try the same thing at some point, using a gas water heater as the heat exchanger. They're already fine tuned to work in the temperature ranges that I want, glass lined and equipped with an anode to reduce rust/corrosion issues, and even include over temp and over pressure safety valves.

Flow rates for the coolant are an interesting subject. You want high enough flow rates that your power plant doesn't over heat of course, but it's also easy to overcool an IC engine and ruin your combustion efficiency. Flow rates that are too high will also lead to parasitic energy losses from the pump as well.

The japanese are doing research (probably the big three too) on internal combustion engines using ceramics and other very heat resistant materials that need no external cooling at all. With higher combustion temperatures come higher efficiencies.

Good luck and have fun!

troy

[\(User Info\)](#)

There is an inexpensive ( \$5.00 ) program available that does pretty much what you desire... plus a lot more. It is designed mostly to help hand carving blades using the Hugh Piggott methods as described in his excellent Axial Flow Wind Generator Plans. It does specify a blade angle at user selected spacing along the radius of the blade. If you want to investigate see:

<http://windstuffnow.com/main/formulas.htm>

Hi Seth

I can't help you with your calculations but I couldn't help notice the degree #s you've used. Are they just an example or the #s you want to use.

The #s on my plastic blades are 23 degrees at the root and about 3 degrees at the tip. This bade is 23 inches long. The hub I use makes tip to tip measure 49 inches.

I've been able to get charging at 5 mph and max out at 80 amps at 40 mph from 4 of these blades.

I've just finished my first 3 blade at 23 degrees. Up untill now my 3 blade have been at 27 degrees or longer than 49 inches. I have the proper hub now and will test the new 3 blade on a 1 hp GARBOGEN soon.

I hope to see 90 or 100 amps for a short peak or burst. This would be a new record for this alt.

I'm sure the blades your talking about are longer than mine?

If I take my plstic blade and lay it on a blade from a very excelent blade from a

([User Info](#)) <http://www.scoraigwind.co.uk>

The way I calculate twist is actually very simple. I reckon the tangent of the airflow incidence angle varies inversely with radius. You could even say that the angle itself varies inversely with radius and be close enough. This means the air comes in a twice as big angle when you halve the radius.

To work out the blade angle I take the angle of incidence of the air and then subtract 4 degrees to give a suitable angle of attack for the blade.

Say you blade angle is 2.3 degrees at the tip. This is a bit too precise to make any sense to me. I'd say the airflow would be 6-7 degrees in this case. 86 is easier to work with here.

Therefore the angles at a series of 5 equally spaced stations along the blade would be

- 5.  $x 6 - 4 = 26$  degrees
- 5.  $/2 x 6 - 4 = 11$  degrees
- 5.  $/3 x 6 - 4 = 8$  deg
- 5.  $/4 x 6 - 4 = 3.5$  deg
- 5.  $/5 x 6 - 4 = 2$  deg

and there's the twist.

Strictly speaking if I used a computer I'd use the tangent of the angle but it makes no difference in the end - it'll fly.  
Hugh Piggott <http://www.scoraigwind.co.uk>

Bob;

While the extra pane of glass might block a small % of the incoming solar radiation I can't help but believe that with the double glazing the net result would be more heat to the heated area. Simply because the inner pane of glass will not be so cold like it would with a single. Go for it.

Cheers.

TomW

Well my solar heater has triple panes of glass out of sliding glass doors, they work excellent. I think they retain there heat better at nite than the one single pane solar heater I have. I would say go for it, I did and found it was worthwhile. From Mike

I just finished building a solar heating panel out of the same type of double glass doors (3'x8'). Double glazing is a must! It gives a layer of protection against the outside elements. Without double glazing, your panel would have to work harder for less heat. The one I just built has been averaging temps of 140 degrees at the peak of the day.

Mark

Re: solar heating ([none / 0](#)) ([#4](#))

([User Info](#))

got my double glazed doors today . glad i decided to wait and ask what people thought rather than just jump in. got them for half the price they were on monday :- ) a whole 5 pounds. thats about 8 bucks i think hehehe. someone gave me some fibreglass insulation so was going to make a frame out of 2x4 timber on top of some exterior 3/4 ply. and put 2 inches of fibreglass then a layer of ally foil. should i put foil on the back instead or as well? cheap enough. then i was going to fix a layer of ally sheet over that and paint it black. will make some channels about out of 2 x 1 x 1 1/4 wide up to the height of the glass and put draught proof seal on the top of that. does that sound like a good plan. will put baffles in the channels as well. i have a 4 inch computer fan if thats not big enough got plenty of fans that one happens to be 12 volt which makes life a bit easier.

([User Info](#))

Just be certain that your fan is pushing the air through the panel, not sucking the hot air out of the panel, which will shorten the life of the fan.

Good luck and have fun!

troy

Simple trick for saving energy

Now that winter has returned to Colorado and it gets below freezing each night, I save a little on my electric bill with this simple trick. I have two plastic gallon jugs filled with water. One is always in my refrigerator and the other is always on my porch. Each morning when I let my dog out I swap the partially thawed jug from the refrigerator with the fully frozen jug on the porch. I could measure the amount of liquid water in the refrigerator jug each morning and calculate how many watts I'm saving but I'm too lazy for that and I'm afraid that it is costing me more in heat for the extra time that I have the front door open. Have a good day,

John

by [Homebrewed12vdc](#) on Tue Nov 18th, 2003 at 09:04:36 AM MST  
([User Info](#))

This does work, I shut my gas fridge off in the winter, and use 8 milk jugs at a time. It saves me money all winter, but I found it takes 4 jugs at a time to make a big difference, I also keep my frozen foods in a insulated box out on the porch in the winter. Every bit of energy saved helps.

Re: Free Refrigeration ([none / 0](#)) ([#2](#))  
by [5kw](#) on Tue Nov 18th, 2003 at 02:04:44 PM MST  
([User Info](#))

I have been gleening ice for years. Low teck and even appartment dwellers can do it. I found that straight water melts at to high a temp to absorb heat fast enough to take advantage of all the free cold.

I have three 2 liter pop bottles, I put 2 tbsp of salt in one, 4 tbsp in the 2nd, and 6 tbsp in the third. I put out any that are mostly liquid at night and take in the frozen ones in the morning. The high salt bottles need a cold night to freeze, but have high quality heat abbsorbing capabilities ie they melt quickly in the frig

Make the wind fun!  
Victor

Summertime tricks ([none / 0](#)) (#3)

by wdyasq on Tue Nov 18th, 2003 at 03:43:58 PM MST  
([User Info](#))

When I lived on a boat for a couple of years we would put gallon jugs in the bait freezer and move them to the boat to keep the food cold. When using regular block ice, one would have the water from the melting ice drain into a bucket and cool the adult beverages. I have been told the same trick can be used for non-alcoholic beverages, but I don't know if it has been tried.

BTW- sail boat folks use a lot of energy saving tricks. Many of the appliances and devices they use have applications in renewable energy.

Ron

([User Info](#))

Hello,

Great tip. - especially at this time.

I have been thinking about your idea, and liked to think that we could use the winter wick makes us use more energy to save even a small amount in the refridgerator.

One thing i thought about when i read your post was the old rule about hot vs cold air: cold air is heavier than hot air. This mean (if my guess is correct), that if you place your frozen ice-bottles at the top of the fridge, then you would allways be heating the higher temp air.

Anyway this arrangement works out for me, since my wife has problems reaching the high level shelves ;-) - and I have'nt heard any complains from her, since she's never using the top shelve.

/Steffen

ah, over unity, well all I can say is that there is "no free lunch".

Dr.D

Re: 2besynergy ([none / 0](#)) (#4)  
by charged on Sat Nov 15th, 2003 at 05:44:02 PM MST  
([User Info](#))

The laws of thermodynamics do not prevent anyone from building a system that can absorb ambient energy and reorder it for producing useful work.

Example #1: windmill - you build and maintain it and in exchange it absorbs enough wind energy to keep itself moving as well as enough to provide useful mechanical input to a generator.

In this case you are directly intercepting a diffuse PHYSICAL FORCE and concentrating it in a rotating shaft.

Example #2: Heatpump - allowing a liquid to "boil" at atmospheric pressure where it absorbs heat, then applying a small amount of energy to compress that vapor and release the once diffuse btu's into a smaller space at higher temperature.

This is an application of a small physical force to move a much larger amount of ambient heat from one point to another.

Example #3: Light concentrators - collection of low level light from a large area and focusing it all on a single small point.

My point is that we readily accept these concepts and the mostly "free lunch" that they provide. At the same time, many in the engineering community disparage anyone that believes there may be an electromagnetic analog to the above processes.

The term "over-unity" also applies to all of the conventional systems mentioned above. Once built and installed (small input) a wind turbine can provide many years of "free lunch". That "free lunch" is many times more energy than the construction and installation required in the first place.

Personally, I applaud anyone that's attempting to think outside the box.

([User Info](#))

Would I be out of line if I inquired just how many union electricians are spending any time studying the applications of modern quantum physics to their trade?

[http://www.quantum-chemistry-history.com/Kron\\_Dat/Kron-1945/Kron-PR-1945/Kron-PR-1945.htm](http://www.quantum-chemistry-history.com/Kron_Dat/Kron-1945/Kron-PR-1945/Kron-PR-1945.htm)

<http://www.cheniere.org/misc/kron.htm>

My point is, our electrical theory texts are about 130 years behind all the advances that we've made in physics. Why is that, I wonder.

I'll never argue that the basic formulas and processes still do what they do quite well. The problem is, they are not inclusive of many known anomolous processes. But then, this is why there are people out there trying to tie everything together with superstring theory.

Perpetual motion does not exist. What does exist is an infinite number a varying potentials in 3-space. All the work that done is a result of tapping the equalization time period between different potentials.

The terms "perpetual motion" and "over-unity" are misnomers.

The term "coefficient of performance" is the only one that can apply. It is already an industry standard measurement of system "efficiencies".

<http://www.aie.org.au/melb/material/resource/cop.htm>

A simple efficiency equation only allows for user-input to work-output ratios that fall under 100%. To apply that same measurement to a heat-pump produces numbers well above 100%. Therefore "efficiency" is an obsolete term. C.O.P. calculations account for environmental energy input plus user input which then more accurately reflects the validity of thermodynamic rules.

The simplest example of a "free lunch" using pure EM theory is a crystal radio. No batteries needed. The intercepted RF supplies the power for the circuit which drives an earphone (linear motor) at varying frequencies to communicate and intelligent signal. From the user's perspective, the power was free. But, we know where it came from and therefore know where to draw the outside of the box.

## [Bedini power generation technology](#)

By [charged](#), Section [Weird Science](#)

Posted on Wed Nov 12th, 2003 at 08:36:05 AM MST

[Free Energy](#)

**Strange power generation system**

A basic replication of this device, as well as several video clips, can be seen at:

[http://nuscam.com/testing\\_now.htm](http://nuscam.com/testing_now.htm)

A young grade-school girl built one too.

<http://www.keelynet.com/bedmot/bedmot.htm>

Think of this device as an "energy gatherer". This is not perpetual motion, any more than a windmill being pushed by the wind is perpetual motion. It's just using certain ambient energy sources by concentrating and releasing them.

For the full theory of operation, read the following page and the links at the bottom of that same page.

<http://www.icehouse.net/john1/intro.html>

Enjoy!

([User Info](#))

Here's a picture of a working model. Instead of using a belt for the timing, this one uses two magnetic gears made up of many small magnets around the outside edge. The two "gears" don't actually touch. The fields lock together like teeth.

The larger wheel turns at about 2 rps and discharges the output capacitor with each rotation.

The main rotor is running at about 2000rpm.

This motor is running on about 150ma input at 12v. Every input pulse is bounced back out to the collector capacitor and sent to a second battery to recharge it. The more you load up the axle, the lower the average input current drops.

It is based on the model design found at:  
[www.keelynet.com/bedmot/bedmot.htm](http://www.keelynet.com/bedmot/bedmot.htm)

Re: Bedini power generation technology ([none / 0](#)) ([#2](#))  
by Kevin L on Sat Nov 29th, 2003 at 01:28:52 PM MST

From the video it appears that alot of energy is first applied to the fly wheel, then the power used by the bulb slowly slows down the flywheel till all the kenetic energy is consumed by the bulb. Fun to learn about basic physics though.

([User Info](#))

Oops. I hit the post button before I finished my reply.

The stator core is made from individually enameled strands of soft steel wire packed tightly and epoxied in place. It's an extremely efficient three-winding 1:1:1 transformer with very low hysteresis and eddie-current losses.

As a PM approaches the core, it generates a positive voltage and current on the base of the transistor, turning it on.

The transistor switches fully on and applies the battery to the primary winding to oppose the PM field. This happens at TDC where the PM field is compressed just enough for the rotor to "glide" past TDC as if there were no stator present.

The transistor just as suddenly switched off, collapsing the current-generated field in the stator. At the same time, the PM field expands at nearly the speed of light and tries to "reach out" to grab the stator core once again.

THIS is where a CAPACITIVE LOAD is applied to the third winding to collect cemf. According to LENZ LAW, the now INCOMING PM FIELD produces a massive power spike and as current is drawn from the winding, an OPPOSING FIELD PUSHES back at the PM field, accelerating the PM AWAY from the stator. The heavier the load of the CEMF the greater the torque on the rotor. Yep, sounds insane on the face of it. But, it works.

This explains the basics of Lenz law.

<http://hyperphysics.phy-astr.gsu.edu/hbase/electric/farlaw.html>

Notice that the law only applies to "fields" not to the "physical structure" that contains the fields. In other words, the physical magnet is a separate entity from it's field. Otherwise, you'd never be able to distort the shape of a PM field in relation to the PM's shape.

In a nutshell, the SHAFT TORQUE is an entity INDEPENDANT of the user's power input and CEMF output collection activities.

This is called ELECTROMAGNETIC REGAUGING.

do you have a source for the enameled "soft steel wire" , oh wait , just came to me  
are you using coat hangers cut to size ,also when you wind the coil do you do one layer  
then go back to the top and start the next , and how big is the core.

Can you use a MOSFET instead of the transistor , I have 100 500v IRF power mosfets

I have a 6" dia x 3" W Al flywheel that I have been want to play with this with

Re: Bedini power generation technology ([none / 0](#)) (#6)  
by charged on Mon Dec 1st, 2003 at 06:42:52 AM MST  
([User Info](#))

Actually, it's just solid MIG welding wire (hardware store). The core is a piece of 1/2" ID CPVC pipe with a couple of PVC discs glued on either end to make a plastic spool.

The strands of wire are cut slightly longer than the core and then stuck in a foam block so they can be spray painted with epoxy enamel. Once completely dry, they're packed into the spool and the ends are cut flush. Then I use some glue in either end of the core to fix them permanently in place.

This particular stator is a 500 turn tri-filar winding of #24 magnet wire. The wire size is not super critical. But, that's a good starting gauge for a basic motor.

The TIP3055 transistor has specific characteristics that make it useful for this application. Various bipolar transistors will work. But, this one is cheap and plentiful. Mosfets will not work in that circuit because they are voltage-controlled, not current-controlled. Darlington transistors won't work either because they can't switch fast enough.

In a nutshell, for this circuit, you need a relatively high gain, fast switching bipolar transistor.

Re: Bedini power generation technology ([none / 0](#)) (#7)  
by ibedonc on Mon Dec 1st, 2003 at 03:12:41 PM MST  
([User Info](#))

Thanks ,,

about the winding pattern , do you wind one layer tape it off go back to the top then wind the next ,, etc

or wind top to bottom , then next layer bottom to top , then start over

Re: Bedini power generation technology ([none / 0](#)) (#8)  
by charged on Tue Dec 2nd, 2003 at 11:12:19 AM MST  
([User Info](#))

While that method DOES allow you to build a transformer with the proper turns-ratio, it gives you three windings with varying impedance. You don't want that.

Make it a "tri-filar" winding. Use three spools of magnet wire. Feed your coil form with all three simultaneously. This will leave you with three windings with matching impedance.

[ [Parent](#) ]

Re: Bedini power generation technology ([none / 0](#)) (#9)  
by ibedonc on Tue Dec 2nd, 2003 at 11:54:45 AM MST  
([User Info](#))

ok , sorry I am not getting idea across , yes my question would have been winding all three at once , so using three spools start with all three wires at the top , wind to bottom , tape off , return to top start next layer winding to bottom

or start with all three wires at the top , wind to bottom tape off start next layer from bottom ,

Re: Bedini power generation technology ([none / 0](#)) ([#10](#))  
by ibedonc on Tue Dec 2nd, 2003 at 11:58:30 AM MST  
([User Info](#))

which one described are you winding ?

Re: Bedini power generation technology ([none / 0](#)) ([#11](#))  
by charged on Wed Dec 3rd, 2003 at 06:33:02 AM MST  
([User Info](#))

It doesn't matter which end you start on or whether it's CW or CCW winding. Just attach all three wire ends to the same spot on the spool at one end and then start winding back and forth until I get 500 turns.

You should just try to keep the windings as neat and snug as you can manage.

I have a 8.5" x 2.5" al flywheel in the works , would it still work if I put the magnets on the side face instead of the outside face ( I am thinking it would)  
it would be a lot safer if I could , would not fly off as easy.

my magnets are 1" x 1/2" round N45 neo's

also would it miss up the effect if the frame was AL.

thanks

[ [Parent](#) ]

Re: Bedini power generation technology ([none / 0](#)) (#14)  
by charged on Fri Dec 5th, 2003 at 08:10:26 AM MST  
([User Info](#))

Almost any embodiment will work. If you're putting the magnets around the outside of the rotor, use superglue to hold them in place and then put a couple of wraps of fiberglass packing tape around the outside. Using neodymium magnets, you'll have a pretty decent gap between the stator core and the PM's so the tape won't get in the way. I just used the glue and left it at that. No problems after many weeks of 2000+rpms.

Uh oh, I feel a "too much info" moment coming on.....

I'm going to quietly suggest that you build with wood or plastic for the frame of the first motor. There are some simple adjustments that you must make to get it running properly.

Aluminum is ok as long as the PM fields don't end up getting dragged through the stationary aluminum parts. That's going to be an eddie-current area that will cause drag on the flywheel. It won't specifically change the inductive effects in the stator. But, it will detract from the available shaft torque and make it run slower.

All the positive shaft torque is provided by only two things.

1. The initial attraction of the incoming PM to the stator core.
2. The CEMF loading (capacitor charging) as the PM is moving away after TDC.

Your battery input is only enough to cause a "null" field at TDC, not a "push" after TDC. You will need to short your battery into the primary winding and adjust the gap between the stator core and the rotor magnet to see where the "null" zone is. Use an almost dead battery (10.5v) to do this adjustment.

More interesting stuff....

1. The incoming attraction for EACH SINGLE PM-STATOR INTERACTION is exactly the same amount of torque, each time, regardless of the RPM. This means that the available working force from the attraction increases in a linear fashion with RPM's.
2. The input pulse from the battery and the CEMF output pulse have a fixed efficiency relationship that is determined by your stator design. The maximum efficiency for battery recharging is by allowing the capacitor to only rise a few volts above the receiving battery's voltage before pulsing. This is why the motor has that simple timing wheel arrangement. ALL MECHANICAL means that you can study things very closely. Using a larger capacitance keeps the pulsing voltage lower and allows greater standard charging efficiency. Always make sure the input and output batteries are the SAME VOLTAGE. The 1:1 transformer effect guarantees that the charging is provided ONLY from collected CEMF and NOT from primary pulse current. This will make more sense if you place a lower voltage battery on the output and watch what happens to the input current and shaft torque.
3. JUST BECAUSE you are extracting the CEMF with the capacitor, the PM gets an extra "push" as it's leaving the stator. This is because the PHYSICAL MAGNET is moving away from the stator at the same time it's FIELD is trying to APPROACH the stator. Lenz law applies and the load during this phase causes a reflected field from the stator that "bounces" the PM away even faster. This is much like dropping your glasses and trying to catch them in

mid-fall, smacking them across the room like a tennis ball. oops.

You may want to take another look at <http://www.icehouse.net/john1/intro.html>

It's been updated.

Re: Bedini power generation technology ([none / 0](#)) ([#17](#))  
by ibedonc on Mon Dec 8th, 2003 at 01:22:12 PM MST  
([User Info](#))

thanks , I see a plexiglass rotor and chassis , and probably only one magnet , but that is just a guess , also from looking at the patents I believe they are using a electronic timer to dump the cap i.e. count 3 pulses , dump ,etc

I guess I have to build one , while I am waiting for my AL rotor to be finished

:)

Very astute observations. Except that the flywheel probably has 3 magnets spaced 120degrees apart near the edge, to maintain balance.

Notice that the "motor" aspect of the device is not used for anything except timing and "firing" the inductors. The rotor magnets must be spaced properly so that they pass the stator fast enough to generate the trigger voltage for the transistor base. But, at the same time, there must be enough time between interactions that the next magnet doesn't overlap any of the electrical action of the previous magnet. Make sense?

The "motor" is an electro-mechanical PWM that set's it's own frequency. Very little interaction between the rotor and stator is required when a very high-gain transistor is used. This CAN be done with fancy solid-state controls. But, a mechanical system is easier to maintain since it keeps your solid-state parts count very low and very simple to work on.

As the webpage describes, the transformer effect uses only the CEMF or "radiant" aspect (ala Tesla) which is pure potential, with no electron current. Until that radiant spike "lands" in a capacitor, it is not "real" power in the truest sense. Funny thing is that you can put the capacitor at the other end of a few thousand feet of wire, and it will fill at the same rate. Freaky stuff to see when you've already been trained to think in standard textbook theory. I've been beating my head against this stuff for several years now and one day, not too long ago, it all finally began to click.

I hope I can help accelerate the learning curve on this for some others.

Re: Bedini power generation technology ([none / 0](#)) (#23)  
by ibedonc on Wed Dec 17th, 2003 at 03:47:40 PM MST  
([User Info](#))

well , I first try at this motor has not worked, this one I made the rotor out the plastic that they use for cutting boards , 1 inch thick , plexiglass frame / 3/16 steel shaft and bearing

used 1/2 x 1/8 round neo mags ( maybe I should use ferrite like bedini said ?)

coil 1/2 cpvc pipe and 1-1/2 spool ends , #24 motor and gen wire #26 tigger , wound until could not put any more on coil form all wires at once .

used .030 solid mig wire to fill core , spray painted each wire.

2n3055 trans , in914 diode , 330 resistor , 1000v bridge and 330 uf 500v cap

no dump yet , just wanted to get the motor to run

lined up coil to mags , I am able to adjust the gap by moving the rotor up or down

coil does repeat , adjust to null zone as per directions , spin rotor and it stops

using 12v battery scope shows waveform on all windings

sometimes the circuit will start to oscillate without the rotor turning and when one of the mags is tdc, when this happens I get up to 150 volts on cap and trans gets hot

any ideas , what kind of mags are you using ?

I have the tigger wire like the patenth

Re: Bedini power generation technology ([none / 0](#)) (#24)

([User Info](#))

1. Make sure you're using a TIP3055, NOT a 2N3055. The gain on the latter will usually prevent it from working properly.
2. Go to radio shack and pick up a 10k, 15 turn potentiometer. The part number is 271-343. Get rid of that 330 ohm resistor and put a 100ohm resistor in it's place. Then put the potentiometer in series with it. Now you can adjust the input pulse-width. Start with the lowest resistance setting and give the motor a spin. Make sure the transistor isn't heating up. Watch the waveform on the scope. You'll see the positive sine, then the transistor "on" pulse, and then an hv spike. Increase the resistance slowly and watch the transistor "on" pulse duration. It should be decreasing. Keep turning up the resistance until you see a second "ghost" oscillation. Stop there and go back down just a hair to make it go away. If you go further out, you'll get wild oscillating and the motor will stall.
3. Yes, you SHOULD be using HIGH POWER CERAMICS, not neos. But, you've already got the stator gap adjusted, so it should work.
4. Disconnect the bridge and capacitor for now. It will interfere with the motor if you are not DUMPING the cap steadily. Without it hooked up, the radiant spikes will not interfere with the motor action.
5. Lastly, You MIGHT have TOO MUCH INDUCTANCE in the windings. This will lower the resonant frequency of the stator and can prevent the motor from running. Since this is the most annoying thing to fix, check all the other possibilities first. If this is the only option left, rewind the stator and stop at about 400 turns. Then try running it again.

Re: Bedini power generation technology ([none / 0](#)) (#26)  
by charged on Fri Dec 19th, 2003 at 06:46:12 AM MST  
([User Info](#))

Ohms don't matter much when it comes to the way this thing works. This might sound weird. But, it's true. You've already adjusted the stator gap, so you KNOW that the magnets are attracted and then "zeroed" with full battery voltage in the winding. Getting "motor" action is now just a matter of proper components and tuning.

I've made all sorts of rotors out of MDF board, plywood (yep, wobbled too much), bicycle wheels, pvc tubing "stalks", etc....

What matters is the switching speed of the circuit, in relation to the magnet interactions.

Once you've dabbled with these a bit, you'll begin to get a feel for what's required.

Look at the specs for the TIP3055. As long as you use a good bipolar transistor that meets or exceeds the voltage/frequency/gain specs, it will work. Don't bother trying any darlington transistors. They REALLY stink for this. Too slow. You will get a nice THUMP noise each time you try to start the motor, though. heh.

trying to get more than given

This prototype has been an experiment for many years, ever changing with understanding and design. It is understood that even still the knowledge is in its infancy.

The windings used to make it move have been "on the front burner" for so long but now it is time to start thinking about delivering power back. I am happy with the circuit design even though changes can be made in order to change its performance.

Now if I could just figure out how to display my images.

Need more info! Whats it do and how does it work, or a nice discription! Thanks!  
Good Work by the way!

Re: becoming synergy? ([none / 0](#)) (#3)  
by Ocean on Wed Nov 12th, 2003 at 01:10:54 PM  
MST  
([User Info](#))

All it does at the present is spin around and around. Two inner windings power it to spin and two outer windings tell it when. (The other two windings in the photo aren't connected) The circuit is simple and it involves two 741s and an NPN, PNP for deciphering the duty cycle and firing appropriately. This particular example is with twenty neodimium magnets and is powered by four rechargeable batteries. I have yet to go higher in voltage because I believe heat may come into play.

There is an extreme amount of learning shown in these photos.

This is still confusing.....Ok, one winding has two parts: it is air core. The inner winding is half the diameter of the magnet on its inside up to the size of the magnet, which is used for powering movement. The outer section is from the inner up to a half bigger and is used for trigger.

Winding (inside = .25-.5 outside = .5-.75)  
magnet=.5

By the way, now I have seen there are four pictures here and there is only supposed to be two.

[heat exchanger for drier](#)

By [erne](#), Section [Weird Science](#)  
 Posted on Wed Nov 12th, 2003 at 07:01:13 AM MST [Free Energy](#)  
**pazman** my drier may help you with ideas for your unit

pazman  
 You need to go and get a old hot water register out of the 50's or earlier. Mine has a 3 inch inlet and outlet and weigh about 120 pounds. I built a box out of a truck air cleaner and put screening in place of the filter. I ran the exhaust out of the top pipe after some experimentation. It heats the iron better. I have the register behind my pellet stove (it hardly shows). Out of the smaller outlet on the bottom, I put a glass bowl out of a truck fuel line to drain the water. I also bring in my air from a hot air exchanger, and have the element disconnected. I also had to change the blower motor to d/c so I could regulate the air flow. It uses to much electric (factory drier) as I am off grid. In the summer I use a bypass valve. When the drier panel is not in use I switch the air to help with the house heat. It produces air in the temp range of about 100 to 120 degrees for about 30 min before it starts to cool. Hope this helps.----erne

I was in Menard's earlier today and they sold this contraption which you could hook up to the end of a dryer hose. It's designed for dryers in which you can't duct to the outside. Supposively, moisture is trapped in the bottom, lint towards the top and air blows into the room. Was only like \$8. Anyone tried it?

Mark

([User Info](#))

I can't imagine much advantage, since you'd still be taking in the same square footage of sunlight. I think would only be advantagous if you could have a huge lense (or lenses together) that focused a big area into a smaller area.

Re: solar heat panel with fresnel lenses ([none / 0](#)) ([#2](#))  
by [pexring](#) on Mon Nov 10th, 2003 at 11:48:02 PM MST  
([User Info](#))

I always wondered if a fresnel lens could be used to create a furnace? Somehow concentrate those beams inside the hot box of a furnace and then kick on the blower. Of course, would have to have real precise tracking. How about using a fresnel lens to build a hot water heater?

As far as heating a home, I'm sold on using/building regular solar heating panels. In fact, I'm about 3/4 done with my next project -- a heated floor system. I live in a mobile home, and the floors are ALWAYS cold no matter how warm it is inside.

So I'm running some 3" perforated ductwork inside the belly. Heat from the solar panel will be blown into the ductwork. As in many mobile homes, the insulation in the belly is below the floor joists and not between the floor joists, so heat will be free to travel and warm my floors! I also bet that the floors stay heated long after the sun goes down. Only place the heat has to go is up through the floor, and that will take awhile. I'll probably have just revolutionized heating in the mobile home industry! Once its up and running, I'll be sure to post results.

I'm hoping its true with my home, but houses I've seen with heated floors always feel warm, and the owners' say the furnace doesn't run much either. Let's hope so!

Gosh this stuff is fun,  
Mark

(#5)  
by RobD on Tue Nov 11th, 2003 at 07:50:57 AM MST  
([User Info](#))

Hi Mark,  
I have radiant floors in my home. When I built it about ten years ago I put Radiantec tubes under the floor. Here's what I have. Tubes are attached to the underside of my floor with thin aluminum plates each about 6" x 10". The plates are stapled to the bottom of the underlayment (3/4" plywood). Above this is 3/4" hardwood flooring. Under the tubes is a special aluminum foil backed paper that sits about 1-1/2" below the tubes. About 10" below this I have Aluminum foiled foam board (R5 I think).  
My furnace is run at between 108 and 110 degrees by a sensing circuit that I built. I asked my boiler company about running boilers this low and they said it is no problem.  
According to Radiantec 110 degrees mean temperature is ideal.  
The floors are warm and I can keep the house temperature lower because the heat is always rising. The system is quiet and my small house has more room because there are no radiators to take up space.  
The only thing I don't like is the delay in getting up to temperature when the sun goes down and the temperature can drop 20 or 30 degrees in an hour.  
I advise having a small heater to keep this from happening.  
Most of the time I walk around in bare feet or socks.  
RobD

([User Info](#))

RobD,

I would have loved to have installed the system you mentioned in my home. Unfortunately, I don't have access to underneath my floors (other than ripping open the belly - NOT).

With my heated floor system, I'll open up one small section of the belly, feed in ductwork along the sag of the belly, and connect the solar heating panel to the ductwork. I realize my floors won't be as evenly heated as yours, but it'll still be a huge improvement!

Nice and sunny today. My solar heating panel on the side of the house is blowing air into the house at a temp of 120-125 degrees (dropping to 115 when some high clouds roll by).

If one is considering using solar heat, they would be well advised to get a copy of Steve Baer's book -- Sunspots -- I think that is the book. My copy was destroyed in a flood several years back but Mr. Baer had many thoughts, and the test results to back them up, on solar heating of air and water.

Remember, you'll never live long enough to make all the stupid mistakes yourself. Sometimes it is best to let others find the way and then just follow.....

Ron

Re: Sunspots ([none / 0](#)) (#6)

by JW on Tue Nov 11th, 2003 at 07:51:20 AM MST  
([User Info](#))

Gameman,

A cheap source for large fresnel(sp?) lenses is 1980's vintage internal projection large screen TV's. I have seen them as large as 3 foot by 4 foot. In the 90's you could find these just about anywhere, now they are more difficult to find, since they stopped making TV's that way. I suspect that TV repairmen have packed some of these away, perhaps there's such an establishment in your area, I would ask questions there.

Be careful not to "melt" (it's going to be plastic) your lens from heat rising from the metal box you plan to construct. Also you may experience some transparency loss, due to necessary support bars or struts, that will keep the lens from sagging. Most likely you will have to force plenty of air thru the box to keep things manageable.

Also be exceedingly careful if you decide to work with glass instead.

-JW

Actually, another place is those old retro tv magnifiers you would see at your old aunt's house or someplace like that. I salvaged a couple and have made some fun stuff from it like a small solar powered copper foundry, where I can pour small amounts of copper just by the sun... But back to the point, one can find these old retro magnifiers pretty much everywhere. Another good place is to find a scrapyard for old office supplies. Overhead projectors have a fresnel lens right under the glass plate, and although they are small, there is a lot of them out there.

-Andrew

Don't forget, you only get so many BTU's per square foot of collector area, whether that's a Fresnel lens, or plain window glass. You can achieve much higher temperatures with the Fresnel lens, but in a much smaller area. So it doesn't multiply the heat, it multiplies the temperature while proportionally reducing the heated area.

Good luck and have fun!

troy

Some simple, but crucial questions about laminates, coils and armature :)

Hi,

I have some small questions, which easily could be answered by the pro's here. For most of those questions I have searched this board, and the old one. But things just stay vague sometimes :-(.

1) Laminates.

Those are used under the coils to get rid of "eddy currents". as far as I have read, the material should allow magnetic "fields", but should not remain magnetic, or something like that?. I have no clue what exact material I should use. Would iron-wire work? or does it need to be like iron strips. (no idea where I can find those over here though :P)

2) Armature.

Does it really have to be a steel backing (I'm using HD magnets). Can't I just glue the magnets to wood (so to speak). Since it's quite hard to find such a steel thing over here :(

3) Coils.

I read the "flatter the better". The smaller the wire "width" (AWG), the lower the A, the higher the V. And vice versa. But what's a nice middle line? How do you determine a bit what type to use, or what is an average? And how should I determine the amount of windings. Just do a guess like, 60 is nice, or 100? Or just when "it gets too big"? :)

4)

Some question rather related to this board. I have found no way to get in contact with someone who didn't public specify his email address. I really hope someone knows the email address of ChrisW, since this: <http://www.fieldlines.com/comments/2003/10/15/102538/69/6#6> post was quite interesting to me. (about using HD magnets, and he managed to do it pretty nice) Unfortunately I cannot find anything on Google referencing to him :-(.

I hope these questions aren't too obvious :) I tried to find all these answers, but I just didn't get the answers very straight. Getting the right materials is my main problem over here.

Regards,  
Sponge

- [Also by Sponge](#)

1) Laminates

use thin strips, .014 silicon steel or so. insulated or paint em with varnish.

2) Armature

Want lots of output or a mouse? Put on a metal backing! steel plate 1/4 min. if you can't feel the magnet behind the material then it's thick enough. You can, though not suggested.. laminate a plate ontop of a plate for thickness.

3) Coils - Do the reasearch on this board.. there are sooooooo many referances to "coils" and making coils, we keep having to anwser the same question a hundred times.. Use search PLEASE!!

Your problem is not materials, it's reading the vast amount of information that is presently available on this board and deciphering a bit of it. (information overload)

Here is a good starting point.. Visit my web site below and click on turbine building and -->>"alt energy links"<<-- that will get you started in the right direction. Look at all the web sites out their! They will amaze you! and give you invaluable information on building.

<http://www.internetfred.com>

I wish you good luck on your journey! it's just begun.

Re: Some simple, but crucial questions ([none / 0](#)) (#2)  
by [Sponge](#) on Tue Nov 11th, 2003 at 01:42:22 AM MST  
([User Info](#))

Thanks! :)

I have been reading through every page I could find though, for a while already. But sometimes the pictures are quite unclear, and they do not explain why they choose a certain wire size or x windings :)

For laminates, normal iron/metal or something won't work out? I doubt I can find that Silicon stuff overhere :). It certainly can't be bought in a large "do it yourself" shop.

I'll try finding a steel platething. It would probably be too heavy for my current design, so I'd need to make a new "head" for the windmill. New challenges! Especially with the amount of tools I have :)

Regards,  
Sponge

[Heat exchanger for a residential clothes dryer?](#)

By [pazman](#), Section [Weird Science](#) [Free Energy](#)  
 Posted on Sat Nov 8th, 2003 at 11:41:01 PM MST  
 Residential dryer heat exchanger?

If my math is correct, an average residential electric clothes dryer in north america is around 5000 to 6000 watts of power. A chunk of this power gets converted directly into heat (not sure how much), dries the clothes and gets exhausted outside for the birds. An average laundry load runs on the dryer for 45 min to an hour. A household with two to three kids can run two to three loads a day. So we could have a total hydro consumption of as much as 18 kilowatt hours a day. It would be great to recover some of this energy...some google searches later I couldn't find anything on the subject (aside from industrial heat exchangers) so I'm not sure if anyone has done much with trying to recover heat from the dryer.

Done the brute force way and vented directly in the basement and with a cheap lint trap, in a new energy efficient house, moisture will quickly become a problem. A source from somewhere told me that an average dryer load removes about 5 litres or so of water. Introducing this into an airtight new house would be bad news with excess moisture/mold etc. Lint is another problem. The best thing I can think of would be a heat exchanger of some sort, but a dryer needs a minimum spec unrestricted airflow in order not to overheat the dryer itself...so the airflow can't be restricted beyond the standard dryer hose spec and beyond the max length of the dryer hose run. Any kind of a heat exchanger that I can think of would need to worry about the water condensing out as well as being able to deal with (remove) the lint at some intervals.

It would be great to recover heat (winter only) from a clothes dryer...but the only way I can think of it being possible (to avoid moisture problems) is with a heat exchanger of some sort (can't think of a cheap way to put one together...car radiator would have piping too small)...and with a heat exchanger one would need to make sure that the airflow would be within spec for adequate cubic volume flow of air so as to not break the dryer itself.

My house already has a heat exchanger, put I can't splice into it and vent the dryer exhaust through it...this would probably plug it up in no time at all.

Has anyone thought of doing something with the waste heat from their dryer and gone through these thoughts as well?

With any normal type of heat exchanger your main problem will be the lint. It comes out of the dryer damp and sticks to anything. The close spaced plates in the heat exchanger will soon clog all the air gaps. You might try a coaxial type where the lint stays inside a convoluted four inch aluminum vent pipe with a six inch fresh air pipe surrounding it. It will require cleaning every month to avoid being a fire hazard. The pipes will have to be long and straight or the air friction will overheat the dryer.  
Garry

Re: Heat exchanger ([none / 0](#)) (#8)  
by pazman on Sun Nov 9th, 2003 at 03:01:06 PM

([User Info](#))

Hi Gary,

Good points about the potential fire hazard. Dealing with lint creates an on going maintenance issue...just the kind of tinkering that always seems to perk my interest towards household tasks instead of mundane things with no challenges :-)

Re: Heat exchanger for a residential clothes dryer ([none / 0](#)) (#2)  
by Junkie ([madscientist@blownup.com](mailto:madscientist@blownup.com)) on Sun Nov 9th, 2003 at 05:52:58 AM MST  
([User Info](#)) <http://www.akuma.dsl.pipex.com/chris>

My dryer is a condenser drier. It's got a condenser built in somewhere that collects the water. So any heat from it get "lost" into the house. Its only 2KW though, about average for a UK dryer, I think.

So maybe you could some sort of large condenser and have the water run into a bucket or something ? Maybe something as simple blowing the outlet over a cold aluminium sheet and collecting the water that drips off ?

Have fun,

-Chris

Re: Heat exchanger for a residential clothes dryer ([none / 0](#)) (#4)  
by pazman on Sun Nov 9th, 2003 at 09:07:33 AM  
MST  
([User Info](#))

That's a good idea. Figuring out a condenser would probably be the thing. I live in a townhouse/"rowhouse" that has the main floor and a basement with a neighbour on both sides of us so we have only two exterior walls to heat. I have a garage that is part of our integrated unit which I just finished insulating. It has no source of heat aside from whatever leaches off from our living space. My initial thought was to vent the dryer exhaust into the garage, but then I saw a posting on the net with the problems that some other people had ran into with extreme moisture and lint. Perhaps I could still go back to my original plan of exhausting into the garage if I figured out the condenser and a drain system for the resulting water. Having a condenser inside the house would present the problem that the heat differential (condenser being room temperature) would not really be there for the condensing to be effective. Venting into the garage I would have the temperature difference for condensing and I could probably deal with the lint problem with a commercial lint trap. All of these are purely "thought experiments" at this stage...gaining approval from the wife for actually buying stuff and cutting into things is another matter :- ) :- ) not to mention that she already thinks that I'm a bit nuts :- )

I live in Northwestern Ontario and our hydro rates are set to go up potentially dramatically. If I ever build a house I would seriously think about scaling it down a bit and going off grid...and give the big raspberry to OPEC as well as the years of mismanagement of Ontario hydro and the debt that all people are paying down above the kvh usage...that's me getting political :- )

spin-dry cut out a lot of dryer time ([none / 0](#)) (#3)  
by Norm on Sun Nov 9th, 2003 at 07:08:23 AM MST  
([User Info](#))

Take an old washer, fix it so it's locked on spin cycle, no water, just hooked to the drain. Spin them almost dry, then put them in the dryer...you'll cut off about 80% of the drying time. You could spin-dry them in your regular washer, but it injects water every once in awhile on it's spin cycle so you would have to shut the water off, also you'd have to keep putting it back on spin-cycle 3 or 4 times. (the wife would probably be hollering about not being able to wash any more clothes until you got thru monkey ing around with the washer.....) Hey! At any rate...keep on having fun! (:>) Norm.

Re: spin-dry cut out a lot of dryer time ([none / 0](#)) (#7)  
by pazman on Sun Nov 9th, 2003 at 02:56:58 PM MST  
([User Info](#))

Hi Norm,

Thanks for the suggestion. I checked with the real expert on this with our current Frigidaire washer (front loader) and she (the wife of course) said that the machine spins the clothes quite dry and according to her does not inject further water in the spin cycle. Another posting on this same topic by Ron made me think that likely a single combo unit (the equator) might be in the cards for me as the washer/dryer combination is more energy efficient than what we have now and is a condensing dryer.

[ [Parent](#) ]

Filter, then cool ([none / 0](#)) (#5)  
by wdyasq on Sun Nov 9th, 2003 at 09:10:56 AM MST  
([User Info](#))

I see this as several problems. But to solve the problem how pazman wants to - to recover the heat, one will need to first filter the exhaust air and get the lint out. I'll propose a large foam-type air filter as is used in automotive applications. I would run the resulting clean, wet air through an air to air heat exchanger as used on large industrial engines and air-compressors. One would need to keep the air flow in a basic down direction so the condensing water would collect at the bottom and could then be drained. There would also need to be a fan to flow air through the heat exchanger into the room. This should cost no more than a few thousand dollars for the parts.

A new Equator clothes processor with condensing dryer is about \$1200. It uses less water meaning less water to heat and buy and needs a 12.8 amps at 115V to run. It also does not require the clothes to be moved from one appliance to the other. But few in the US know of the Equator brand appliances.

While I find it stupid to buy and waste electricity, it is convenient to do so. And, conserving energy is not that as socially correct as having a new and 'proper' washer, dryer, a refrigerator that self defrosts and a high electrical bill to complain about while one sits in front of the TV on election days. This same person will have thermostat set to 78F, gets his cold beer out of the refrigerator when it is freezing outside and tell you Solar energy is not practical - and for him, it ain't.

Ron

Re: Filter, then cool ([none / 0](#)) (#6)  
by pazman on Sun Nov 9th, 2003 at 02:51:31 PM MST  
([User Info](#))

Hey Ron,

Filtering and then cooling and condensing the moisture out would definitely be the right combination. Not sure if there is a homebrew way of doing it economically...I'm a cheap bugger :-)

Thanks for the tip on the equator unit. I'm checking it out on the web. Not sure if they have distribution in Canada or not. We currently have a two unit Frigidaire front loading team that is now pushing six years old. At the time these were one of the best rated and energy efficient in the market when we got them. The dryer has always been a bit troublesome, running way too hot even when it is set low...many repair visits and bills are starting me to wonder the diminishing returns of spending money on the old unit...the equator condensing model might be just the ticket...definitely the better choice than spending thousands on a heat recovery system for an old dryer...still just a "thought experiment" at this stage.

I totally agree with your view on energy waste. This is a mindset that is starting to change, little by little...although us folks in North America are far behind the rest of the world and far out in front in the generation of green house gases. Connection to politics, convenience, the consumerism mentality and the default to do the same as always are all big mountains to move...the thing that does sometimes work the best are rolling blackouts, outages and a higher energy bill.

[ [Parent](#) ]

Forget greenhouse gas ([none / 0](#)) (#9)  
by wdyasq on Sun Nov 9th, 2003 at 03:33:56  
PM MST  
([User Info](#))

Pazman,

I'm not too worried about the -greenhouse gasses- or other -the sky is falling- stories. I figure we haev been able to guess what is going on with measuring devices built in the last 50 years. With these short -rulers- we are predicting things beyond our knowledge base.

I relate it to measuring from LA to NYC with a micrometer and stating the results in inches - change the temperature 5 degrees and even if everything was perfect in the first measurement the result isn't going to look the same.

I insist on paper bags at the grocery store. When one of the - Save the Tree\_ crowd says something I tell them - I'll go plant a tree. You go hatch a dinosaur. Let's see who gets a product to market first.-

I am the founding member of the -Save the Oil Well- foundation. We believe there are a lot better things to do with oil than burn it in IC engines or make plastic bags. Of course, all of this is controlled by governments. If our

electricity wasn't so subsidized by them, North Americans would embrace low-energy consumption appliances. We would have heat-pumps that recovered waste heat going down the drain and take the reject heat from the frig and freezer and use it to heat water.

But, with the false cost of energy, it just isn't financially feasible to do these things.

Well, off the rant now...

Ron

[ [Parent](#) ]

Re: Forget greenhouse gas ([none / 0](#)) (#10)  
by pazman on Sun Nov 9th, 2003 at 03:59:46 PM MST  
([User Info](#))

Hey Ron,

Lots of conjecture, very little hard science and a good dose of politics. I agree with your rant. To get the popular opinion and public on side with conservation, the issue is totally financial and political, and not necessarily even in that order. We haven't been the best custodians of the earth thus far, hopefully human kind is getting smarter collectively as we go.

Things get political very quickly, at least from north american view, with foreign oil and things like the OPEC. If the political will isn't there for conservation, then we are going to need to get more of the black stinky stuff by hook or by crook. Affordable energy drives the economy...even with that a point comes sooner or later the time to consider a different strategy as opposed to more of the same.

I dry my clothes on a line too. What do the Amish do in the colder months when it stays below freezing? Do they just put the clothes near the fire or do they have some other technique?

Martin.

[ [Parent](#) ]

Winter line drying ([none / 0](#)) (#16)  
by TomW on Mon Nov 10th, 2003 at  
07:53:47 AM MST  
([User Info](#))  
<http://oneota.net/~earthsourcepowr/>

Martin;

We use both line drying and an electric [ouch] dryer. In winter we have a line that deploys near the woodburner but you can just put them out on the line. Our dry climate and freezing tend to dry them well just not as fast. Sheets and large items get pretty rigid until the ice starts to evaporate.

Interesting phenomenon that water can go from a solid to a vapor without becoming a liquid again.

Just what I have done.

Cheers.

TomW

Heat exchanger and spinner ([none / 0](#)) (#12)  
by Kemper73 on Sun Nov 9th, 2003 at 08:14:39 PM  
MST  
([User Info](#))

Well, everyone,, I live in Kingston Ontario, and have already made installed and currently using a simple air to air heat exchanger that I built for about \$150 bucks canadian..

All I did was make a simple plate heat exchanger that has a larger x-sectional area than the standard dryer vent tubing,,

Check out [aexusa.com](http://aexusa.com). It has some good info on how to design them. I was originally going to build and sell them but was worried about the liability if someone doesn't clean them out. Mind you,, after running all winter (and checking regularly) there was very little lint inside the unit, and all the water just trickled out into the laundry tub. Good little unit

Also take a look at <http://www.spin-x.com/> I've seen them at public pools, they work great.

Jeff

Jeff,

Would sure be nice to get a better idea of how to build one. Know of any plans available, or do you have plans you could e-mail, and a supplier for the parts?

I've seen dryer duct with square plastic boxes built inline. What do those boxes do, maybe just divert a little of the heat/moisture into the room?

Mark

([User Info](#))

Now I know this is getting low-tech, but I went to my local Canadian Tire store and found two different products for about 15 bucks (Canadian, each). One is a box you put in your dryer exhaust vent line that acts like a switch closing off the outside line and blowing through a lint trap (which you have to clean with each use) marked with the cryptic settings of summer and winter. The other is a thing for houses that have no dryer vent (and can't have one for some reason) it goes on the end of the dryer vent hose and is like a vented bowl filled with water (I guess to catch the lint) and you have to clean it with each use as well.

I was thinking of getting one (the box switch thingy), but there is only two of us, and we only do laundry once a week. It wouldn't solve my basement heating problems. I need a little bit of heat all the time... Not alot for a couple of hours a week.

I'm still thinking about what I could do with that dryer heat.

Cya,  
Chris

Heat exchanger for a residential clothes dryer?  
([none / 0](#)) ([#17](#))  
by jt72 on Mon Nov 10th, 2003 at 12:44:54 PM MST  
([User Info](#))

There exists a contraption for recovering heat from woodstove stovepipes. It is a box that mounts inline with the stovepipe through which pass several tubes with a fan on the back side. As the hot smoke passes by these tubes, they are heated and the fan blows the hot air through the tubes and into the room. I'm sure it is nowhere near as efficient as many high tech heat exchangers used in furnaces and air conditioners but it really does work. I'm thinking that a similar setup mounted inline with the dryer exhaust with a small 12 volt fan may allow you to capture and return at least some of this otherwise wasted hot air.

I'm going to start putting a little thought into making something like this just to see if it works and will post results.

Jim

Heat exchanger for a residential clothes dryer?  
([none / 0](#)) ([#18](#))  
by Kemper73 on Tue Nov 11th, 2003 at 08:01:43 AM MST  
([User Info](#))

This is almost exactly what I built. Mind you I used a plate heat exchanger not a tube type. You just have to make sure that you have a large enough area for the airflow or you will have a higher potential for fire.

I wouldn't buy any of the canadian tire units for a dryer, all they do is put dusty, moist air into your basement. Eventually (usually very quickly) you will start having mold growth in the basement which is bad for your health.

I had mine custom made by a local sheet metal fabricator, I will post a drawing of the unit if I ever get a chance

Re: Heat exchanger on stove flu ([none / 0](#)) ([#20](#))  
by bob02 on Fri Nov 21st, 2003 at 03:45:45 PM MST  
([User Info](#))

Jim, Jeff...

Be very careful robbing heat from any combustion device. Doing so lowers flu gas temp, increasing chimney deposits (gases condense sooner at lower temperature). After an initial market introduction, the devices you describe were declared illegal in many provinces and states after UL and CSA tests... and many fires. You may reclaim some heat, but you could get more heat than you bargained for from the fire department, your insurance company, or a chimney fire. Clean that chimney very frequently and make sure your liner is in good shape!  
Bob

for just 5-10W it seems like a lot of trouble to go through. I have a small stepper motor that puts out about 6-8W into a battery in low winds I think that you might have better luck with something like this, but it is your call

It will have to be a very small 12 volt battery...5amp/hr.  
Well anyway try <http://www.picoturbine.com/>  
their more advanced alternator 3phase should work you  
wouldn't necessarily have to hook it up to a vawt. Have  
Fun! Norm.

([User Info](#))

I signed up on this board with the same basic question. Looking for a "portable" wind generator to be set up and used when camping, which will mostly be in the Oct-Dec timeframe, and out in the woods. Not good for wind generation, but not good for solar in the northern part of the U.S. either. My homemade furnished camper will be heated via a tent stove, it will have LED for basic lighting(at least to prevent stubbing a toe!), and possibly a radio. So my electrical loads should stay small. However, I would like to experiment for the learning experience as much as anything, not to mention having multiple sources of power for flexibility. So, being in the woods(major wind blockage) and having to stay portable, I am severely limiting the available wind to be harvested. Therefore, I would like to build something that is maybe the size of a box fan or slightly larger, that will at least contribute to battery maintenance. This raises another question; if the batteries are somewhat low, will the increased load of a low battery stall a small wind generator in low winds? I have recently built a lawnmower engine-powered GM alternator to do bulk recharging of batteries, but would rather not even use it at all. As it is, I had to build a variable pulse width generator to reduce the motor load on the tired ole garbage-picked lawnmower engine when the battery is low, or it would stall. Perhaps this pulse width modulation could be used for a small wind generator when used on low batteries? I have read many posts on this board as well as some other sites, and it is very confusing. Number of poles, phases, number of windings, number of prop blades and design, stator diameter, etc. Very hard to figure out for a small capacity battery maintainer that I would like to build. Any suggestions would be appreciated.

Since your needs are very low, and you dont have access to either a good vind, or a source of good sunlight, you might want use the possibility of using a bicycle connected to an alternator?

[http://www.otherpower.com/otherpower\\_experiments\\_bicycle.html](http://www.otherpower.com/otherpower_experiments_bicycle.html)

The owner of this site claims that he can get 60 watt without struggling, and 120 watt, when he is pedaling as fast as he can.

your needs are very low, so if you could pedal while you are listening to the news or doing other things, and you would get an excess amount of power, - probably enough to power your lights and other things during the evening?

Look at the bicycles boat owners use - they are very compact. If you cut one of those apart, (remove everything you dont need, like the saddle and the wheels), and connect it to an altenator you would end up with a small human powered generator, which you

# A quick, ugly "pedal generator" made from an old 3 speed bicycle.

---

**This is a brief page about a simple pedal bike we made from a 3 speed bicycle. Although none of us really cares to "pedal" for power, we thought it would be interesting to see just how much power could be generated this way. It also served to test a low rpm alternator we built from a single phase 1/2hp induction motor. Although most folks who live off the power grid probably get plenty of exercise doing other things, this could provide significant power if used daily. We built this in about 1 hour, if a person actually had a need, it would be well worth taking a little more time, and making certain improvements to the design. The two things are necessary to build one, a bike, and a low rpm generator/alternator. We used an old 3 speed, although the gears on a 10 speed might be more appropriate. We removed the back wheel, and took the sprocket off it.**

The sprocket was welded to a hub which fit the shaft of the generator. A design improvement would probably be to have a flywheel on the same shaft as the generator. The generator fit into a bracket which we welded near the back of the bike (approx where the rear wheel was). We welded "feet" together out of some re-bar left over from a concrete project. Another design improvement would be more rigid feet. The feet

were welded to the back of the bike so that it was level, and high enough off the ground to operate. I'll have to admit...it's kind of wobbly and a little bit scary when pedaled at full speed. Better feet, and a flywheel at the generator would help a bunch. Another improvement would be a higher gear ratio. The gears from a 10 speed would be excellent, at least with the alternator we used. The generator, is actually an alternator we built from a 1/2hp furnace blower motor. The lower the rpm for this type of motor, the more poles, so that it generates at lower rpm.

This was a 1200 rpm 6 pole motor. We removed the armature and cut a slot into which we inserted 6 surplus computer hard drive magnets, with alternating poles facing outwards. Although the magnets were not a perfect fit for arc, and diameter, they were more than close enough. The gaps between the magnets were evened up

by sliding the magnets, fitting feeler gauges between them, and then using "super glue" to hold them in place. The magnets are a light press fit into the slot cut. We then put the armature back into the motor, and it becomes an effective low rpm alternator. Alternating Current(AC) is rectified into Direct Current(DC) using a bridge rectifier (4 diodes). Although I have not tested this alternator for exact speed vs output information, it seems to start charging 12 volts at approx 80 rpm. When coupled to the bike, I was able to generate 5 amps(60 watts) in a leisurely way, and if I pedaled as fast as I could, I'd get about 10 amps(120 watts). This seems to be in line with claims we've seen for other peoples plans, although it seems clear that with a higher gear ratio, one could generate significantly more with this alternator.

In summary, again...none of us really feels the need, or want to pedal for electricity, which is why we didn't invest a great deal of time here. Seems like, with a few improvements to the bike, and a 1 hour workout daily, one could produce easily 100 watt hours per day, which is significant, and might actually be practical for some folks who have small power systems. Especially when one considers the efficiency of new light bulbs and LED's, a daily 1 hour workout could easily provide lights, and radio for a small, simple power system. With the use of a welder and a hack saw, it took about 1 hour to make our bike. The generator took another hour, of course, it required use of a metal lathe.

[High voltage at very low rpm](#) | 7 comments (7 topical, 0 editorial)

Re: High voltage at very low rpm ([none / 0](#)) (#5)  
by Moogly on Sun Jan 4th, 2004 at 07:06:41 AM MST  
([User Info](#))

Thank you for your advices I know that building a wind generator is a complicated way to get 10W and will turn out to be more expensive than simply buying a solar cell, but I'm interested in building my own alternator and maybe it will be a prelude for a bigger one eventually. There's still one question unanswered: Is it better to have 1 coil with a lot of turns or 10 coils with 10 times less turns each in series. Thanks

[quote]"Is it better to have 1 coil with a lot of turns or 10 coils with 10 times less turns each in series."

Yes. With your windings evenly distributed around the circumference of the machine, all of the available magnetic flux is acting on coils at all times.

I believe that the most efficient layout for an axial-flux machine is the twin-rotor three phase.

Discussion Board](#)

[Genealogy](#)

The MacLarens  
settled in Cable Head  
West on Prince  
Edward Island 200  
years ago. [Go there](#)

This web site is for those who make their living in the world of electrical construction and maintenance - the **apprentice** or **journeyman electrician**, the electrical **contractor**, and the electrical **inspector**.

The focus of the site is on professional development, continuing education, exam preparation, and technical literacy.

There have been a great many changes in the electrical industry in the last couple of decades. Many of the new systems and equipment require electricians to have some knowledge of basic electronics, both analog and digital. Power quality is an important specialty. Industry is into digital control in a big way. Data communication systems are being installed in almost every facility.

**Survey** - We believe there are many electricians that could make use of study materials that they could work on at home in spare time. These home study courses and practice exams are being developed right now and will be available soon. To let us know which modules are most needed please [fill out our brief survey](#).

**Discussion** - Most of us have code questions that we can't find the answers to from time to time. Post your question for others to answer, or supply answers to other's questions, at our [discussion forum](#).

**News** - If you know of anything new with regard to employment, training, new products or tools, or anything else related to the occupation that you think others would be interested in, [send it to me](#), and we will put it on our [news page](#).

**Home Study

I post a lot of drawings. I use the Wondoze Paint program and convert the file to a GIF Image so the file size will be real small.

Small file size is important, I suggest you use GIF images for drawings and JPG images for Photos. And try to keep the pic size under 650 pixels.

[Is 15.3 volts too high to leave my batteries charging?](#) | 2 comments  
(2 topical, 0 editorial)

battery charging - ([none / 0](#)) (#1)  
by VermontMaple on Sat Jan 3rd, 2004 at 02:05:49 PM MST  
([User Info](#))

Zmoz

Charging batteies is a tricky business. And floating them for an extended period is even a harder. I have had a lot of experience over the past decade floating lead acid batteries. Most trickle style battery chargers have some minimum current always being fed to the battery . This is fine for a short time (1 week or so) however if you are not cycling your batteries...like most off the off-grid poeple do, you will boil out the acid in your battery. Many years ago I had a very useful conversation with a battery engineer at C&D corporation about proper charging and maintenance of lead acid batteries. His advice is as follows. Never allow the float voltage of the charging device exceed the natural float voltage of the battery. The natural float voltage of the battery can be found by initaly charging the battery very hard for enough time that you are satisfied it is fully charged..The battery will usually be warm/hot...for a standard car style battery charge it at about 10amps (about 1/10 to 1/3 of the amp hr rating of the unit 60-100 amp/hrs for car batteries = 6 to 10 amps) And charge it for about 24 hours. The voltage of the unit should be well above 14 volts at the end of the charge cycle. Now let the battery rest for 15 minutes after removing the charger, then measure the voltage of the battery (to 2 decimal places if possible). This is the natural charged voltage of this particuluar battery. Set the voltage out on your charging unit not to exceed this voltage. If the battery is kept at this voltage it will not evaporate its electrolyte, and be always ready for use.

As for paralleling batteries, one will usually discharge the other until the lowest voltage unit is at its natural voltage. If the battery have the same natural voltage (or very close +\_ .1 volts) than they can be paralleled without a problem.

Stacking, paralleling batteries is a complex subject. Whenever possible stack/parallel batteries from the same lot if possible or at least the same capacity and age. There are tricks using fuses as swamping resistors (and saftey devices) to help better stacking/paralleling...but I will save that for a future post if anybody is interested.

battery charging - ([none / 0](#)) (#1)  
by VermontMaple on Sat Jan 3rd, 2004 at 02:05:49 PM MST  
([User Info](#))

Zmoz

Charging batteies is a tricky business. And floating them for an extended period is even a harder. I have had a lot of experience over the past decade floating lead acid batteries. Most trickle style battery chargers have some minimum current always being fed to the battery . This is fine for a short time (1 week or so) however if you are not cycling your batteries...like most off the off-grid poeple do, you will boil out the acid in your battery. Many years ago I had a very useful conversation with a battery engineer at C&D corporation about proper charging and maintenance of lead acid batteries. His advice is as follows. Never allow the float voltage of the charging device exceed the natural float voltage of the battery. The natural float voltage of the battery can be found by initaly charging the battery very hard for enough time that you are satisfied it is fully charged..The battery will usually be warm/hot...for a standard car style battery charge it at about 10amps (about 1/10 to 1/3 of the amp hr rating of the unit 60-100 amp/hrs for car batteries = 6 to 10 amps) And charge it for about 24 hours. The voltage of the unit should be well above 14 volts at the end of the charge cycle. Now let the battery rest for 15 minutes after removing the charger, then measure the voltage of the battery (to 2 decimal places if possible). This is the natural charged voltage of this particuluar battery. Set the voltage out on your charging unit not to exceed this voltage. If the battery is kept at this voltage it will not evaporate its electrolyte, and be always ready for use.

As for paralleling batteries, one will usually discharge the other until the lowest voltage unit is at its natural voltage. If the battery have the same natural voltage (or very close +\_ .1 volts) than they can be paralleled without a problem.

Stacking, paralleling batteries is a complex subject. Whenever possible stack/parallel batteries from the same lot if possible or at least the same capacity and age. There are tricks using fuses as swamping resistors (and saftey devices) to help better stacking/paralleling...but I will save that for a future post if anybody is interested.

you could try draining the acid after you have fully charged them. never tried it but batteries will keep for years like this. just pour the acid back in in spring. no charging, no freezing, and you can just forget about them till you need them. do a google on battery maintenance, its all there somewhere.:-) bob

[connecting 12 Volt Batteries.](#)

By [mmulzer](#), Section [Homebrewed Electricity](#)  
Posted on Thu Jan 1st, 2004 at 11:08:22 AM MST [Batteries](#)

Somebody help??If I conect several Batteries inline,will I still have a 12 Volt Battery or ??????

[conecting 12 Volt Batteries.](#) | 5 comments (5 topical, 0 editorial)

Re: conecting 12 Volt Batteries, ([none / 0](#)) ([#1](#))  
by [stm](#) on Thu Jan 1st, 2004 at 11:30:00 AM MST  
([User Info](#))

You can connect 2 or more 12v bateries in parallel if you need more amphours (connect the poles + to +, and - to -).

By connecting the bateries in parallel you will still measure 12v between + and -. - and your bateries will be charged/used simultaneously. - a lot of people use this method of doubling the capacity of the batery to power their home/cabin in the periods without sun and wind.

If you make a series connection on 2 bateries (+-+-) your result will be 24 volt using the same batery.

/Steffen

yes. your 12 volts here is a constant ( tho your meter may read 10 to 14). the added batteries simply add time/load you may draw from your pack between charges. good luck.

its worth remembering that the batteries should all be the same type or around the same age at least. the reason for this is that if one battery has a dead cell all the charge will leak away though this cell and flatten them quickly. if you cant measure the voltage on each cell, should be between 1.9 to 2.4 or thereabouts depending on the type, at least test all the cells with an hydrometer. bob

an artical I found about batteries that have Thermal Runaway

I was looking at an artical I found at <http://slashdot.org> talking about Lithium-Ion batteries that explode from Thermal Runaway caused when the batteries are heated like being in the trunk of a car. [http://www.infoworld.com/article/03/12/19/500Preality\\_1.html](http://www.infoworld.com/article/03/12/19/500Preality_1.html) They are also mentioning Lithium-Ion Batteries that weigh 60 pounds.

### [Can I see sulfation on battery plates?](#)

By [zmoz](#), Section [Homebrewed Electricity](#)  
Posted on Sun Dec 28th, 2003 at 08:19:53 PM MST [Batteries](#)

I wrestled the battery out of my boat today to store it in the garage for the winter and charge it up.

(it's a starting battery) I would guess it's at least 3-4 years old, but I don't really know as it was in the boat when I bought it. I opened up the cell caps to check the water level - it looks like there is something white flaking off of the plates. Is that bad? Also the acid in one of the cells looks a bit more cloudy than the others...I'm guessing it's not supposed to be?

[Can I see sulfation on battery plates?](#) | 7 comments (7 topical, 0 editorial)

Re: Can I see sulfation on battery plates? ([none](#) / [0](#)) (#1)  
by [bill541](#) on Sun Dec 28th, 2003 at 08:40:14 PM MST ([User Info](#))

You sure can, lead sulfate is a white scale that builds up on the plates and can sluff off.

In a starting battery this age, a certain amount is normal, but it does degrade the performance. You could try a full charge cycle and then check the electrolyte using a hydrometer. All cells should read the same. The exact reading on the hydrometer is based on the electrolyte mix used by the manufacturer, it does vary.

If any of the plates are exposed, just add enough distilled water to cover the plates, then charge the battery.

Hope this helps, Bill

Re: Can I see sulfation on battery plates? ([none](#) / [0](#)) (#3)  
by [wooferhound](#) ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Mon Dec 29th, 2003 at 02:32:24 PM MST ([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

What happens if you add ordinary Tap Water to the batteries, instead of distilled water, like the last time that I topped off my battery ?

Alright, I let the battery charge overnight @ 1 amp. When I checked it this morning with the charger still attached it read 15.5 volts. I'm guessing that's bad too? :) Do any of those products you put into the battery acid actually work to help the sulfation?

Re: Can I see sulfation on battery plates? ([none / 0](#))

([#4](#))

by kell on Mon Dec 29th, 2003 at 06:39:54 PM MST

([User Info](#))

There was a charging circuit posted here a while ago that is supposed to help freshen up a sulfated battery. I don't know how to post diagrams but I'll describe the circuit. You need a full bridge rectifier rated for at least a couple hundred volts peak inverse voltage. Basically you are running rectified line power (120 v) into the battery, but you limit current by simply feeding the ac into the bridge through a capacitor. The capacitor should have a voltage rating of at least a couple hundred volts. The capacitance determines the current. For a fairly big battery you could go for a few dozen uF (microfarads).... it's not an exact thing; just monitor current and voltage. Attach the dc output of the bridge to the battery. Keep an eye on the battery voltage so you don't overcharge it. You can do a couple of discharge/recharge cycles. The cap needs to be non-polarized. There's also a way to use polarized capacitors and diodes to pass ac, but I won't go into that here.

In effect this is a constant-current high voltage pulse charger, so the monitoring is important because it will overcharge your battery if you don't watch it.

Re: Can I see sulfation on battery plates? ([none / 0](#))

([#6](#))

by Scott on Tue Dec 30th, 2003 at 07:14:14 PM MST

([User Info](#))

Remove the charger before checking the battery voltage.  
You're probably reading the voltage that the battery  
charger is putting out rather than the actual battery voltage.

Posted on Sat Dec 27th, 2003 at 07:26:33 PM MST

Would it be ok to leave two batteries on the same trickle charger?

Right now I have two car batteries sitting in my garage - one is brand new from my totaled Jeep, the other is from my boat. Both will be sitting in my garage until summer. I don't really want to buy one of those fancy battery maintainers for them. I have a 1 amp trickle charger...would it be ok to wire the batteries in parallel and hook the charger to them both? And then just leave it plugged in until summer? The batteries are different sizes...if that makes any difference.

Usually when connecting two batteries in paralell, they must be of the same type and age. You can get away with it as long as you know your charger will never fail and that both batteries have the same voltage when bridging them together. I would not recommend doing this in your situation.

Since they are of different types (one starting battery the other a deep cycle?)you would probably be better off with an isolator between them and then connect that to the trickle charger.

Since you are only using a 1A charger, a couple of schottkey diodes could serve as the battery isolator. Connect both diode anodes together and then connect them to the battery charger positive lead. Connect the cathode (has the stripe) ends of the diodes to the battery + leads. One diode to one battery. Then you can connect both battery neg leads to the charger neg lead.

The diodes should be rated at =>25 PIV, and say 3 Amps to be safe. The diodes prevent any charge current going from one battery to the other and will allow for imbalances during charging.

There will be a small voltage drop across the diodes, but at least they wont go dead during storage.

Take care, Bill

([User Info](#))

They are both starting batteries. The boat battery isn't a marine battery either, and is at least a few years old. Would it be better maybe to leave the charger on one battery, and change it to the other battery every week or so?

I have float charged several different types of batteries (same voltage) in parallel after making sure they were all fully charged and all of acceptable integrity. To the best of my knowledge there were no problems. They were all in great condition in the spring so i assumed it worked fine.

No harm in trying to do what you want. If you find they are "imbalanced", then charge them alternately or do the shotky diode thing. It is good that you intend to charge them at all. If they are older batteries there is a possibility they won't make it 6 months even with the best care.

Re: Maintaining two batteries with one charger?

([none / 0](#)) (#5)

by zmoz on Sat Dec 27th, 2003 at 10:23:58 PM MST

([User Info](#))

So a continuous .5 amp charge for several months won't be a problem for these batteries?

([User Info](#))

zmoz,

It is a good thing that you are keeping the batteries on a maintenance charge while storing them. Most people do not, and they should. You can keep the batteries on a continuous float charge around 13.8 VDC for a 12-volt flooded battery. You can remain at this charge rate for a long time with no damage.

All you will be trying to do is make up for the self-discharge of the battery. If your charger levels off at around 13.8 VDC, then very little current will be flowing into the batteries and you will be below the gassing voltage.

It would be a good idea to check the electrolyte level now and again to make sure the plates stay wet. Your idea of swapping the charger manually between the two would work equally well as the battery isolator, just requires a bit of labor now and then.

Take care, Bill

Long term you want to float; that's even less than a trickle charge. I'd check with an ammeter.

buy 2 2n4001 diodes from radio shack..... use them as a battery isolator....

I can't make you a pic.. but I'm sure Tom or Mech could.  
Since you have only 1A of charge.. those diodes will handle the current fine.

Re: Maintaining two batteries with one charger? ([none / 0](#)) ([#10](#))  
by Harry Luubovv on Tue Dec 30th, 2003 at 07:03:18 PM MST  
([User Info](#))

Hi Zmoz,

I do not recommend trickle charging two very different capacity ratings of battery with one set of charge leads even when one is not a deep cycle bat. As the high capacity bat will certainly discharge into the smaller cap bat, aside from what's going into the small cap bat from the charger itself. This will make the large bat unfull at times while the small bat receives more than its share of trickle charge. Aside from that, nothing's wrong with hooking them all together from one charger. But be sure that the polarities are hooked up the same between 2 bats !! Otherwise you will get some pretty high sparks !! Explosion is a possibility since the wet fluid inside the bat can be flammable especially during charge, even at slow charge and hotter weather or hotter room temperature.

But you don't really have to keep the charger on everyday during winter. Since this wears out the transformer inside the charger and other components. And if you are on alternative energy scheme, you are wasting off more electricity than you need to. I would recommend trickle charging perhaps 3 days in a week. But have them on charge every day of the week if the weather gets to be very very cold, or if the bats are old old bats.

At last if anyone wants small capacity diodes at about one amp, I have tons of them new. I will send them to you free in an airmail envelope, they are small enough anyway. I am not going to bother charging for them since they are about a dollar or two each. In other words, I am not going to charge anything that you are going to use to charge something else with, this will become double charge :-). Just say so on this board, give your email or street address, or your proxy email address or your proxy street address.

Hey Yo, be nice,  
be the best dice.  
Be my friends,  
again,  
be your neighbour's friends.  
Again,  
be friends to yourself.  
Luubovv.

[Batteries](#)

An offer too good to miss.

Hi all, I have been offered 24 Tungstone Challenger plus 2volt 400Ahr Gel Cell batteries free for the taking. They were used as a 24 volt dc supply for a gas turbine control system which is now redundant. They are about 5 years old, have never been used in anger, were kept fully charged by a large industrial microprocessor controlled charger and had 6 monthly checks carried out by the battery vendor. Before I say yes to the offer, would they be suitable for my wind genny and if they are, are their any special requirements for charging / maintaining gel cells. i.e. maximum voltage, equalising charge. Any info or guidance would be appreciated.

John S.

## NiMH Batteries

By [Tom in NH](#), Section [Homebrewed Electricity](#)

Posted on Fri Dec 26th, 2003 at 09:07:53 AM MST

[Batteries](#)

How would they be for solar PV apps?

Is anyone out there able to tell me about the potential of Nickle Metal Hydride batteries in solar PV applications? They seem to have a lot of kick in my power tools that use them. Do they offer advantages that make the extra cost worthwhile? How do they stack up against Lead Acid batteries in terms of power consuming, cycling and charging? Anyone know of any WWW links to NiMH design info? --Tom

Ever have any experience with the Rayovac 3 in 1 charger for AA and AAA NiMH batteries? When I first got the charger I plugged it in at like 8:00 AM...24 hrs later the lights were still on so I E-Mailed a representative and he said that they had to go thru a kind of a 'break in cycle', something like you charge them for about 12 hrs. use them for awhile...charge, use...charge, use 2 or 3 times, then charge until the lights go out(red indicator lights on the charger go out that is...) so I usually charge them after ('breaking them in)till all the indicator lights go out..most of the time some of the indicator lights go out a couple of hours before the others...and they do get really warm (good hand warmers) aside from this they seem to be really rugged little critters. I use them mostly in my digital camera. I've been reading that they do have some rapid chargers. Norm.

I was thinking of maybe wiring up a bank of NiMH cells to make a 12 volt battery pack on the order 75 amp/hours. I found some good info on how to charge NiMH cells at <http://www.powerstream.com/NiMH.htm> Powerstream also has info on NiCd's which may prove to be a better choice given the costs involved.

The info at Powerstream suggested that warming of NiMH batteries can be caused by the production and reabsorbtion of oxygen at the end of the charge cycle and it can be taken as a sign that charging is complete. --Tom

I think the biggest problem with NiMh here would be the self discharge rate - about 1% per day. Much much more than with lead acid batteries.

### [AGM battery-last rights?](#)

By [Mike Wolak](#), Section [Homebrewed Electricity](#)  
Posted on Tue Dec 23rd, 2003 at 04:30:04 PM MST [Batteries](#)  
Dynasty AGM 12-140 absorbed glass mat battery.

Dynasty AGM 12-140 absorbed glass mat battery. These battery's appeared new but used. Looking inside the battery was dried, no water level at all. Charging these battery's they never charge over 10 volts. I decided to fill the battery's with water. The battery charged to 12 volts, but when applying a load from the batter tester they showed dead. Is this battery dead? Did I kill them applying water? Is the car battery tester to much of a load for this type of battery? So gang what you say?

Have a happy holiday, stay warm, may the sun shine down on your solar panels!

Be careful how much you put in.  
I have revived a few AGM batteries back to full health  
by adding water, But you can put too much water in.

When you look in the batteries, you should see  
the top of the plates, and the fiberglass separators.  
You add JUST enough CLEAN water to saturate the  
fiberglass separators.  
You don't want ANY free liquid water in the batteries.

Then close the top vents and give a good healthy EQ  
charge.  
Some times, it takes a while before the battery will start  
taking charge again.

The water content of AGM batteries is lost over time.  
You only want to bring the water content back up to what  
it was when it came from the factory.

Do NOT add acid.  
It already has all the acid it needs, locked in the plates.  
With that type of battery, you can't dump out the acid and  
add fresh water, if the acid content is too high.

And there is no chance it lost any acid by leaking, so  
There is no reason to add any more.

If the battery plates had sulfated (from drying out) to the  
point  
That it won't accept a charge after you add water, then the  
Battery is too far gone to worry about.

Re: AGM battery-last rights? ([none / 0](#)) (#5)  
by Mike Wolak on Fri Dec 26th, 2003 at 08:45:58  
PM MST  
([User Info](#))

They were dry. I filled them over the plates just a  
quarter inch from top of fill hole. Should I only  
dampened the plates or do they swim in water?  
These were used in UPS telecom application. They  
were never used, appear new, dry. I am using a  
Sears car charger, plain, 2-6 amp charger. Had the  
charger on for 48 hours. The battery is a Dynasty  
ups12-140 battery. I hear about glass matt  
recirculates hydrogen back to water. Is my flooding  
of these so called dried battery's wrong?

Re: AGM battery-last rights? ([none / 0](#))  
(#9)  
by N9WOS on Fri Dec 26th, 2003 at 11:12:30  
PM MST  
([User Info](#))

Yes, it is not the proper way to fill them.

I will give you a detailed description of an AGM battery, and why they are designed like they are.

The main problem with a flooded battery is they will pour out acid when damaged, and they can't be used in any position beside right side up. Other wise, they will pour our electrolyte. (acid)

The GEL cell batteries were the first ones to get past that problem. They are basically the same as a normal flooded cell, but they use a silica gelling agent in the electrolyte to immobilize it. That way, you can crack the case and you don't have to worry about total electrolyte loss, and damage to other equipment from the lost electrolyte. And you can use the gel cell in pretty much any position.

Problems with the gel cell. You can only charge it so fast, and so much. If you charge it too fast, or overcharge it, bubbles will form in the electrolyte, and the electrolyte will dry out. That will almost permanently damage the battery. You can only discharge it so fast, If you discharge it to fast, you will also cause bubbles and heating of the electrolyte, which will permanently damage the battery

The AGM battery is a relatively new design as batteries go. It is also know as a starved electrolyte battery. They use a dense fiberglass mat in-between the plates and around the plates, between the edges of the plates and the case. The matting provides support for the plates ,acts as a plate separator, and provides a way to immobilize the electrolyte. It acts more like a flooded cell. It can handle the same quick discharges that the flooded cell can. It can tolerate quick charges, and moderate overcharging, without much damage. And yet, you can turn it upside down, or what ever, and you have no worry about spilling electrolyte.

The electrolyte level is critical. There is just enough electrolyte in the battery to saturate the fiberglass. There is two ways to fill a new AGM battery. The first is by carefully measuring out the electrolyte, to the exact amount that the design requires, then dumping that in each cell.

The second is completely overfilling the battery

and letting the bubbles work out of the matting, then dump ALL the extra electrolyte back out, then seal the battery.

Both ways, you get about the same result. When a new battery is put into service, it will have a break in period. With the glass mat fully saturated, there will be no gas cavities in the matting for gas recombination to occur . So, during the first charge cycles, the battery will vent a moderate amount of gas. As the battery loses electrolyte from gassing, air pockets form in the fiberglass. After enough pockets form, gas recombination (in the pockets) becomes more apparent, and gassing becomes almost non existent. When you refill the battery, you want to restore the original factory condition. That is put only enough water in the battery to totally saturate the fiberglass, and nothing more.

DO NOT put acid in the battery. The acid content of the original electrolyte is still in the battery, that is something that can't be lost, unless the case is cracked. It is just locked in the plates, in the form of sulfate. When you add water and charge the battery, you pull the sulfate out of the plate and turn it back into sulfuric acid.

If you add too much water, there isn't enough sulfur in the plates to bring the acid content up to working level.

If the battery has sit too long, uncharged, it will suffer from the same thing any other lead acid battery will suffer from. The sulfate in the plates will crystallize and the battery can be rendered useless.

That is why I say, if you fill them to the proper amount, and try charging them, but they won't take any charge at all, then forget about it, they are dead.

If they take a little charge, then try cycling them to see if you can bring them out of their hiatus.

I have found that it is best to refill the level on AGM batteries before they totally die from drying out. If you wait until they totally stop working, then the plates have probably crystallized beyond use. So replacing the missing water will be of no use.

Re: AGM battery-last rights? ([none / 0](#)) ([#13](#))  
by Mike Wolak on Sun Dec 28th, 2003 at 02:48:44 PM MST  
([User Info](#))

Hey it works! I emptied the battery, put a EQ charge (14.7VDC) on for 24 hours, more liquid appeared after charging occured. I will empty the extra bubbling water (electrolite). It charged well, put the load tester on it and yes it held a good charge. (Chicago Electric Battery Tester). I have 9 more of these batterys to go. I will take some PIC's for all to see. It was a good freebe!

Thank You

[ [Parent](#) ]

Re: AGM battery-last rights? ([none / 0](#)) ([#14](#))  
by N9WOS on Sun Dec 28th, 2003 at 04:06:20 PM MST  
([User Info](#))

Do not empty the extra liquid while charged.

It contains a moderate portion of the sulfuric acid.

If it is just a small amount, leave it.

The extra water will vent in the form of gassing,

during the charging, and the liquid level should be able to work it's self back to normal.

(ie) Vent enough water to form a few air pockets in the

Fiberglass to allow for recombination.

If there is a large amount of free water in the cells.

FULLY discharge the battery.

And make sure it's dead flat.

That will put the sulfur back into the plates,

and turn the electrolyte back to almost pure water.

Then you can dump the water without losing any of the acid content.

Thank you. Here are some pics of the battery plant that was given to me. The 60 volt chargers, four of them were used in parallel and series for a 120VDC plant. I'm only using 12 VDC plant.

[ [Parent](#) ]

Re: AGM battery-last rights? ([none / 0](#))  
([#16](#))  
by N9WOS on Sun Dec 28th, 2003 at 05:11:22 PM MST  
([User Info](#))

The battery should be fine.  
The rise in fluid level is a result of all the gas bubbles trapped in the fiberglass from the heavy charging.  
After a few hours, the gas bubbles should dissipate and the fluid level should go back to normal.

**SAFETY NOTE.**  
Please keep the valves in place during charging and use.  
One function they provide is explosion prevention.  
If the vapor above the battery ignites, it will prevent the flame from propagating into the cell cavity.  
That will stop the battery from exploding if a spark ignites the vapor above the battery.

The dynasty battery uses plug type valves.

The AGM battery that the charger is setting on (gray case battery) Uses a rubber cap for the venting valve.

Both types of valves provide the same function.  
They isolate the cell

cavity from the outside  
to stop flame  
propagation into the  
cell.

And they raise the  
pressure of the cell to  
promote  
gas recombination by  
the fiberglass mat.

power company.

They have to  
change out these  
battery's even if  
good. I removed  
the battery from  
under the  
charger. If you  
looked at my  
postings you  
would see that  
I'm getting ready  
to set up a  
battery bank  
charged by a  
solar panel  
running a  
inverter. Looked  
you up on ARRL.

Thanks Bennett!

([User Info](#))

You probably diluted the acid when you filled the cells.

Put this across the battery and let it run for a while. This particular circuit can be used to very neatly desulfate supposedly "dead" batteries that won't take normal charging anymore.

This circuit should have connections A and B shorted together for storage.  
Circuit produces "constant current" pulsed D.C.  
The output voltage only rises to a potential sufficient to allow current to flow through the load.  
This means that if you leave A and B in an "open circuit" configuration, the voltage will reach maximum (120 v).  
This circuit works GREAT for charging car batteries and can even de-sulfate "dead" batteries.  
It works well for producing "watergas" because it only raises the voltage to the potential necessary to force current through the acid solution.

I've revived small 12v SLA batteries by flooding with deionized water and running a SMALL version (< 100ma) on them until most of the water was gassed off. Then, I SHOOK them to get the remaining liquid (concentrated electrolyte) back into the matting.

They now take a full charge as if it had never happened.

This circuit uses the capacitor's reactive component to get nearly 100% charging efficiency from the incoming AC waveform. This translates to a bit better than 80% efficiency when charging lead-acid. Go ahead, check it with a watt-hr meter.

The voltage might climb quite high on a severely sulfated battery. I've had some go up to 70v or more for short periods of time before falling back into normal charging range.

Leave your cell caps OFF so that all the gas can be fully ventilated ASAP. Shorted plates can cause sparks and you don't want any hydrox gas mix sealed into the cells if this happens. It gets messy.

All the usual "use this at your own risk" disclaimer whot-not applies.

Re: AGM battery-last rights? ([none / 0](#)) (#7)  
by Mike Wolak on Fri Dec 26th, 2003 at 09:02:00  
PM MST  
([User Info](#))

This is scary. Were rectifying 120vac to out put 120vdc pulsating. Won't this cook the 12 volt AGM battery? Or is this used to fry off sulfating and the battery will only take 12.7 volts and rest of energy is turned to heat or gas? Still a little confused, we have battery chargers that out put around 14 volts. A rise of 2 volts, this application of applying 110 volts over normal charge is bogging. Could you give a little more info for me to understand.

([User Info](#))

Think of it in terms of total current flow.

Forget the voltage for just a moment.

What you have is a capacitor that is limiting the total current flow by restricting the amount of charge that can pass through the circuit during each part of the AC cycle.

I've charged every kind of battery I can think of using that same circuit with different capacitor values.

Using small 200v poly caps, 3uf will give you approximately 100ma from 110VAC line.

If any of the battery cells have a major physical flaw that's preventing normal charging, this charger is not what you want to use.

But, if the cell is simply sulfated, it will clean it up.

You can charge one battery at a time. Or you can put them in series and place on them. The current flow will remain the same while the voltage will be reactively adjusted to match the total battery voltage and maintain that current flow.

Watch a watt-hr meter and you'll see that the wattage used increases as you add more batteries in series.

Re: AGM battery-last rights? ([none / 0](#)) (#12)  
by Mike Wolak on Sun Dec 28th, 2003 at 02:42:44 PM MST  
([User Info](#))

now that makes sense, this capacitor is a current limiting device before the rectifier. Not a filter after the recitifier. I'll try this.

Thank You

Need some help..

I have 8 batteries at 75 AH 12 volt  
I have a Specialty Concepts mark 111/15  
I have a Inverter 3000 watt input 10 to 15 vdc.  
I have a Trace Engineering C30  
I have a pelton turbine with a Delco GM alternator  
2500 feet of 4 inch PVC pipe dropping 700 feet  
And a gen set.  
I have a basic picture of how to wire up the system  
from this web page  
Basic Home Power System Diagram.  
<http://www.absak.com/diagram/general/index.html>

I have some questions ?? as I have never done this  
before  
and am really new to this.

Do I wire battery up in series ?  
Can I use the S.C mark 111/15 ?  
What is and how do i wire in a shunt  
Do I need one ?  
Trace Engineering C30 charge controller ??

I am doing this for a friend and this is the parts  
He has so far..  
I know we still need some more but I understand the  
rest I think at this point.  
Just need a bit of help to get started.

Want to try to just run the batteries for a bit then  
recharge  
with gen then hook up turbine and try it all  
Then put gen inline also when I find a AC transfer  
switch.

Maybe a little bit of a wiring drawing or something

Thanks guys...

--

If it's to be a 12v system all your batteries need to be in parallel.

What is a mark 111/15?

A shunt is usefull for mesuring the current to and from the batterys.

Dr.D

Most of what you need to know about shunts:

([none / 0](#)) ([#2](#))

by TomW on Thu Dec 18th, 2003 at 10:28:14 PM MST

Tuesday night I totaled my truck. :( The battery, however, is still good and is only a month old.

Tuesday night I totaled my truck. :( The battery, however, is still good and is only a month old. I don't have a use for it right now, but I'm not going to leave it in there for the insurance agent to tow away. :) If I'm going to let it sit, possibly a year or more...what should I do? I don't really want to spend any money to keep it, but I do have a 1 amp trickle charger. Should I leave that on it? Should I put it on a timer so it charges for an hour or two every day? Should I just let it charge up once a month?

Thanks

Zmoz- Sorry to hear about your truck. Did you get hurt?

First, make sure it's well charged. Then cover the vent holes and clean it with a light baking soda/water solution, this will eliminate acid on the outside of the battery that can conduct electricity, which will discharge the battery. Then figure out where you're gonna stash it; don't worry about cement floors. Cool and dry is best. If you can spare the \$\$, get an actual battery maintainer or solar panel type charger. Harbor Freight has the solar panel types for ten bucks or so, if you catch the sale. If not, your trickle charger will work, on a couple hours a week. Hook up the maintainer, then let it be. Make sure you check the water just as often as you would if the battery were in actual service.

I'm a little sore...but I'll be ok. (hit the ground hard enough to break the front axle in half) What if I dumped all the acid out of it, and stored it dry? Although I guess I've never heard of anyone doing that before, so it must be a bad idea. :)

Re: How should I store my battery? ([none / 0](#))

([#5](#))

by troy on Fri Dec 19th, 2003 at 10:01:59 AM MST

([User Info](#))

The only time you can store a flooded lead acid battery in the dry state is when it is newly manufactured (ie before they ever add electrolyte.)

Once it's filled, if you drain it and let it dry out, it's shot.

Don't forget that used electrolyte is loaded with heavy metal contamination and lead poisoning will cause brain damage. So disposal is an issue.

Boy I'm just full of good news today!

Anyway, good luck and have fun!

troy

18th, 2003 at 10:58:19 PM MST

([User Info](#))

Glad you're okay.

I've only heard of storing a battery dry, never actually done it or seen it done. If I was going to, I'd dump the acid, fill with distilled water, charge for a bit, dump the water, refill with water, charge, then dump and let it dry. I wouldn't do this. Too much hassle, still have to buy more acid, and possible damage to the battery. Just put a solar charger on it and let it be. Make sure and keep the battery clean while it's in storage, and make sure the terminals can't be shorted by a dropped wrench or the like. I prefer to keep it in a battery box, \$8-\$10 for a group 24.

Now, what could be done, and I'm not suggesting I would(wink wink), is take the battery back to the place of purchase and claim it is bad. If it's only a month old, I'm sure they'll give you your money back. When the time comes, buy another battery. Battery storage problem solved. HTH

Demetri

Re: How should I store my battery? ([none / 0](#)) ([#4](#))

by zmoz on Fri Dec 19th, 2003 at 12:12:05 AM MST

([User Info](#))

Funny you should say that. :) Now that I think about it, the battery is about 2 months old, and I accidently ran it completely dead overnight once. I think I'll take it back and at least get a new replacement...the sticker on the side says it's already a year old.

(#6)  
by Harry Luubovv on Wed Dec 31st, 2003 at  
04:41:16 PM MST  
([User Info](#))

I am sorry Zmoz, but if it were me, I'll hang onto things such as integrity and such. Honesty best, it is just material thing, it is not worth it to lie to get something from others that you know you do not deserve.

I am sorry, I can support you wholeheartedly on your projects or anything else but ..... So please excuse me for talking when not asked.

Please do not pour out the acid liquid from a battery once it is there, this is not a good practice. Putting new acid in is not the same as using the original first set of acid when the bat was new.

Ciao,  
Luubovv  
PS : Happy New Year Zmoz !

Having trouble will not let me post it all ?

I have A Specialty Concepts mark 111/15  
it has battery then a number bar under it 9 up to 15 D.C. volts  
under that it has solar panel then a number bar under that 0 to 15 D.C. amperes.  
It also has a fuse and a charging light  
It has 3 wires a red yellow and a black  
how and where to i hook this up  
Is it like a shunt

RE:Having trouble will not let me post ([none / 0](#)) ([#4](#))  
by [Norm](#) on Thu Dec 18th, 2003 at 04:54:27 AM MST  
([User Info](#))

When you submit a posting right at the start you have bulleted instructions one of them starts out:

Text in the INTRO box (which shows on the front page) is limited to 30 words or less  
...so just type in a short sentence in the INTRO box even tho' it is as big as the EXTENDED copy box  
that is just below it, type the main part of your text in the EXTENDED copy box. This should solve the  
problem. (:>) Norm.

## [Weird problem with SLA battery](#)

By [drdongle](#), Section [Weird Science](#)

Posted on Thu Dec 11th, 2003 at 07:03:27 PM MST

[Batteries](#)

Reverse polarity??

I encountered a weird problem today with a relatively new SLA battery one of my clients has been using. It seems that the battery which has been working properly has swapped polarity. To clarify the Positive terminal is now negative and the negative terminal is now positive. At first I thought that I had a shored battery when I hooked it to the charger and it popped the circuit breaker, then I tested it with my meter and then I thought that my meter was wacky. I verified that the meter was working properly.

Has any one ever heard of this?

Dr.D

by [RobD](#) on Fri Dec 12th, 2003 at 05:00:30 AM MST  
([User Info](#))

Dr. D,

I've seen it with Ni-Cads. Gel sells are lead acids with a gel replacing the acid. Two things to watch for are over charging and over draining. Over charging causes the gasses to escape through a one way valve and this eventually dries out the battery. My hunch is your customer ran the batts into the 'mud' or there is something off in the charging system. Check with the battery maker and look at their charging data. Not all gel cells use the same charging data. The problem is most gel cells charge to a specific voltage, usually 14.7 then go to about 14.1 volts float. This is why they are difficult in wind systems.  
RobD

Re: Weird problem with SLA battery ([none / 0](#)) (#2)  
by [jubalearly](#) on Fri Dec 12th, 2003 at 12:42:26 PM MST  
([User Info](#))

I accidently reverse charged a gell cell once. It won't maintain normal voltage or very much capacity for long that way. I never did get it straightened out, even after a slow & complete discharge using a resistor and several slow complete charges with the correct polarity.

I work on UPS and Emergency Lighting Units and have seen this occur usually from a high impedance battery. The battery string tries to provide current to the load which is low impedance and the total string voltage ends up across the high impedance battery. If it stays like that long enough the batt will be permanently reversed. We had one on an ELU that went to 80vdc when we tried to run the inverter. If you only had 24 or 48 vdc total in the string and it tried to support the load with a weak batt, I could see this happening. Did the reversed batt have any current capacity? Put a load on just that one and see if doesn't drop it's voltage really quick. You might want to check the low dc cut-off on the load(s). Low DC cut-off is critical to protect batteries from being discharged below a recoverable level, usually about 1.67 volts per cell or 10v on a 6 cell (12v) SLA. I also have used reverse charging to recover weak batteries, works pretty well on small NiCds. You just give a quick discharge from a capacitor in the reverse direction a few times and it may take a charge again. You have to be careful with SLAs and use a current limited supply.  
HTH,  
Mel

I can't really answer these questions as the battery has been returned for warranty replacement. This is the only battery in the system to ever have this happen though, and we have been running it several years (not a RE system). Actually they are being used to power a TV camera and UHF transmitter on a thrill ride.

[22 batteries 48 volt bank.](#)

By [Jerry](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 9th, 2003 at 11:24:47 PM MST

[Batteries](#)

This is my 48 volt battery bank.

I just did an upgrade to copper bars instead of wire jumpers. These are 24 volt aircraft batteries. There are 20 in the picture there is an equivalent to 6 more out of view the total amp/hrs is 546.

I charge these with 2 separate 24 volt sources. Out of view on a shelf above is a 3500 watt sine wave inverter. I would like to see other folks systems also.

JK TAS Jerry

There is a local aircraft service center here. I guess the FAA will only allow so many HRs on aircraft batteries. I've done some house trading with a guy who knows a guy. One of those things. They are rated 42 amp hrs at 24 volts. They are 85 lbs each.

by Jerry on Wed Dec 10th, 2003 at 10:28:09 AM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

They are a sealed gell cell. They were used in helicopters. Because of this they are very rigid and reliable. The guy I got these from said the first time he saw one a guy was welding with it. I believe that cause when I accidentally shorted the terminals there was quite a fire ball.

I think some folks here have said this type of battery is not good for RE use but I got them cheap and they've been working great for me.

by Chuck on Wed Dec 10th, 2003 at 03:14:49 PM MST  
([User Info](#)) <http://www.greeley.net/~cmorrison>

Since you asked...

These are 1/2 of the 2880 AH of telco type batteries I have in the shed. There are two 24v strings in the shed. The other 1/2 is identical and located to the left of the photographer. They're about 2 feet deep and stack about 3 ft high and 4 feet wide per string. 3000 lbs per.

These are also ones that are "not recommended" for RE use. I think the main reason people shy away from them is they don't like to be deep cycled. IMHO if you have enough amp hours available, you don't have to deep cycle them.

Chuck

by [Budgreen](#) on Wed Dec 10th, 2003 at 07:31:32 PM MST  
([User Info](#))

well, here we go (beware dialup)

to many batteries

to few racks

these racks will hold 24 of the 60 cells I have, each is rated at 2v200AH so the total in my basement when i finish getting it hooked up will be 24v@400Ah

Electric Car?

Ok, make fun. I can take it. I have this 1995 GM Pontiac Tran Van (dust buster) all fiberglass body with a blown engine. Yes I have this issue of throwing out things (pack rat). I am dreaming of removing the engine and replacing with electric. Is there sites about this? Any tips, knowledge, jokes, ideas. Hate to give car away to charity. Its still a nice ride. So dieing to hear your thoughts.

## [Chemical Rejuvenation Of Batteries](#)

By [bruce1](#), Section [Homebrewed Electricity](#)

Posted on Fri Dec 5th, 2003 at 07:37:42 AM MST

[Batteries](#)

Has anyone used something like this?

Isn't there some sort of chemical that is marketed for use in batteries, to desulfate them, or rejuvenate them somehow? I've seen stuff before in the past, is it any good or a waste of money? Any names come to mind.

I have some forklift batteries that I've been cycling to see if they are good. I think they are OK, but I know they could be better.

Thanks, Bruce

There is a Food additive that has been used by me many times to rejuvenate batteries is called EDTA (ethylenediaminetetraacetic acid).

Unhappily, this food additive has been used for about 30 years to do CHELATION in humans, so it makes it difficult to get it cheaply, a true cost is about 50 to 75 cents of a dollar per pound ( in a sac of 100 pounds ), but you have to be well known by the company to sell it to you.  
Or you can buy a lb for about 10 dollars or so.

The last time I used it, I bought it from TRAILHEAD SUPPLY 1-800-226-6630 , I do not know if they are still in business.

Best way get boiling water and start dissolving the EDTA until you saturate the amount of water you have ( a car battery may take 1/3 lb total, equally dividing the liquid into 6 parts -- I used a large Plastic Syringe to place around 100-150 CC in each cell.

I let the battery stand for about 48 hours, then I start to charge at around 10 % of amp capacity for a long time -- several days, until all the cells show equal voltage ( few millivolts down from a new cell). I used a small drill to perforate the inter-cell links covering to be able to read each cell voltage. The last one I did could not take charge, not even start a car after a charge, after the treatment it has been working beautifully for the last 5 years and still strong.

THERE IS ANOTHER SYSTEM TO DO THE SAME JOB and it is an ELECTRONIC DESULFATOR a small pulse generator that is attached to the battery that after many hours of work; the sulfates are practically removed and the battery is rejuvenated.

I do both EDTA then ELECTRONIC DESULFATION-

([User Info](#))

Radio Shack Bridge rectifier, part #276-1181a, 250v 6amp rating, or something similar.

The capacitor is just a "motor run" capacitor for an AC induction motor. These are available from a bunch of different places.

www.digikey.com should have some. Every 24uf of capacitance will give you about 1amp average current from a 110vac line.

Here's a link to a commercial product sold through JC Whitney:

<http://www.jcwhitney.com/webapp/wcs/stores/servlet/ProductDisplay?productId=31&catalogId=10101&amp;langId=-1&storeId=10101>

Re: Chemical Rejuvenation Of Batteries ([none / 0](#)) ([#7](#))  
by bruce1 on Sat Dec 6th, 2003 at 08:13:26 AM MST  
([User Info](#))

Thanks for the info everyone. Has anyone used the Chemical additive from JC Whitney?

Also, I'm having trouble finding that capacitor for the electric desulfator. Digikey did not have one, I called their 800# and talking to a knowledgeable person. He thought maybe Grangier, and they have capacitors, but its all pretty Greek to me. Anyone know where I can find the capacitor? Thanks to the earlier note, I know the rectifier to use.

Thanks again, Bruce

Newark.com is one big electronics supplier, I don't think they have a minimum order. Make sure to specify ground shipping because their default shipping is the more expensive second-day. I know Allied Electronics has that kind of cap, bunches of them -- but they have a \$50 minimum order. Best for cheap stuff (surplus) is All Electronics ([allelectronics.com](http://allelectronics.com), I think). No minimum, \$6 shipping. I think I got some 22uF 450v caps from them a while back. Caps with wire leads, not the heavy duty cans like you see on motors, but they would still work. And way cheaper. Get their catalog. You might end up ordering more stuff from them. Mouser is another supplier, but their prices are like retail.

Forcefield magnet magnate MattB has about 3000 a/h of surplus SLAs from ChuckM installed at his place -- they went online a couple weeks ago. So far so good! We'll see how they perform, but my opinion is that if the SLAs are in good shape when you get them, and you use the proper regulator (in his case a c-40 set for SLAs) to prevent overcharging, they are probably just great. We've seen lots of dead SLAs, but I think they were murdered by the owners...you can't just add distilled water, so it's critical to not overcharge and boil them.

His SLAs were mounted in steel racks, horizontally. There are 4 racks, and each weighs about 800 lbs. We used an engine hoist to unload them from Chuck's truck into Matts. Matt stated that he used a variety of Mankind's most basic tools to unload them and get them up the hill to their spot underneath his house -- the lever, the fulcrum, the wheel, and the chainsaw :-)

DANF

PS -- the chainsaw was used to widen the doorway so they would fit thru!

PPS -- we'll try and get some pics posted.

<http://www.greeleynet.com/~cmorrison>

Hi Rob,

I picked up the batteries in Denver from a guy who was disposing of them for US West. Last I spoke with him it looked like he had made arrangements to have the rest (about 10 48v strings !) sold in mid november. If you are interested, contact me off list and I can make sure they're gone (or not). (See my web site for my email address)

Yes, it was Surplus Center of Lincoln, Neb. They might have sold them by now too.

Chuck

Re: SLA batts ([none / 0](#)) (#3)  
by Chuck on Mon Dec 1st, 2003 at 01:00:03 PM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

I'm curious if the ones I (and Matt) have are the same type as you ask about. The ones we have are SLAs, but are specifically VRLA, or Valve Regulated Lead Acid. These are the type that Surplus Center was showing on their mail out flyer. They are huge in size, weight and capacity (1440 amp hours) and were made originally for telcos. They use a calcium paste on the plates rather than antimony that is used in most liquid lead acid type batts and should not be drawn down below 50% if you want them to last. They were designed to last 20 years and I'm hoping with care, they will.

I've been using my original set (12 2v cells strung for 24v) for the past couple years with 600 watts (rated) of solar panels and occasional wind from my homemade gennies. I use a c-40 for the wind and a Solar Boost 3048 for the PV. There is temperature compensation on both units as I don't have a constant temp where the battery is.

There are other SLAs that are completely sealed, including some car batteries. It would depend on the make and specific type as to how good they might be in RE applications.

The main thing about using SLAs, as DanF said, is to not abuse them. Never overcharge them as you would when equalizing a liquid lead acid battery, and try not to draw them down too low. Having said that, I've read a study done by East Penn (makers of the VRLA telco batts <http://www.eastpenn-deka.com/> ) which shows no discernable degradation of performance after several hundred complete discharge cycles, but I don't know if I really trust tests done in idealized conditions.

Chuck(M)

## [Making a drill battery pack - can I up the voltage a little?](#)

By [zmoz](#), Section [Homebrewed Electricity](#)

[Batteries](#)

Posted on Thu Nov 27th, 2003 at 01:36:36 PM MST

Can I run a 7.2v drill at 9.6v?

I have an old craftsman cordless drill, but the 7.2v battery pack has been long dead. I'm going to make a new one for it, although it will be external with a wire going to it. Am I going to kill the drill if I power it with 9.6v rather than the original 7.2v?

[Making a drill battery pack - can I up the voltage a little?](#) | 10 comments (10 topical, 0 editorial)

Re: can I up the voltage a little? ([none / 0](#)) ([#1](#))  
by Norm on Thu Nov 27th, 2003 at 03:50:23 PM MST  
([User Info](#))

I'm beginning to think that a low-voltage drill will burn up quicker than a higher voltage one...my neighbor got a 9 volt drill about the same time I got my 14 volt drill, both Craftsman, his lasted about 3-4 months just driving standard 1 inch wood screws. Mine is still goin' strong after 2 yrs of driving couple...3 hundred 3 and 4 inch deck screws. My next cordless is going to be an 18 volt or more...These baby's really pack a hunk of torque! I used to nail stuff together now I screw em together with deck screws...if I make a mistake I can always unscrew it and reposition.Fun! Norm.

([User Info](#))

This drill won't be used that often...or put to work too hard, I've already got 4 others. :)

Oh Well if you've already got 4 others....I'd sure try it, if the smoke gets out...it gets out! BTW where are you getting the cells to make this battery pack and are you just using the old shell and substituting ni-cads or whatever...? or making the whole thing from scratch? Norm.

by zmoz on Fri Nov 28th, 2003 at 12:25:17 PM MST  
([User Info](#))

I'm going to put a coaxial connector jack in the casing of the drill to plug in an external battery pack made from NiMh AA batteries. Not the best option for a "cordless" drill, but better than throwing it away because replacement batteries cost more than a new drill. :-)

[ [Parent](#) ]

Re: Making a drill battery pack - can I up the... ([none / 0](#)) ([#7](#))  
by ThomasK on Fri Nov 28th, 2003 at 02:25:57 PM MST  
([User Info](#))

Hello to All,  
Myself have 5 units and i´ll repair the battpacks as needed.  
my opinion is that higher voltage will destroy the Drill and so i´d just repair it.  
But if you want to do so it is for a try - you´ll find it out.  
About the cable, What size? it seems that it will draw lot of amps under full load.  
When there is need for replacement of cells i have a few always on hand from so called surplus because after a while a specific type of Drill is sorted out of sale shops sell sometime Battpacks for cheap away where i live. This seems a good source for my tinkering with that problem.Also i´m trying to get Drills from scrap and / or Battpacks. Thats why i´m having 5 units. Exept 2 of them fit together, the others don`t.  
Have fun...  
Thomas

Re: Making a drill battery pack - can I up the... ([none / 0](#)) ([#8](#))  
by Norm on Sat Nov 29th, 2003 at 10:13:01 AM MST  
([User Info](#))

I think ThomasK has the best idea  
....making a batterypack with new cells  
from another incompatible batterypack,  
Some of the cells from a 9.6vdc battery  
pack might be the same size as the ones  
in the 7.2. Another good one that would  
probably work is a 6v sla 4Ah for  
PowerWheels like I got at a Walmart  
clearance sale for \$3 apiece (pretty good  
deal). I really don't think those AA NiMh  
will work out too good ...but you have  
got me to thinking about trying out a  
couple of things...I think I'll try 4 of those  
AA NiMh in a little cheap drill that is  
supposed to take 4 alkaline batteries and  
check the difference in power also a few  
other experiments with some of the other  
expendable cordless devices that I have  
laying around. Have Fun at any rate.  
Later...(:>) Norm.

Re: Making a drill battery pack  
- can I up the... ([none / 0](#)) ([#9](#))  
by zmoz on Sat Nov 29th, 2003 at  
02:43:54 PM MST  
([User Info](#))

The battery pack I am replacing is  
only 1.2AH NiCd, so 2AH NiMh AA  
batteries will still be quite an  
improvement. The main reason I  
wanted to use them is because,  
first I have about 30 of them that  
I'm not using, and I have a good  
charger already for them. I would  
have liked to rebuild the original  
batteries, but they are "versa-pack"  
batteries and they are inside of a  
metal tube, and I doubt I could  
ever get it back together if I took it  
apart.

[Do array of batteries want an equal distance to positives](#)

By [zbotrobot](#), Section [Homebrewed Electricity](#)  
 Posted on Tue Nov 25th, 2003 at 07:54:02 PM MST  
 What to know about wiring parallel batteries

[Batteries](#)

Thanks for you help, I have assumed that the wires to the positive posts all be of an equal distance, I end up with a bundle of 4 foot wires all fused together each wire goes to a positive post - the negative posts are all connected as they are. Two rows of batteries are arranged so that the negatives are close to each other while the positives are on the outside. This arrangement is also less likely to short if something stupid should happen - which has happened to me before. So the negatives have heavy wire wound around them with peices of foil pressed on the posts to insure against a poor contact. The equal distance of positives is the theory that when I charge/discharge a battery that each battery has no advantage over another.

I have noticed or imagined that corrosion occurs on the "first battery" if they are not wired in equal distances. This would seem be as if I was charging the first battery, then that battery would charge the next and so forth down the row.

A friend also theorized that the row of parallel batteries could also have the negative at the far end and the positive at the opposite end thus forcing an equalization as the electrons at the far ends would have to make the same effort as the ones in the center.

My question is what is the method, and also what should the diodes and fuses be on, the + or -. I have not noticed any differance. Lastly what direction if electricity considered a physical matirial? I had heard that it flowed from negative to positive. High speed phots of lightning show that one creates a path and then the other flows through that path. Please answer I appreciate it. Thanks alot otherpower and folks.

Batteries ([none / 0](#)) (#1)  
 by Demetri ([corvettemach1@yahoo.com](#)) on Tue Nov 25th, 2003 at 09:01:01 PM MST  
[\(User Info\)](#)

If you're using big enough cables, the distance between the batteries that are next to each other will make very little difference. I don't know what kind of terminals you have on your batts, but actual battery clamps and grease are a must for a good connection. Fuses are generally put on the positive post, but if you do good quality work and keep everything neat, they're not needed on each individual battery. There is a voltage drop through both diodes and fuses, I would be far more worried about that than equal length wires. Hope this helps, and good luck.

Demetri

Do WHAT? ([none / 0](#)) (#2)

by wdyasq on Wed Nov 26th, 2003 at 04:52:18 AM MST  
([User Info](#))

your statement: So the negatives have heavy wire wound around them with peices of foil pressed on the posts to insure against a poor contact.

I'm not familiar with this techniqe. I am familiar with electrolysis, which occures when dissimilar metals can create a battery like reaction. I'll use a quote from this site :  
<http://www.metserve.co.za/Corrosion/Galvanic%20Corrosion.htm>  
as an example.

~~~~~  
In its most general meaning, galvanic corrosion is caused when two metal pieces, in electrical contact with each other, or two adjacent metal areas are at different electrochemical potentials. In this case the two metal parts will constitute a "galvanic cell", in which the metal part with the lowest electrochemical potential (i.e., the more active metal or metal area) will corrode. At the same time, the more noble metal part, with the more positive electrochemical potential, will be "cathodically protected" from corrosion.

~~~~~  
I don't know what - foil - you are using but I suspect Aluminum foil may be a poor choice.

Ron

equal distance to positives? ([none / 0](#)) (#3)

by drdongle on Wed Nov 26th, 2003 at 06:08:49 AM MST  
([User Info](#))

All good comments above, Distance isn't really a problem as long as the wires are heavy enough, use proper battery connections and battery terminal grease. The diodes usually are installed in the + line, though as it is a series circuit it will work either way. The convention for many years has been that current flows from + to - but physics determined that it in fact flows from - to +, but it doesn't really matter as long as proper consideration for polarity is observed when interconnecting devices.

hole theory ([none / 0](#)) (#4)

by JW on Wed Nov 26th, 2003 at 10:06:06 AM MST  
([User Info](#))

zbotrobot,

I found your last ques interesting, "which way to the electrons move? towards positive or negative" The answer is both, according to "electron theory" electrons move towards the negative terminal, and according to "hole theory" its the other way around, as the "holes" mirgate towards the positive ground. At one point hole theory was mainstream and as a result several positive ground systems were constructed for various tractors and very early automobiles. it seems 'hole' theory has been abandoned but its always interesting, at least for me, when I read about it.

If you want to stop corrision at the terminals, use those green and red round felts that they sell at the local autoparts store. they are to be mounted on clean battery terminals then the cable lugs mount on top of them just like usual, in cars these will keep the termials corrosion free for about three months depending on the enviroment, personally I just pour mountain dew on mine periodically, without the felts, but I have seen very good results with the felts as well.

Re: hole theory ([none / 0](#)) (#6)  
by JW on Mon Dec 1st, 2003 at 08:24:07 AM  
MST  
([User Info](#))

Hi Thomask,

Yes mountain dew, as in the soda pop, coca cola also works well, basically any carbonated soda pop. mechanics often use soda pop on really corroded battery terminals, sometimes its the only way to get the bolts loosened on the terminal lugs.

[how many volts dose it take to charge?](#)

By [scagger2002](#), Section [Quarantine Zone](#) [Batteries](#)  
Posted on Tue Nov 25th, 2003 at 05:01:43 PM MST  
Will 8 volts charge 7.2V Battery?

If my generator produces 8 volts can I charge a 7.2V battery or should I make a 6V instead?  
I'm building a remote controled mini zero turn mower out of RC parts. It's going to have 3 deck motors with 5" blades and two wheel motors. I would like to make a nitro generator out of a twin in line motor set from a old RC boat. Thinking of 3 very effcent RC motors or 6V motors for the deck since I think I will only be able to produce 8V. If 8V would hold up 12V batterys for awhile, I would do that but I don'k know if the generators would do anything untill battery Voltage gose down to 8V. Another idea is to run the deck directly of the generator but I could only use one because I still need batterys for the rear drive wheels, the reciver and servos that will need charged to.

any advice?

Thanks,  
lawn boy

by [scagger2002](#) on Tue Nov 25th, 2003 at 05:14:39 PM MST  
([User Info](#))

Also I was wondering if anyone knows of a better generator that is small but powerful enough to run 5 RC motors constantly from a nitro engine.I have to gear it down from 30,000RPM max. I would like to keep the engine down around 20,000 if it has enough power. What happens if I over spin the generator?

 homebrewed batteries

Has anyone ever considered building their own batteries? It seemed to be simple technology, could a person melt and pour lead for plates, acid is cheap, etc. Are the positive and negative plates both made of the lead? Could I melt down old car batteries?

[diy batteries](#) | 6 comments (6 topical, 0 editorial)

Re: diy batteries ([none / 0](#)) ([#1](#))  
 by TomW on Mon Nov 24th, 2003 at 10:25:07 AM MST  
[\(User Info\)](#) <http://oneota.net/~earthsourcepowr/>

bigdan;  
 We have discussed this before and the general consensus is that it probably can be done but:

You would have an inferior product compared to professionally manufactured units

You risk your health and the health of anyone around the operation as well as the health of generations to come from lead that escapes your operation.

Not to be the wet blanket but those seem to be big deterrents to building your own lead acid batteries. A lot of risk for a few hundred or even thousand dollars.

On another note. I have in the long ago past made my own sinkers and even a few bullets from dead batteries. It is a very nasty process and in a lot of the dead batteries the plates are not solid lead like you might think but a spongy oxide or something that does not yield good quality lead.

Just my opinion and may not be shared by others

Cheers.

TomW

Half of the plates should be spongy lead (Lead oxide?). If he were to cast his own battery plates he'd need that type of lead for them.

think it would be better to try and get dicarded batteries working. according to one report on a site dedicated to building pulsers 85% of batteries are discarded before there time. thats a lot of batteries. i seem to get about 30% back to working condition just by charging them. and they only cost 1 dollar each from the junk yard.

bob

I considered this, (best to find a friend somewhere that discards batteries). Anyway one would have to do a lot of smelting if it was hot it would burn cleanly. Dangerous. You would need to get a jar of lead dioxide and bake it on. It can't be painted on, and it seems that it doesn't really meld to the plate chemically so they make a close physical bond that is baked on probably just under the melting point. The other plate is just lead. I imagined casting a thin plate (liquid lead and water are explosive!!) perforating the plate with some sort of mallet and then rolling the two plates between felt or something into a big roll and seating it in a 5 gallon bucket. This would be worth while if you had the facilities to do, knew how to do it and set it up so it was easy to simply melt down the old one and make a new one. The cost of doing all that would be about the same as simply getting decent used batteries. The best thing is contact a semi-truck fleet maintenance center, or somewhere where they throw them a pile and are happy to have someone take care of them so they don't have to deal with recycling the damn things. If they test 12.5 under a load, (light bulb on a volt meter) they're good. If they are 8-9-10 they suck. Lead plates are useful maybe for a bomb shelter.

### Dry Battery

I have a marine deep cycle battery which was never abused, however it was never kept on a charger. I popped open the cells and found they are almost dry. Is there a rehab recommendation to save this battery or is it doomed?

[Dry Battery](#) | 4 comments (4 topical, 0 editorial)

Re: Dry Battery ([none / 0](#)) ([#1](#))

by Norm on Sun Nov 23rd, 2003 at 07:38:24 AM MST  
([User Info](#))

It's too soon to know and not enough data add distilled water to bring the level up to normal...will it take a charge? What is the voltage of the battery. a marine deep cycle battery which was **never abused**, however it was **never kept on a charger**. I popped open the cells and found **they are almost dry**. However...there may be hope...after bringing the level up...check the voltage and post back. It really needs to be charged a little bit and get the specific gravity with a hydrometer of each cell before the condition of your battery can be determined. My 2 cents worth (every little bit helps to make a dollar) Norm.

Re: Dry Battery ([none / 0](#)) ([#2](#))

by 5kw on Sun Nov 23rd, 2003 at 01:44:43 PM MST  
([User Info](#))

Because the electrolyte will expand when charging you should just cover the plates, then charge untill full , then add water to desired level.

I would do all of my conditioning with the plates just covered to avoid losing electrolyte

too much water ([none / 0](#)) ([#3](#))

I'd like to know if anyone can tell me if fork lift batteries are good to use on a windpower system. If so, you reccommend low voltage high amperage or the other way around??  
Thanks  
Guerreiro

[Fork lift batteries](#) | 1 comment (1 topical, 0 editorial)

Re: Fork lift batteries ([none / 0](#)) ([#1](#))  
by [scoraigwind](#) ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Sat Nov 22nd, 2003 at 01:36:06 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

You can use any type of battery for a windpower system but on the whole I do not recommend forklift truck batteries. They are designed for many, deep cycles but they are not so good at holding their charge during calm periods, especially as they get older. This is because the plates contain a lot of antimony.

Forklift batteries are expensive and if you need to do a lot of deep cycling they are worth it, but if you want to have a big battery that will last several days then this is not the best choice to buy new. If you buy them second hand, watch out for a tendency to go flat just sitting there.  
Hugh Piggott <http://www.scoraigwind.co.uk>

## [Forklift Battery](#)

By [bruce1](#), Section [Homebrewed Electricity](#)  
 Posted on Thu Nov 20th, 2003 at 12:23:26 PM MST [Batteries](#)

Another question about a forklift battery I found

I dug a forklift battery out of a salvage yard that showed 22v. I bought it, busted it out of the steel tray, broke them all into 12 2volt cells. I drained the acid, flushed them out, refilled them with new acid and am now charging 6 of them reconnected into a 12v fashion. I cannot charge them in 24 series, so I will charge them for now, as 2 12v batteries while I see if they will be something I can use. My question is how do I know if they will be 'good' batteries? How heavy of a draw should I put on them to cycle them, and at what voltage of each cell should I stop discharging? I'm not sure how to go about knowing what I actually have. The only numbers I could find on the case is.....TYPE (I think) is a 85G-13, and I can see it says.....6hr capacity 510AH. Thats all the info I have about these beasts.

If you know of a link that will explain alot of this, that would be great.

Thank you all, Bruce

Re: Forklift Battery ([none / 0](#)) (#1)  
 by [Budgreen](#) on Fri Nov 21st, 2003 at 06:48:04 AM MST  
[\(User Info\)](#)

most 2v cells (like the ones I have) are rated for a full discharge around 1.75v and a full charge voltage of 2.1-2.3v 510Ah@6hrs could mean 3060Ah total but not sure..

3060Ah would only be if you're drawing at 2 volts with all the cells in parallel. Otherwise, it remains 510Ah, but at the voltage of the string of cells.

Bruce is asking about testing the cells to see if they're any good. I'd suggest finding out who manufactured them and get the specs and charging/testing instructions from them if possible. Otherwise, find someone who makes a similar battery (like trojan) and go by their recommendations.

Chuck

([User Info](#))

figure out the Ah rating for each cell.. let that determine for a load test  
for example a 2v 200Ah cell has a 4 hour discharge to 1.75v rating of 48A  
so putting a 48A load on that cell should drop it's voltage to 1.75 after about 4 hours

also you can charge them and check specific gravity to get an indication

## [Equalization charge](#)

By [bruce1](#), Section [Homebrewed Electricity](#)

Posted on Wed Nov 19th, 2003 at 09:24:57 AM MST

[Batteries](#)

Manual or automatic?

I just received my c35 charge controller. What do most of you people do about the equalization charge, do you do it manually when the individual cells get alittle out of balance, or do you set it automatically for once a month, and let it do it?

Also, what do you recommend for forklift batteries, as far as the bulk and float voltage settings? I'm not sure what category those style of batteries fall into in the manuals recommendations. Default was 14v and 13.5v.

Thanks all, Bruce

[Equalization charge](#) | 1 comment (1 topical, 0 editorial)

Re: Equalization charge ([none / 0](#)) ([#1](#))  
by 5kw on Wed Nov 19th, 2003 at 10:28:03 AM MST  
([User Info](#))

Automatic can only work if you have an excess of energy at the time of equilization. I prefer to eq. manually and oppertunistically, ie when the batteries are full and I have an excess of power, ie during a wind event. I am not fully accuainted with this feature of the C35.

I think the defaults are set intentionally low in case the controller is connected to sealed batteries by a person not versed in proper voltage settings. Are your batteries at constant temperature or are you using temp compensation. If not your bulk setting will be changing with the seasons. I set my bulk settings high enough to produce noticable but not excessive gassing and have enough loads that I,m not getting to bulk voltage daily.

Make the wind fun!

Victor

I don't know, all it says is "Sealed rechargeable lead acid battery" on the front. Only reason I know it's gel cell is because it's out of a portable jump starter.

([User Info](#))

Is this a new battery or an old one and you're having trouble with it or just curious? I would think it would be just a little over 13volts just like any other lead-acid battery I looked around on Google and there are a few people that do stuff like unsealing sealed batteries to see if they can bring 'em back to life. [http://www.4unique.com/battery/battery\\_tutorial.htm#Battery](http://www.4unique.com/battery/battery_tutorial.htm#Battery) Maintenance. Later. Norm.

[proper battery venting](#)

By [Budgreen](#), Section [Homebrewed Electricity](#)  
 Posted on Mon Nov 17th, 2003 at 01:02:51 PM MST [Batteries](#)  
 what are the options?

hello,

as I stand now, I am in the process of setting up my battery bank in my basement, it consists of 3 racks holding 24v@200Ah each, I currently have 2 racks in my basement room (kindof walled off with door to keep kids etc. away) my dilemma is that 2 racks fit along the wall right beneath a window for venting, the third will be around the corner thus not directly under a window. what would be the best option to keep this vented properly? the basement is large enough and open enough that i'm not very worried about gases building up, but I do want my installation to be as safe as possible. any input on this would be greatly appreciated as I have found no other good resource online as of yet.

Josh.

[proper battery venting](#) | 4 comments (4 topical, 0 editorial)

Re: proper battery venting ([none / 0](#)) ([#1](#))  
 by jubalearly on Mon Nov 17th, 2003 at 01:36:44 PM MST  
[\(User Info\)](#)

Well, let me start this out with a couple of points.  
 Hydrogen is lighter than air so it rises. That means it could accumulate near the ceiling if the window is much below the ceiling.  
 Hydrogen gas is not generated during most battery operations - it occurs during charging when the battery is usually bubbling or during high discharge rates when a lot of heat is being generated in the battery. A high discharge rate would normally be at least 10% of capacity and you would probably be a bit higher than that before you got a significant amount of hydrogen gas. Another consideration is acid splashing/vaporization & corrosion with high charge/discharge rates.

I haven't found any good guides on just how much ventilation is required, but it isn't much. You can tell that from looking at how ventilation requirements are handled on commercial battery boxes or battery rooms. One common design for small battery banks seems to be a 3 in. PVC pipe without a fan but run up from the battery and arranged (like a sewer line vent) for air flow over the roof to pull air thru it. I suspect there are some general guide lines in the MSDS for batteries or the fire code (local or NFPA) for battery rooms. I'd sure like to see if anyone comes up with some regulations or other authoritative recommendations/requirements.....

Re: proper battery venting ([none / 0](#)) (#2)  
by JohnS ([john.slaven@btinternet.com](mailto:john.slaven@btinternet.com)) on Mon Nov 17th,  
2003 at 03:54:43 PM MST  
([User Info](#))

Hi Josh, I started off with some ex fork lift batteries in a small room which had no ventillation. During charging there were some horrendous fumes from the vents in these batteries. What I did was to build a wooden plywood box with a lid to fit the batteries in. I fitted a 12dc fan from an old computer power supply to the inside of the box and screwed a 40mm plastic pipe fitting to the other side of the box. All the fumes are now taken away via a 40mm plastic pipe to an outside vent. I haven't had any problems with fumes in the room since. The fan is connected to a timer which switches on the fan for 5 minutes every 30 minutes. Make sure you fit the fan with the correct direction of air flow. The power drawn by the fan and timer is in the order of 50mA when running which will not be a problem with your battery size. Hope this is of some help Josh. Hang loose. John S.

by Budgreen on Mon Nov 17th, 2003 at  
09:11:30 PM MST  
([User Info](#))

depends on the type of fan I suppose >:)

my basement windows butt up to the ceiling,  
and I was thinking of putting a small fan in  
there, that will take the gas out from the 2  
main racks, the third would be iffy. I may have  
to box it in and do it that way, thanks for the  
ideas

Josh

### [Will this battery ever recover?](#)

By [Norm](#), Section [Homebrewed Electricity](#)  
Posted on Mon Nov 17th, 2003 at 04:25:18 AM MST [Batteries](#)

I was wondering if there is something more that I can do

to this regular car battery? I got this car battery from a friend he was having trouble with it. After close inspection...no wonder..they hadn't secured it in the battery holder and it had bounced around a number of times wearing out a bottom corner enough so all the acid had leaked out. I flushed it out with water sealed the hole with JB Weld, filled it up with acid from an old battery and stuck it on charge for about an hour at a time 13.3v. put a light load on it then charge again seems to be working to a point. the total voltage 13.3 voltage of the weak cell 1.92v. and it doesn't have a light trail of bubbles like the good cells. So is there anything more to help this battery out? Norm.

([User Info](#))

You can use a very low amp constant current charger to "clean up" that particular cell.

Any cells that reach full charge will begin to produce hydrogen and oxygen bubbles. Just use a low enough amperage to keep the battery from getting hot. Bubbling won't hurt the plates. But, heating them unduly will cause damage.

A 500ma constant current charger should work for a car battery without causing it to get hot.

This one can be dangerous if you don't know what you're doing. Use at your own risk. This is dirt simple and very effective. Never plug it in until it's already connected to the battery. Always unplug it BEFORE disconnecting it from the battery. Shorting the contacts together is the safest way to store it when not in use. The open-circuit voltage can rise to around 180v DC. This means, DON'T PLUG IT IN UNLESS

IT'S HOOKED TO A BATTERY. Get it?

<http://bbs.vtdl.net/I-/KEELYNET/DIAGRAMS/WATGAS1.GIF>

Believe it or not, this circuit will usually desulfate lead-acid batteries and also works as an efficient general purpose charger. I have a switch on mine that engages a max voltage safety across the DC output. I use that setting for normal charging. I only disengage it for desulfating. The voltage clamp is set to 20v peak.

I've used these countless times, at various amperage designs, to bring back sulfated battery cores that I picked up for \$5 a piece at the autoparts store. They won't all come back. But, many do. After charge-discharge cycling several times, the battery will reach it's maximum destined capacity.

12uf-15uf capacitance would give you an average of about 500ma depending on exact line voltage and frequency (it varies). The capacitor limits the current on the AC side of the rectifier. The rectified DC, when connected to the battery, will only raise the battery voltage enough to pass that amperage.

Here's the procedure I've used that's produced the best results.

On the first day, I charge it for about an hour. then I put a light load on it for an hour. Back and forth like that for 6 hours. Then I just put the charger on and leave it.

Check the specific gravity of the individual cells to get a real idea of the charge state. The sulfated cell might do some bubbling and then stop. Don't be fooled into thinking it's done unless you check the electrolyte.

Bizarre notes: if you are charging at an amperage that is below the heating threshold of the battery, the battery sometimes drops to a LOWER than ambient air temperature. Apparently the capacitive pulse waveform can sometimes induce an endothermic chemical reaction in the cells. Whodathunkit?

Once batteries are fully restored, they'll charge within the normal voltage limits for a new battery. At this point you may recharge several batteries in series on that charger with the overvoltage clamp disengaged. I usually use a maximum of 5 batteries at a time in series. This works great for recharging your bank quickly and efficiently from a backup generator too.

bob

With 240v service you'll need to cut the capacitor value in half to get the same amperage. So, about 6uf-7uf would give you 500ma.

Yes, a 400v capacitor (motor "run" type, not "start" type) would work. As long as the diodes can handle the current level and the peak voltages they'll work.

The clamping is just a 20v zener that feeds the base of a 2N3055 power transistor. The transistor is across the DC side, collector to positive and emitter to negative. The zener goes from the positive to the base of the transistor. Pretty simple really.

On a 1 amp charger, a 22v turn-on produces only 22w power dissipation in the transistor. I probably didn't even need to put it on the heat-sink. But, better safe than sorry.

I don't ever plug the thing in unless it's connected to a battery anyway. so the clamp never really gets to do much of anything.

Here's a safer but more complex charger you might try. You won't need to do any clamping since it isolates the line power from the output. And the output only has a voltage when the output transistor is turned on. Quite safe.

Use an SG3524 PWM chip. They are cheaper than dirt, old IC technology. It is internally regulated for frequency stability and requires only a few external components to make it work. All the specs for it are out there on the web in various places.

It has two discrete output transistors that never overlap their "on" states. I think the max duty-cycle is 45% per transistor. This is good for our purposes here.

You can use a photoflash capacitor for this charger, 330v rating at about 150uf would work. At 60hz pulsing (dumping 60 times per second) this cap will give you an average of about 900ma if you're using a 110v source and charging a 12v battery. Larger capacitors will obviously give you greater total current flow for any given frequency.

Be careful with rapidly charging and discharge electrolytic caps. Some of them get cranky when you push the frequency up and they'll get hot and explode. If you want to make a heavy-current charger it's better to use larger capacitance by building a big parallel bank of electrolytics and then slow cycling them at speeds under 60hz. The batteries only care about the average current over a period of time. Frequencies under 60hz seem to work just fine. You just run the pulse-width at maximum.

Use the SG3524 PWM to control two heavy power transistors through a pair of opto-couplers.

One power transistor charges the capacitor from the transformer. The other power transistor dumps the capacitor across the battery(s). Very simple.

Use a multi-tap step-down transformer and put in a switch for selecting different voltages (25v, 50v, 110v). This part isn't that critical since you can use capacitive voltage dividers, or multipliers, etc... with any suitable transformer to achieve the required voltages.

You can adjust the frequency up and down to vary the average current to the battery.

Select the highest setting (110v) and run the charger for about 15 minutes. Then put a light load on the battery for a while. The HV pulses pierce the sulphate layer. Discharging dissolves some of it and shrinks the crystals.

Then drop it to the 50v setting and let it run for a few hours. Keep an eye on it to see where the charge state is. If the battery voltage is floating higher than 25v, leave it on the 50v setting until it drops down to normal looking battery voltages. Then switch the charger down to the 25v setting for normal charging.

Or, just use the 110v all the time. As long as your average current never exceeds the threshold for plate heating, the battery should accept it without complaint. It's just not quite as efficient as the low voltage for normal charging.

I hope this helps.

Hi, Not easily or efficiently. Car alternators are designed with a narrow specific purpose and while they can be used in other applications they usually don't excel. RobD

Hi, I seem to remember a pamphlet i received from linsay publishing telling how to easily turn an alternator into a motor, but there's a catch (there always is). you had to remove the diode pack and bring the three field winding wires outside the case. so now what you have is a three phase motor with slip ring feed to the rotor. (most of us dread a three phase motor) but in this case the idea was to also remove the diode pack from an alternator that was being used to produce power, there by turning it into a three phase generator that could feed the motor. i'll try to find the information, i'm too tired to think. but its a good tired, i just got back from North Carolina with my new GM-90 engine from Mike. I'm going to post the experience when i can think (better).

Re: Automotive alternator used as motor ([none / 0](#)) (#3)  
by kell on Sat Jan 3rd, 2004 at 07:48:29 PM MST ([User Info](#))

Interesting to think about... putting three-phase ac into the stator would set up a rotating magnetic field? Seems like you would still have to put direct current into the field. And what about the voltage regulator? Like to hear more.

([User Info](#))

You can forget about the regulator, you just turn the alternator as fast/slow as you want, to generate the amount of voltage you want. But of course if you want a specific amount of current and be able to hold to a certain voltage, then you will need your own electronics regulator. But for simplicity, it is not necessary at all to have the regulator, just adjusting the RPM is enough. You can also rectify the AC output to feed the rotor current requirement. Or have Neo Mags fitted to it and forget about drawing unnecessary electricity from the output for the rotor all together !!!

I like something what I read in this board, so I'll repeat what other person said :  
"Put the bunny back in the box". Or was it supposed to be "Put the bus back in a cage !" ? ? :- Gettin' old, cannot remember too well.

Ciao.  
Luubovv.

See what I meant ? Gettin' old really .....  
because, I said to rectify the AC output to feed  
the rotor. I was still thinking to use the  
alternator as a generating source. But in true  
fact, you can rectify the same AC that feeds the  
alternator to supply the rotor need. Or you can  
try to have a separate small coil fitted to the  
rotor, and let this coil generate some current as  
the generator/motor turns, to feed the rotor.  
You will also need a couple of diodes here too.  
This contraption is rightfully called " Self  
excited circuitry" All of these are totally and  
entirely possible ! !

Put the bus back in the page !  
"Page" or "Cage" ? ..... Couldn't rememebr too  
well again :-  
Luubovv.

[Automotive alternator used as motor](#) | 6 comments (6 topical, 0 editorial)

Re: Automotive alternator used as motor ([none / 0](#)) (#6)  
 by kell on Sun Jan 4th, 2004 at 07:32:45 PM MST  
 ([User Info](#))

The \$64,000 question: would it run as an induction motor or a synchronous motor? The rotor on an alternator is very different from the rotor of an induction motor. It could work, but probably very, very inefficient. Theoretically you could make it run like a synchronous motor, but you would have to put in an alternating current to the rotor that's synchronized with the current going into the stator, and chances are the phasing you would need for that current would not be precisely in phase with any of the three phases going into the stator. Maybe if you use a capacitor to shift your rotor current 90 degrees from one of the phases of the stator, the magnetic fields of the stator and rotor would be close but just off enough to give you some torque. Otherwise you might have to do something like installing hall effect sensors to register angular position of the rotor and signal a controller to apply power of the necessary polarity to the rotor. In that case it would be running like a brushless dc motor and you might use dc in the stator... now I'm confusing myself. Ha ha. But you see the problem. An alternator is just not designed like a backwards motor.

Wild bill, It is presently a four pole motor, to use more poles than this it would have to be rewound, twelve poles would be an obvious choice. Is it worth it? At low speeds this would yield a very low power unit. Most induction motor conversions start with a much larger motor. I think Jerry uses 3/4 or one horse motors for his garbogens which have only about 4' diameter blades. Make the wind fun!  
Victor

Hi WildBill I have some wind test results from a very simular 6.7 amp, 1725 rpm, 1 ph., 120 volt garbage disposal motor. 10 mph 5 amps, 15 mph 8 amps, 20 mph 12 amps, 25 mph 23 amps, 30 mph 25 amps, 40 mph 40 amps, 45 mph 45 amps. This is using 3 of my plastic blades at 49 inches tip to tip. These same blades have done 1200 watts top end on the 1 hp. If you were using a 1 hp motor the out put above 15 mph would just about double. Your motor has 4 start and 4 run windings. The starts may be aluminum wire. Also it appears the starts have the typical coil sizes. That is 2 of the start coils are small and 2 are large. Reassigning the coil arrangements will yeald proper results for 12 volt charging. Tom W has a scimatic on his web page. My alt have been made with the old Wondermagnet #29 curved neos. They fit the lamination bore perfect. However the amature in this motor is to short for these magnets. I take the armature from a furnace blower motor. All these motors are free at your Heating and air conditioning shop or at your plumber or at motor rewind shop or at your garage door shop. And Harbor Freight has nice new unit 3/4 hp \$60. I'll post more latter I must go to work now but there is much more I'll share with you on this subject. JK TAS Jerry

Thanks for the info Jerry. While I was sitting around this morning I decided to check windings. They are both aluminum. Large winding shows open circuit, connecting ohm meter between where small wires connected together and red wire shows open, same connection between small wire splice and blue wire is the only one shorted resistance reads.3 ohms. Correct me if I'm wrong but there should be continuity in all, yes? I guess it spent to much time under water. I might as well unwind, maybe I'll learn something. I have some difficulty picturing how these are wound. I'm still very interested in doing the induction motor conversion I guess I'll just have to find another test subject, this one seems to be shot.

Wildbill

P.S. In one of your postings(I think it was you)I read that it was getting hard to get those curved magnets. Are they still hard to get or was that just a temporary shortage?

Hi WildBill All Electronics has the cuved neo magnets for \$5.50 each. the problem is they woun't garranty N,S, pairs. If you ordered 4 magnets you may end up with any combination like 3 Ns 1 S or all S or all N or who knows what?. For a 4 pole motor you need 2 N and 2 S. It impressive to see just 4 little \$5.50 magnets do 1200 watts. And even more exsitting when powered by 3 \$10 blades. I have very clean 4 pole stators for \$10 each. These range from 5.6 amps to 7.6 amps. The diferance on the garbage disposal motor is an unusual large diameter bore. This is partly why they preform so well compaird to standard motors of the same HP rating. They are also very easy to reconect the coils for bettery operation as a wind genny. JK TAS Jerry

Hi Jerry,

Have you seen these guys?

<http://www.rare-earth-magnets.com/SearchResult.aspx?CategoryID=21&Keywords=Segment&All=True>

They list some arc shaped magnets and have separate part numbers for North and South magnets.

But I'm not sure if they are the right size for the induction motors or not?

Have a look and if they are I might try one of these too!

Ted.

Hi WildBill All Electronics has the cuded neo magnets for \$5.50 each. the problem is they woun't garranty N,S, pairs. If you ordered 4 magnets you may end up with any combination like 3 Ns 1 S or all S or all N or who knows what?. For a 4 pole motor you need 2 N and 2 S. It impressive to see just 4 little \$5.50 magnets do 1200 watts. And even more exsitting when powered by 3 \$10 blades. I have very clean 4 pole stators for \$10 each. These range from 5.6 amps to 7.6 amps. The diferance on the garbage disposal motor is an unusual large diameter bore. This is partly why they preform so well compaired to standard motors of the same HP rating. They are also very easy to reconect the coils for bettery opperation as a wind genny. JK TAS Jerry

Hi Jerry,

Have you seen these guys?

<http://www.rare-earth-magnets.com/SearchResult.aspx?CategoryID=21&Keywords=Segment&All=True>

They list some arc shaped magnets and have separate part numbers for North and South magnets.

But I'm not sure if they are the right size for the induction motors or not?

Have a look and if they are I might try one of these too!

Ted.

That thing with All Electronics bums me out. To get the mags in pairs you would have to know somebody that lives in L.A. and willing to go to their store to pick the mags. I know it's doable that way because I talked to somebody in L.A. that went to the store and picked out mags by polarity. But really All Elec should just get a clue and put the mags in two big piles. I tried talking to them but they just won't listen.

## [Magnetic Wire Question](#)

By [cvo](#), Section [Homebrewed Electricity](#)

Posted on Thu Jan 1st, 2004 at 04:26:50 AM MST

[Wiring](#)

Mag Wire

Is there any difference between magnetic wire and wire used in houses, besides size? I've got a lot of it left over from remodeling jobs and thought I could waste it away building coils. Stripping it down is not a problem, one of my employees could do it. Thanks for the replies.

[Magnetic Wire Question](#) | 5 comments (5 topical, 0 editorial)

Re: Magnetic Wire Question ([none / 0](#)) ([#1](#))  
by [wpowokal](#) on Thu Jan 1st, 2004 at 04:37:13 AM MST  
([User Info](#))

Basically yes, magnetic wire has an insulating coat which allows you to wind a coil layer on layer wire alongside wire.

Normal household insulated wire having no "varnish" would short out to touching turns. To my limited understanding that is the only and of course essential difference.

Allan

Re: Magnetic Wire Question ([none / 0](#)) ([#2](#))  
by [cvo](#) on Thu Jan 1st, 2004 at 05:37:13 AM MST  
([User Info](#))

Thanks for the reply. Cheaper to go buy mag wire, but then again that's too easy! Thanks again.

Re: Magnetic Wire Question ([none / 0](#)) ([#3](#))  
by [kell](#) on Thu Jan 1st, 2004 at 10:15:33 AM MST  
([User Info](#))

Some vinyl insulation has lead in it. Tell that to your employee and give him or her some gloves.

I think the main difference is being missed: magnetic wire has a much THINNER insulation which allows more coils in a tighter space, and the insulation is designed to tolerate the heat generated inside the motor/generator.

Re: Magnetic Wire Question ([none / 0](#)) ([#5](#))  
by Electric Ed on Fri Jan 2nd, 2004 at 07:29:57 AM  
MST  
([User Info](#)) <http://www.electric-ed.com>

Right, also, the voltage difference between adjacent turns of a correctly wound coil is quite low, thus permitting the thin insulation.

Electric Ed

## [picture diagram area](#)

By [JB](#), Section [Magnets & Magnetism](#)

Posted on Tue Dec 16th, 2003 at 07:06:40 AM MST [Wiring](#)

I was wonderin if we could add a picture and diagram area to the board.

I was wonderin if we could add a picture and diagram area to the board. I had some diagrams of the fluxpath etc in my hotlist I go back to to study but they are no longer there. I guess the intro box is back again. Thanks JB

[picture diagram area](#) | 10 comments (10 topical, 0 editorial)

Re: picture diagram area ([none / 0](#)) (#1)  
by [kurt](#) on Tue Dec 16th, 2003 at 10:14:51 AM MST  
([User Info](#))

if people would upload pics at a reasonable size instead of megapixel jpegs and huge bitmaps each user would be able to keep 2 dozen or more reasonable sized pictures in there album no problem and then the pictures would be available for people to go back and reference do we really need to upload pictures at 8"x10" or larger format one would think that 3"x5" or smaller would get your point across and save alot of server space.

overly large pics ([none / 0](#)) (#2)

Kurt: Seems as if some mean well but they don't realize what they are doing like the Lithianian(sp?) one just recently posted it took this poor computer about 15 min. to scroll down to the bottom. I was glad to see that he had succeeded those on the board have always been patient with newcomers it sure would be nice if there was some way to avoid this...I guess that's all in the game computers are always doing what you tell 'em to do instead of what you want them to do, eh?  
(: >) Norm.

I strongly concur. Giant pictures are a huge pain. I wish that Admin. could/will do something to automaticly limit pictures to a reasonable size.

by JB on Tue Dec 16th, 2003 at 11:54:39 AM MST  
([User Info](#))

Im not complaining about no picture size but Dan had a diagram on wiring coils and Cevonk posted some interesting diagrams on where the flux path is that I have been studying these but they are no longer there, I didnt think they were big, Electric Ed has some nice diagrams. Im definitely not a electrical whiz but this is the kind of information that I like to look at to understand things without having to post redundant questions that is why I keep them in my HOTLIST. Trash the big pictures but The diagrams shouldnt be thrown out but put in the wiring area. Just my opinion. JB

Issues with pictures and graphics; ([none / 0](#)) (#4)  
by TomW on Tue Dec 16th, 2003 at 12:17:40 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

JB;

There have been lots of ongoing issues with pictures and diagrams on the board.

Several people have uploaded such huge pictures [file size] that they exceed their storage quota. Some have deleted some of them to get more space for their next set of uploads. To the best of my knowledge none of the admins have removed any uploaded files. Once the files are removed by the user they are no longer available for display on the board. Frankly it is almost exclusively a user problem not a board problem. It is very inconsiderate to post a picture that is much bigger than 200 or 300 kilobytes to a forum like this but some of our users regularly post several 900 kilobyte plus sized pictures and diagrams in comments & stories. One recent comment had over 3 megabytes of diagrams from one user and that takes a very long time to download for a dialup user.

Others link to external pictures they have hosted other places. In that case there could be any number of reasons they do not display that I can't begin to explain here.

Here is my suggestion for you:

When you see something you like you should simply download it to your own computer and then it will be available to you any time.

How you do that depends on your operating system and your browser.

Cheers.

TomW

Have you considered a ban on BMP files as they are probably the real problem. If everyone stored their diagrams as GIFs and their photos as JPEGs wouldn't the problem go away.

Unless you have a very old computer, there are programs installed with the operating system that can do the conversion.

Martin.

If there is ever a post you want to keep for reference you can always save it as an HTML file just go to file click save as and put it where you want.

This way you don't have to print it and you do not have to come here to review it.

Re: picture diagram area ([none / 0](#)) (#5)  
by JB on Tue Dec 16th, 2003 at 01:39:01 PM MST  
([User Info](#))

Unfortunately Tom that one diagram didnt get put in my favroite places and it was a diagram Id go back to to think about. It was like reading a newspaper and somebody Trys to grab it from you. You know what happens then. You get ticked. I was under the impression that with the new board all information was the property of otherpower thats why we got to register. I know it all goes to google because i used to put my hometown on my replys and i found myself on google one day. Why it all goes there I dont know., But I thinking Im not the only one that a diagram part would be nice and helpful. It would clean up the board and keep the redundant ??s down in my opinion. I do the hotlists stuff so I can go back to it easily and I thought It would still be there.I dont need cheese with my wine but I found it frustrating that the diagrams that had me thinking and exercising my brain were gone. JB

### [Switch over power](#)

By [RobD](#), Section [Homebrewed Electricity](#)

Posted on Sat Nov 22nd, 2003 at 03:58:02 AM MST

[Wiring](#)

Has anyone built a power switch for their main box?

I'm looking to build a power switch to flip over to my batteries when the power fails. I've never seen one. How are they set up? Does the main fuse come out and a plug go into it to xfer the line to a switch box?

What's the code and where do you get the parts?

Thanks,  
RobD

[Switch over power](#) | 7 comments (7 topical, 0 editorial)

Re: Switch over power ([none / 0](#)) ([#1](#))  
by Electric Ed on Sat Nov 22nd, 2003 at 05:45:48 AM MST  
([User Info](#)) <http://www.electric-ed.com>

Codes require a double throw transfer switch to prevent the stand-by power source from ever getting into the utility lines. The utility transformer would step it up to a voltage that could be dangerous to utility linemen.

There are liability/insurance issues if the installation is not done to code.

Example of a generator/transfer switch below.

Electric Ed

Re: Switch over power ([none / 0](#)) (#2)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sat Nov 22nd, 2003 at 07:05:46 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Just out of curiosity... If you break or pull the mains from the house's main panel box and tie a generator to the same box through separate mains, is there any way to feed the utility line? If not what about the neutral line? Any possibility of feeding back on the neutral?

Windstuff Ed

What you describe is safe enough, it's just that the inspection authorities do not accept transfer schemes that rely on an individual REMEMBERING to open the main. Because they deal with the public they require it to be "idiot" proof, and usually with good reason.

You wouldn't believe what some folks will do. :-)

There normally wouldn't be any "feed back" on the neutral. The reason my example sketch shows a three-pole transfer switch is to deal with a grounding issue. If the generator neutral is NOT bonded to the frame, a two-pole transfer switch would be required, as shown below.

Electric Ed

Couldn't you take two single throw boxes, mount them handle to handle and end up with a very inexpensive power transfere system? Going handle to handle puts one box upside down and the other right side up. bolt the handles together, one breaks the connection to consumer line and the other connects the gen to it. Much cheaper than those Gen boxes and allows you to use a common main panel.

Mine is set up on the "remember" theory right now but I'm looking for ways of meeting code cheaper...

Have Fun

by Jerry on Sat Nov 22nd, 2003 at 09:49:49 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Guys.

This is what I've done. I went to the big box home improvement store and picked up a metal switch box that has room for 9 lite switches, picked up 9 double pole sigle through light swiches. The are the type wall switch that lets you turn of one lite in a room at two locations. By this door or by that door. One lite 2 switches.

I sellected 9 circuts in the house. These circuts are wired to the sellecter part of the switch. Now I have 2 terminals left over. One term. is wired to the circuit breaker where the Utility power is coming from and the other is wire to my inverter. However on each one of these I've wired a seperate circuit breaker for safty.

I works realy slick I can select any circuit I want or all. Home power or grid power just flip a switch. I'm going to do the rest of the panle this way. However this is only for 120 volt use. Thats the CAUTION here.

For my aplication thats all I need. And there is no danger of sending power back to the grid.

I think I did this hole project for less than \$20. The big box store whanted \$200 for there switcher box that dose the same thing.  
It works good for me. Use at your own discesion?

JK TAS Jerry

Re: Switch over power ([none / 0](#)) ([#6](#))  
by RobD on Sun Nov 23rd, 2003 at 02:37:03 PM MST  
([User Info](#))

Thanks for the help everyone.

Nice idea Jerry!

WS Ed. I'm going to use the main fuse as a 'breakout' to feed the three terminal relay. I like the three terminal relay idea and I may build a sensor to switch it over when the power fails (which happens a lot up here) like an UPS configuration. I'll check with my rural co-op to see what they say first.

Thanks again everyone,

RobD

Re: Switch over power ([none / 0](#)) ([#7](#))  
by Joseph Turrisi on Sun Nov 23rd, 2003 at 06:05:17 PM MST  
([User Info](#))

It shouldn't be too hard to build your own switch but I wouldn't recommend it. If it is not UL approved and installed according to the national electric code, your homeowners insurance will have an excuse not to pay out if something bad happens like a fire or electrical shock.

## [Should neutral be grounded near house if meter is a long distance away?](#)

By [storrence](#), Section [Remote Living](#)

[Wiring](#)

Posted on Sun Nov 16th, 2003 at 04:59:29 AM MST

My meter is 350 meters from my house hookup and am wondering if I should put a copper stake near the house to ground neutral?

I have been told the power companies prefer that the neutral pass through the meter but I'm not sure on this.

I have a meter that is 350 meters from my home. At the meter there is a 2 meter copper stake in the ground. The installer said this was because the last place the neutral was ground was far from my meter and better to be grounded. Now I'm wondering if it's better to also ground the neutral near my house. My questions are:

1. Should I still use the neutral going to the meter and just tap into it and connect it to a copper stake in the ground next to my house?
2. Does it matter if it's close to the copper stake I already have in the ground for my ground wire coming from my breaker box?

I've also been thinking if it makes a difference on the strength of my electricity here. The way I understand it is the 60hz phase coming from one of the phase lines is just 170v oscillating from + to - 60 times per second. I assume that this oscillation only takes place when it can connect with ground/neutral. If the neutral or ground is not well grounded then does that make the phase line weaker just like if you were using to thin of a wire and going over a long distance. Sort of like to much resistance so the phase doesn't oscillate very strong. I also visualize it like water pipes that pumps and pulls 60 times per second. The potential is there as if you had a pump at the other end and it was reversing direction 60 times per second. But you wouldn't benefit from that at the other end of the hose unless you opened it up and in the case of electrons connected it to ground. So in the case of water if you connect it to the returning pipe but the returning pipe is much smaller than it should be (much thinner wire creating a higher resistance) then wouldn't the power of the system be reduced?

I'm using 25mm2 wire to run the 350 meter distance. 3 lines for the 3 phases and 1 for neutral. What would happen if I either connected the neutral directly to ground at my house and/or disconnected the neutral going to the meter at the street. Would I improve my power at the house?

Your "neutral" should be most definitely grounded at the house and tied to the ground bar in the circuit breaker panel, use at least # 10 ( US gage) or larger copper wire. Not having a proper ground doesn't change the voltage level it just creates a safety hazard. I suggest that you not mess with the incoming drop cable from the street/ meter unless there is a disconnect at the meter that allows you to cut off the house.

Dr.D

Re: Should neutral be grounded near house  
([none / 0](#)) ([#2](#))  
by storrence on Sun Nov 16th, 2003 at 03:43:47 PM

([User Info](#))

I'm not sure in AWG but here I'm using 4mm<sup>2</sup> ground wire from the box to the grounding stake at the house.

The way it's all set up is:

The meter is at the street. From there I ran 4 25mm<sup>2</sup> wires (seems like the size of a writing pin). 3 for the 3 phases and 1 for neutral.

These go directly into the box inside the house. 3 go to a tripole 40a breaker. 1 goes to the neutral bar.

I have a separate neutral and ground bar that are currently not tied together.

So the neutral goes to the neutral bar in the box with a 25mm<sup>2</sup> cable.

The ground bar which is not connected to the neutral bar goes out of the house on a 4mm<sup>2</sup> cable to a 2 meter copper grounding rod. This ground wire is 4mm<sup>2</sup> and seems about 1/5 the size of the wires coming from the meter.

Since I already have a grounding wire and a good size cable coming from the neutral bar but just not getting to earth until the street which is 350 meters away. Should I just T tap into that neutral and connect it to the ground stake and then connect the ground and neutral bars together in the box?

Your neutral is neutral, and ground is ground!. Inside your service entrance box the neutral is insulated from the box( unless someone turned in the bonding screw.)and box is grounded to ground connection bar and ground rod, as per the electric code here in the U.S. Anyway else will give you tingles!

Re: Should neutral be grounded near house ([none / 0](#)) (#8)  
by jubalearly on Mon Nov 17th, 2003 at 09:07:37 AM MST  
([User Info](#))

Frequently one of the bolts in the box is used to connect the neutral to the ground bar. This connection may not be visible, or, anyone not familiar with that style of panel may not recognize it. In the USA it is often done with a green bonding screw or bolt. That bolt would simply be removed when the panel is used as a sub panel and the neutral - ground connection is not wanted.

Re: Should neutral be grounded near house ([none / 0](#)) (#4)  
by signweld on Sun Nov 16th, 2003 at 07:28:41 PM MST  
([User Info](#))

Dr D., I only mean well, but you may want to check the NEC, or your local electrical code. The neutral should NOT be wired to ground at your service entrance in your house. The only place it is bonded to ground is in the meter box only. after this, the neutral carries the load and the ground only provides a current path to trip the breakers or blow the fuses.

[ [Parent](#) ]

Re: Should neutral be grounded near house ([none / 0](#)) ([#5](#))  
by drdongle on Sun Nov 16th, 2003 at 09:11:14 PM MST  
([User Info](#))

Well my box passed inspection with a link ( provided with the load center) from the neutral to the box ground ( screwed to the metal of the box). At the meter or load center both neutral and ground are at the same potential. Perhaps there have been changes since I did mine.

Dr.D

[ [Parent](#) ]

Re: Should neutral be grounded near house ([none / 0](#)) ([#9](#))  
by jubalearly on Mon Nov 17th, 2003 at 09:36:29 AM MST  
([User Info](#))

Dr. D, the NEC still requires a ground to neutral connection in the (residential) main panel box which is required to be located at the service entrance in the USA. See NEC (NFPA 70, 2002) sections 250.20 and 250.64 as well as a number of parts of article 250 where applicable.

Note that industrial and utility requirements (or apartment complex) may be different in the US, and other countries have all sorts of diffent systems which may have unique requirements. Note that the meter may be either before or after the service entrance and is not necessarily service equipment. There are too many variations to say whether the meter box is grounded, although there normally is a ground at the service entrance. Its all up to the local authority.

Re: Should neutral be grounded near house ([none / 0](#)) (#7)  
by jubalearly on Mon Nov 17th, 2003 at 09:02:23 AM MST  
([User Info](#))

You should ground the neutral in accordance with the National Electrical Code or your countrys equivalent (Brazil?). Be careful of any advice you get here because it may not apply in your country.

In general for the USA, the neutral is also connected to a ground bar in the main circuit breaker box. You MUST only ground the neutral in one place (per US NEC). The NEC also requires connections (to the ground bar in the main panel box or to the ground rod) to things like gas & water pipes. The possibilities are too numerous to go into here but you should do a web search.

As far as grounding the meter goes, this is usually up to the power company. Every utility has different grounding requirements and a meter ground is about 50-50 in the US. Unless you have a receptacle or circuit breaker (not a disconnect) at the meter, I wouldn't worry about whether it is grounded or not. The ground is primarily a safety feature & you need one near the breakers to insure that they can trip properly. That's why there is one in the panel. The neutral is only grounded once to prevent circulating currents & to make sure that devices like a GFCI work properly.

I don't know about your countrys power, but 3 phases should be balanced - that is, they should all have the same voltage between the Hot & ground. Ideally there should be no voltage between ground and neutral. You might read a low voltage between ground and neutral because of the long run or because your load on each phase is not exactly equal. Are you using all 3 phases? and what voltage are your appliances?

You might be able to improve the ground at your house but that is another involved subject that you should do a web search on (residential grounding). Do you have a local electrical inspector? I would get his advice or talk to an engineer at the power company before you do anything. You want to be sure you do not create an electrocution or fire hazard, or nullify any safety equipment.

Re: Should neutral be grounded near house ([none / 0](#)) (#10)  
by storrence on Mon Nov 17th, 2003 at 11:16:22 AM MST  
([User Info](#))

Oh reading this reminds me of when I lived in the states :-) You would be surprised at how these things are done here, especially in a rural area. People literally drop a small cable over the street lines to hookup their house. Saves on the month bills quite a bit :)

Well we decided to do it a little more official and have the power company come out and install the meter and I went from the meter 350M to our house up the mountain. It's as close as they would go :)

In the US is grounding the neutral done at every pole or is it carried directly from the distribution point? I had understood at least here that it is connected to a grounding rod on every pole. This is why the power company put the neutral to a new grounding rod at our pole which was put in at the same time. Since I'm going underground another 350M from that point to my house I'm curious if I should reground the neutral at my house. Possibly using the same rod I'm using for the ground now. Asking someone here about this is impossible. 10 different electricians will give you 10 different advices and they all work for the same company! For me the US standards will do fine if I can adopt them to my situation. I wonder what they do or if you ever have a situation where the street meter would be some distance from the house connection. What would they do in that situation? Carry the neutral from the street or reground it at the house?

The meter itself doesn't have a separate ground from what I remember but it does have the neutral grounded. Same thing? The meter does have a triphase 40A breaker.

Our 3 phase here is balanced. 126v when I test each phase against neutral.

When an installation is done in the US do they put in a ground rod for the house and then connect that to the grounding bar in the circuit box? And do they also connect the neutral leads to this bar also?

[ [Parent](#) ]

The answer is ([none / 0](#)) ([#11](#))  
by [wooferhound](#) ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Wed Nov 19th, 2003 at 08:20:37 PM MST  
([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

The answer is . . .

There should be an earth ground rod connected to every Breaker Box with some rather high gauge wire, regardless of whether the neutral is screwed to the ground of the box or not.

} = - W o o f - = {

 any info would help

I built a small wind gen out of one of those little honda 1000 watt gens that had the little weedeater engine shot. As a wind gen it is producing 6 to12 volts dc not much I wired the 110 ac side of it up and connected to the diodes for the actual dc side thus that is what is producing the voltage. Ok now the question microwave trans are ac. so I unhooked one of the 3 ac lines comeing in and hooked it to the trans it seems to be bumping that lines voltage up to 100 to 300+ volts I need to know if it is ac or dc my multi meter seems to give me readings on ac or dc its got me lost which is it?

all transformers are ac. be very careful of microwave oven transformers, will kill you very quickly if you get across the high voltage side. they are usually 110 or 240 in and 2100 volts out, so even if you only put in say 25 volts you have 500 volts on the output. not a good idea to play with high voltage transformers even on low voltage systems till you know more about the risks.

play safe  
 bob

## [Power Transmission](#)

By [AMA](#), Section [Homebrewed Electricity](#)

Posted on Wed Nov 12th, 2003 at 07:26:45 AM MST

[Wiring](#)

I need help with info on how to transmit power efficiently from a hombrew wind turbine to batteries

Hi

I have been using Hugh Piggot's plans to build a 500W wind turbine, and have nearly a completed turbine, i.e. blades carved, batteries purchased, casting jigs made and resin casting probably this weekend. However I intend to put the 500W wind turbine about 200 Yards from the house (battery location) and therefore I need help on how others transmitted power similar distances. My main problem is that in the plans it says to use diodes to change from AC-DC but this would only make the losses worse so I was thinking of transmitting the 5 phase AC to the battery and then perform the rectification, however 5 core insulated wire for this kind of power is expensive!! is their any way that is not to expensive that I can do this? What is everyone else doing regarding transmission between turbine and house???

Regards

Aodhan MacAleer  
Ireland

[Power Transmission](#) | 4 comments (4 topical, 0 editorial)

Re: Power Transmission ([none / 0](#)) ([#1](#))  
by [charged](#) on Wed Nov 12th, 2003 at 07:54:53 AM MST  
([User Info](#))

You need four things to efficiently transfer your DC down the long wire.

1. Large capacitance for both ends of the wire.
2. A heavy inductor (microwave oven transformer primary)
3. A high current transistor with a pulsing circuit (556 timer IC with voltage regulation added)
4. A high voltage/medium current rectifier

The first capacitor goes across the DC output at the turbine. Figure out what your maximum voltage is and use and over-rated capacitor. This will be your primary charge reservoir.

The negative lead is then fed directly to the house.

The positive goes to the transistor collector. The transistor emitter goes to one side of the large inductor. The other lead from the inductor goes directly to the house as the positive lead.

The positive and negative leads in the house connect to the second large capacitor. This is your secondary charge reservoir.

The heavy rectifier is connected in reverse bias mode, between the turbine negative lead and the transistor

emitter.

The transistor base is driven with the 556 IC set up as a PWM (Pulse Width Modulator).

First, set the pulse frequency very low. Then adjust the "ON" time for the transistor (pulse width) so that the current is turned on JUST LONG ENOUGH to build an 80% field in the inductor. This is called the "field moment" of the inductor. The waveform looks like a sawtooth. If you see ANY steady current flowing after the sawtooth then you need to shorten the pulse width.

Next, turn the pulse frequency up until you are at 50% duty-cycle.

Each time the transistor shuts off, the inductor field collapses and the CEMF is sent down the wire to the house as a "spike" that also gets collected in the receiving capacitor.

Set up a second pulse circuit to dump that capacitor into your battery bank with a second transistor and pulse circuit.

You can efficiently transfer DC power from point to point over VAST distances with few losses using this method.

There are some slightly more complicated methods to utilize a pure CEMF from a 1:1 flyback inverter that allows VERY fine wire for power transfer. But, that's a bit more complicated. Dig through Tesla's old patents from AFTER 1891 and you'll see some interesting stuff that works quite well in our "solid-state" age of tech.

charged,

Do you have any measurement data from a real-life example of a setup like this that gives an indication of voltages, power transmitted and efficiency?

Thanks,  
Dave in PA

[ [Parent](#) ]

Re: Power Transmission ([none / 0](#)) ([#4](#))  
by charged on Thu Nov 13th, 2003 at  
11:11:38 AM MST  
([User Info](#))

Hi Dave!

Nope. But, it's the same thing as a "buck boost" capacitive charge transfer IC circuit. You know, power isolation chips?

Only, this setup is a larger version. CEMF doesn't care how long the wire is. It doesn't develop any "real" current component until it impacts on a capacitance. Just make sure your capacitors are rated for 200v or so and you won't pop the internals when the spikes come down the line.

Do a slow charge transfer test with two caps and a long wire and you'll see what's happening.

For even more fun, don't use a long ground lead. Just drive a long copper rod into the ground at both ends to replace the ground lead, just like the old telegraph systems.

Sounds bizarre. But, with some tweaking, the stuff works.

Enjoy!

## [Question for Zubbly](#)

By [Garry](#), Section [Homebrewed Electricity](#)

Posted on Mon Nov 10th, 2003 at 07:40:41 PM MST

[Wiring](#)

Could you give me a short explanation of connection methods inside a 15 hp motor.

When I was in trade school thirty some years ago they had us scraping and soldering coil and lead connections inside motors. I am reconnecting a 480 volt only motor to 240 volt by placing groups of coils in parallel. The coil connections appear to be melted in a blob. Are the wires stripped first? Is a flux used? Is a copper brazing rod like is used in refrigeration containing silver applied, or just heat used to melt the wire ends into a blob.

Thanks  
Garry

[Question for Zubbly](#) | 2 comments (2 topical, 0 editorial)

Re: Question for Zubbly ([none / 0](#)) (#1)  
by [zubbly](#) on Mon Nov 10th, 2003 at 08:12:36 PM MST  
([User Info](#))

hi Garry.

the most common method in motor rewind shops today to connect the magnet wires is as follows.

twist the magnet wires tightly together 5 or six times, and cut off the free ends.

for the lead wire connections, wrapp the magnet wire around the stripped end of lead wire and cut off free end.

depending on the size of your connections, quickly burn the wrapped part of the magnet wire to a dull cherry colour. do this to all the connections including the lead wire connections.

I suggest that you use silfoss 5% silver for the best connections. flux is not needed. they also use this in refrigeration repair of the units cooling coils. quickley re-heat connection to a brighter cherry colour and touch sifoss to wire while applying heat. you will quickly see the sifoss take to the wire. now apply more heat to the tip of connection and actually melt the tip to completely amalgamate copper wire-lead wire, and the silfoss. take care when doing these procedures as not to use too much heat and totally melt off the whole end. an oxy-acetalene gas with a small brazing tip works well.

wrapp your connections with a mylar tape if possible and slide over a piece of insulating tube ( called sleeving ) to cover the connection up to and a little over the unburned portion of connections.

a word of caution. since you are re-connecting and the length of magnet wire may be quite short as compared to when motor was originally wound, I would suggest that you just scrape the wires clean, twist together as i mentioned, use solder paste, and use 40/60 or 50/50 solder with a

MST  
([User Info](#))

Thanks for all the info. This motor was wound three-in-hand so there would be a lot of scraping. I use silfos on copper pipe so I will try that. The jumpers in this motor go almost half way around the stator.

### [How to get from here to there](#)

By [robotmaker](#), Section [Homebrewed Electricity](#)

Posted on Tue Nov 4th, 2003 at 01:37:26 PM MST

[Wiring](#)

I just stumbled across this board, and I must say I am so happy I did.

I have been an advocate of alternate energy for, well, lets just say I was around to see the first issue of Mother Earth News, was a subscriber for quite some time, and have built several of their projects. I currently have a waste oil heater in my 1200 sq ft. shop, and it heats it quite nicely.

I have moved on to wind power, and have a burning question that I hope someone like Zubbly or someone can answer. I found several posts for extremely good links on building windmills. And I thank you. I have available to me several sizes of brushless AC servo motors, which at first glance, work EXTREMELY well for generating power. I take the three phase out of the delta wound stator, and put it thru a 3 phase bridge feeding a nice size capacitor bank, and just by turning the motor by hand, produces what looks like a healthy amount of energy. I already cut my first PVC prop this last weekend too, and will attempt to scale it up to a 4" diameter version this weekend.

Question: How to get the wire from the motor, down the mast, to the electronics. I have seen a couple references to running it inside the mast? What about twisting?

God I love this stuff!!

rj

A lot of people don't bother with slip rings and periodically untwist the wire or have a plug at the bottom that they periodically disconnect and unwind.

I have two rubber coated wires running down the center of the mast and when they twist on themselves they act like a spring eventually the resistance created between the wires will cause the next movement to spin the other way. I manually wound the genny before putting it up and after just a little over 2 turns and releasing it it spun completely around.

Re: How to get from here to there ([none / 0](#)) ([#3](#))  
by zubbly on Tue Nov 4th, 2003 at 06:45:47 PM MST  
([User Info](#))

hello Robotmaker. thankyou for the mention of use of some of my ideas as well as from others. being still relatively new to the genny field, i often refer to the advise of others who have already done and experimented in paticular fields with great success. sometimes the simplest ideas and solutions work out to be the best in the long run. the subject of slip rings does ring a bell to me as i have repaired many of these units for years. for some reason i seem to keep adding more projects to the ones i have not yet completed. i do have some ideas on simple slip ring assembles that can be made from discarded circular pump parts. need alittle time though. i will post when i complete the design and model. for now, accept the good advise from the people that have been there and done it.

keep having fun, its what it's all about--zubbly

([User Info](#))

A method I saw here somewhere which I used on mine was to bolt a short cable with some slack between the top(turning part) and stationary pole. The cable keeps it from winding one way too much. They say it will unwind itself eventually if it winds all the way up.  
Kevin

Thanx for all the feedback, I really appreciate it. I still have to work out how the cable will get INTO the mast at this point, but being a model engineering student, wanted to explore all the obvious pitfalls first. Thanx again.

([User Info](#))

I have run the cable inside the mast with some slack for the two wires to wind up and down (#6 THWN/THNN). No problems after a month and others say that there is never a problem with this arrangement (although they recommend the more flexible welding wire).

### [How far can you carry your electricity?](#)

By [thegingerone](#), Section [Homebrewed Electricity](#)  
Posted on Thu Oct 30th, 2003 at 05:06:50 PM MST [Wiring](#)

**What is the rate of loss of energy over distance travelled?**

Hi,  
I am totally new to this .  
I have been reading all the websites I get my hands on over the past couple of days on the topic of wind power. The use of homebrewed electricity to keep the lights on in the outhouses on the farm seems very appealing. In evaluating whether this source of alternative energy would be suitable for me, one question has come up which I cannot answer: How far can u carry the energy, either as a DC, or an AC current from the point of generation to the point of use? Or what is the rate of loss of energy over distance travelled?

[How far can you carry your electricity?](#) | 5 comments (5 topical, 0 editorial)

Re: How far can you carry your electricity? ([none](#) / 0) (#1)  
by [drdongle](#) on Thu Oct 30th, 2003 at 06:05:28 PM MST ([User Info](#))

General rule of thumb the larger the wire size(gage) the farther you can send the juice ( the lower the loss). I'm sure some one out there has a resistance table close to hand.

Dr.D

([User Info](#))

You can carry it as far as you want, with as small a diameter wire as you want, with no losses. That is, IF you don't FORCE the power through the system.

Here's how you can prove it to yourself.

Get two large capacitors of equal capacitance. The bigger, the better you'll see what's going on. Two of those big car-stereo caps will work very nicely.

Charge one of them to 12v and discharge the other to 0v.

Charge the empty one with the charged one through some short jumper cables. You'll get 6v in each. Nothing special.

Now, get yourself a long roll of wire like telephone cable or just about anything. The smaller the better.

Start with 12v and 0v again in the two caps. This time, charge one cap with the other THROUGH the long wire.

It takes a little longer. But, in the end, you still have 6v and 6v in the two caps. The resistance doesn't EAT CHARGE. It only slows down the transfer time.

In a nutshell, engineer your power transfer system to carry your maximum generated power in a PASSIVE manner and you won't have ANY significant losses, regardless of distance.

Tesla was using these "interruptor" circuits in the 1890's. Just go look at his patents. The concepts work much better with our modern solid-state devices than they ever could with his mechanical interruptors.

2 different voltage tape drive gennies running on one line to batteries

I have one 40v tape drive mill and just ordered a 99v Ametek motor. Can I run them both into one transmission line to the batteries. I will put a blocking diode on each one before they connect together so one doesn't feed the other then connect them together for the 75' run to the batteries. Will the voltage just average out?

Thanks  
Scott

by TomW on Tue Oct 28th, 2003 at 07:37:18 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Scott;

Since these produce DC and you are using blocking diodes I see no reason not to share the line if its capable of handling the combined current from the mills without too much voltage drop. The current will be the sum of both current sources [gennies] so size your wire accordingly the voltage will simply be the voltage of the highest source. Its what I would do. If they were producing AC I think it will be a bit different and tough to isolate them.

Cheers.

TomW

Mmmmm... I don't think your tape drives are actually producing DC (I could be wrong here), so you'd probably want bridge rectifiers before transmission (as it were).

Cya,  
Chris

Thanks for the replies. For wire I have 2 runs of 12-3 romex, it's what I had around at the time. There's 8 #12 conductors total, 4 per + and -. It should be fine for now.

Scott

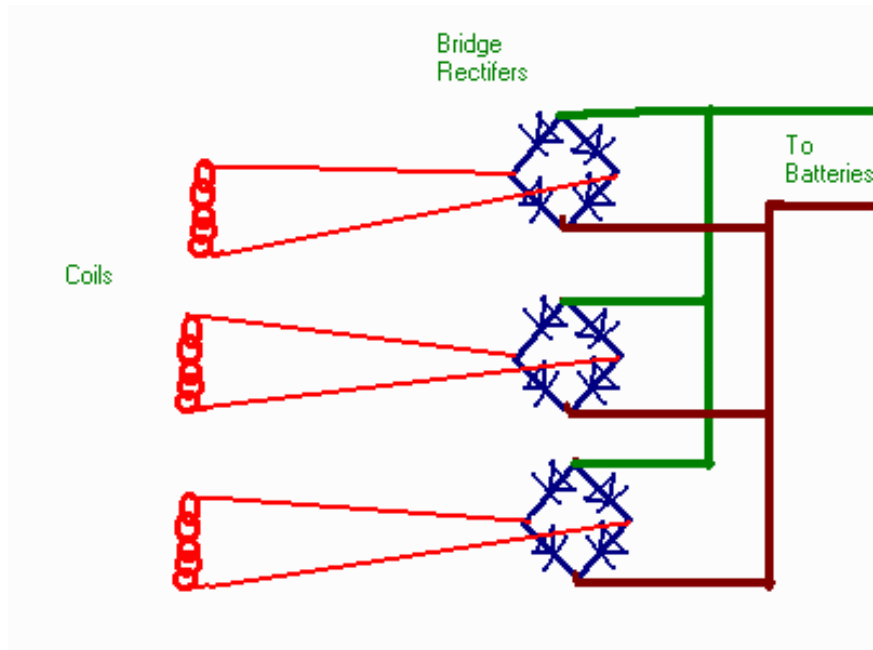

Re: 2 Gennies on 1 line ([none / 0](#)) (#5)  
by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Wed Oct 29th, 2003 at 01:02:49 AM MST  
([User Info](#)) <http://www.internetfred.com>

Filter the outputs at the pole!! You will have higher output and less ripple and more consistant power. Causes less problems. That voltage seems great! Match the temprature as well. Caps run at different tempratures, find one that is sutible for the lowest temprature in winter conditions. The higher the farad randge on your cap the better. Also this will lessen the load on the generator durring high load conditions. Acts like a small battery that will feed a bigger one, but charges smaller one first before feeding big one, hence produces lesser load and higher consistant voltages.

Good Luck  
ifred

You can hook a lotta sources up to the same wire as long as there isn't too much current for the wire. I'd hook 'em together like this . . .

[SALE: 50 lbs #10 GUAGE 0.1051" DIA. ESSEX ALLEX 240 DEGREES C MAGNET WIRE : \\$6/lb](#)

[Wiring](#)

By [Christina](#), Section [Classifieds](#)  
Posted on Tue Oct 28th, 2003 at 12:15:39 AM MST  
For Sale: 50 lbs of #10 Guage 0.1051

Hi Everyone,

I have for sale 50 lbs of #10 Guage (0.1051" Inches Diameter) Essex Allex High Temperature 240 Degrees C Magnet Wire. Price: \$6 per pound (lb).

This type of magnet wire is used in applications where temperature specific requirements are paramount and is ultra high quality stuff with proprietary insulation methodology being used from Essex. It is their highest temperature rated magnet wire that they sell. Here is a URL to Essex's Website for more information on this magnet wire: [<http://www.essexwire.com/oem/products/magnet/allex.htm>].

Will accept Paypal, or any other payment method including Escrow, USPS Money Order, Cash, etc. You can come and pick this up also for free if you are in the area (Zip 33147, Miami, FL).

Please note shipping would be whatever method you choose including your own FEDEX or UPS Account Number (insurance option must be used with these methods) and will be based on the exact amount of what is quoted to me from the Carriers. Please note I only use World Class Trackable Carriers/Shippers so that when product ships you will be emailed a Tracking #.

Will also be willing to sell this batch on a per pound basis.

I am a verified user of Paypal with paypal email being [[cyrix333\\_1999@yahoo.com](mailto:cyrix333_1999@yahoo.com)]. Also note that for Paypal payments sent online I will not ship to unconfirmed addresses for reasons relating to fraud. I am aware that someone might just want to have their stuff drop shipped to another location but as Paypal have it and to protect you and me it cannot be done.

Thanx a lot for your patience reading this.

Respectfully Yours,

Christina

([User Info](#)) <http://www.internetfred.com>

Hi Ya!

That was a trick. What I did was make a temporary inside diameter ring out of some sheet metal, which stands about an inch and a half high; if you look close you'll see it. I used finishing nails to hold it in place and soldered it tight. I made guidelines everywhere (inside radius, coil radius and coil center). When the coils where installed I lined it up to the inside ring first, then to the guides. Each coil on the underside was glued with some white silicon (all I had at the time, but ok) and positioned each coil all the way around, then corrected it as it was drying (mostly by eye and by the guidelines. Since the inside ring held the exact position around the inside circumference, did not have to worry about that alignment just the center alignment of each coil and it's position to the guidelines. I kept re-adjusting during the dry to get it as accurate as possible. A good eye helps, if I do it again, I would use a ruler attached to the center going outwards and use it as well to eye up the coils even better.

Once the coils where dry, I went to a friend of mine (car shop) who has a hand operated downward vise. I put the completed form in between two pieces of wood and slowly and carefully squeezed them flat more or less with equal pressure between the boards, this produced a nice flat coil form. It flattens the tops down a bit. I then checked all the coils again with an ohmmeter and no coils where damaged due to the squeeze. That's about it. If you have further questions, please feel free to ask. Good Luck!

Fred

Step 1 - Make lots of guide lines  
90, 45, 22.5 deg

Step 2- Make some round center guide lines.  
make a sheet metal ring 1 inch in diameter,  
marked in red. the other two are center guide and  
outside coil diameter guide

line up coils to sheet metal  
ring and to guide lines

Re: hey internet fred, quick question... ([none / 0](#)) (#3)  
by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Thu Oct 23rd, 2003 at 10:22:12 PM MST  
([User Info](#)) <http://www.internetfred.com>

P.S. After the coils are all done and dried, remove the sheet metal ring, the nails and since you should have it in a form, make a centerpiece of wood to replace the metal ring and the center hole. Coat the entire form with varnish and when dry, wax or grease. Next cut out the fiber for your form for fiberglass and fiberglass it. Good Luck!

How is it done?

I think I know how, but I'd like to know from someone who knows for sure. What I was wanting to do is to take my 3 outputs(ABC), use A and C as the hots and B as the neutral for both A and C in hooking up two GFI outlets. I'd have to split B into two wires to hook to both outlets to have an equal load between one of the hots and B at the point of the GFI outlet, which I read is what the GFI looks for. If the current going through the hot and neutral wire isn't equal it indicates a "leak" to the GFI which trips out. Please let me know if I got this all right, thanks.

Kevin

Re: Hooking GFCI outlets to STAR alternator ([none / 0](#)) ([#1](#))  
by [jubalearly](#) on Mon Oct 20th, 2003 at 08:54:59 AM MST  
([User Info](#))

You can't use two phases (A & B) on a 120v GFCI outlet. One of them must be a neutral. You need to bring out the center of your star (WYE) and use it with any of the 3 phases. Read the instructions that come with the GFI outlet. They cover the requirements in detail. And note that you will probably only be able to use this in a restricted speed range, unless you have some way to set the frequency & voltage seperately. Give us some more details on your alternator and you can get some more informative answers.

Re: Hooking GFCI outlets to STAR alternator ([none / 0](#)) ([#2](#))  
by [kww](#) on Mon Oct 20th, 2003 at 10:39:46 AM MST  
([User Info](#))

Should the center of my star(WYE) be grounded with what I'm doing? Should it ever be grounded? My alternator is a 12 pole 9 coil 3-phase, makes 36 vac at my drill's max. rpm while turning it between any combo of ABC, 20 vac is found between AB or C when compared with the WYE connection. I don't have the equipment to measure frequency, amps, etc. so I can't really give a lot of detail. Anyway, thanks for the info.

Re: Hooking up GFI outlets ([none / 0](#)) (#3)  
by drdongle on Mon Oct 20th, 2003 at 03:31:07 PM MST  
([User Info](#))

If you have a grounded system (recommended) then the common point of the star should be at ground. and if you intend to use phases independently (as required with a GFI or any standard outlet) it will also be the neutral return connection.

Re: Hooking up GFI outlets ([none / 0](#)) (#4)  
by kww on Mon Oct 20th, 2003 at 08:27:14 PM MST  
([User Info](#))

Dr.D

Thanks for the info., but you've caused me more questions :-)  
that I hope you will answer. Would it be okay to ground the WYE connection at the windmill and run the 3-phases of ac through an underground romex cable to a box which has 3 romex cables coming out, each carrying one phase and a ground/neutral made at the house? I guess 2 wire romex would be fine coming out of the box since they'd go to GFI outlets?

Re: Hooking up GFI outlets ([none / 0](#)) (#5)  
by drdongle on Tue Oct 21st, 2003 at 06:28:14 PM MST  
([User Info](#))

You can use any wire you want so long as 1) you have at least 4 conductors, phase A, phase B, phase C, and the Ground/ Neutral (though ideally the 4th ground/neutral should be two wires in most situations you probably won't have any problem). 2) it is large enough (gage wise) to deliver the juice to the load. 3)and lastly that the insulation is rated for the application (300 and 600 volts is pretty common, so this probably won't be an issue.

If I understand your other question you want to run the drop from the genny to a junction box then split up the phases, yes you can but you need to use a fuse or circuit breaker on each phase. I would recommend a small stand alone 3 phase circuit breaker box which will hold 3 fuses or circuit breakers, and can also act as a junction box. If you have a lot of loads they you will really need some sort of "load center" with several circuit breakers for each "spur" circuit.

Re: Hooking up GFI outlets ([none / 0](#)) (#6)  
by kww on Tue Oct 21st, 2003 at 07:48:41 PM MST  
([User Info](#))

So I need a four wire underground cable I guess. Btw, I read today in "Windpower Workshop" that I need to ground only at the source(windmill). Also, I read(same book, which is coming in very handy as I understand more of this stuff) that an overcurrent device isn't suitable for a windmill or inverter, instead use an RCD(residual current device), which I'm guessing is the same as a GFCI. Thanks for the info.

Re: Hooking up GFI outlets ([none / 0](#)) (#7)  
by drdongle on Wed Oct 22nd, 2003 at 05:03:40 PM MST  
([User Info](#))

I would question the statement that an "over current device" is not needed. Smaller wind generators with limited out put don't pose much of a problem in this regard but it's till a good idea. As far as inverters go I would definatly have some sort of circuit breaker or fuse, and I'll bet the manufacturer has two built into the unit already, one on the input and one on the output. Personally I think it unwise to do with out, if nothing else it may protect you equipment from being seriously damaged or destroyed.

Re: Hooking up GFI outlets ([none / 0](#)) (#8)  
by kww on Wed Oct 22nd, 2003 at 08:33:41 PM MST  
([User Info](#))

Think about it this way, the windmill can't make more current than I'll be trying to use and the 400watt inverter sure can't give me more than I want. So to put a breaker rated above what the windmill or inverter can put out seems pointless and putting one on below the current I want(within the windmill or inverter's capacity) is not using the full capacity of the machine, seems pointless again. Maybe there's a good reason, I'm very open-minded, but I haven't found it yet and you haven't given me one, except that you think it's a good idea. :-). Btw, I'm not trying to be disrespectful or anything else, just telling you how I'm seeing it. Also, I think you're right about the inverter possibly having an internal fuse, but that's something needing little power hooking up to something that could fry it 100 times over, my windmill would probably blow away before it cooked the 4 heat lamps it'll be powering. It will take a little study to see how much potential load to have waiting in reserve. Anyway, thanks for your info.

I tend to agree Kevin, but Im no electrician!  
but... if you put a fuse, or a breaker... between  
your heater and your wind turbine - then, if it  
ever blows it'll surely be on a windy day. If it  
blows on a windy day - yoru windmill will  
become disconnected from the load and....  
overspeed, and possibly blow up.

Hard to say... but Im personally afraid to put a  
fuse or breaker between the windmill and the  
load. I've got no experience with professoinal  
installations though.

I think what we have is a difference in  
definitions. When I think of an "over current  
device", I'm referring to circuit breaker or fuse  
rated near the maximum safe current level of  
the device ( or circuit) being protected. An  
example would be a 20 amp fuse on the DC  
side of an inverter, when the inverters  
maximum DC current draw is 20 amps. If the  
maximum is exceeded the fuse blows  
protecting the inverter from damage that will  
happen when that inverter tries to draw more  
than 20 amps.

I agree it would be pointless to use a fuse  
rated at 40 amps as it would offer no  
protection, and a 10 amp fuse would severely  
limit it usefulness.

I simply suggest that if you generator puts out  
5 amps per leg then use an appropriately sized  
fuse or circuit breaker. If you using less than  
full capacity then a smaller fuse is OK, just  
don't exceed the maximum the device can  
deliver or draw.

Dr.D

I think what the problem is that you don't fully realize what I'm up to, which is running heating loads only with a windmill and the heating loads will be able to handle all and then some of the windmill's output. This setup makes overcurrent devices useless because the system is designed to handle more power than it could ever see, unless lightning hits it, but from what I've seen fuses and breakers are useless for lightning protection as well and seemingly have no use in my current application.

([User Info](#))

I understand what you want to do and that's great, however.. let's say that you expect the genny to be able to deliver 10 amps to each leg with no overloading, no overheating ( fat and happy), your heaters are rated at 10 AMPS. Perfect match no problem, now some well meaning soul plugs in a second heater on one leg, you have a stiff wind so it powers right up, no problem? yes problem, the winding on that leg starts to overheat, it starts to deform, and soon it burns out, because it was delivering more than it was designed for. If you think that will never happen, or you can prevent it, great. I just know that if it were me and I went to a lot of trouble to build a genny and erect it I wouldn't want to chance damaging or destroying it and having to start over. Even if you can guarantee that you will never overload the circuits with appliances what happens if some one accidentally drives a nail through a some wires or some other unforeseen accident happens? Circuit breakers are cheap, fuses are even cheaper, you're time and energy aren't.

([User Info](#))

Around here I really can guarantee that no one will mess with things and a short would stop the windmill in the same way my brake switch does. Not to mention I've got it designed so that it can't be overloaded by it's own ability to make power, lightning's another story, but breakers and fuses don't protect other things around here from lightning so... You put up a good effort, but I'm still not convinced. :- ) Would you believe I've been called stubborn? :- )

Sorry to butt in, but I was doing a search on GFI and fusing and came across your conversation. I am kind of new to this, commenting and the GFI business, but I think I can help. From what I understand the turbine has three hot lines possible and a single return in the core. The way a GFI works is sensing that current in equals current out, if not the circuitry opens. I am planning on using this idea in a new instrument to act as a fault protector. I am tired of having to fuse all the different lines that are in my circuit. I have a master relay that turns on the power to the downstream circuit where I want my protection. As long as

all the power going to and from the circuit passes through a single GFI then all is fine. If there is a short or leak the GFI will trip, irregardless of the current. So, in your situation if you take one of your hot legs and connect it to whatever circuit through the GFI and ensure the return for this circuit only goes through the same GFI it should protect from shorts and failures no matter what the current, unless of course the high current melts the wire and causes the short or leak in the first place. All the returns can be tied to the center on the generator side of the GFI, but just make sure each branch has a separate return. Consumer GFIs must trip at 6 milliamp, UL Standard. In your case, and mine, we will need to alter that circuit to allow for small leaks, otherwise I think it will be trip every time there is a glitch. We are using the GFI for fault safety, not current limiting or lighting protection. The lowest rating fuse in my system is 375 milliamp, so I think I will set mine to trip at that level. Not sure how to do it yet, but if you are interested I could pass it on once I do. Whatever your generator can put out make sure the circuit can handle it that you have it hooked up. The too many heater example is a good one.

Thanks for the info. Btw, I found GFI outlets at Home Depot, 3 for \$15, so I've decided to just use 3 of those, one for each output. It's the GFI breakers that cost around \$39 each, which is too much in my opinion, considering I'd need 3.

([User Info](#))

Hi Kevin -  
good deal  
3/4/\$15 - I  
have taken  
them apart  
and I am  
not sure  
that they  
will work  
directly on  
the turbine  
output as  
designed.  
Easy to  
check. Have  
the system  
running and  
take a light  
bulb, at  
least

enough wattage to get 6 millamps of current and hook one side up to the hot circuit downstream of the GFI and the other side up to the return on the upstream side of the GFI. This way there will be an imbalance on the input and output lines running through the GFI. IT should trip. If not then it won't work. The inside circuitry has a rectifier and a couple of diodes and a GFI chip, probably made by Fairchild. The rectifier is for the solenoid to cut off the power and the diodes are to change the typical AC into DC for the chip. The chip contains internal components that act like a comparitor to sense the imbalance and send the power signal to the cut off solenoid. You will also find

some resistors and caps that are used to set the sensitivity, trip current, and trip speed, resistance to spikes.  
Todd

Coil winding

Hello all, I have a set of plans from Hugh Piggot for the 2.4 mtr wind turbine and the coil spec calls for 80 turns of #15 wire or 90 turns of 1.4mm wire to produce 12volt coils, unfortunately I have purchased 1.7mm wire (as shown in his free plans) the question is ... can I use the 1.7mm or should I buy the correct size wire?

Iggy

then try 85 turns!!!!

Re: coil winding data ([none / 0](#)) ([#2](#))  
by [Inspector Gadget](#) on Tue Oct 7th, 2003 at 01:34:38 PM MST  
([User Info](#))

Struggling to find data here but I thought that #15 AWG was 1.450mm ! My 1.7mm is closer to #14AWG so I was expecting something like 70-75 turns!!! Once they are wound and installed there is no turning back, but thanks anyway Seth.

If you have enough of this thicker wire to do it...

I wouldnt compromise # of windings too much as it will mean youll need higher rpm. Hughs wind turbine is slow anyhow - so perhaps a small compromise would be OK. Id consider slightly shrinking the hole in the center of the coil so that perhaps its only 3/4" or 7/8" wide instead of 1", this might make give you a little more room for windings. In the end - it is also a compromise which would cost you rpm some, but I think less so than simply eliminating the windings.

Iggy, Number of turns is relevent to voltage generated, all other points being equal. Gauge of wire is relevent to total resistance of coil, this of course is relevent to  $I^2 R$  losses at a given current which means heat in stator.

I suggest you do not stray too far from Hughs given turns, welcome to a field where every parameter has an effect on the other ie gauge of wire v coil thickness v air gap v flux strength etc. Try one test coil first.

The attached URL is to copper wire conversions which may be usefull.

<http://www.thelenchannel.com/1wire.html>

regards Allan

([User Info](#))

You just gave me an interesting idea, in my opinion at least. :-)  
Flatten each coil individually before putting it in a stator. I guess you'd need a mold shaped just like the coil you want to end up with and some sort of press. If you over do it and cause a short or break no huge deal, it's just one individual coil.

hey kww, you would not have to flatten coil. when you make the coil former, make the width between coil plates the same width as the flat wire. #14 flat wire measures .030 thick by .119 wide. with the two coils on top of each other the total thickness would be less than 1/4 inch.thick. the turns would be completely symetrical with no cross overs. turn 1 touches 2, turn 2 touches turn 3 and so on.

<http://timmythy.home.mindspring.com/timmy.htm>

I have some spare speakers laying around. Well a speaker is a coil in a magnetic field. I have'nt yet done this, but I wanna hook a bridge rectifer to a 15" or larger speaker and see what the output is. Yes I understand it will be quite low power.

This size speaker can be excited by more energetic means than sound. Anything giving a 1/2 inch motion on these speakers would produce considerable voltage, I believe in the 36v range (mechanical, not audio excitation), and they ere very durable operating in the 10 - 500hz range for years.

Re: better drawing of flat coil ([none / 0](#)) (#7)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Mon Sep 22nd, 2003 at 08:22:26 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I made some similar to this using copper sheet stock. I made the strips.375 tall and the width was .014. I made the start by folding it into a 90 degree angle and the end of course was fine. I insulated the copper with paper. You can get alot of turns of thin sheet stock, more than with the equivilant size of round stock. The problems I found using this method is the coils tend to heat up quicker.

Enamaled ribbon wire is much better for the same process. Using sheet stock, ribbon wire or square wire is about the best way to utilize a given space.. but it will increase eddy currents in the copper. Square wire is a bit more difficult to work with but the amps you get from the system is quite rewarding. Round wire in a hole is about 75%efficient, Round wire in a square hole is about 80% and about 85% in a rectangular hole, but sheet, ribbon, or square stock is close to a 100% efficient space fill factor. Using Hughs dual rotor coil arrangement for 3 phase would work the best when winding coils with this type of an arrangement, overlapping arrangements become very difficult but not impossible.

Have Fun winding!  
Ed

[how to make flat wire coils](#)

[Wiring](#)

still trying to post a picture. hope it works.

a few months ago i sent an e-mail to Hugh Piggott suggesting he try using flat wire to make a tighter and very flat coil. Hugh replied with ( how do you get the inside out of the coil and still keep it flat), well i figured it out.

lets say you use #14 flat-.030" thick and .119" wide. make half your turns as in #1 and the other half as in #2. now flip #2 onto #1, as if you were turning the page in a book. now in diagram#3 here are the two coil halves ontop of each other. solder the two ends together in the centre and the two outsides are your start and finish. coil will be less than 1/4 inch thick. COMMENTS PLEASE!

P.S. if the picture does not come out, sorry forwasting your time.

sorry for the lousy picture. i guess it worked. i should also have mentioned that the coil former plates should be spaced so that the wire just fits in between them. if you want 60 turns total in your coil, put 30 turns in each half.

zubbly

Re: flat wire coils ([none / 0](#)) (#3)  
by RobC on Sun Sep 21st, 2003 at 10:19:37 PM MST  
([User Info](#))

On my coils I made a form twice as wide as the wire. I found the center of the wire needed to make the coils and starting in the middle wound one wire one direction and the other wire in the opposite direction. This made a very flat 2 layer coil with both ends on the out side. For what its worth. RobC

Re: flat wire coils ([none / 0](#)) (#4)

([User Info](#))

You probably noticed my other comment down below about pictures...

This one works, because its a .bmp, your photos didnt though because they are microsoft word perfect files (.wps)... no chance there!

But even .bmps are a bit tedious compared with the .jpg format. .jpg will upload (and download) faster, as the will be smaller files. Try to make all your pictures .jpg and I think theyll start working better for you!

Regarding Flat wire... interesting to think about! I got some big stuff Im dying to play with. I got about 20 pounds of 1/2" wide X .1" thick flat enameled wire... It'll be fun when the time comes!

Re: flat wire coils ([none / 0](#)) ([#5](#))

MST  
([User Info](#))

Big motors (2300-4160v and higher) are made with form wound coils. It's rectangular wire, custom made to fit the slot. One would calculate the number of turns required and select a wire size to fit (after allowing for insulation). I've got a piece of an old winding with about .125x .250 wire, 8 turns (2 groups of 4) with around .2 inches of insulation around it. The whole 3" chunk is about 3/4 inch x 2.5 inches and makes a good paperweight.

## Copper Tubing instead of Hi\$ Wire

By [LowTechWreck](#), Section [Homebrewed Electricity](#)

Posted on Wed Sep 17th, 2003 at 02:05:51 PM MST

[Wiring](#)

Stranded Vs/ 3/8

It looks like I'm going to have several Battery Banks some at every tower.  
What size copper tubing would be the equivelant(sp) '0' Wire.

[Copper Tubing instead of Hi\\$ Wire](#) | 6 comments (6 topical, 0 editorial)

Re: Copper Tubing instead of Hi\$ Wire ([none / 0](#)) (#1)

by J Steele ([Jvsinthai@yahoo.com](mailto:Jvsinthai@yahoo.com)) on Wed Sep 17th, 2003 at 03:28:19 PM MST ([User Info](#))

1/0 cable has a cross section area of .083 in<sup>2</sup>. 1/2 od copper tube has a wall thickness of .048" so it has a cross section of .068 in<sup>2</sup>. 3/4 type L copper tube has an OD of .880" and a wall thickness of .044 giving it a cross section of .115 in<sup>2</sup>. I don't have any 5/8" tube in my shop. Wire is nearly pure copper while tube is some alloy so you may want to overkill a bit.

Have a good day.  
John

Re: Copper Tubing instead of Hi\$ Wire ([none / 0](#)) (#3)

by jubalearly on Wed Sep 17th, 2003 at 04:12:46 PM MST ([User Info](#))

After reading John's reply I went back & checked my references. I thought maybe I used circular mils instead of square inches, but no. I did find this in the '93 NEC, chapter 9, table 8. 1/0 is .373 in. diameter & .109 in. sq. area. (105600 circular mils, if anyone cares). I'm also assuming 75C rise copper (not aluminum 1/0) rated at 150 amps max. Are you sure 1/0 is big enough in your application?

My previously quoted wall thicknesses came from a McMaster Carr catalog which did not state the actual diameter. I'm a little surprised that it is that far from nominal. At any rate, there is no set standard for wall thickness (just meet pressure specs.) AFAIK. Using these as lugs, there is usually enough contact area to avoid overheating the lug/wiring connection.

Russ H.

'o' wire ([none / 0](#)) (#4)  
by LowTechWreck on Thu Sep 18th, 2003 at  
02:27:50 AM MST  
([User Info](#))

Yes you are right.  
'O' wire probably not big enough .  
I remember in one of Chucks posts  
He mentioned '000' wire.  
I might even need bigger.  
What I want to do is connect several battery  
banks together that are 30 to 50 feet apart.  
I haven't priced it but I might have to  
take out a second mortgage for that size wire.

([User Info](#))

I actually found a chart on this once. It isn't a simple question. I think it was in a Homepower magazine article where Richard Perez did this. It was about using tubing for homemade lugs for copper wire. Which is what I often do, myself. You might search their site or email him.

My NEC book doesn't list 'O' size. Another reference gives .372" diameter and I calculate an area of .108 sq. in. ( $\pi r^2$ ). You might use 1" tubing, if you don't mind it getting HOT. The wire is sized for a temperature rise of 75 deg. C, usually - higher than boiling after adding the ambient temp. ( $75 + 25 = 100C$ ).

However, I wouldn't use this without checking or revising the numbers myself. There are various alloys of copper used in tubing and they do not all have the same conductivity as copper wire. That means you have to allow for more heating in the tubing. I think if I got over 3/4" tubing I'd just use bar stock tho.

Also, there are several different tubing thicknesses depending on type of use. 3/4" type L tubing (for water) comes in 2 common thicknesses: .045 & .032. That particular reference does say what the actual OD is...Using .75, & .032 I get  $3.14 \times .75 \times .032 = .075$  sq. in. OK, we're close.  $1" \times .035 \times 3.14 = .1099$  sq. in. Note that 2 pieces of 1/2" is not the same as one of 1".....My approach here would be to use 2 3/4" for each connection (or bar stock about 1" x .25"). HTH,  
Russ

Ive seen so much good heavy gauge copper wire thrown away. It bothers me everytime I see this. when I say thrown away I mean scraped for recylcing at 5 cents a pound or whatever. you should check with the local metal recycler in your area, this is where most of it will end up. Most electrical contractors pull this stuff out of a service and let the journeyman sell it at the recycler. Most will not take the time to strip the wire so the insulation is usually intack.

I happen to have three peices about 50 foot long, real nice and flexable stranded type. It was used after hurricane andrew in miami fl to hook up service from a diesel gen-set. this stuff is about 1.0 inch in diameter and the lot of it weighs about 200 lbs.

(guessing here) last week while helping my dad clean some stuff in the back yard we ran across it. He seid why dont you take that down to the recycler and get rid of that stuff. Anyway I managed to talk him out of it, and its still sitten there.

If you go searching you will find something simular. actually there is this place I found in the local phone book under used electrical supply. whenever I have to find transformers for hooking up big lathes I check there first. I buy the transformers for like \$500.00 or \$800.00 that cost \$5000.00 new at that place. Never had to check for wire but I bet its there. Good hunting.

-JW

### [Rewiring 120vac1.52KW transformer](#)

By [LowTechWreck](#), Section [Homebrewed Electricity](#)  
Posted on Sun Sep 14th, 2003 at 02:48:55 PM MST  
Secondary Removed

[Wiring](#)

Ok it's Gonna Blow up or work>>>one of the two.  
This is the one:  
[http://zephyrgennys.tripod.com/tony\\_van\\_roon\\_inverter.doc](http://zephyrgennys.tripod.com/tony_van_roon_inverter.doc)

I got lucky and found a monster Microwave Transformer 1.52KW.  
Here it is:  
<http://zephyrgennys.tripod.com/120v1.52w1>  
<http://zephyrgennys.tripod.com/120v1.52w2>  
<http://zephyrgennys.tripod.com/120v1.52w3>

I need some help on this.

Should the Secondary wire be the same diameter as the Primary  
For 1KW output?

I used 22 gage wire just to see if I can get anything flowing.  
It looks like the Primary might be 16 Gauge.

12 turns>twist loop>12 more turns:

[http://zephyrgennys.tripod.com/120vac\\_12vdc1](http://zephyrgennys.tripod.com/120vac_12vdc1)

See at the bottom> the two terminals are connected to the  
Primary  
Big 16 ga. or so.  
The two red wires above it Go nowhere!  
Continuity check says infinity.  
They must have been part of the Secondary  
But they are not conected to anything except each other.  
Should I cut them out?

In this picture is the new secondary winding>  
12 turns>twist loop>12 more turns:

[http://zephyrgennys.tripod.com/120vac\\_12vdc2](http://zephyrgennys.tripod.com/120vac_12vdc2)

There are no shorts.  
How do I check to see if I have this right?  
Plug in the primary and take a reading from the  
Center tap as ground and then check the voltage  
on the two ends of the new Secondary windings.

[http://zephyrgennys.tripod.com/120vac\\_12vdc3](http://zephyrgennys.tripod.com/120vac_12vdc3)

Those two red wires are starting to bug me.

wmbays@grandecom.net

On your secondary I would go with 16 ga if you have 22 it may not handle the amps. I would leave the two red wires the manf. could have them in there as a spacer. As for the reading you have it right.

Re: Rewiring 120vac1.52KW transformer ([none / 0](#)) (#2)  
by LowTechWreck on Sun Sep 14th, 2003 at 06:19:12 PM MST  
([User Info](#))

Well as you can see in:

<http://zephyrgennys.tripod.com/120v1.52w2>

They must have been the secondary connections with one of them going to a giant Capacitor and then connected to the other side must have been a center tap or something.

I guess I need to carefully remove the Paper and see if infact a secondary wire was connected to them. I think the center tap was a ground.

Red Wire ([none / 0](#)) (#3)  
by LowTechWreck on Sun Sep 14th, 2003 at 07:21:22 PM MST  
([User Info](#))

In fact it was not connected to anything. I guess this would be a good time to look up electromagnetic flux or what ever it is. Up until this point it has been an:

e·nig·ma (Ã nigÆmÃ), n., pl. -mas, -ma·ta (-mÃ tÃ).  
1) a puzzling or inexplicable occurrence or situation

This is a "ferroresonant" transformer there will be four windings, the primary (120vac,)the large 16 gage winging is for the magnatron filament and the 22 gage wire was for the HV ckt, (one side will be to ground) and the resonating winding for the capacitor.

Dr.D

DR. D ([none / 0](#)) (#5)  
by LowTechWreck on Sun Sep 14th, 2003 at 08:03:26 PM MST  
([User Info](#))

Thank You Sir  
Very Informative...Yes Indeed.  
I have removed the Red wire.  
No connections to the secondary on it,  
unless it was metaphysical.

If I wire it as the schematic demands,  
as I have wound it.(for test purposes)  
rewind with equal dia.wire (secondary)  
will I get the desired results..  
see schematic:

It's probably to late now but in future versions leave the  
capacitor and it's winding intact as it will assist in making  
the transformer "resonate" at 60 hz and may in fact result in  
an output that will be more of a sine wave.

([User Info](#))

Low tech, The size winding wire depends on a number of things.

1. The wattage you plan to achieve from this inverter, which comes back to what transistors you plan to use.
2. Your primary is I assume 120v, so lets say at 1kw thats  $1000/120=8.33A$ . A secondary wound with the same diameter wire would give a theoretical(without losses)  $8.33A*12V+100watts$ . From my charts 16 gauge has a capacity of 10 amps.
3. I used 14 AWG 1.68 MMsq on some of my tranies and run them at around 25 amps charging my 24v system with forced cooling. 14 SWG rating is 15A. Others I used 2 strands (bi-filia wound) of 18 SWG 1.02mm sq.
4. From the pics you first posted you have heaps of room for more wire so use 2 or even 4 strands. They don't have to be wound together, ie they can be wound on top of each other, just be super careful about start and finish markings, the purests would argue about this but it works. Microwaves have a cooling fan venting the transformer area.
5. The other circuit worth considering, (apologies if someone else has suggested this one)but if I go back to check all this will scoot off into cyber space.

<http://www.uoguelph.ca/~antoon/circ/555dcac.html>

If this message flips to the second page and I miss any more questions 'e' mail me at wpowokal@bigpond.com

regards Allan

hard to rotate PMA

Hi all.  
I have just completed assembling pma for my windmill and have wired it to 3 phase.  
When i rotate it by hand its quite hard, then soft, then hard etc when it goes through the fields.  
I then disconnect 1 wire that joins fields together, it rotates ok and sparks when i reconnect  
It hasnt been wired through rectifier or connected to dc as yet.  
Is this normal? or will it rotate ok when i connect through rectifier and connect to battery.

details of machine are follows.  
Dual 15" dia rotor (12 off 2"x1/2" dia neos) for each rotor  
Stator is, 9 off coils 14awg x 60 turns each 1/2" thick  
Gap in stator 1mm each side.

Thanks Paul.

Hi Paul - presumably this is a Delta connection?  
Presumably you checked each phase individually to see that output is good, and the same on each phase?  
id unhook each phase from other others and try again - I think you probably have it miswired.  
It gets stiff - then hard, then stiff - because one phase is under a load, thats how it would feel if you had a load on 1 phase. Once all 3 phases are under load it would be completely smooth. My guess is you have the Delta connection wrong... should be very easy to fix.

It seems to me that you might have the coils wired wrong (out of phase). When you wire the coils wrong (out of phase), the current generated in each coil is fed back into an adjacent coil and it actually cancels out the current from the first coil (not good, and this is why its hard to turn). If your wiring in three phase, your going to have three 'sets' of coils and three series legs. To make up the legs, you have to wire every third coil around the circumference of the stator together and you should go... start finish, start finish of each coil. If you were to wire start to start and finish to finish (this is how you would wire a single phase stator) it would not work correctly in a 3 phase stator. You need to be careful, though. This could fool you if your magnet spacing and coil spacing was not correct. The best way to be sure you get this right is to spin the alternator up to speed and just go around the stator connecting every third coil and make sure the voltage increases for every coil you connect. I hope this isnt too hard to understand. I probably didnt word it the best. Have fun!! RoyR

## [How do I wire a 220 motor to run on 110?](#)

By [dwhit](#), Section [Homebrewed Electricity](#)

[Wiring](#)

Posted on Wed Sep 10th, 2003 at 10:37:17 AM MST

How to wire a 220 motor to 110

I have some blower motors off of indoor air handlers that run on 220v AC. they have a starting capcitor on them.

Can anyone point me in the right direction as far as how to make them run on 110v AC?

thanks

Re: How do I wire a 220 motor to run on 110? ([none / 0](#)) ([#1](#))

by [Kilroy2k1](#) on Wed Sep 10th, 2003 at 11:26:34 AM MST ([User Info](#)) <http://home.cogeco.ca/~woproject>

Hi Dwhit,

Some motors are not able to be changed over to 110V operation, If you pull the cover off where the wiring connections are made and there isnt an alternate wiring scheme on the inside sticker or on its name plate then i recommend calling up a local rewiring or repair facility. If its possible they will know just by the make and model #'s Hope this Helps

Tom S.

The problem is that the Width= part of the image tag is not correct (maybe this new resizing thing?).

Anyway, this is the URL to the image :)

[http://www.otherpower.com/images/scimages/57/NY\\_blackout\\_satellite\\_view.jpg](http://www.otherpower.com/images/scimages/57/NY_blackout_satellite_view.jpg)

I can see the picture.

I don't know if I can see it because I was not in the area of the recent blackout in Helsinki, Finland.: =).

That blackout made me to think.  
As much as America's blackout.  
I already tens of years ago realized how easily grid systems fail. If somebody wants them to fail or if somebody wants them not to fail.

In Indian big cities blackouts are really common.

Here, Maybe this will make more sense

The red section is where the the lights should have been on August 14 at almost mid-night. Look at this pic and then look back at the other one. You'll see the black hole across the eastern seaboard. Look at that and then realize that buy then a bunch of people already had their power back.

Cya,  
Chris

When I posted the original photo and previewed it and then posted it everything was perfect. I went back and refreshed and checked it as a new posting also and everything was fine. I was surprised to see the photo missing this morning ! I'm trying this again but now it will be an attachment to a comment (maybe different in some way) Anyway I figured most would realize the black hole to be the black out, great photo. Dave B

Usually when photos disappear it means that the server was slow in dishing up the photo, so your browser said "\$#&\$ it!" and gave you the page minus photo. Did it show you a "broken picture" icon? If so slow serving, either because of prevailing internet problems, constipation, etc. is the problem.

We have awesome bandwidth and storage space on our servers, but if Scoop starts acting real slow for everyone we'll turn on message archiving and some other tricks that will speed things up.

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Folks;

Late last nite I was browsing through and noticed that the image, which had displayed fine earlier, was just a tiny square at the end of the text of the story and a comment or two wondering why they couldn't see it.

I removed the width=80% in the image tag and it displayed nicely so I updated it that way. No idea what was up with that since it was OK previously altho that was a different computer and browser.

I am beginning to see that the image display issue may not be as simple a fix as it first seemed. Perhaps the users will have to learn how to size images themselves rather than an internal Scoop automated system?

Cheers.

TomW

Sponge;

Sorry, I don't have the answer but this thread is an example of what obviously doesn't work:

<http://www.fieldlines.com/story/2003/8/22/171154/307>

The huge drawing in there is not big byte wise but displays in a huge size which, for me anyway, makes the thread very difficult and annoying to read.

Bottom line is that the person posting should "preview" and adjust so it fits but that seems unlikely to be something people will do. There is no way to edit comments so as an editor I cannot fix the images in comments like I can in stories.

Tweaking Scoop is DanFs thing so not much I can do from here beyond make suggestions.

Cheers.

Re: Coil Wiring ([none / 0](#)) (#1)

by Electric Ed on Wed Jul 23rd, 2003 at 08:42:06 PM MST

[\(User Info\)](#) <http://www.electric-ed.com>

The type of connection depends on whether you want to maximize the voltage or the current. The example shown is a 4-pole winding, but the principles can be applied to a winding with any number of poles.

**Example of a 4-pole winding. All coils are wound the same direction.**

**In a three-phase, 4-pole machine, this represents one phase.**

Electric Ed

Thank You Ed, Are there only two main wires that connect these coils and comes down from the tower? and what is the better to have? voltage? or current? And Is current Amps? Or maybe both, and thats why its wired both ways? I'm tryin to learn. Thanks for your help Ed

[ [Parent](#) ]

Re: Coil Wiring ([none / 0](#)) (#3)  
by Electric Ed on Thu Jul 24th, 2003 at 06:19:46 AM MST  
([User Info](#)) <http://www.electric-ed.com>

"Are there only two main wires that connect these coils and comes down from the tower?"

Yes, if it is a single phase machine. Could be three, or even four, wires if it was a three phase machine.

"And Is current Amps?"

Yes, current is measured in amps.

"and what is the better to have? voltage? or current?"

It is the current flowing through a load device, such as a lightbulb, heater, or motor that makes it operate, but voltage is required to force current through the resistance of the device. So both are required for the device to do "work". The rate at which work is done is measured in watts, and watts(W) are calculated by multiplying volts(E) times amps(I).  $W = E \times I$

"Or maybe both, and thats why its wired both ways?"

The option to connect the coils in series, parallel, or series-parallel, helps adjust the machines output to match the requirements of the load.

For battery charging, which is the most common application for wind generators, the charging current must be forced through the battery "backwards", so you need sufficient voltage to overcome the battery voltage, plus the internal resistance of the battery.

Electric Ed

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Hi,

in order we can know  
that you are doing it the right way,  
you need to tell us,  
how your alternator is made.

-----  
If you made it like 'The Volvo Alternator'  
of the otherpower.com  
with laminates,  
then your magnets  
are not all the same way but  
... ,N,S,N,S, ... ?  
-----

In that case to put your coils in series  
to get maximum voltage  
you have to hook your coils:  
- in - in - out- out -

The easiest way to get it right is to connect the coils one by one and by turning the alternator by hand and measuring with a volt meter to make it sure that every time you add a coil the voltage rises.

In principle if you put all the coils in 'series' you get the maximum voltage at the lowest RPM.

In some cases if you made your coils with really many turns you don't need to put them all in 'series', but can use the same wiring as the original 'Volvo' alternator so that two halves are in series and those halves are then wired 'parallel'.

- Hannu

#### [quick question on 22 gage magnet wire](#)

I have some 22 gage magnet wire and am interested in knowing the voltage and amps that the wire can handle.

Also one other thing, when you clearing off the coating to make a connection do u guys just scrape it off or burn it off?

[quick question on 22 gage magnet wire](#) | 4 comments (4 topical, 0 editorial)

Re: [quick question on 22 gage magnet wire](#) ([none / 0](#)) ([#1](#))

by [DanB](#) on Wed Jul 23rd, 2003 at 10:20:42 AM MST ([User Info](#))

It really depends on it's length... if its in an alternator it depends on how the coils are wired together etc... What are you using it for?

Here is a pretty good chart that should answer your questions for the most part.

<http://www.thelenchannel.com/1wire.html>

To clear the ends.... I usually scrape the insulation off with a razor, although burning it off and then sanding it moves along pretty fast too. Although a soldering iron can do it, I like to use a propane torch (it goes REAL fast)

Re: [quick question on 22 gage magnet wire](#) ([none / 0](#)) ([#2](#))

by [headhunter](#) on Wed Jul 23rd, 2003 at 10:55:29 AM MST

Re: quick question on 22 gage magnet wire ([none / 0](#)) ([#4](#))  
by zubbly on Wed Jul 23rd, 2003 at 03:02:07 PM MST  
([User Info](#))

hello headhunter,

after winding hundreds of transformers and being in the electric apparatus repair service for years, i would recommend the following. for small air cooled transformers in the 25va to 1000va, i would say anywhere from 400 to 600 circularmills per amp of expected load. for transformers of expected higher inrush as in motor starting transformers, from 800 to 1200 circularmills per amp. most magnet wire today can safely be used for 600vac applications.

hope this helps,  
good luck-----zubbly

## [New Service wiring](#)

By [storrence](#), Section [Homebrewed Electricity](#)

Posted on Sun Jul 20th, 2003 at 03:59:47 PM MST

[Wiring](#)

Adding new electrical service in Brazil

I have a few questions about wiring we just had done for a new construction in rural part of Rio de Janeiro. I don't know if they do it here the same as in the rest of the world. I lived most of my life in the US and am used to 110/220v service. To describe what we have here: The main lines come to the edge of our property and have 4 wires. I'm assuming 3 wires for 3 phase and 1 for neutral. Each 110v I assume but haven't yet tested. But I think they use 126v here. We have the electrical box there on one of the line poles and then 4 separate wires are run underground for about 500-600 meters inside a hard plastic non rigid tubing that they also use here for water when it's run a long distance. Something that probably wouldn't pass code in other countries.

The meter box on the pole has a 40amp breaker that looks like it has 6 wires connected. I suppose the 3 hot leads.

I know this is 3 phase service but will I have any problem with running this distance?

Will I experience a voltage drop going this distance?

I haven't checked the guage of the wires but what would be the required guage for this type of service. Probably it depends on how much load I will be putting on it but our house is pretty typical. Probably less than what is typical in the US. We have a refrigerator a few water pumps, gas stove, electric washer and dryer. Single room airconditioner, A range of other devices like home stereo and about 6 computers. Oh and possibly an small electric water heater.

I am pretty sure with this type of service I would have 3 separate 110-120v legs and 3 separate 220-240v legs and 1 330-360v service. Am I correct or is there a way to test it? I have a multimeter.

Is there some sort of chart that shows the wire guage in relation to distance and load to know the correct guage to use?

Thank you!

Re: New Service wiring ([none / 0](#)) ([#1](#))  
by [zubbly](#) on Sun Jul 20th, 2003 at 08:33:39 PM MST  
([User Info](#))

hello Storrence, it is good to read your posting. if things in your part of the world are the same as here in Canada, i think i know what you have. when you have a 3 phase service run to a residential dwelling, you have 3 208 volt lines with neutral. to get your 120 volt 1 phase service in your panel, you end up using 1 of the 208 volt lines plus the neutral. if you look at a star or sometimes called a wye connection, your 120 volt comes from one of the 208 volt lines and the star point ( the common connection where all three phases come together ). the voltage measured from line to star is always 58% of the incoming line voltage-- 120 volt. if you look inside your new panel in the house, you will see the three incoming lines plus neutral. the breakers or fuses will be connected ( zig zagged back and forth ) from all three lines to give you equal distribution on all three lines. put your volt meter from one of the three lines to the neutral, you will get 120 volt. also, if you are using an electric dryer, it should be 208 volt compatible. when you measure voltage across any 2 of the three lines, you will get 208 volt.

i hope this helps you!--zubbly

([User Info](#))

Hello Zubbly!

Thanks very much for your help. I initially tried to test the voltage using my volt meter. It has a common connector and 2 + (1 that says 10A). I used that but accidentally put one of the hots on the neutral of the meter and another hot on the + of the meter and fried the fuse :-/ Well at least it wasn't the meter! I then did a test touching each wire with one hand and the other to the earth (they teach you this stuff in Brazil) :-) And found the common. Now today I will go test to see what the voltage is and report back.

Do you know how I can find a chart on the internet that would tell me what guage wire I should use for this distance to avoid any voltage drop? What are these charts usually called?

I know yesterday I did a test with a 110v light bulb and when I plugged it on 2 hots it was very bright and likely would have burned out in a minute. When I connected it to one neutral and one hot it worked fine.

Thanks again,  
Steve

([User Info](#))

Being not very fond of math myself, I look stuff up on a 10% loss chart, 5% loss chart, 3% loss chart, etc. The handiest ones I use here are in my Sunelco catalog. There are a few on the internet if you search Google.

I also have a nifty wire size/voltage/amperage/distance --> voltage drop calculator that was made by Onan in 1970 -- one of those cardboard slide rule things! It's great and I use it all the time. I don't think they still make them.

[ [Parent](#) ]

Re: New Service wiring ([none / 0](#)) (#6)  
by storrence on Mon Jul 21st, 2003 at 05:48:23 PM MST  
([User Info](#))

Thanks Matt. It's not coming up now but I found quite a few on Google  
<http://www.google.com/search?q=voltage+drop+calculator&ie=UTF-8&oe=UTF-8>

Using these calculators I'm wondering if we have sufficient gauge wire. I need to see the gauge tomorrow. Hopefully they are using AWG or something else that these calculators work with. From what I'm seeing with these calculators I believe I have something like a 10 or 12 gauge solid copper wire just from visually looking at it. If I plug that in to the calculator and also the distance which is about 1200 feet and just consider 110v service using one neutral and one hot it seems the voltage drop would be huge. Something like only 25 volts at the load if I was pulling 40 amps. I put in 40 amps because that is the rating on the breaker at the meter and probably would be what the average house would draw.

It seems the gauge I would need according to these charts is 2/0 AWG to stay within a 5% voltage drop on a single phase 110v line. We have 3 phase with 4 wires (they tell me it's 3 110v lines and 1 neutral). I don't know if this makes a difference in these calculators so I just inputted it like it was 110v single phase since I will have that situation if I use 1 hot and 1 neutral.

Re: New Service wiring ([none / 0](#)) (#7)  
by jubalearly on Mon Jul 28th, 2003 at 04:27:29 PM MST  
([User Info](#))

My rule of thumb is to go up to 100 ft. at the 60 deg C amp rating (20a for 12ga.) of the wire for 3% or less voltage drop, 1 phase. That's for normal residential wiring where you're allowed 5% total drop from the service entrance. It could put you a hair over 3% in some cases. Also, it's for 120v. For 12v, use 10% of that (10ft., 1 way).

Most of these formulas on the internet are for house wiring or DC applications. Note that DC wiring usually has higher amperages for ea. wire size (often 105 deg C rating) & therefore higher voltage drops. Residential wiring should never use more than the 75 deg C amperage rating (you can't get 90 deg C connectors) AC or DC. The NEC tells you how to allow for ambient or conduit (as opposed to "in air").

For long distances outdoors (underground or overhead) I prefer to use the more complicated formulas that work from the area of the wire (or the resistance per ft. - Ohm's law) and account for worst case environmental conditions (temperature, effect of conduit, etc.). The basic formula is

$$CSA = (kIL)/Ed$$

where L=distance in feet one way, I=amperes, Ed=voltage drop, and CSA is the required circular mil area. k is a constant, usually 22-24 for a complete circuit (copper, alum is 36-39)

The constant can be varied with load & temperature (like for those 105 deg C DC circuits use k=26-29). Being able to go down a size or 2 using underground ambients of 25 deg C is nice when your looking at several hundred feet of large wire. I've had fun talking to power company engineers - ask them what they use for underground or overhead & what they recommend.

HTH,

Russ

[rhall11thacr@jayco.net](mailto:rhall11thacr@jayco.net)

Does anyone know what #14, #16, #18 Ga. wire is in thousands..I know that #12 [12/2 household wire] is .080.. I have 2 sizes of Mag. wire, and not marked, but smaller than #12..I can relate in thousands not gauges..Help.

The other question I have, is transformer, coated wire the same as magnet wire?

Yep, you guessed it, I'm a green horn, but very interested. Pearl

If the wire comes from a transformer, yes, it more then likely to be coated magnet wire and you will find no difference. All magnet wire has a thin coat of varnish or other coating that prevents shorts. If you take wire off a transformer, be carefull not to knick the wire or bend it to much. Good Luck!

Pearl,

A "GOOGLE" search for wire guages will find you a table of wire gauge/diameter in whatever format you desire.

1-7 coil spacing instead of 1-4

1-7 jumper spacing. hi guys. has anyone experimented with 1-7 coil spacing? this connection was commonly used in very low rpm 3phase motors to cut electrical noise produced because the poles were jammed so close together. instead of jumpers within the phase connected 1-4, they were connected 1-7 ( skip pole ) would this create any usable effect for gennys?

[skip pole](#) | 2 comments (2 topical, 0 editorial)

Re: skip pole ([none / 0](#)) (#1)

by Electric Ed on Mon Jun 30th, 2003 at 06:13:40 AM MST

([User Info](#)) <http://www.electric-ed.com>

I don't believe the 1-7 connection has any effect in alternator windings.

Each coil will have an "alternation" or, half-cycle, generated into it in the order that the magnets pass it, in other words, either clockwise or counter-clockwise, so the phase sequence will be either a-b-c or a-c-b.

There are some magnet/coil arrangements that result in the three phase voltages being generated 60 deg out-of-phase.

In order to connect the phase windings in wye or delta the voltages must be 120 deg out-of-phase, and this somtimes requires the interchanging of the "center" phase leads.

**In a three phase winding, the three windings are spaced so that the voltages are generated 120 degrees out of phase on purpose.**

**Magnet Spacing is still equal to the coil span**

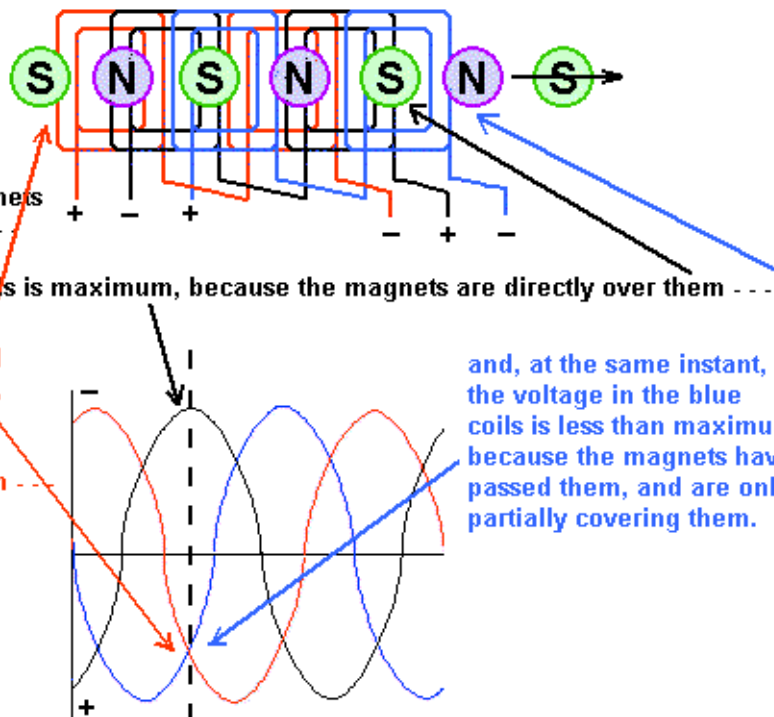

Visualize the magnets moving past the coils - - -

At the instant that the magnets are in the position shown - - -

the voltage in the black coils is maximum, because the magnets are directly over them - - -

while the voltage in the red coils is less than maximum, because the magnets are approaching them, and only partially covering them - - -

and, at the same instant, the voltage in the blue coils is less than maximum, because the magnets have passed them, and are only partially covering them.

**Note - At any instant, one phase is always opposite in polarity to the other two**

Hi,

your post looks interesting.

I think that if we would make a really low RPM generator,  
there would be problems to make it running smoothly.

Maybe the idea of yours would help.

Could you, please provide more info, what you mean?

A rough picture of the arrangement?

- Hannu

[Can I split an inverter](#)

By [Anonymous Hero](#), Section [Homebrewed Electricity](#)

Posted on Mon Jun 23rd, 2003 at 12:05:17 PM MST

[Wiring](#)

230 volts AC from 12 voltsDC

I was wondering instead of buying a real expensive 12 volt to 230 volt inverter if they are made for the US type 230 not the European type 230 or buying and running 2 separate 115 volt 1500 watt inverters could I take lets say a 3000 watt inverter and run 115 ac off 2 of its receptacles in the front into each leg of a 230 volt ac quick disconnect type box so I can run my lathe and mill of 230 volts instead of 115 and keep my systym better balanced with the lights and ac plugs in my little shop. only one would be goin at a time. Has anybody tried this without any damage to the inverter or would the 230 feedback into the inverter and ruin it. Any ideas.??????? Im getting closer. Thanks JB Dayton Nevada

([User Info](#))

I dont think that would be possible because there would be no way to sync the frequency of both inverters. Those things are pretty inaccurate to begin with as far as voltage and frequency are concerned. You would have to have 2 115vac sources in phase in order to add them in series. And even if you could do that, the wattage would remain constant, 1500w (not 3000w). RoyR

Re: Can I split an inverter ([none / 0](#)) (#2)  
by [Anonymous Hero](#) on Mon Jun 23rd, 2003 at 01:21:30 PM MST

Howdy Roy. Maybe you didnt quite understand my ? but maybe you did. If I cant do it with one 3000 watt inverter and I had to use 2 of the same kind of 1500 watt inverters what I was thinking was then running one 115 voltinverter into one leg of the 230 box and the other 115 inverter into the other 230 leg and both neutrals into the neutral lug. Wouldnt that give me 3000 watts at the 230 outlet. Thanks JB

([User Info](#))

You can only do this with inverters that are designed to work in sync this way (180 degrees out of phase, to get 230v from two 115v sources). There must be electronics to accomplish that, the voltages don't add linearly. Think about that sine wave voltage, it varies between 115v and -115v.

The easiest solution is that there are 230v inverters (and paired 115v inverters for dual voltage setups) available for the more expensive sine wave inverters. Another approach (usually cheaper) is to use a 115/230v transformer. There is no easy/cheap way to do it with any inverters that aren't designed for it.

Russ

Re: Can I split an inverter ([none / 0](#)) (#3)  
by electronbaby ([electronbaby@hotmail.com](mailto:electronbaby@hotmail.com)) on Mon Jun  
23rd, 2003 at 01:55:16 PM MST  
([User Info](#))

Well, it would give you 3000W if the inverters actually put out 1500W each. Unless your using a Trace or Xantrex unit or something of higher quality, I wouldnt expect the full output. They are just built cheaply. As far as wiring them together, theoretically, that should not be a problem as long as the phasing is the same. AC likes to be in phase. Especially with all these fancy new mosfet switching supplies all the newer inverters use. I suppose if you knew how to tinker with that sort of thing, you could probably open them up and find on the circuit board what circuit controls the phase regulation of the output and you could tie both units to that signal which would put them both in phase with each other. You would just have to worry about signal loss into the sensing circuitry due to loading it down. It sounds like you would be running some heavy machinery with it. What kinda start up current would you see being drawn though the inverter? Ive heard of people wanting to parallel up 110VAC inverters to get more wattage but never to series them like you want to do. In both cases, you have to worry about phasing. You can phase shift with a transformer, but you lose some efficiency. Maybe you would be better off buying the 3000W model. :/ RoyR

Re: Can I split an inverter ([none / 0](#)) (#5)  
by jubalearly on Mon Jun 23rd, 2003 at 03:16:09 PM MST  
([User Info](#))

Regardless of how many plug outlets you have on the 3000w inverter, they are all the same 115v. Think of it as a bunch of parallel sockets. So you can't get 230v that way.

Re: Can I split an inverter ([none / 0](#)) (#6)  
by Anonymous Hero on Mon Jun 23rd, 2003 at 04:39:53 PM MST

Hello RoyR Russ and others. Basically the mill is a 2hp using 16 running amps at 115 volts and 8 at 230 or 1840 watts. The lathe is 3/4 hp 13.4 amps at 115 and 6.7 amps at 230 volts or 1541 watts. The lathe likes the 230 volts better as it slow down at the start of a cut but that could be the extension cords im using from the other part of the garage for right now. Id like to run this room off my wind generator only. Its my play room and when the grid power goes down I can still play and have my independence. the mill seems to handle 115 volts allright for what I do with it. I put quite a few 25 amp 230 outlets in the shop for them. Oh well. My next ? is the phasing and transformer?. If the were both sine wave inverters, which I cant afford them but here is the ? would true sine wave inverters 2 of them take care of the phasing part of the 230?. ?#2 How much of the power would a 115 volt to 230 transformer eat up.  
Thanks JB

Re: Can I split an inverter ([none / 0](#)) (#7)  
by Anonymous Hero on Mon Jun 23rd, 2003 at 07:14:47 PM MST

No matter how you do it they must be in phase. Trace has a little cord to put two together like you want, but it gets pricey. The transformer is the cheapest way to go Ken

Re: Can I split an inverter ([none / 0](#)) (#8)  
by RobD on Tue Jun 24th, 2003 at 04:40:51 AM MST  
([User Info](#))

I've seen this done with Trace DR inverters. I went to a location where the person ran the two inverters into his house box just like standard 220. Each inverter carried 1500 watts. It's important to have inverters that can phase together so ask the seller if their's do before you purchase them.  
RobD

Re: Can I split an inverter ([none / 0](#)) (#9)  
by troy on Thu Jun 26th, 2003 at 09:22:42 AM MST  
([User Info](#))

Yes, if the two inverters aren't designed to lock in phase, you WILL cook something. Otherwise, the idea is a sound one.

Best regards,

troy

by Electric Ed on Sun Jun 22nd, 2003 at 10:41:54 AM MST  
([User Info](#)) <http://www.electric-ed.com>

There is a maximum limit to the amount of power that can be generated by any given magnet/core strength and arrangement.

In lieu of a fully engineered unit, I recommend the following "trial-and-error" steps.

1. Determine the voltage that you must have for your specific application.
2. Build the rotor and the stator coil supporting structure first.
3. Make and mount one coil, using, let's say #16 wire, with as many turns as you can fit within the physical space that will be available for a single coil.
4. Connect a variable load to the coil, and spin the rotor at the desired "cut-in" speed, and measure the voltage and current.
5. Evaluate the voltage at various loadings to determine if you need more turns of smaller wire to increase the voltage, or less turns of larger wire to increase the current, bearing in mind that you will be connecting the other coils in series, parallel, or even series-parallel, with the test coil.
6. If you want to evaluate coil heating at this time, run the test setup for at least an hour under load, and

And i am using a volt and amp meter as a power grid meter 172kwhours so far..But its a tricki to meter the watts, have sen 450 volt and 3.5 amp, max power i think is 700-800 watts ???

put it upp yesterday for testing...

For the small 2 meters i havet got so far with

Hello DR.D :) The bigger 3 meters is a 16 poles pmg and with 2.18/1 gearing i am using it for heating and that in a series resonant circuit with capaciteters it works perfekt.

[Coils "Shorting out laminates"](#) | 3 comments (3 topical, editorial)

Re: Coils "Shorting out laminates" ([none / 0](#)) ([#1](#))  
by Electric Ed on Sat Jan 3rd, 2004 at 05:55:11 AM MST  
([User Info](#)) <http://www.electric-ed.com>

The sharp edges of the steel laminations could wear through the thin enamel insulation on the copper magnet wire, and short out the coils, so there must be insulation between the two. Motor rewinders use a material they call "fish-paper".

Here is a photo (thanks to zubbly), showing the slots insulated, and ready for the coils, for one of his induction motor conversions.

[http://www.otherpower.com/images/scimages/253/us\\_stator\\_insulated.jpg](http://www.otherpower.com/images/scimages/253/us_stator_insulated.jpg)

[Coils "Shorting out laminates"](#) | 3 comments (3 topical, 0 editorial)

Re: Coils "Shorting out laminates" ([none / 0](#)) ([#3](#))  
by zubbly on Sat Jan 3rd, 2004 at 08:48:44 AM MST  
([User Info](#))

hello Sponge.

Magnet wire on its own does have an insulative coating. this coating is intended to only serve as electrical insulation between turns of the coil only. It should never be relied upon to insulate the coils from the laminates.

the material i use is DMD 180 degree celcius(dacron-mylar-dacron) which is intended for this purpose. thickness available ranges from .003-.025 inches. you should be able to obtain some from any electric motor rewind shop or another suitable material. if insulating stator slots, you just cut it to size. if insulating a flat laminate surface, i suggest using a thin coating of 5 minute epoxy on the laminates and applying the insulation in one thickness layer.

hope this helps

Zubbly

[coil shape and size for pm axial field alternator using donut magnets](#) | 7 comments (7 topical, 0 editorial)

Re: coil shape and size ([none / 0](#)) (#1)  
by Electric Ed on Fri Jan 2nd, 2004 at 04:44:35 PM MST  
([User Info](#)) <http://www.electric-ed.com>

Some of the basic principles are illustrated below.  
I believe "straight sided" coils, preferably a trapezoidal shape, so that the coil sides are aligned with the radius of the machine, will give good results.

To maximize the field flux density, I recommend that you use two mild steel rotor discs, even if the second one does not have magnets on it.

### Magnet / Coil Spacing

**In order to connect coils in series or parallel, so that the voltages, (or currents in parallel) will add instead of cancelling, the voltages induced in the coils must be "in phase" with each other.**

The only way to ensure that the coil voltages are in phase is by accurate magnet / coil spacing.

Magnet center-to-center spacing should equal the coil "span".

The objective is to have the leading edge of a NORTH pole reach one side of the coil - -

- - just as the leading edge of a SOUTH pole reaches the other side of the same coil.

by Oliver on Sat Jan 3rd, 2004 at 03:11:47 AM MST  
([User Info](#))

Hi Electric Ed, Thanks for your reply, very nice diagrams! So should the inner diameter of the coil be the same as the outer diameter of the magnet? I was originally thinking of having the coils the same size of the magnets to get the most flux passing through them. Thanks for your help Oliver

That depends on the magnet and coil sizes.

Refer again to my diagram. The important part reads - "Magnet center-to-center spacing should equal the coil span"

Does that make sense?

## Magnet / Coil Spacing

In order to connect coils in series or parallel, so that the voltages, (or currents in parallel) will add instead of cancelling, the voltages induced in the coils must be "in phase" with each other.

The only way to ensure that the coil voltages are in phase is by accurate magnet / coil spacing.

Magnet center-to-center spacing should equal the coil "span".

The objective is to have the leading edge of a NORTH pole reach one side of the coil - -

- - just as the leading edge of a SOUTH pole reaches the other side of the same coil.

Electric Ed

Yes, that makes sense that the coils and magnets must be spaced accurate to limit any phase difference in the output of the coils. Thanks for your help Oliver

Electric Ed, when is the emf induced in the coils? - when the whole coil is over one pole e.g. N OR when one leg of the coil is over N and when one leg of the coil is over S? Thank you.

[ [Parent](#) ]

Re: coil shape and size for pm axial field altern ( [none / 0](#) ) (#6)  
by Electric Ed on Sun Jan 4th, 2004 at 06:50:02 AM MST

Re: coil shape and size for pm axial field altern ([none / 0](#)) (#7)  
by Oliver on Sun Jan 4th, 2004 at 11:34:46 AM MST  
([User Info](#))

Thanks for the clear reply Ed, I may have to re-think my coil design as at the moment it will do the following both legs of the coil will be over the same magnet (n-pole), then one leg over north pole - other leg over air (gap between magnets) one leg over north pole - other leg over south pole one leg over air (gap between magnets) - other leg over south pole both legs of coil over south pole on same magnet I assume this would cause a problem with the sine wave i.e a positive half cycle - a space until coils line up - then a negative half cycle and so on. My coils are already quite big due to the size of the magnets - might have to make the even bigger? Cheers Oliver

## Batteryless Bicycle Flashing Safety Light System

- \* No Batteries!
- \* No Friction!
- \* No Drag!
- \* No Resistance!
- \* Always On, standby light when stops at traffic!
- \* One White Flashing Light in Front!
- \* Two Red Flashing Lights at Back!
- \* One standby light at back!
- \* Bright Enough to Be Seen in Daylight!
- \* Get Energy Almost Free! (At Least on Bicycle)

This product is based on a newly invented high efficiency electrical generating device; to see how it works [CLICK HERE](#)

### Product Advantages

- ★ No batteries needed (save your money and protect the environment).
- ★ No friction on any parts of the bicycle.
- ★ No drag can be detected in this device; it is not a traditional dynamo. With this innovative, electrical generating system you will not feel any extra weight when you are cycling.
- ★ Small size (approximately 1 by 2 inches).
- ★ One white light and two red safety lights flash as the wheel rotates (even at very slow speed). No need to switch them on/off.
- ★ On standby version, a standby red LED at back will keep on for 1-2 minutes after your bicycle is stopped by traffic lights.
- ★ The lights are bright enough to be seen in daylight - 24 hour safety lights free!
- ★ Very reliable and simple design, no maintenance needed.
- ★ Friction free design works well in all weather conditions.
- ★ 2 year warranty on the generating unit.
- ★ You will be in better legal position by using this safety lights if a traffic accident occurred. Because you can prove, the safety lights were always flashing on your bicycle in any weather conditions (e.g. in a dark day) or road conditions (e.g. under a bridge or inside a tunnel).
- ★ Alternatively, this safety lights can be used as a backup, in case your battery powered safety lights are not working when you are cycling in dark.

★ Another extra benefit of having this light system on your bicycle is: It may prevent the bicycle being stolen, as bicycle-thieves may think the light system is a security alarm system. Because many people told me, they first thought the "strange device" was a electrical security alarm.

Improved design using the latest LED products, the flashing lights become very bright. In fact, the lights are now too bright for the naked eye in a short distance.

### WHY I DESIGNED THIS PRODUCT?

I used battery powered safety lights for many years. To keep battery powered lights in good working order, you must spend time, money and pay lot of attention to them. When I started cycling I was worried about: Are my safety lights on? Are batteries in my safety lights fully charged? Many times I rode my bike in the dark without safety lights because I simply forgot to switch them on, or the batteries were flat. When I arrived home I often forgot to switch the lights off. This why I designed this product!

**Real Products**

This product is now available in hand-made version.

To install this product on your bicycle, see instructions below:

(Picture 1) To install: (1) First stick the moving magnet onto spokes of the wheel by magnetic force, cover it by plastic film to prevent rust. (2) Fix the generating unit on tube of the bicycle as picture shown, make sure the moving magnet passes close to bottom part of the unit, but not touch each other (see picture 2 below for details).

(Picture 2) shown the moving magnet (covered by plastic film) passes close to bottom part of the generating unit with a 0.5-1 cm gap. There is no friction between them, and you will feel no extra weight when cycling.

(Picture 3) Two red lights at back, one white light in front and wire from the generating unit.

(Picture 4)

(Picture 5) shown the standby version of the product. At back, the 2 LEDs are flashing if you ride the bicycle without holding rear-wheel brake. The standby light switch's paddle is at open position.

(Picture 6) shown the standby version of the product. As you held the rear-wheel brake to stop the bicycle at traffic lights, the movement of the brake cable will push the switch paddle into close position, 1 of the LEDs will be lit. The LED will keep on until you released the brake. On other bicycles, there may be some other designs of rear-wheel brake, the standby light switch can be installed at another convenient place in order to get same result.

## Buy on-Line

★ Normal flashing lights, £13 per unit, add £2 for worldwide postage.

### [12 Volts or 240 Volt Lighting](#)

By [JohnS](#), Section [Homebrewed Electricity](#)

Posted on Mon Dec 22nd, 2003 at 06:08:41 PM MST [Lighting](#)

Deciding whether to use an inverter or batteries to power my house lighting.

Hi All, Just after a bit of advice. I have converted most of our interior lighting to 12V spots. (the ones that use a 240V to 12V transformer) I was going to run in new 12V wiring from my battery bank to run these spots which would require additional switches and wiring. Would I be just as well using an inverter to tie in to the existing 240V wiring with a single changeover switch or stick to running in a separate 12V system. Are there any problems using modified sine wave inverters with lighting transformers?

Any thoughts or advice would be most helpful. Hang Loose. John S.

[12 Volts or 240 Volt Lighting](#) | 4 comments (4 topical, 0 editorial)

Re: 12 Volts or 240 Volt Lighting ([none / 0](#)) ([#1](#))  
by [drdongle](#) on Mon Dec 22nd, 2003 at 06:48:44 PM MST  
([User Info](#))

Transformers tend to saturate more easily with square waves but yes it will work.  
12 volt has the advantage of no conversions but larger wire is required to efficiently deliver it to loads. anything you do is a trade off.

Dr.D

Re: 12 Volts or 240 Volt Lighting ([none / 0](#)) ([#2](#))  
by [dconn](#) on Mon Dec 22nd, 2003 at 07:13:17 PM MST  
([User Info](#))

The other nice thing about using the power through your Inverter, rather than a 12v system, is that the Inverter will, most likely, have a low-power shutoff to protect your batteries from under-charge.

I find the CFL bulbs to be really good running on the Inverter (although I've killed one CFL bulb after about 2 years of life somehow and another has taken to buzzing when turned on - I should probably fork out for a sine-wave Inverter).

All the best,

Derek

Re: 12 Volts or 240 Volt Lighting ([none / 0](#)) (#3)  
by RobD on Tue Dec 23rd, 2003 at 07:12:57 AM MST  
([User Info](#))

I like the idea of low voltage lighting. Even if you aren't getting the best efficiency now there are a lot of options coming along and you'll be ready for them. I'm going to run the house on 24 volts. (I'd like to go to 48 but my mills are 24).

The new LEDs coming out now are great in both power and color. It won't be long before even the CFL bulbs are out dated.

I also use the small 8 watt 8" long CFL lamps that I've built drivers for to run on 12 volts, 24 volts, 120 volts or D cells. So no matter what I have in power I get light.

The thing about low voltage is you can use several different sources to drive them and save your inverters for other needs.

Here's a trick to save power and have your incandescent lamps last forever. Put a diode in series with the lamp. I solder a 1N4007 diode, direction doesn't matter (use two for higher wattage bulbs), on the tip of the light, wind the other end in a small coil and stick a blob of solder on it. It drops the voltage down to about 55% so if you use 100 watt bulbs you get about 55 watts with a greatly extended life and half the power waste. Have you ever noticed how hard it is to get low wattage bulbs?

I buy the diodes from Digi-key 100 for \$7.00. I give them out to my neighbors.

RobD

Re: 12 Volts or 240 Volt Lighting ([none / 0](#)) (#4)  
by windrules on Tue Dec 23rd, 2003 at 06:00:50 PM MST  
([User Info](#))

Depending on the inverter you use you need to be carefull using the long fluro lights as on some cheeper inverters the fluro's will fry the inverter unless you remove the capacitor that is housed inside of the tube (not the start capacitor).Just found this out with a bad experience with 18 watt fluro on a cheep sine wave inverter, is now beeing repaired,realy dead.

Mos

## [LED for headlamp](#)

By [Tim C](#), Section [Homebrewed Electricity](#)  
 Posted on Sun Dec 21st, 2003 at 04:58:18 PM MST [Lighting](#)

I have an inexpensive headlamp which takes a screw in incandescent bulb.

I think it is 4.8 v 700 m. I have look everywhere and have not found a replacement. I found two white LED's at The Electronic Gold Mine. One is a 5 mm and has a minimum output of 7,000 mcd@4.0V DC. The other is 10mm white LED operates on 3.6V to 4.2VDC @ 30ma.

My light uses 4 AA batteries. Can I simply wire this in or will I need a resistor. If so can anyone recommend one? I realize if operated at over the rated voltage, the LED may not last as long. This is OK since the current bulbs do not last long anyway. Thanks for any and all help.

Tim C.

[\(User Info\)](#)

I just got a Dorcy solid state (white led) from QVC about 2 months ago the batteries (4-AA) last a lonnnngggg time and the bulbs probably lifetime. The only drawback...about half the length of a regular flashlight...so I keep misplacing them. BTW They would make a nice Christmas Present... (batteries last a lonngg time)  
 (:>) Norm.

Thanks for the help. So what would I need to make this LED operate? I have read the information on the board on the use of LEDs. They can work without the resistors, but may last a shorter time if you exceed their voltage.

Re: LED for headlamp ([none / 0](#)) (#4)  
by Gordy on Sun Dec 21st, 2003 at 08:39:18 PM MST  
([User Info](#))

If your worried a about over voltage, could'nt you just replace one of the batteries with a peice of wood dowl with a hole drilled down the center and some wire in the hole and a tack on each end. To pass the current through from the other batteries.

Just a  
thought,  
Gordy

[ [Parent](#) ]

resistor built in with the led? ([none / 0](#)) (#7)  
by Norm on Mon Dec 22nd, 2003 at 07:38:35 AM MST  
([User Info](#))

The 'Dorcy' looks almost like it has a regular flashlight bulb...except you can see the diode instead of a filament maybe they have a built in resistor?

Re: LED for headlamp ([none / 0](#)) (#5)  
by visionarynz ([dynamics\\_feedback \(at\) hotmail \(dot\) com](mailto:dynamics_feedback@hotmai(dot)com)) on Mon Dec 22nd, 2003 at 01:12:34 AM MST  
([User Info](#)) <http://www.dynamics.orcon.net.nz>

Going by the formula I use for the LED lights I make, you would want a 150 ohm resistor wired in series with each LED.

Running from 4x 1.5volt cells, this should keep the current through each LED down to around 20mA, and at this current level the LEDs will work well, and likely last longer than you do. Also your batteries will last a very long time, even if you put 4 or 5 of them in there.

There are a few special cases where LEDs can be connected straight to batteries, but this isn't one of them, they will likely die in a matter of seconds without a resistor.

vis\_nz

Re: LED for headlamp ([none / 0](#)) (#6)

MST  
([User Info](#))

Rechargeable batteries (NiCD or NiMH) have a nominal voltage of 1.2 volts, so if you use them, you'd need a smaller resistance value to get the same brightness from your LED... Or, if you get the 4.6V LED, you could get away with running without a resistor (as long as you dont forget and put regular 1.5v batteries in!)

Dave in PA

Re: LED for headlamp ([none / 0](#)) (#8)  
by RobD on Mon Dec 22nd, 2003 at 07:50:03 AM MST  
([User Info](#))

Yes, that's right. LED's are CURRENT devices. That means the voltage is relatively unimportant. What you want to control is the current.

I'm not sure how bright your LED needs to be but the 20 ma. ones won't give you much light.

I have several LED flashlights that I built using high power LEDs but they require a current limiting circuit.

If you are not concerned with brightness and want just a cheap indicator light you can figure your current with ohms law ( $E=IR$ ) this way:

First you will need to know the voltage and current specs of the LED for example, let's say your LED is rated at 20 ma(.020 amps) and 1.7 volts.

4.  $8 - 1.7 = 3.1$  volts.

3.  $1 / .020 = 155$  ohms.

The closest standard resistor to 155 is 150 ohms and this will be fine.

$.020 \times 0.020 \times 150 = .060$  or 60 mw (milliwatts) so you can use a 1/4 or even a 1/8 watt resistor.

What is happening here is the resistor is dropping the excess voltage (3.1) and allowing the 1.7 volts to go to your LED. The 1.7 volts will not overdrive the LED so the 20ma will not be exceeded.

You would put this in series with your LED(battery-----//----->|---ground). Make sure the LED is in the circuit in the right direction (The flat spot (collector) is the ground end and goes to the neg post on your battery).

Hope this helps,  
RobD

Re: LED for headlamp ([none / 0](#)) (#9)

MST  
([User Info](#))

I think it is a good idea to always use some resistance to prevent thermal runaway. That having been said, I often power LEDs from NiCads or NiMH batteries at 3.6v (3 batteries or in a minim@g, 2 batteries @2.4-3.2v) with no resistor. However, if there is room, even a 10 ohm resistor will usually prevent thermal runaway.

Note that the rating of 3.6v or 3.6-4.2v is the SAME thing. The one that gives you the range is telling you the typical variation in Vf (forward voltage). Higher quality LEDs tend to vary less.

I would recommend the 3 batteries + a dummy as was mentioned above. With 4 batteries you waste most of the 4th battery (70%?) in heating the resistor. Also, I very rarely have any LEDs fail at 50ma, even when they are rated for 20-30ma max. So I would use something around 50 ohm for your 4 battery setup or 10-20 ohm for the 3 battery setup assuming alkaline batteries.

If you use NiMH rechargeables, the voltage will be much flatter (about 1.25v/battery with a 50ma load) and you can use a smaller resistor (22 or 27 ohm with 4 batteries). Note that the actual value of the resistor varies enough that exact values aren't critical. So just use whatever is closest to your calculations.

Thermal runaway ([none / 0](#)) (#10)  
by Norm on Mon Dec 22nd, 2003 at 09:38:45 AM  
MST  
([User Info](#))

Isn't this what would happen in fluroscent lights you have to have something to limit the current and whatever happened to the big heavy ballast that they used to have in the old fluroscent lights? To my understanding a ballast is a 'choke coil' they used to use them quite often in the old tube radios. Norm.

So could I simply replace one of the 4 AA batteries with "spacer" wired with a 10 to 20 ohm resistor?  
The light still needs to be practical but I do not want it to burn out right away.

Re: LED for headlamp ([none / 0](#)) (#11)  
by RobD on Mon Dec 22nd, 2003 at 05:34:17 PM MST  
([User Info](#))

Basically a ballast 'absorbs' the initial high inrush current of cool low resistance filaments. Now we don't need them because we have very good current limiting circuitry that never allows the inrush current to go above a specific point. In the old days the military used to keep their tubes on constantly because they found they lasted longer. Apparently they did because we changed very few of them. An important point about LEDs in flashlights is to keep the voltage of the source close to the working value of the LED to limit losses from heat through resistors. This is why I use PWM (pulse with modulation) drive circuits through MOSFETS with low internal resistance to cut my losses. If you are dropping half your current in a resistor your batts will burn down in half the time.

by Gordy on Mon Dec 22nd, 2003 at 07:56:22 PM  
MST  
([User Info](#))

While we're on the subject of led's, has anyone thought of using them on christmas light strings and what would be involved in doing so. A 50 light string at Wal-Mart is \$1.49 a 50 led light string would be \$???????

Just tierd of changing bulbs, and thinking of how much electricity the "old lady" insists on wasting with 1000+ of these little buggers running 12 to 18 hours a day.

wishfull thinking

Let me know if I'm just

Gordy

Re: LED for headlamp ([none / 0](#)) ([#13](#))  
by hydrosun on Mon Dec 22nd, 2003 at  
09:23:47 PM MST  
([User Info](#))

We bought a bunch of 120 volt Led Christmas lights last year. Only one hardware store in town carried them. We bought one string for \$15 but later they were discounted to \$7.50.

They plug in like regular strings and can be connected in series and parrallel and use 1/8th the power of regular bulbs. also check ebay or a search of the web to find who is carrying them this year. We really liked the blue almost glowing strings.

I've converted many regular bulb christmas strings into 12 volt led strings. I had to cut and splice and add resistors . I'd put 5 in each group for red, green or yellow, and 3 in each group of white or blue (I'd calculate 2 volts each for the first group and 4 volts each for the whites and blues) usually I'd use one resister for the whole string. The trickiest part is keeping the polarity straight with the direction

of the leds.

I've found the best deals for Leds at Superbrightleds.com I ve order from them 3 times. I used 50 in a string of 12 volt christmas lights that are on in the living room all year. Very bright and chearry. I especially like the 12 volt cluster of 24 white for \$15. I use it for my bike light.

I've used 12 volt 12 led clusters for a couple bright headlamps. I use 12 volt nmh battery packs to run these led clusters. One pack was two cell phone batteries I rescued from the recycling bin . One other battery was from a camcorder. I ususally take my multi meter when I take in my recycleables and rummage through the old batteries. Many still have lots of life for low power applications. they have great desriptions and outputs of each individual led.

by desertratjack on Wed Dec 24th, 2003 at 10:52:44 PM MST  
([User Info](#))

Backwoods Solar sold LED light strings (12 vdc) but I found that by buying the WalMart colored light strings and rewiring the 120vac strings to 12 vdc that I could make the strings alot dimmer so that they are more pleasing to the eye and they also run on a lower voltage with longer life. If I remember right the bulbs I had were 5 in series for 12 vdc. Be aware that there is great variability in bulbs so different strings from different manufacturers have different resistances so it becomes a big puzzle (worse than just finding a bad bulb)if you mix different bulbs :-)

I bought a couple of LED "bulbs" designed to retrofit to a standard flashlight. They were something like \$8.00 each from some guy on eBay. These were not screw-in, but the bayonet type. Each bulb was actually three LEDs. The resistors were internal and already wired in there. I used these to replace bulbs on a bike light. Worked pretty well. Just a bit of bluish tint to them.

Bach On.

[LED and 12Volts power supply HELP!](#)

By [SamSaveMax](#), Section [Homebrewed Electricity](#)  
Posted on Thu Oct 23rd, 2003 at 12:26:03 AM MST  
LED

[Lighting](#)

Hello everyone!

I've been learning and fooling around with LEDs diodes for a month now and able to produce and modified a few things as for accent lighting around the house. BUT... till now....it got me wonder about the information listed on the back of most 12volt power supply.

I built a LED light using 3 LEDs in series inline with a resistor rated at 470 ohm 1/4 watt. Using with a 12volt power supply as listed below....my LED light works.

My 12volt power supply listed: input: 120V AC 60Hz 6W  
output: 12V DC 250mA

12V is usable for LED....but how about the 250mA current listed??

Most LEDs forward current in a range of 20mA to 30mA.

Would the rating on the power supply of 250mA matters? Would it ruin LEDs quicker?

I appreciate anyone with the technical knowledge could assure my LED design is OK !

Thanks

SamSaveMax

Re: LED and 12Volts power supply HELP! ([none / 0](#)) ([#1](#))  
by [wpowokal](#) on Thu Oct 23rd, 2003 at 06:05:05 AM MST  
([User Info](#))

SSM, The 250ma means you can run 12 led's at 20ma each (250/20 ma). The voltage is aproximatly constant and is the paramiter you chose your resistance to suit. Voltage equates to water pressure while amps equates to water flow.

If I understand you correctly you have 3 led's in series ie +12v led led led -12v. If this is what you mean as oposed to paralell, then as each led has a voltage drop of 2v, 3 in series equal 6v drop. Therefore you could go as low as 220 ohm resistor with this arrangement, but please be sure of your arrangement before substituting a lower value resistor.

hope this helps regards Allan

by veewee77 on Thu Oct 23rd, 2003 at 06:08:02 AM MST  
([User Info](#))

The 250MA rating on the transformer means that that is the max load you can put on it. It won't push more current than the load requires. If you put the 470 ohm resistor in there, and use the formula  $E/R$  where  $E=Volts=12$  and  $R=470$  ohms, that will mke the current in your circuit 25ma, within the range of your current limits on your LEDs.

DS

by 5kw on Thu Oct 23rd, 2003 at 07:51:25 AM MST  
([User Info](#))

DS don't forget the voltage drop of the LEDs ~ 6 + volts. Current is probably closer to 10-12 ma. If the supply is a wall wort it may have very poor regulation, it wouldn't hurt to check things with a meter.  
Make the wind fun!

Re: LED and 12Volts power supply HELP! ([none / 0](#)) (#5)  
by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Thu Oct 23rd, 2003 at 10:44:41 PM MST  
([User Info](#)) <http://www.internetfred.com>

All devices take the amount of current that they need. They take no more or less than they are rated for generally. If the device is for example say 10 ma and your battery can handle 100 ma, it means that there is 100 ma available from the battery, The device will use 10 ma (presumed per hour in this example) for 10 hours. If the device requires more than 10 ma, say around 50 ma, then it will run for 5 hours using 50 ma of current per hour and run for 5 hours. Most batteries suggest a rating of Ah or amp hours. Example: 2.0 Ah at 12vdc. You can drain 1 amp per hour for 2 hours at 12 volts. Yours suggests 12vdc 250 ma which is milli amp hour.

Current is just the available power per unit time. Voltage is the pressure that a device requires to run optimal. Good Luck!

Re: LED and 12Volts power supply HELP! ([none / 0](#)) ([#6](#))  
by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Thu Oct 23rd, 2003 at 11:05:34 PM MST  
([User Info](#)) <http://www.internetfred.com>

say around 50 ma, then it will run for 5 hours using 50 ma of current per hour and run for 5 hours  
opppsssss.. Correction.. 100ma, 50 ma drain, 2 hours not 5 hours...

Re: LED and 12Volts power supply HELP! ([none / 0](#)) ([#7](#))  
by SamSaveMax on Fri Oct 24th, 2003 at 12:25:22 AM MST  
([User Info](#))

Thank you very much everybody. Those replies really helpful.  
I understand now.....it means maximum load rating.  
It means that I can be able to run maximum 4 series of 3 LEDs each in paralell.  
You guys are too advance for me.... :)

One question to Allan...If I use a 220 ohm resistor, would that makes my LED light any brighter??? Series arrangement of the light: +12v,resistor,led,led,led,-12v

To be honest with everybody...my power supply is just a regular AC adaptor.  
I collect for those useless no longer need AC adaptor that used to power small household electronics and use them to power LEDs. It doesn't have to be 12V. It could be 9v, but use 2 LEDs instead. I am sure that every house would have atleast 2 or 3 laying around somewhere useless.  
LED would make a perfect accent lighting, under kitchen cabinet lighting anyone?? nightlight? discrete spot lighting for your collectable? inside a curio cabinet??  
how about landscape lighting??.....which I just finished my project. I am a freak of LED for white light and low power

sip. Even my lighted house number has been converted. :0)  
Anyone has an advance project care to share with me? Thanks again everyone.

Re: LED and 12Volts power supply HELP! ([none / 0](#)) ([#9](#))  
by SamSaveMax on Tue Nov 11th, 2003 at 11:15:25 PM MST  
([User Info](#))

I just used a 47 ohm resistor with 1/2 to 1/4 watt...a big difference in brightness.  
I am now experimenting with parallel instead of series connection.  
I notice that most of the resistor are rated at 1/2 to 1/4 watt.

Parallel: 14.4 volts with 12 LEDs = 47 ohm resistor with rating of 3 to 4 watt required.

Would it matters if I use the 47 ohm 1/2 watt rating that I already have with the above requirement?

Does anyone know a good source where I could purchase higher wattage rating resistor?

Thanks guys  
SamSaveMax

### Compact Fluorescent Lighting

I built a cabin this summer and I am trying to design a 12VDC/120VAC system.

I currently have a solar panel, 12V, 17aHr batteries and a 400 watt inverter.

I was trying to use 120VAC Compact Fluorescent screw in type lights but they keep

blowing after several on/off cycles. Are these types of lights prone to failure

if used on an inverter. I have burnt out 3 so far. Maybe there is a better lighting

solution. I do have some older 4 tube 4' fixtures and fluorescent tubes with the 30 - 40w starters. Also have a couple of newer fixtures. maybe

these would be better suited if modified to blend into the camp environment. Any ideas or help is appreciated. Been reading all the

goodies.

Thx  
Mark

by [DanB](#) on Wed Oct 22nd, 2003 at 08:35:01 PM MST  
([User Info](#))

I wonder what sort of inverter you have? I suspect (not sure) that an older square wave inverter might be hard on them. They seemed to have short life for me when running off my modified square wave inverter.... and they buzzed. I've had no problems (yet) since I got a true sine wave inverter.

Depending on your system (and your plans...) it may be wise to use 12 volts for lighting. I like the new 12 volt DC compact fluorescents.

I agree with Dan on the CF 120 AC lighting. I use a Trace DR1512 to power some outdoor CF 120 AC fixtures, and, depending on the manufacturer, I have had some duds, and some that worked well with the Trace modified sine inverter..

Not really sure on the reason for the short life, but some will die after a few on/off cycles, while others will work with no problem. When I tried 12 volt CF lights, i havent had any issues..

Some food for thought,  
JimU

Thx guys

Looks like I will be looking for some CF 12VDC at the local RV place. Suppose 12 volt stuff costs a little more but if it works and is reliable then thats better than blowing 8\$ lights continually.

Re: Compact Fluorescent Lighting ([none / 0](#)) (#5)  
by Scott on Thu Oct 23rd, 2003 at 06:59:53 PM MST  
([User Info](#))

Wal-mart sells 12v fluorescent lights for about \$8. They are setup for 8 AA batteries but also have a 12V ac adapter jack or do like I did and clip the wires from the battery terminals and solder wires in. I set my cabin up last week with all new lights from walmart. Very low power usage and descent light, I use 2 where I need more light and 1 in the bedrooms. I got the idea from somewhere on this board.

Don't know for sure but suspect they don't like nasty square wave power as suggested above. 120VAC CF's last for years on a Trace SW series inverter.

Re: Compact Fluorescent Lighting ([none / 0](#)) (#8)  
by mkseps on Fri Oct 24th, 2003 at 06:19:06 PM MST  
([User Info](#))

You should be aware that those Walmart and other similar lamps are under driven. By this I mean that if they are using 4 watt tubes, the power input should be something greater than 4 watts. In most cases, they are only driving them with about 2-1/2 watts (makes the batteries last longer). To make up the difference and to obtain adequate useable light, they use phosphors that emit light at about 5100 degrees Kelvin. This isn't the best spectrum for reading but it does get the job done - of sorts.  
Gene

Re: Compact Fluorescent Lighting ([none / 0](#)) (#9)  
by troy on Mon Oct 27th, 2003 at 05:07:16 PM MST  
([User Info](#))

Lot of vendors (Wal-Mart, Harbor Freight, most auto parts stores) now carry 12 fluorescent trouble lights. Pretty inexpensive and saves you the trouble of adding battery clips. Underdriven as noted by another poster, so not the nicest wavelength, but cheap and effective. For a warmer light, go with the RV fluorescents or get something from otherpower.com.

Good luck and have fun.

troy

[\(User Info\)](#) [change AT: bach\\_on AT hotmail.com](#)

Gameman,

I've tinkered around with these right much. I even created an Excel spreadsheet to calculate the resistors needed. It calculates the milliamps of current that the LED will get based on the ohms of the resistor; too high, and the LED will be toast.

You need to know two things:

What is the voltage of your power source? (It must be higher than the LEDs voltage rating.)

What is the voltage rating of your LEDs?

Usually, whites and blues can tolerate 3.2 - 3.6 volts. Reds, greens, yellows, and other colors usually take 2.2 - 2.6 volts. They may take more, but it changes the current - and that can be bad.

Most LEDs are rated for 20 milliamps. You can go over that on most to about 35 milliamps, but it usually shortens the life of the LED. Too, white LEDs often start to turn blue if the current goes over 25 mAmps. Sometimes this change is permanent, so be careful.

Place the resistor between the source voltage and the LED. It doesn't usually matter which pole gets the resistor. Make sure the wattage rating of the resistor is high enough for the number of LEDs. Too much, and the resistor will get

pretty hot. Don't try to run an LED without a resistor.

They're fun to play with, but they often don't put out a lot of light for general lighting. They are probably better for close-up spot lighting.

Made from metalbestos stove pipe and tupperware...

My father is renovating an ancient log cabin which has one more smoke stack than he needs. It's brand new and shiny inside, it's already installed in the roof, and I think that with a little creativity it could be made to work like a "solatube".

He's thinking of putting a "ship's light"- one of those half diamond shaped multifaceted things used as skylights in boat cabins- in the bottom. Seems to me that this would diffuse the light too much- a focused beam would be better, but then it's not my cabin.

I'm thinking that a clear tupperware bowl would work for the dome on the top, with the additional thingy that catches low angle sunlight.

Has anybody tried this?

[A Cobbled "Solatube"](#) | 1 comment (1 topical, 0 editorial)

Re: A Cobbled "Solatube" ([none / 0](#)) ([#1](#))  
by [Motorhead](#) on Fri Aug 29th, 2003 at 08:59:10 PM MST  
([User Info](#))

My Solitube's works pretty well, I like the sunlight beaming into the rooms it occupy's (especially the bathroom).

During the winter months I swear it warms the house ev'n tho I never see frost here.

[Lighting](#)

Finally out of the shop

Here's my latest flashlight using the Luxeon Stars. The drive circuit is a switching power supply I designed with On-Semis chips and the reflector is machined from a piece of T-6 aluminum. The light is very powerful and the batteries last several times longer than with a bulb.

well i am kinda curious how expensive and how hard it is to make things like that .. unfortunately i went the cash way out and bought a flashlight from sharper image

<http://www.sharperimage.com/us/en/catalog/productview.jhtml?pid=57680500&pcatid=1&catid=103>

-----  
Hummer Shake Flashlight  
\$29.95

Hummers® always have the right of way -- and Hummer Shake Flashlights are always ready! All the rugged Hummer® flashlight ever needs is a quick 30-second shaking to generate power for up to five full minutes of bright illumination. Inspired and licensed by GM's intrepid Hummer, this shockproof, rubber-guarded, waterproof and floatable flashlight is ideal for outdoor use and perfect for every vehicle or home emergency kit.

Its LED bulb never needs replacing and there are no batteries to worry about -- ever! Faraday's Law of Induction explains how the relative motion of the built-in magnet sliding between metal coils charges the light's capacitor. For prolonged use, just shake for an additional 10 seconds every three minutes. Rugged translucent plastic housing measures 8" long. Weighs 8 oz. Select translucent case of yellow or red. 90-day warranty.

-----  
not like im trying to advertise for them or such just though it was a nice LED flashlight that seemed to be somethign like your tryin to do and well they work well also

Nasher

### [12 volt led's for houseboat?](#)

By [Anonymous Hero](#), Section [Remote Living](#)

Posted on Thu Jun 26th, 2003 at 02:37:30 PM MST

[Lighting](#)

Hi I'm looking for some reasonably priced 12 volt led bulbs or fixtures for my father for his houseboat. I am thinking that I'll have to make them which shouldn't be a problem either. Any tips on where to aquire premade bulbs or plans for making them up? I'd like to make about six fixtures that would each give off enough light so as not to be straining the eyes. Thanks, Joe

[12 volt led's for houseboat?](#) | 7 comments (7 topical, 0 editorial)

Re: 12 volt led's for houseboat? ([none / 0](#)) ([#1](#))

([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

My advice is don't try to light things with the LEDs. Use fluorescents instead. You'll get a much better result for only slightly more than the battery usage. There are 12 volt fixtures out there that will do a nice job. The bluish tints so many LEDs provide will not be pleasant and will not provide nearly as much light. That might not be a problem now, but it might be as he (and you) get older.

by [Anonymous Hero](#) on Thu Jun 26th, 2003 at 07:00:44 PM MST

you can buy 12 inch DC florecent lights at walmart for 10\$ they take 8 AA batteries. at 1.5 volts a piece thats 12 volts. I put them in my sail boat and they work great. very low power consumption and they throw great light. You have to take them apart and solder wires directly to the circuit board then hard wire them to the boats power. Be very carful about positive and negative wires they will not tolerate being hooked up backwards. I learned this the hard way and smoked one. I at least got a spare bulb out of the deal. I used 3m adhesive strips to install them without drilling holes they come with velcro strips but I wanted a more permanent instalation. good luck Bob

LEDs are really great only for replacing tiny incandescent bulbs, for which there are not any fluorescent replacements. Reading lights, flashlites, map lights, etc. For room lighting, way better to go with fluorescents.

We have 12 and 24vdc compact fluorescents available on our site, and also 12vdc white LED clusters that fit a car taillight bulb socket.

Click "products" at the top of this page....

Cheers

DANF

by Anonymous Hero on Sun Jun 29th, 2003 at 07:28:41 AM MST

I was at Autozone and saw some replacement tail lights with LED's. I thought they would work in my camper but the bulb was wrong size for my fixtures. I am not sure how bright they are.

Don't buy the Autozone bulbs, I finally bit, and they burnt out in two days. Took them back, got my money back. They weren't very bright to begin with. Good luck, just stay away from Autozone led's.

leds are good - flouresents are "jumpy" fast flickers but nice and bright. White Leds come in two varieties: cheaper-dimmers and better-brighters. They are good for lighting an area like a table, but only really useful for times when you really need to conserve electricity like in a flashlight. Brigher leds like car headlamp could be very functional but the cost of course is more. Try a car led haedlight if cost isnt an issue :)

I agree LED`s are too blue for house lighting but outdoors they work fine. The nice thing about LED`s is the light doesn`t diminish over distance so mount them high and they`ll light up a large area like moonlight. I`ve used a 57 diode light for 3 years now and am impressed with it`s lumens and durability. 7 years off the grid and counting

### [I want to build an LED lighting system but ...](#)

By [Maharaja](#), Section [Homebrewed Electricity](#)

Posted on Tue Jun 24th, 2003 at 04:46:32 PM MST

[Lighting](#)

Beginner attempts to build LED lighting system

... i have no experience in electronics really other than gcse electronics which i was crap at! although i have good common sense etc and i have soldering gear and can manage that much, this might not actually be that difficult, it certainly doesnt seem so but id appreciate some reassurance from you guys who i am guessing are experts. anyway to the point...

i want some LED 'fairylights' to dangle around my room when i use my LED headlamp in a darkened room it gives a cool spooky light which i want to recreate and im assume thats the 'LED look' not some other property of the headlamp.

Ive been doing some research and i cant see any reason why this WOULDNT work and wanna check it out...

this transformer

[\[http://www.maplin.co.uk/search/results.asp?CartID=03062422253282&ordercode=NL50E\]](http://www.maplin.co.uk/search/results.asp?CartID=03062422253282&ordercode=NL50E)

with these LED's

[\[http://www.maplin.co.uk/products/module.asp?CartID=03062422253282&moduleno=17821&modulecode=\]](http://www.maplin.co.uk/products/module.asp?CartID=03062422253282&moduleno=17821&modulecode=)

but i dont know which of the power supplys to choose for the number of LED's, im not sure how many i do want but im guessing there is a formula. and wiring up a few parrallel cicuits of x number of LED's in a series...  $12v / 3.6 = 10.8v$  + a resistor to resist the remaining bit as detailed on site.

visually i was going to leave bare dangling wires connecting the LED's for visual effect! and then dangle them from the ceiling of something.

any tips/advice or whatever would be much appreciated!

cheers.

N.

If you have a maplin catalogue, look in the LED's section. You will find how to calculate the series resistor.

If not,  
Resistance (ohms) = (Supply voltage - LED voltage) / LED current (AMPS).

So for running one led of 12V supply:  $(12 - 3.6) / 0.03A = 280$  ohms.

If you add LEDs in series, you must add the LED voltages up for that to work, if they are in parallel you add up the currents. If you wanted say, 50 LEDs to run of a 12V supply, you could connect sets of two in series and connect all those sets in parallel, then you would need to supply  $25 * 0.03$  (LED current for on set) which is 0.75amps... And the power supply would need to supply 9watts ( $12 * 0.75A$ ).

[http://www.otherpower.com/otherpower\\_lighting\\_leds.html](http://www.otherpower.com/otherpower_lighting_leds.html)

Hope this helps.

-Chris

[\(User Info\)](#) [change AT: bach\\_on AT hotmail.com](#)

I bought a bundle of 100 white LEDs about a year ago from a guy on eBay. To be frank, most of these have a rather harsh - almost bluish color.

My goal was some spot lighting here and there around the house for when the power goes off. I already had a 12 volt back-up lighting system. I wanted something that had a very light drain on the battery to give more back-up time.

The best you can do is about 3 LEDs per resistor at 12 volts. Too, you'll need 1/2 watt resistors for 12 volts - 1/4 watt get very hot with 3 units. I did an Excel spreadsheet to help me play "what if" on the various resistors and voltages. Let me know and I can send it to you.

I was not happy with the results of the LEDs, but it may be that I just bought bad LEDs. I've since bought several 12 volt fixtures. They have better drain on the battery than incandescent bulbs, but put out a much better light than the LEDs. I think LEDs are better suited for close up spot lighting or flashlights.

Just thought I'd throw in my experience for whatever it might be worth.

Bach On

[Lighting](#)

Fluorescent Voltage

Hi,  
I plan to make a simple inverter for small to medium sized fluorescent lights (4-10 watts) Does anyone know the voltage that a light would normally light up? (Hopefully without shortening the life of the tube.) I have the circuit designed, so all I need now is the voltage for the tube. I'm using a reversed step down wall wort transformer. The peak resonance is about 60khz so I'm using a 555 and a 1kohm, a 11kohm and a 1nF cap (I think this is right) If anybody wants I can post the circuit.

p.s. Is there a range of frequencies a light runs at?  
I think 60khz will be fine though.

-Andrew

[Fluorescent voltages](#) | 9 comments (9 topical, 0 editorial)

Re: Fluorescent voltages ([none / 0](#)) (#1)  
by [mkseps](#) on Fri Jun 13th, 2003 at 05:35:11 PM MST  
([User Info](#))

Consider the fluorescent tube to be just like a neon light. At low voltages, less than about 60 volts, the resistance is infinity. However, once the internal gasses fire into conduction, the resistance drops to a virtual short circuit. The operation of a ballast is to provide a high starting voltage and then introduce an inductive reactance to limit the current that limits the current through the lamp. The voltage must be AC lest the tube turns black on one end. I would suggest that the optimum frequency for maximum exitation of the phosfers is between 15 khz to 25 khz. I would expect your tube will fire about 125 volts but that the current must be limited to the power rating of the tube. To accomplish this, a capacitor should be placed in series with the tube. The size of the capacitors reactance is the element that limits the current.

Re: Fluorescent voltages ([none / 0](#)) (#2)  
by [Andrew](#) ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Fri Jun 13th, 2003 at 06:32:24 PM MST  
([User Info](#))

Ok, looks like I have to wind another transformer. I'll try it. My step up circuit boosts the voltage to about 300v. Would this change anything? Thanks.

14th, 2003 at 02:48:31 PM MST  
([User Info](#))

Well, all goes well except for one thing, apparently I needed a cap across the primary windings of the transformer. I tried putting a 0.001uf Cap (1 nF), and it seemed to be damn close to resonance. I worked it out, and instead of the straight 60khz, I was resonating with the cap at 54.4khz. Anyone know a nifty program that can calculate the resonance between a capacitor and an inductor. I just assumed that for a resonance of 60khz on the transformer, the primarys should be around 5mh? What do you think, is this even in the ballpark? I might be looking on digikey for a real "step up" transformer, since mine is just a reversed 110v to 4.5v "wallwort". Also, the frequency is a bit high isn't it, so i probably need a new transformer anyways.

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

John;

The wide display mode is almost exclusively from folks posting humongous pictures in the comments or stories. Large pictures can be reduced easily by an editor in a story but not in a comment because we cannot edit a comment's content. I am fairly certain it is on the "to do" list.

As a temporary work around you can simply set your browser to not display the pictures in the preferences but thats a kludge.

Cheers.

TomW

([User Info](#))

TomW,

I certainly hope that it is on a "to do" list to restrict the text width in posts. If it isn't it sure needs to be. I believe that I saw somewhere (in preferences?) the user option to change the posting width, so it seems that the administration can easily change the maximum allowed post width, unless the maximum value is set and unchangeable without a hack into the code. I believe that these wide posts are from posters that have set their posting width to fit their monster screen without knowing how it affects the rest of us who don't have the large monitors that they have.

This thread starts with just text, no picture, so a monster picture has nothing to do with the wide text field here.

I am trying to control the width of this post by creating new lines with the "enter" key. We'll see if it works.

John

[Lighting](#)

Sixty cents(USD) each.....

Found a website that sells 6000 mcd white led's for \$0.60 each. Minimum order is ten led's, shipping is one dollar to the contiguous 48 states, two to anywhere else in North America, and four anywhere else in the world. That's one(two, four, whatever) dollar period, one dollar if you order ten led's, one dollar if you order a hundred, one dollar if you order ten thousand(except right now he's only got 200 white led's, but if they're popular enough he'll order more when they sell out.) The same guy also sells blue for \$0.45 each, same deal on shipping and minimum order.

Thanks Kurt your a gent, i just couldnt seem to be able to find any circuits.....sean

[ [Parent](#) ]

Not a conversion exactly but a way to use them. ([none / 0](#)) ([#3](#))  
by [TomW](#) on Fri May 23rd, 2003 at 08:14:37 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Sean;

It seems to me that the easiest thing to do would be to find a cheap 140 or 150 watt automotive inverter and run them off that.

Cheers.

TomW

<http://homepage.ntlworld.com/s.amesbury/homepage.htm>

I know what your saying Tom but im toying with the idea of keeping as much stuff 12v as possible making my rather small system as efficient as possible. Other ideas i have is a 12v television and using a car stereo for sound.....sean

## [800 watt inverter doesn't light a 500 watt light?!](#)

By [zmoz](#), Section [Homebrewed Electricity](#)

[Lighting](#)

Posted on Fri Apr 4th, 2003 at 11:44:33 PM MST

I'm trying to light up a 500 watt Halogen light with my 800 watt (1600 surge) power inverter.

Whenever I try and turn it on it comes on for a second then the inverter shuts off. What the hell?!

[800 watt inverter doesn't light a 500 watt light?! | 2 comments \(2 topical, 0 editorial\)](#)

No Uncommon ([none / 0](#)) ([#1](#))

by [ToddH](#) on Sat Apr 5th, 2003 at 02:51:07 AM MST ([User Info](#))

My wife has had the same trouble as you. It would take turning on & off the inverter a few time to get the TV to work. She is powering a 13" TV (32watts) and we kept returning the inverters until one worked as advertised. It was the fifth one that starts the TV everytime. Different wattages & brands were tried too. My guess is they all come from the same china factory.... My advice is to return em' till' you get a good one.

inexpensive imported inverters ([none / 0](#)) ([#2](#))

by [troy](#) on Sat Apr 5th, 2003 at 09:04:10 AM MST ([User Info](#))

Because the cheapie modified square wave inverters have become a comodity item, competition has become very fierce. So they are cutting corners like quality control and the wattage rating system is "generous" to put it mildly.

So I'd return it and try another, or step up to the really good inverters like Exeltech or trace. Of course, way more expensive, but they will start more than their surge ratings as they are rated conservatively.

Good luck and have fun!

troy

Re: 1.5 hp induction conversion ([none / 0](#)) ([#1](#))  
by zubbly on Fri Jan 2nd, 2004 at 03:50:15 PM MST  
([User Info](#))

Hello again.  
There is one important piece of information that I forgot to include with the posting concerning the multiple connections.

The winding was wound with 1#19 1/2 magnet wire. As you change connections, so does the number of magnet wire conductors to make up the connection. As you increase the number of circuits, the amount of copper handling the amperage also increases. Also, this makes it more versatile to match your battery voltage system. This is the added value of using multiple connections.

For this particular winding, here is how the magnet wire adds up.

- 1. Y-1 #19 1/2
- 2. Y-1 #16 1/2
- 1. D-1 #16 1/2
- 2. D-1 #13 1/2

Hope this makes it easier to understand my use of multiple connections.

[Energy from sound?](#) | 10 comments (10 topical, 0 editorial)

Re: Energy from sound? ([none / 0](#)) (#1)  
 by Rich G on Fri Jan 2nd, 2004 at 07:23:50 AM MST  
[\(User Info\)](#)

The ear is a very sensitive and broad range detector. I believe that the energy of the least sound detectable by the human ear is something like 10 to the minus 12th watts/meter squared. For those who are not comfortable with scientific notation that is .00000000001 watts spread over a one square meter area (if I got the zeros correct). That is, I think the reference level for sound Db comparison. At 100 Db hearing damage is a threat. This level of sound energy is still less than 1 watt/meter squared. You are absolutly right, of course, that sound can be coverted to electrical energy. As you observed, microphones do just that. I suspect that the reason that ambiant sound is not tapped as an energy source is the low energy density. I may have this all wrong. These days, I am not an expert in anything -- just check with my wife! The world is a fun place to explore! Rich

Re: Energy from sound? ([none / 0](#)) ([#1](#))  
by Rich G on Fri Jan 2nd, 2004 at 07:23:50 AM MST  
([User Info](#))

The ear is a very sensitive and broad range detector. I believe that the energy of the least sound detectable by the human ear is something like 10 to the minus 12th watts/meter squared. For those who are not comfortable with scientific notation that is .00000000001 watts spread over a one square meter area (if I got the zeros correct). That is, I think the reference level for sound Db comparison. At 100 Db hearing damage is a threat. This level of sound energy is still less than 1 watt/meter squared. You are absolutly right, of course, that sound can be converted to electrical energy. As you observed, microphones do just that. I suspect that the reason that ambient sound is not tapped as an energy source is the low energy density. I may have this all wrong. These days, I am not an expert in anything -- just check with my wife! The world is a fun place to explore! Rich

hey Rich,  
thanks for the input...  
my father (a V E R Y serious person) once tried explaining Db's... something like...  
for every 1Db increase the noise level increases by a factor of 10  
i also remember somewhere people melt at around 220 Db  
I hear what ur saying about the low energy density of sound...  
These days, appliances are smaller and use less energy.  
I once owned a Radiogramme... a beautiful piece of 1950's furniture that had a record deck and a LW/MW/SW radio built into it, 240v (UK) mains only and soaked up loads of juice.  
Now i have a mobile phone that can store+play 60+mins of MP3 music and recieve FM radio... the phone does the same job on much less power (and can be hooked up to an amp in car or home.) + i can talk to ppl too!  
places like under motorway bridges get very loud, as well as airports...  
sound may be low density energy... tap it and it's free energy for low powered devices :)

Sound does not contain very much power. In order to get power from a speaker you must move it mechanically like you were doing when you were tapping the speaker cone. I never hooked an LED up to a speaker, but I find it hard to believe an LED would light just from sound. Even if you could light the LED with sound, That is not very much power and you will want to run it through a Bridge Rectifier in so you can store the power in a battery. the bridge rectifier will pull the power down by 1.2 volts and you won't have anything left coming out.

I messed around with trying to get power from a speaker

<http://www.fieldlines.com/story/2003/10/11/204029/79>

But I could never figure out how to get enough 1/2 inch motion to generate anything usable.

Well now of course as you all know, that the day will come one day, that we could use sound as energy source. Just look back not very long ago, scientists got themselves killed trying to fly in the machines they built. Others laughed. Now everyone takes flying for a normal thing, noone says if it is possible or not possible. Time is a funny thing ! Mankind will advance in technologies until the world explodes oneday ! !

Happy New Year.

Luubovv.

## [Using a Speaker to make power](#)

By [wooferhound](#), Section [Homebrewed Electricity](#)

Posted on Sat Oct 11th, 2003 at 08:40:29 PM MST

[Magnetism](#)

mechanicly moving a speaker cone to generate power

I have talked about trying to make electricity by mechanically moving the cone on a speaker. After all a speaker is a tight wound coil of large gauge wire moving in a very thin airgap inside of magnets that weigh pounds. The arrangement is very similar to a dual rotor machine with 2 magnets and 1 coil.

So , I hooked it all up tonight, and it works. I used a 12 inch speaker with a 1 1/2 inch Voice Coil and about a 3 pound magnet. I hooked the terminals up through a Bridge Rectifer and then a 4700mfd capacitor, then added a 1000ohm resister across that so the capacitor would'nt top out with the voltage.

I don't have a good way to give motion to the cone so I did it by hand, I think I was able to get 4 cycles a second with a 1/2 inch of cone travel. I measured 4 volts with the 1000ohm load and 250ma short circuit.

With a 1/2 inch travel I'm getting about 1 volt per cycle, and about an amp at 16 cycles. At this point I really don't know a good way to get a 1/2 inch vibration, maybe a fast windmill with an offset rod mounted to the shaft, and the other end of the rod mounted to the Voice Coil ?

Also I would want to cut large holes in the cone to minimize air resistance. I have 15 inch speakers with 8 pound magnets and 4 inch Voice Coils, but these cost over \$120, I'm thinking that cheap 15" speakers off of E-Bay with large Voice coils would work fine.

i like it.. how about using pneumatics? could use a small actuator on the mill and pipe it all down a tube and seal the tube over the front of the speaker to start with. that way you could make it all weatherproof. I would assume you get the same power out as the rating of the speaker. at low impedance. Small spring return acuators run about 30 bucks in the uk but havent looked on ebay. A bike pump would be a start.

still having fun

bob

It's an interesting experiment but I doubt that you will ever generate usable amounts of power.

([User Info](#))

While it will work you are essentially making a low efficiency generator.

Re: Using a Speaker to make power ([none / 0](#)) (#6)  
by wooferhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Mon Oct 13th, 2003  
at 04:48:02 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

Well I'm getting 16 volts at 1 amp while moving it at 16 hertz, or 16 watts

If I quadruple the frequency to 64 hertz would'nt that be 64 volts at 4 amps, or 136 watts? The speaker is capable of taking 300 watts from an amplifier before burning out.

It would need a fast prop to run it at 16 hertz or 960rpm  
or 64 hertz would equal 3840 rpm

. >=- W o o f -=<

Hi Wooferhound-

Intriguing!

How about replacing the cone material with something that can stand some heat, and mounting several of these converted speakers into, say, a metal 10 gallon paint container, then using the whole thing as a muffler for your generator. The exhaust pulses from a single cylinder engine will be in the range of 15 hz or so assuming 3,600 rpm and a 4 cycle motor...

Why not simply build a linear alternator. This way you'll actually make some power. If your still using rotary motion to drive the alternator why convert it to linear. The speaker components would make a cool free piston stirling project though! You could drive it with an air or steam powered linear piston engine. A tiny one would work quite well with speaker components. Have Fun Ed

Re: Using a Speaker to make power ([none / 0](#)) (#7)  
by wooferhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Mon Oct 13th, 2003  
at 04:58:45 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

I think your picture is of a Free Piston Stirling. This looks like it would reach the frequencies that I need. But it requires pressure that I really don't have. Also looks like it would wear out quickly?

About transformers and sound ([none / 0](#)) (#5)  
by Norm on Fri Jan 2nd, 2004 at 09:10:52 AM MST  
([User Info](#))

A transformer has moving parts....same as a guitar string, if something is humming its vibrating and if its vibrating ....whatever is vibrating is a moving part. Norm.

thanks Norm, good input!  
does that mean a transformer could be made much more efficient by stopping bits from moving and not lose energy through vibration?  
does a transformer vibrate as a complete unit or are there internal parts that disipate energy by banging against each other?  
so many questions have i...  
need more good input...

Re: About transformers and sound ([none / 0](#)) (#8)  
by Electric Ed on Fri Jan 2nd, 2004 at 10:01:40 AM MST  
([User Info](#)) <http://www.electric-ed.com>

The sound is created by the core laminations vibrating.  
Transformers are given "sound ratings" by the manufacturers, and quieter models cost more.  
The laminations have to be clamped together more securely.

Electric Ed

Transformers buzz because the magnetic fields interact with the windings and the magnetic relationships between the wires that are next to each other in the winding. So the wires may all be attracting each other at one instant and then all repelling each other at another instant. And of course all of those magnetic forces are interacting with the iron core.

Speaking of sound, check out this cool article:

<http://www.memagazine.org/backissues/march98/features/sound/sound.html>

MacroSonix Corp. (Tim Lucas) has built these oddly shaped vessels to concentrate sound energy to be used as compressors, particle seperators, and combustion [generator] devices. The devices don't "receive" energy from the ambient noise around us; instead, they are driven with a solenoid at about 400 - 500 cycles per second, and although they are only displaced about 100 microns the gas inside is accelerated to generate resonant sound waves that build into enormously powerful compression waves. The resulting compression waves can then be valved for various uses. These guys also ganged up with Los Alamos National Labs to do interesting work with Acoustic Stirlings, apparently lending a hand with a resonance chamber that could be used for liquifying gases particularly natural gas that would normally be tossed while drilling for oil.

Happy New Year Everyone!

I love this website just as much as the day I found it.

-Elliott Bell

Yup!

It's true - they often hold back the best for other markets. Check this one out - it's from where I used to work. I had this thing doing 155 mph at least once a week, not really even breathing hard.

V8, rear wheel drive, all independant suspension - puts a lot of high performance offshore stuff to shame.

[http://www.gmarabia.com/content\\_data/LAAM/SA/en/GBPSA/chevrolet/models/lumina/lumina\\_coupe.htm](http://www.gmarabia.com/content_data/LAAM/SA/en/GBPSA/chevrolet/models/lumina/lumina_coupe.htm)

Oh well one can always hope!

Ted.

**Permanent Magnet  
Motor / Generators**

---

---

**Create electricity from any  
type of rotating tire or wheel!**

**NEW friction drive rollers will solve  
many problems for wind turbine  
designers and open new doors of opportunity for  
others looking for remote and portable electric power  
generation!**

**Can't figure out how to get enough RPM's from your wind turbine to  
power your PMA? Now a 40/1 gear ratio is EASY to achieve!**

**Gears, chains and pulleys all have their own unique problems!  
Noise and the constant need for lubrication are just a few of those  
problems that our new friction drives have eliminated.  
Friction drives are VERY inexpensive and very dependable!!!**

Friction drives use ordinary rubber tires as the main

gearing mechanism. Gear ratios of 40 to 1 are easily achieved using cheap mass produced rubber tires. Many types of rubber tire hubs are also equipped with brakes so over speed protection is very inexpensive and in many cases built right in to the hub! We have used trailer tires with electric brakes, golf carts tires, buggy and carriage rims, motor cycle and even bicycle tires. Don't worry about flats as there are few nails or thorns floating around in the air. Tires can also be urethane filled and then balanced at your local tire shop for only a few dollars. Our roller drives have brought new life to many Darrieus turbine designs and other VAWT's with a horizontally mounted tire drive. Any slow turning turbine design can benefit greatly from roller drives and fast turning wind turbine designs can be turned into **really powerful machines!** With a roller drive system its easy to get your [PMA's](#) spinning at well over 10,000 RPM without very much work or expense. Our rollers have a 7/8" OD and are 3" long. They have a 17mm ID thread that fits right on [all our standard PMA's](#). We recommend using some type of industrial strength thread locking adhesive so they can't come off of the shaft unless you want them to. The best trick is to design your system to keep the roller spinning clockwise (Always tightening).

*Advantage ratios are easy to figure out.*

This 20" tire has about 62.8" of surface length per rotation (20" x 3.14) so with our roller you will get an output ratio of about \*23 to 1 at your [PMA](#) shaft. *Impressive!*

This means if your wind turbine is rotating at a mere 500 RPM your [PMA](#) will be screaming at about 11,500

RPM!!!!!!!!!!!!!!!!!!!!!! That's very useful advantage ratio for a drive mechanism that anyone can pick up at a junk yard for only a few dollars!

Roller and tire friction drives are also very silent unlike gears and chains plus they never require any type of lubrication or maintenance. We figure that a tubeless tire designed to handle 500 lbs. for 50,000 miles ought to last about 30 years+ under the minute amount of stress that a roller friction drive demands and that's the best news wind turbine designers have heard in a long time!

**Tech Notes:** Remember that a drive roller **MUST** have spacers on the shaft between the bearing and the roller to keep the rotor shaft from moving back and forth within the PMA housing!!!!!!!!!! Drive roller includes a 15/16" hex nut head (not shown) that needs to be driven on the PMA shaft with an impact gun.

**Efficiency:** Tire pressure is critical to efficiency. A mushy tire causes lots of drag. Pump it up to maximum pressure and your power transfer efficiency will be 99% or better once the PMA is rev'd up. Friction drives are best suited for use on type [12 series](#) high revving PMA's

### **Design notes:**

If you design your mounting arm to pivot closely to the "center of rotation" the roller will get tighter as the RPM's go up and it will loosen as they go down providing "living" roller pressure. This is important as you would not want to have too much roller pressure dragging the turbine down at low start up speeds. As the tire spins faster and faster the PMA starts to create amperage causing the roller to "drag" thus pulling downward against tire harder and harder making more solid roller contact at precisely the time it is needed **most** and all because of the ingenious way this simple pivot design reacts to the rotation of the tire. The closer to the center of rotation you place your arm the more pull down or contact power this design will transmit to the roller. Be careful because if you design your pivot arm to be overly close to the center of rotation you can create so much pull down pressure that things start to get inefficient and also tire pressure can become overly critical. As a general rule a friction drive must be used with a heavily inflated tire so that the contact interface is extremely hard! A soft or mushy interface can be very energy inefficient.

The illustration below shows the arm placed in the "sweet spot" which is about 50% of the way between the center of rotation and the outside of the tire itself. This is what you should aim for and is exactly how we are going to be building our new Blue-Max Turbines when they are reintroduced in July of 2004. Testing is going VERY good!

PMA Selection Note: Drive rollers work best on [12's Series](#) PMA's. [SC series](#) PMA's can slip on the tire since they are so powerful and can create excessive drag. SC's series can be made to work with roller drives but only in applications with slow speeds and low amp loads.

**Part number #DR1 Steel Drive roller only \$49.95 plus \$6.50 S&H fee**

Made of hardened steel with a rough knurled finish for extra grabbing power on rubber tires.

**Part number #RDR1 Rubber Drive roller only \$89.95 plus \$6.50 S&H fee**

Tough urethane rubber coated for traction on steel wheels and rims. (1.5" OD)

\*More math ( $.875 \times 3.14 = 2.7475$  <rounded> 2.75 then  $62.8 \div 2.75 = 22.8$  RPM <rounded> 23)

Another way is to NOT use any gearing at all. Just use a big wheel with lots of small neodymium magnets around the outside edge. Make a modular cluster of stator windings having an even number of stators to match the magnet spacing on the wheel. Wire them in series. Make several of these stator clusters and place them around the wheel at ODD INTERVALS so that the wheel can't cog. Each stator cluster gets a single rectifier and an electrolytic capacitor. Wire the capacitors together in series, taking power from the top and bottom capacitors in the chain. Simply put, the larger the diameter of the wheel, the faster the velocity of the magnets on the rim. Voltage is determined by (flux strength X flux velocity X number of turns), roughly. Since wire resistance reduces available power, using fewer turns, stronger magnets and faster velocities is the preferred method.

 ([User Info](#))

Another way is to NOT use any gearing at all. Just use a big wheel with lots of small neodymium magnets around the outside edge. Make a modular cluster of stator windings having an even number of stators to match the magnet spacing on the wheel. Wire them in series. Make several of these stator clusters and place them around the wheel at ODD INTERVALS so that the wheel can't cog. Each stator cluster gets a single rectifier and an electrolytic capacitor. Wire the capacitors together in series, taking power from the top and bottom capacitors in the chain. Simply put, the larger the diameter of the wheel, the faster the velocity of the magnets on the rim. Voltage is determined by (flux strength X flux velocity X number of turns), roughly. Since wire resistance reduces available power, using fewer turns, stronger magnets and faster velocities is the preferred method.

### [Bio Diesel recipe](#)

By [Homebrewed12vdc](#), Section [Remote Living](#)

Posted on Thu Oct 9th, 2003 at 10:30:54 AM MST

[Bio-Fuels](#)

Easy way to amke Bio diesal

I just wanted to post this becuae I tried this recipe and found it works good for Bio Diesal.

First off all screnn out 40 gallons of WVO

second pump it into a 55 gallon drum

third add 4 gallons of kerosene to it

fourth using a subermisibile bidge pump let it stir for 24 hours

fifth let stand for 48 hours

sixth pump out from the top down to the last 4 inches in the barrel into a clean barrel

Now you have a fuel that well run in a diesel engine for the small amount of about 20 cents per gallon, I have been doing this for almost a year and have found it works good, and have had only one problem with it, I found that at first I went through 4 fuel filters before I didnt need to change them anymore. Hope this helps somebody out.

Is this bio-diesel in the sense we know know and love (ie WVO + lye +  
methanol) or something different? Does the stuff stay mixed?

Martin.

Re: Bio Diesel recipe ([none / 0](#)) (#5)  
by Homebrewed12vdc on Thu Oct 9th, 2003 at 12:51:29 PM MST  
([User Info](#))

This recipe does not require the lie and methanol, just the kerosene,  
and yes it does stayed mixed if you do it the way I do.

Sounds good, but I have two questions. Will the Bio-Diesel stay stable (no more separation) for long term storage, and is the fallout on the bottom glycerin, the same as with recipes using heat and chemicals?

What I find in the bottom of the barrel isnt really glycerin, but its a heavy dirty fuel that is only good for starting the woodstove or a bomb fire. As far as the seperation goes, I dont know, I use a batch up in about 4 weeks time and it seems to hold together fine. I well set soem aside next batch and let it sit for a few months and let people know what I find.

Well wildbill, I would think so sence its a lot cleaner than #2 fuel oil that is used in a oil furnance, I would say try it, worst that could happen is you plug a nozzle up.

Posted on Sun Aug 31st, 2003 at 07:01:35 PM MST  
[More on Woodgas generation](#)

[Bio-Fuels](#)

I was going throught all the links on wood gas of a few days back and came across this link:

[http://www.webpal.org/webpal/b\\_recovery/3\\_alternate\\_energy/woodgas/fema\\_wood\\_gas\\_generator.pdf](http://www.webpal.org/webpal/b_recovery/3_alternate_energy/woodgas/fema_wood_gas_generator.pdf)

It seems FEMA has prototyped and has plans for a woodgas generator at the proper price - FREE.

Ron

Exactly.

This is the same plan I already pointed out.

One of my friends made a decision to try building one accoring to these plans. (Not in Finland.)

We hope to see some results later.

## [Energy from wood](#)

By [hvirtane](#), Section [Homebrewed Electricity](#)

Posted on Thu Aug 28th, 2003 at 04:05:56 AM MST

[Bio-Fuels](#)

You can run your engine by chunks of wood

---

- 1)  
You can run your car with wood.
- 2)  
You can run your car with charcoal.
- 3)  
You can generate electricity from wood by running your engine generator set with charcoal or with wood.
- 4)  
It is not difficult to make yourself a wood gasifier for a normal combustion engine.

---

The technology was quite well developed during the second world war in Europe and in Australia.

Because there wasn't much shortage of oil in America, that technology is not very well known there.

To make a wood gasifier to make wood gas (producer gas) for the engine is maybe an easier way to make electricity from wood than by steam engines.

It is as well quite effective. According to

- [http://www.colostate.edu/programs/cowood/Useful\\_links/Wood-gasifiers.htm](http://www.colostate.edu/programs/cowood/Useful_links/Wood-gasifiers.htm)
- [More on Bio-Fuels](#)
- [Also by hvirtane](#)

my old handbook of technology  
(printed 1946 in Finland)  
even 90% of the energy of wood  
can be converted into  
energy in burning gases,  
hydrogen, carbon monoxide and methanol.

During the time of the second world war  
more than 80% of all the traffic  
on Sweden's and Finland's roads  
was powered by wood gasifier  
trucks and cars.  
In Denmark the usage was even higher.

There were small workshops  
powered by wood  
gasifier engines, too.

Many of the wood gasifiers at that time  
were home made in Finland.  
There were as well many  
commercial producers of gasifiers.

At present there are about  
20 'wood gas' cars  
on the roads of Finland.

---

For a very general description  
of wood gasification chemistry,  
please see:

[http://www.wikipedia.org/wiki/Wood\\_gas](http://www.wikipedia.org/wiki/Wood_gas)

Recent ways how to do it  
in practice can be found here.  
There are as well links  
for very good descriptions of the theory:

[http://www.colostate.edu/programs/cowood/Useful\\_links/Wood-gasifiers.htm](http://www.colostate.edu/programs/cowood/Useful_links/Wood-gasifiers.htm)

---

Most otto engines work well  
without any modifications  
with producer gas.

To make them working effectively  
it is good to rise the combustion ratio a lot.  
Without that modification  
about 40% of the power is lost

compared to gasoline power.

Diesel engines work well with wood gas, too.  
But because the gas will not ignite  
under the pressure inside cylinders,  
it is necessary to inject  
a little diesel oil (biodiesel), too.

Hannu;

Nice pair of links to books you can buy.

Here is one they offer on wondermagnets.com:

<http://www.wondermagnets.com/> Item#: 1106

I would have included the direct link but it is so long it ruins the format of the forum. But heres a picture of the cover:

Producer Gas for Motor Vehicles by "John and Martin Cash. I am currently rereading it and it is quite interesting with lots of good information for the \$13 price tag.

Books are all well and good but take money to buy and you have to wait for them to arrive.

I much prefer the online resources for instant information. Here are a couple free links to enough info to build one from scratch without any cost for books or waiting for delivery of said books.

<http://www.fortunecity.com/greenfield/bp/16/woodfire3.htm>

<http://members.tripod.com/~highforest/woodgas/woodfired.html>

This is an area of interest to me because we have a fairly large tract of hardwood timber resources and I have an old rustbucket 4 cylinder pickup with a good strong motor I could convert to woodgas for experimental purposes to run a large induction motor for AC and heat from the coolant, etc.

Cheers.

TomW

([User Info](#))

There's been one thing that has always bothered me about gas producers. I wonder if anyone can help.

It seems to me that once the gas has been seperated from the wood it has lots of other stuff in it that you wouldn't want to put into an IC engine. I assume that there must be some sort of filtering needed and passing it through a water bubbler would do both filtering and cooling. My question/concern is that this water is going to quickly turn black with wood tar and who-knows-what-else. What do you do with the stuff - is it hazardous?

I'm guessing that a portion of it is creosote and that has some use but I can see you quickly getting overrun with the stuff unless you are in the fence painting business.

Martin.

[ [Parent](#) ]

Re: Energy from wood ([none / 0](#)) ([#4](#))  
by TomW on Thu Aug 28th, 2003 at 06:09:53 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Martin;

From what I have read you can feed the tar and creosote back into the gasifier and extract more gas from it. Plus it seems that if it is operating properly the gunk will be minimal.

Much like the creosote I get from my chimney when I clean it I simply feed it back into a hot fire in the wood burner and it burns up. Of course that stuff from the chimney cleaning is usually a dry residue not the oily tarry stuff you may get from a gasifier wet filter.

I have no experience with burning woodgas in an engine but actually create it often when making charcoal for my melting furnace setup.

I can tell you from experience the stuff burns quite well and more often than not once I start getting gas off a batch of wood I can remove the external heat source and the charcoal making becomes self sustaining as the flammable gas cooks off. It certainly isn't rocket science.

Cheers.

TomW

Re: Energy from wood ([none / 0](#)) (#5)  
by hvirtane on Thu Aug 28th, 2003 at 06:38:37 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

The most commented problem in the earlier days of wood gas engines was that there was tar in the gas. That created problems inside engines. Many kinds of filtering of course have been developed during 100 years of the development of wood gas engines. Filtering with water is one obvious solution. Some systems use centrifugal purifiers. One good solution is to use high temperatures (> 1000 C) to burn the tar in the process, when producing gas.

---

The idea, which I have, following many others, recommended is to use pure charcoal for the engine. Filtering charcoal gas is easy.

When making pure charcoal many really good stuff including tar and kinds of 'pyro-oils' (, which themselves as well can be used to run diesel engines!) can be manufactured from the process.

---

Tar was earlier one really valuable product of Finland. Most of the early wooden ships, which British empire used, to occupy half of the world, were coated by tar from the forests of Finland, for example. Tar was valued high by older time Finns for health care purposes, too. But remembering what the British colonialists did with tar, it has probably done more bad than good.

At present European Union is planning to get tar banned to be used for anything. Many people here use tar on the bottom of their cars to prevent rusting, put on their wooden boats to prevent them to rot. (I just put tar on my Saab 96 from 1978 on its bottom plate, too.)

More online and free ([none / 0](#)) ([#3](#))  
by hvirtane on Thu Aug 28th, 2003 at 06:04:03 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I forgot to tell that this American  
really good booklet  
for practical construction  
is available online and free:

<http://www.gengas.nu/byggbes/index.shtml>

There is as well a .pdf version of the same available free in the Net. The link for the .pdf version  
is available from my second link in the original post.

I preferred to give only a few general links, because seeing those will lead to see that there  
are a lot of information available about  
those things... and then you get many other  
ideas, too.

- Hannu

Re: More online and free ([none / 0](#)) ([#6](#))  
by JW on Thu Aug 28th, 2003 at 07:58:05 AM MST  
([User Info](#))

I was hoping this sort of discussion would come up. I have speculated that this might be  
possible, I'm glad to see so much input. Presently I use corn burners for my AE  
experiments. I do use a gasification principle in the corn burners that I use. All I can say  
is if this mechanism loses its flame, then its smoke city. And trust me it will fill the whole  
yard with thick pure white smoke. I have not seen this in recent years of experimenting,  
but thinking about the sheer volume of smoke that can be achieved, I wonder about  
possibly running an Otto engine this way. Not sure about the tar content in corn smoke,  
but it must have a lower tar content than wood. I'm going to buy that book "Producer Gas  
for Motor Vehicles" Thanks for bringing that up TomW.

by hvirtane on Thu Aug 28th, 2003 at 11:21:03 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Because lots of information about wood gas is available in Sweden and in Finland in native languages in Net, and links in those languages are not easy to find for people, who don't know the languages, I did some more search in the Net:  
(By the way, wood gas is 'puukaasu' in Finnish and the gasifier is commonly called 'häkäpönttö')

any tried a steam engine?

hi there

in winter i get a bit short of power. the creek's dried up, the wind dont blow and the sun is pretty low in the sky. i could buy a stack more solar panels, but i reckon that a steam engine could be the go. powered by a renewable wood burner. i've found a few references to flash steaming on this board, but has anyone tried a good old fashioned steam engine, up to about 1kw in size? can you get them or do you have to make one?

I always wanted to try a steam engine. Years ago, I started gathering up parts, like 6" sleeves out of a big diesel engine, to build a steam engine.

The engine is the easy part. The boiler is the difficult part, unles you stick with "low" pressure.

Now that would be real fun,  
Electric Ed

Re: steam engine ([none / 0](#)) (#4)  
by hvirtane on Wed Aug 27th, 2003 at 02:41:26 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Hi,

I think that the idea is a good one.

The difficult part is the boiler.

My friends here have made one years ago.  
They are not using it, because it consumes  
too much wood About 2 kW machine.  
It is in working condition and they would  
like to sell it even...  
But maybe too costly to be sent to your place.

I asked them for the drawings  
of the whole machine and especially  
of the boiler to be  
sent to India,  
but they refused telling  
that it is too dangerous  
to build such things...  
but they made it themselves anyway...

You can find drawings here:

<http://www.rainbowtradingpost.co.uk/guides1.html>

There are other good drawings available there.

Re: steam engine ([none / 0](#)) (#5)  
by JW on Wed Aug 27th, 2003 at 08:06:40 AM MST  
([User Info](#))

I kind of agree with what was told to Hannu. Most steam engines are quite dangerous. Usually when an individual whole heartedly takes up the task of building a steam engine, they are aware that there taking there life into there own hands. Unfortunately some do get hurt, usually small burns etc. I think unless you are willing to put absolut full commitment into it, you should not do it.

Various new or modern evolved flash steam engines are exploring safer operation. This is mainly thru the removal of a large capacity live steam boiler. But in most cases high pressures are developed in a small low capacity tube arrangement. One way that these very recent designs deal with getting away from the large boiler, is the use of block heating. so that the engine block itself can become the boiler. I am currently involved in one of these projects. When we started this it was innitally just for the challenge. However over time these systems are proving to be way safer than predicted. So at this point things look good, but who knows where it will lead.

At this time, all things considered, Bio Diesel looks like the best bet. You can run any diesel engine from bio diesel, that would include a small 12 or 20kw diesel generator. This is one user freindly method of getting power without standard fossil fuels. Also If you really wanted to use wood you could try gasification, I belive some good results have been obtained using turbines, but unsure about running piston engines this way.

I believe in the future thermo-generators will fill this need. They are solid state devices that have no moving parts, or pressurized parts. And make DC current directly from heat. This will be the best solution for the end user. perhaps in our lifetime someone will make a significant break thru.

-JW

Re: steam engine ([none / 0](#)) ([#6](#))  
by troy on Wed Aug 27th, 2003 at 08:48:24 AM MST  
([User Info](#))

I have modest experience with hobby steam, and can tell you with certainty that a conventional boiler must be supervised at all times and built properly, or it can kill you. One gallon of water (not a big boiler at all) turned into superheated steam, contains approximately the same destructive force as a stick of dynamite.

The newer, higher tech tube boilers are indeed safer, but require much more sophisticated controls to operate. A conventional steam plant will keep a guy pretty much occupied all the time to keep it running and properly supervised. It is not by accident that running a steam engine locomotive required both an engineer and a fireman full time.

Tiny power has nice products at reasonable prices, including machines big enough to run a boat.

Best regards,

troy

by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Aug 27th, 2003 at 09:29:46 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've been exploring the possibilities of different engines ( gas, diesel, steam, stirling etc.) and reducing the amount of parts to achieve higher efficiencies. One of course was the possibility of steam. Unfortunately, like all has stated... steam is dangerous unless constantly monitored. Also, it is very inefficient because of the way we have to transfere one fuel into another. The typical steam engine is only around 15% efficient.

I have a tendency to design something then spend a mountain of hours trying to simplify its design. Below is a diagram of a reciprocating steam/air engine with only one moving part...

The cylinder is ported to match the ports on the piston. The piston doubles as the valve. As shown the piston is to the left which opens the port to the power chamber and the right side piston is ported to the exhaust. One side drops pressure the other side inserts pressure driving the piston to the other side to restart the cycle. This is the equivalent of a 2 cylinder steam engine.

This will drive a linear alternator with more efficiency than a standard crank driven unit. Since all the power going into the piston would be converted to torque you reap the benefits without the losses. A small model of this with a 1" piston inside a honed pipe goes like crazy. I don't know what the cycles ( or rpm equivalent) the one built had no output shafts for driving anything simply the reciprocating piston... a model to prove it would work basically.

Now, if only I could get a grip to simplify the diesel model to this extent... still working on that one...

Have Fun  
Ed

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

This engine is great in my opinion.

Do you have any idea how effective it is with compressed air?

Did you try it with steam?

Did you try with any coil outside?

- Hannu

[ [Parent](#) ]

Re: steam engine ([none / 0](#)) (#11)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Fri Aug 29th,  
2003 at 10:11:30 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

The model was driven by 40psi of compressed air. I haven't built a model with an output shaft as yet. To build one with magnets on the piston would take some special materials for the cylinder so the output shaft would be a better way to go for a linear alternator. I'm not convinced that the "air/steam" motor of this type is actually very efficient. Obviously would be much more efficient than a crank driven unit. It would provide 2x the torque directly to the alternator as opposed to running it through a crank and reducing the overall torque. I'm not sure I will build a practical working model of this, I'm concentrating on a diesel version of the same thing which will be much more efficient.

Trying to find the least amount of conversions from one fuel to another. Sort of like a gas can with a plug outlet... if only it were that easy...

Have Fun  
Ed

"To build one with magnets on the piston would take some special materials for the cylinder so the output shaft would be a better way to go for a linear alternator."

---

I think that you could just put the magnet inside your piston made of teflon cylinder? Running inside another teflon cylinder?

Or maybe you could just run two magnets glued on teflon parts S-N-TEFLON-S-N and the teflon parts a bit smaller so that only the nickel coated magnet parts would touch a teflon cylinder?

And the coil outside around it?

---

"I'm not convinced that the "air/steam" motor of this type is actually very efficient."

---

Probably not very efficient, but maybe enough...  
If using free solar energy...

Let's say, we would make the air pressure somehow with solar energy...

A bimetal rod bending because made hot by a solar concentrating mirror pushing a big piston making air pressure in a big cylinder... ?

The bimetal 'string' bouncing back, when some cold water was dropped on it... and at the same time

a shadowing sheet comes over the bimetal...?

Just rambling with ideas.

- Hannu

Aug 29th, 2003 at 06:51:11 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Just to simplify it a bit, you could build it with 2 displacer chambers each feeding the opposite end. This would turn it into a stirling engine which could be run directly from solar. This would increase the complexity a bit and the piston valving would be a bit different as well as an offset arm to allow a slight timing offset. Easy enough to do but not as powerful.

Another possibility would be to make a large low delta stirling with part of the engine burried in the ground and a top plate exposed to the sun. A styrofoam displacer driving a large diaphragm piston. Depending on the size you could easily get 100-200 watts from a simple motor design. This would also run backwards at night drawing the heat from the ground and cool from the night air.

Tons of ideas, just low on time and funding for all of them...

Have Fun

Re: steam engine ([none / 0](#)) (#14)  
by Gary on Sun Sep 7th, 2003 at 11:51:35 AM MST  
([User Info](#))

Nice.

If you compounded this engine so that the outlet went to the inlets of another that handled the lesser pressure it would become efficient. Since the design is cheap especially if the piston is a light ceramic magnet( housed in plastic), the pipe plastic and a coil wrapped on the outside, compounding isnt expensive.

Re: steam engine => gasification ([none / 0](#)) (#9)  
by hvirtane on Wed Aug 27th, 2003 at 04:07:40 PM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

It is not difficult to make a wood gasifier for a normal combustion engine.

The technology was quite well developed during the second world war in Europe and in Australia. Because there wasn't much shortage of oil in America, that technology is not very well known there.

To make a wood gasifier to make gas ('producer gas') for the engine is maybe an easier way to make electricity from wood than by steam engines.

It is as well quite effective. According to my old handbook of technology (printed 1946 in Finland) even 90% of the energy of wood can be converted into burning gases, hydrogen, carbon monoxide and methanol.

During the time of the second world war about 80% of all the traffic on Sweden's and Finland's roads was powered by wood gasifier trucks and cars.

There were small workshops powered by wood gasifier engines, too.

Many of the wood gasifiers at that time were home made in Finland. There were as well about 20 commercial producers of gasifiers.

At present there are about 20 'wood gas' cars on the roads of Finland.

For a general description of wood gasification, please see:

[http://www.wikipedia.org/wiki/Wood\\_gas](http://www.wikipedia.org/wiki/Wood_gas)

And the American quite modern way to do it can be found here:

[http://www.colostate.edu/programs/cowood/Useful\\_links/Wood-gasifiers.htm](http://www.colostate.edu/programs/cowood/Useful_links/Wood-gasifiers.htm)

Most otto engines work well without any modifications with 'producer gas'. To make them working effectively it is good to rise the combustion ratio a lot. Without that modification about 40% of the power is lost

compared to gasoline power.  
Diesel engines work well with 'wood gas', too.  
But because the gas will not ignite  
under the pressure inside cylinders,  
it is necessary to inject  
a little diesel oil (biodiesel), too.

- Hannu

## [Modular Methane System](#)

By [Arletta](#), Section [Homebrewed Electricity](#)

Posted on Mon Aug 11th, 2003 at 10:14:31 PM MST

[Bio-Fuels](#)

While I'm waiting for my alternator, let's discuss gas...

Hi all, have any of you read George Adkisson's book "Methane for the Masses"? He has a modular methane system (load it and forget it, he says) made of 55 gallon drums, assorted tubing, connectors, etc, and a 30 gallon plastic garbage can suspended in a drum of water for the gas trap. A nifty little system of counterweights automatically turns on a compressor when the trap is full. Unlike every other methane system I've ever read about, there is no energy used for heating because the drums are painted black and being so small the sun keeps them sufficiently toasty. It apparently works well enough that his wife cooks with the methane.

This is what I eventually want to build and run on my future homestead and the main reason for the wind turbine...to charge batteries to run a DC air compressor to move the gas from the trap into pressure tanks. I realize it won't reach propane pressures but a third of a tank of free, independently produced gas is better than a whole tank of propane at \$2.50 a gallon, in my opinion. Especially since there will be numerous chickens and several bovines producing the necessary raw material.

Anyway, my problem is figuring out how to get the DC air compressor to suck the gas from the gas trap- all the DC compressors I've seen have intakes on the sides and top, not simple intake hoses like AC compressors. I speak of DC because I'm too cheap and lazy to buy an inverter just for operating the thing for several hours once a week or so. Adkisson suggests building an airtight bladder around the compressor, but that would mean operating electronic equipment in an atmosphere which one can only greatly hope and pray is too oxygen deprived to combust. I view this with minimal enthusiasm.

Any other suggestions? Discussions of/improvements on Adkisson's system? Share your thoughts, especially if you've read the book and tried the plan.

Also, why is it that DC compressors are usually rated to 275 or 300 psi and AC compressors have much lower psi ratings, like 70 to 100?

Thanks.

Arletta

Hello,

I've seen writings you pointed to.

I used to think that biogas is an interesting possibility.

I've been working with some people, who have done hundreds of small biogas plants in Nepal.

Recently I just sent a description of an even simpler biogas plant than made of drums to a friend.

It is basically a polyethene film tube. About 5 m long 1 m diameter, 0.2 mm - 0.4 mm gauge.

You close both ends, put there about 1 m long 20 cm diameter plastic tubes for inlet and outlet. Fix a small plastic tube in the middle for gas. Make a good hole on the ground to keep it without holes. Keep the inlet about 5 cm higher than the outlet. The stuff inside flows slowly out from the outlet. If you add it every day a suitable amount, it produces good amounts of gas for cooking even running a tiny engine.

Recently had a discussion with one of my friends here involved in RE business. He said that in his opinion small biogas tanks leaking there and there among a billion Indians, among a billion Chinese, among other billions in other countries would provide a problem.

He said that in the nature naturally created methane dissolves in the lower atmosphere, because amounts in one place are small.

But he said that if we have got a leaking biogas plant that would make such methane 'bubbles', which wouldn't dissolve in the lower atmosphere, but would go far up, where they would stay for a long, long time. Much worse than carbon dioxide he says.

What do the others think?

- Hannu

Re: Modular Methane System ([none / 0](#)) ([#2](#))  
by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Mon Aug 11th,  
2003 at 11:30:38 PM MST  
([User Info](#))

AC compressors are designed to power air tools at reasonable pressure and useable volume, where as the little DC powered compressors are designed to air up tires. It's not possible to pull enough amperage from a cigarette lighter to produce high volumes of compressed air, but high pressure is quite easy even with a small power source. The 275 and 300 psi ratings are touted for the advertisement value, they sound impressive. I'm sure they actually do produce their stated psi, but at very little volume, so it will take a while to fill a tire and be impossible to run any air tools. Most tires are rated at 28-35 psi, with a few going to 65 or 70, and none to 300. You might make your own DC air compressor using an air conditioning compressor off of a car and a large DC motor. If you go this route, use a York compressor. They are piston compressors(as opposed to the more common vane types)

that have a crank case full of oil and do not require oil in the gas they are pumping to operate. However, for your application, one of the little DC compressors sounds fine, as it will draw far less power (ten to twenty amps, while the 3.5 hp motor needed to run the York compressor will draw about 218 amps @ 12 volts), albeit over a longer period of time. 300 psi would be better (and is close to what propane is stored at, I think) for methane storage than 150 psi (Which is what my home shop compressor max's at, though the York compressor will put out 300 psi no problem), and you don't need high volume because you won't be pumping much volume. Whatever you choose, I wish you luck.

Demetri

This might be off the subject but how do you get the sulfurous gases out of the methane. Apart from the smell of them, they are poisonous. Cooking outside may be OK for India etc but I am assuming that you would want to cook inside. Is there some kind of filter you could/should use.

Regarding your pumping issues, I heard of a man that did the gas thing. He stored the gas in old truck tires. When he was ready to use one, he would put a heavy stone on it and get instant presure.

Martin.

sulfur removal ([none / 0](#)) (#5)  
by TomW on Tue Aug 12th, 2003 at 08:30:55 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

wolfie1;

Another area I am no expert in but have read some on it years ago.

I seem to recall that they suggested bubbling it through water which dissolved the sulfur out of the gas.

That info is probably from that 70s era Mother Earth News string of articles.

I actually built a 30 gallon batch digester that let the gas out through a layer of water into an inverted barrel. The stuff worked OK for cooking and we used it inside with a standard kitchen range and I never noticed a sulfur smell or ill effects. We had to adjust the weights on the barrel when we used the gas but that was trivial.

Of course this is all from 30 years back so i may be mistaken. We quit doing it for some reason I don't recall exactly but probably related to a transition from unemployed with lots of time to employed with no time.

Cheers.

TomW

Re: Modular Methane System ([none / 0](#)) (#6)  
by jubalearly on Tue Aug 12th, 2003 at 12:47:32 PM MST  
([User Info](#))

Methane is essentially the same as natural gas as far as burning it in appliances. IIRC, the normal regulated pressure is 11 oz. rather than the 5lbs. or so used for propane appliances. There is a reason that they don't normally try to store compressed natural gas. It must be more trouble than it is worth for domestic use.

Remember, propane turns to a low volume liquid at reasonable pressures at room temperature. Methane is only liquid under very high pressures or very cold. There's no reason you can't pressurize it, it's just expensive to store in the normal gaseous state. If your generation matches your use fairly closely, then you can do this economically. Most people can't produce enough to make it worthwhile, but it may work out for your situation. Good luck, HTH, Russ

PS, I've also considered using it but I think I'm going to have to buy propane instead.....

by Arletta on Tue Aug 12th, 2003 at 05:37:05 PM MST  
([User Info](#))

What an interesting discussion...I was impressed by Adkisson's methane system because it's both small scale and scavenged. Also the passive solar heating thing- keeping the stew at gas production temps seems to be the achilles heel of most systems.

I checked my old issues of TMEN...they had a huge tank designed by Ram Bux Singh but apparently their welder didn't make it sufficiently air tight and the whole project died a quiet death. They were going to heat it either with warm waste water (say that five times fast) or a methane gas ring fed directly from the collection tank.

There's also an article about Harold Bates and his "Chicken Powered Car" in issue #10. He actually compressed his methane into liquid form (1,100 psi- good grief) and used it for his vehicle. TMEN sure was a great magazine back then... Another interesting thing; one TMEN article says that a nitrogen/carbon ratio of 30/70 (or something like that)is ideal, the other says just the opposite, and Adkisson doesn't use any plant material at all in his drums, just cow manure and water. Also the recommended optimum temperature range varies from 50-110 degrees F. So apparently methane has a pretty large margin of sufficient operation.

Drawing the gas directly from the collection drum to the stove or whatever would be ideal, but since I live in the frozen north I have a limited solar season and I'll have to store it in tanks for the winter. Why do I get the idea that gas won't store well at low pressure? Leaks? Or does it separate or something like petrol does?

Hannu, seems to me that the minimal leakage from worldwide methane systems wouldn't be more significant than the current natural evaporation of methane from barnyards (especially industrial size ones), compost piles, sewers, etc. where the material is just left lying around. If methane became a mainstream fuel, individuals and industries would be cleaning that stuff up as fast as it was produced. So I bet it would balance out. Besides, just imagine what the atmosphere must have been like when mighty herds of dinosaurs roamed the earth. And people complain about cows... :)

Thanks for all the compressor info. I think 100 lbs psi will be sufficient. Nothing I've read about methane so far has mentioned sulfur fumes...but isn't that the added "rotten egg smell" that propane has so we can smell leaks?

Well, the weather is crummy outside so I'm going to go find a chocolate chip cookie and read my book about tripods from outerspace who brainwash everybody and then take over the world. Have a great day folks.

Re: Modular Methane System ([none / 0](#)) ([#11](#))  
by troy on Tue Aug 12th, 2003 at 06:39:16 PM MST  
([User Info](#))

The methane doesn't really care about the temperature, but the bacteria and other microscopic wildlife that cause the fermentation of the cow poo which causes the production of the methane gas, ARE very sensitive to temperature. They like it at about the same temperature as the inside of a cow, so 100 is nice and chummy. They'll work at 50, but much slower, at 32 they've quit entirely.

Best regards,

troy

one quite interesting site

---

Started to look for 'flash steam engines' and found one quite interesting site:

<http://www.flashsteam.com/>

What do you think about the concept?

Anybody tried anything similar?

Instantly came to my mind that why not using instead of a four cycle engine a simple steam turbine and a solar parabolic mirror to make flash steam in the front of that turbine...

I also found it interesting in the article that he's using corn as fuel...not ethanol made from corn. That's great, no reprocessing just burn it. That could work good for a Stirling engine as well.

The idea of using flash steam in a turbine is a good idea since it would open up the possibility of using simpler valving and perhaps even utilize a batch process where you would heat a small reservoir of water (maybe a 50ml shot at a time); a temp senser could then pop a solenoid open to the turbine for a short burst and generate electricity. Then reload with condensate and start over. The vessel and tubing would have to handle serious pressures. Not something to taken lightly.

Here's an interesting aside: <http://www.blastwavejet.com/rocketcar.htm>

"Hot water rocket engine" that used a 2 foot metal ball filled with water, heated, then crack the valve...whoooosh!

E-man

tiny experiments ([4.00 / 1](#)) ([#34](#))  
by hvirtane on Wed Jul 23rd, 2003 at 08:37:44 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I just made the first experiments with the flash steam (solar) turbine.

I got from a friend a tiny tin toy turbine.

I connected that with a coffeemaker, where I extended the tube where the hot water and steam comes out, with a plastic pipe, which goes into the inlet tube of the turbine.

It works well.  
There is very little power, of course, because the turbine is made with the vanes of flat metal sheets.  
About 5 cm in diameter.  
But it goes fast.

I will later send pictures of this experiment when I get my film from a lab.

Basically the coffee maker works exactly with the principle as described earlier.

I think that Andrew's suggestions

are just right.

As the flash tube, a metal tube works  
and we need no pressure to get water in.

There is a small very hot chamber and  
a ball valve letting  
the cool water to come in to the hot tube.  
The other end of the hot tube is open.

That system of the coffee maker  
of course works with electric heating  
for the hot chamber.

-----  
But you can use any heat of course.  
Solar heat, too.  
-----

If you will try to duplicate the experiment you  
might have to modify the valve, which lets  
the water in to the hot tube.  
Mine was just suitable  
broken so that it lets the water in as small droplets,  
when the water is quite finishing.  
Or maybe the extra pressure from the extended  
tube made the valve leaking.

Next I have to ask somebody to make for me  
a little bit bigger turbine,  
which I could connect to a bicycle dynamo.

I will maybe visit a workshop  
to ask them about the prices to make a small  
crossflow turbine.  
Or a Pelton wheel as suggested by Andrew.

I've got one solar concentrating mirror  
of 80 cm in diameter,  
made of a satellite antenna.  
Glued a kind of chromium tape on it.

I've once tried to run a toy piston steam engine  
(with a normal boiler) with that mirror.  
It works well.

Of course this kind of solar turbine is quite  
inefficient, however good technology  
we will use for the turbine wheel,  
but that is not necessarily  
a problem. Solar energy is practically unlimited.

The main thing is to make the system cheap and possible to be built with really low level technology so that any blacksmith in developing countries can make it.

The clockwork for moving solar mirror is maybe the trickiest part of the project, but Scheffler lens people have already shown how to make a clockwork simple using mainly bicycle parts.  
(Please see the link provided above.)

([User Info](#))

I'm very interested to see your pictures. I hope you haven't given up on this idea.

One concern I have is to the cost of the turbine and the safety of the high pressure connection between the boiler and the turbine.

Have you considered using an existing motorcycle engine with the intake valve blocked, a standard fuel injector in the sparkplug hole to feed water rather than fuel, and the exhaust valve modified to stay open until top dead center (to avoid pressure during injection). If you apply heat to the head (the fins make that easy) then you should be able to get a nice burst of steam inside the cylinder (designed for high pressure) on each water injection.

That should be easy to try. Just open the head and snap off the intake valve stem with a hammer or grind it down, then adjust the timing so the exhaust valve closes much later and grind off part of the exhaust cam so that it opens at the same time. Bodge some way of inserting the fuel injector into the spark plug hole and wire it to fire at TDC.

I had a similar design drawn up.

It was a simple engine that on the top of the piston, was a little thing that would poke a ball valve on top of the cylinder head. The boiler was simple, I tank of water that would have a one-way valve going in for air inlet so no vacuum was drawn, a tube leading from the bottom of tank with a one way valve going out, and the tubing would make a small coil at the heat source. The tubing from the tank to the heat source would be heatsinked, and so what happens is the water flows into the coil, instantly vaporized, gets pushed out in both directions from coil (to the tank, and away to engine) it cannot go into the tank and immediately gets cooled by the heat sinks. a vacuum is drawn that sucks up water instantly into the coil again and the process works the same. Also the tubing going to the engine should have a ballast so that the steam output is more even and not the usually putputting from the coils. Those little putput boats that you would put a candle under the coil and they would put around work on the same principle.

Re: Flash steam ([3.00 / 1](#)) ([#14](#))

by hvirtane on Fri Jun 27th, 2003 at 05:20:56 AM MST

[\(User Info\)](#) <http://www.cc.jyu.fi/~hvirtane/cooker/>

The above is my very rough picture of a solar flash steam turbine.

I simply got enough of drawing with a computer and wanted to put the main idea first here. I will make better pictures later.

#### DESCRIPTION:

##### Part A.

1. There is water in the container. In the bottom of the container there is pressure, because of the gravitation forces. A water tube starts from the bottom of the container.
2. Sun rays hit the parabolic mirror 3. The available power from the Sun is about one kW per one square meter.
3. The parabolic mirror of 2 square meters reflects all the sun rays hitting the mirror to the chamber 4. The water from the tube goes inside the chamber.
4. The flash steam chamber is finned inside with spiral fins so that the water coming in

is effectively suddenly heated.

There is needle valve letting the water in the chamber from a small hole.

The chamber is made of ceramic at least outside, so that it can be heated by the parabolic mirror more than 1000 C hot.

The chamber is expanding inside towards the outlet end. Inside the chamber flash steam is generated.

5. The flash steam coming out from the chamber hits a crossflow turbine made of ceramic. The crossflow turbine runs a generator.

--

#### Part B.

The parabolic mirror is arranged to be turning round on an axle, which is on the same angle as the axle of the earth.

There is a clockwork to move the mirror so that it all the time focuses in the chamber.

--

#### DISCUSSION:

1. The main power is coming from the Sun.
2. Water gravity is used to jet the water inside the flash steam chamber.
3. No big and complex boilers are needed for this kind of steam turbine.
4. This solar flash steam turbine is simple to build even in rural workshops,

if ceramic craftsmanship is known in the area and somebody teaches the right shape of the mirror (parabolic), which can be made of cement using small mirror pieces as reflectors.

Reflectors can be made quite easily by pressing machinery from steel as well:

--

5) The electric energy available out of the process?

a) As told above, there is about one kW heat energy available for one square meter from the sun.

It is quite safe to assume that we can arrange more than 50% of the sun rays' heat energy

to be absorbed as heat energy in the chamber body.

b) All that heat can be transferred into the flash steam heat and kinetic energy, because the energy cannot escape other way?

c) A simple crossflow turbine generator can be made maybe 20% effective.

---

So if our mirror is  
2 square meters,  
we might expect  
200 watts from the turbine?

Re: Flash steam ([4.00 / 1](#)) ([#15](#))  
by JW on Fri Jun 27th, 2003 at 10:18:07 AM MST  
([User Info](#))

 I like this idea because it incorporates the tall water towers. These water towers will receive sunlight from all angles of the sun's travel. Hence the only need for tracking is for the flash tube. And I believe these towers can accumulate allot of energy. Its definitely something to work with. If these towers are of significant height the solar reception qualities will improve. Also the pressure on the water should be significant. However at the top of the column you will most likely have some issues. Due to convection circulation. but it would be interesting to learn from such a device if it worked or not. I'm not quite sure how to deal with the exhaust from the turbine. Or how to get the water back in the towers. often solutions present themselves with diligence and discovered options. JW-

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Hello,

don't worry.

It happens to many people.

My late aunt's name was 'Hanna'.

By the way 'Virtanen' is the most common surname  
in Finland.

Hannu is a quite common first name as well.

So there are hundreds of 'Hannu Virtanen'  
is this country.

If you want to correct it on the board,  
you can do it easily I think.  
You make the correction on  
the original, which you've got  
upload it with the same name as the original  
replacing the original.  
Then it is there?

- Hannu

Re: Flash steam ([4.00 / 1](#)) (#17)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Fri Jun 27th, 2003 at 08:28:20 PM MST  
([User Info](#))

Looks promising.

I like the idea of using the water towers as solar collectors to build up some small pressure before the flash tube. The valve is a great idea, as it simply lets some low pressure water squirt in, and when the water flashes, it seals shut. Its a great idea. Looks promising. Might try and build a small solar flash boiler for fun.

Although I would reccomend some heat sinks installed before the valve to simply draw a slight vacuum at the valve. (as pointed out in my idea above.)

Also, I have seen solar boilers before that incorporate a darkend tube running through a focal point of an elongated parabla. (I think the Mojave desert solar thermal power plants runs this way)

Re: Flash steam ([4.00 / 1](#)) ([#19](#))  
by troy on Sat Jun 28th, 2003 at 08:50:07 AM MST  
([User Info](#))

The big advantage of parabolic trough collectors is that they only have to be tracked in one axis, in comparison to a parabolic dish collector which must be tracked in both altitude and azimuth. Plus the boiler/heater tube in a trough collector sees less photons and heat per square centimeter, reducing the need for exotic high temp materials that still have good heat transfer qualities. Furthermore, a very good approximation of a parabolic trough can be made using plywood ribs and aluminum foil or mylar, so the cost becomes very inexpensive. For something more durable, the trough may be made of many 1.5" wide strips of glass mirror mounted on parabolic ribs.

Best Regards,

troy

Re: Flash steam ([3.00 / 1](#)) ([#20](#))  
by Anonymous Hero on Sat Jun 28th, 2003 at 10:58:46 AM MST

I think if you can keep that parabolic mirror on the focus point (ball flash chamber) at 1000 degrees or close, you might not need a valve at all. The flash explosion would both spin the turbine AND back the water up for a brief moment. Who knows? anyone?

[ [Parent](#) ]

Re: Flash steam (3.00 / 1) (#22)  
by hvirtane on Sun Jun 29th, 2003 at 05:21:00 PM MST  
(User Info) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I started to think that there should be first  
(after the water pressure tank)  
a parabolic trough mirror heater to heat the water.

There would be a ball valve  
to stop water going back, if it starts boiling in that area.  
So there would be already some real steam power for the  
flash chamber.

Then there would be the real flash chamber, heated with  
a point focusing parabolic mirror. The water would  
come in trough a small hole, with a needle valve.

The focusing mirror can be going around  
with the same clockwork and axle as the trough mirror.

-----  
To Troy:

If a point focusing parabolic mirror is moving the same  
way as a trough mirror we have no need to  
track it with altitude and azimuth?

-----

How to make parabolic mirrors cheaply even in rural areas, there are many drawings, if you look at my pages with my 'user info'.

More drawings are available for example here:  
<http://www.solarcooking.org/>

-----

How to pump water high up?

Maybe the best way is to use solar.  
I've given some ideas how to build simple solar pumps earlier.  
Please look at my earlier comments.

- Hannu

Re: Flash steam ([4.00 / 1](#)) (#23)  
by troy on Mon Jun 30th, 2003 at 03:08:51 PM MST  
([User Info](#))

Any dish mirror that brings the sun's rays to a single point focus must be tracked in two axes very precisely, just like a telescope, which, come to think of it, uses a parabolic dish mirror.

The parabolic trough only needs vertical tracking, as the focal "point" is a long tube, so it doesn't matter where on the receiver tube the sun hits, so that lets you out of dual axis tracking.

Best regards,

troy

[ [Parent](#) ]

Re: Flash steam ([4.00 / 1](#)) (#24)

"Any dish mirror that brings the sun's rays to a single point focus must be tracked in two axes very precisely, just like a telescope, which, come to think of it, uses a parabolic dish mirror."

Please see:

<http://www.geocities.com/davidmdelaney/scheffler-precis/scheffler-precis.html>

An extract from that text:

-----  
The optical system of Scheffler's community solar cooker forms a heliostat. An article on heliostats in the eleventh edition (1910) of the Encyclopaedia Britannica defines a heliostat as "an instrument which will reflect the rays of the sun in a fixed direction notwithstanding the motion of the sun. The optical apparatus generally consists of a mirror mounted on an axis parallel to the axis of the earth, and rotated with the same angular velocity as the sun."

The heliostat of Scheffler's cooker comprises a primary reflector, a secondary reflector, and a clockwork powered by gravity or photovoltaic panels. The primary reflector produces a converging beam of sunlight aligned with an axis of rotation which is parallel to the axis of the earth, and which passes through the centers of both reflectors. The clockwork rotates the primary reflector around its axis of rotation at a rate of one revolution per day, keeping the reflected beam aligned with the axis of rotation as the sun moves. The fixed secondary reflector reflects the beam from the primary reflector onto a cooking pot or frying surface.

-----  
This kind of movement needs seasonal adjustments, however. The movement around the axis must be precise of course.

Scheffler reflectors are providing an example, which kind of simple powerful solar devices can be constructed. Even a 'normal' small steam engine boiler can be powered with these reflectors, of course.

- Hannu

experiments? (3.00 / 1) (#26)  
by hvirtane on Fri Jul 4th, 2003 at 05:33:30 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

In my opinion the problem  
is to make it cheaply and simple.

I'm not intending to make now any 500 kW power, but  
about 50 W - 500 W power.

Because sunshine is

(still, it might happen that big American companies  
will try to patent sunshine? <grin>)

free, the machinery doesn't need to be so  
efficient,

built cheaper than PV cells and possible to make  
in rural conditions.

-----

In my idea the water would come injected  
inside of a really hot  
chamber (about 1000 degree),  
where it instantly becomes steam, which  
goes into the turbine.

I got the idea to use ceramic (or stone) inside Sauna.

You ever go to any Finnish Sauna?

In a sauna there is a container ('Kiuas')  
with stones, which are made  
hot by a fire or by electricity.

You pour water on the stones, and  
steam is coming out.

(The air temperature inside sauna is normally  
about 80 degrees Celsius.)

The stones are generally about as hot  
as red hot iron.

Yes, I know about a problem with most metals  
and 'red hot'.

Normally a barrier of hot steam between water  
and metal stops steam formation if the metal is too hot.

This is the reason I suggested using ceramic or stone chamber and injecting the water inside. Injecting the water with reasonable pressure might solve that problem with metals. too.

Even if stones in a 'kiuas' are as hot as you can ever get them, it produces steam very effectively. In an electric sauna kiuas there are red hot electric resistors, in between the stones. It produces steam very effectively, you have no need to inject the water in. You just pour it on the stones. The water makes many many movements in between stone pieces, before it is all steam.

Many people probably got all the necessary machinery to try it.

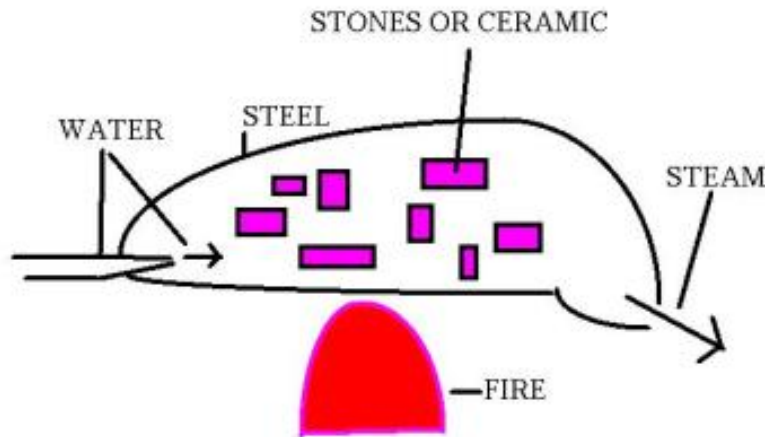

You might try with a quite big chamber made of reasonable good steel, put in stones or ceramic pieces (for example broken wares from your kitchen will do). Lead a pressurized water pipe in with a small pipe hole. Heat first the chamber outside red hot for half an hour.

Make the chamber body shaped such a way that the steam has a way to escape from the other end so that it produces a good flow of steam.

You certainly can produce steam this way. If it is cost effective, I don't know yet.

Here is a very rough picture of the concept

To refine the concept I think that the first thing to do is to make an adjustable needle valve for the water injection.

Hannu Virtanen  
hvirtane@cc.jyu.fi

P.S.

Did you see those homepages (User info) of mine?  
Including pictures from Nepal?  
It is possible to make good  
parabolic mirrors even in rural conditions.

Re: experiments? (2.00 / 1) (#27)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Fri Jul 4th, 2003 at 01:16:18 PM MST  
([User Info](#))

Thats Ingenious!

I was thinking on just that on how to solve the problem of water just "skating" off.

I think a mesh of ceramic coated wire inside the flash chamber would be effective. (like steel wool) The problem now will be how to conduct heat rather quickly from the outside edges to the inside ceramic. (I have no idea on the thermal conductivity of ceramic)

-Andrew

"I think a mesh of ceramic coated wire  
inside the flash chamber would be effective.  
(like steel wool)  
The problem now will be  
how to conduct heat rather quickly from  
the outside edges to the inside ceramic."

You are probably right.  
It is a problem.

Your design is something similar  
I've got in my mind.  
We might make holes in some  
stones, but iron bars inside,  
weld the bars on the container body?

My design idea is coming directly from sauna kiuas. With electric kiuas the hot iron resistors are there in between the stones. They are conducting heat to various places in the stones.

With a fire wood kiuas the fire is under the stones, the water is poured on the top. Some of it boils directly on the top. Some of the water goes further deep in between the stones. Finally all the water becomes steam anyway.

It might be better to design the chamber such a way that the water is injected on the top of the stones, and the steam could go out from the top only?

We can make in the water heat and pressure enough already in the in coming water so that it comes inside the chamber as flash steam?

Some water maybe could escape from the bottom of the chamber as well, because we can maybe design the turbine such a way that it can accept both steam and water?

I'm thinking that we should just somehow transmit the all the heat to the water coming in so that the heat energy is there in the water and the steam coming out to the turbine.

Then we could use the heat still coming out from the turbine to power a heat pump to get the water back to the water tower?

- Hannu

Re: experiments? (2.00 / 1) (#29)

by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Sat Jul 5th, 2003 at 06:22:54 PM MST  
([User Info](#))

I would think that you would get more pressure if you went with a long and skinny chamber. It would vaporize the water in the front, and would be superheated along the way out by the rocks in front of it. As the pressure would increase, you would need the longer chamber because it would be too cool for steam because water boils hotter and higher pressures. Regarding the heats transmission. I was thinking that instead of drilling one hole in the rocks, just drill many smaller holes in the rocks (as much as you can) and weave a small iron or steel wire (6 guage?) through it. You would get more uniform heating as there would be more surface area covered. -Andrew

[ [Parent](#) ]

Re: experiments? (4.00 / 1) (#30)  
by hvirtane on Sun Jul 6th, 2003 at 02:12:17 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I think that you are right.

a)

A long and skinny chamber is probably better.

b)

And we need enough surface to transmit the heat from the chamber body to the stones.

It is a matter of experimenting concerning the right dimensions.

And it might work quite well, if we just make quite many bars inside the chamber, welded inside the container, but not fixed on the stones? Because electric sauna kiuas works this way.

-----  
I'm trying to keep the pressure quite low and to use as low level technology as possible so that we could beat PV cells in price and power.

I'm trying to make this using 'village technologies'. For example in India and in Nepal I have seen that common blacksmiths in rural villages and in small towns are very very skillful (because many of them represent a tradition of the same 'clan', 'caste' or 'extended family' hundreds of years old) , but they are lacking modern materials and tools.

We people as well often are lacking the most

sophisticated tools and materials and in general normal 'self-made people' or school-educated engineers in the western world are far less experienced using their hands than village blacksmiths of the 'East' or of Africa'.  
-----

Concerning the chamber body itself.  
Maybe the easiest low level technology would be to use cast iron?

But the problems include

- a) welding on it is difficult.
- b) it rusts quickly if heated red hot.

So maybe the best would be to use a steel pipe?

The next problem is how to get the bars inside and...

Maybe we need to cut it open with an angle grinder, weld the bars, put stones in and weld it together?

Or we might just put in mixed steel bars and stones?

Concerning the water columns.

I think that it would be easiest to use normal black painted pipes.

- Hannu

Re: experiments? (4.00 / 1) (#31)

by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Sun Jul 6th, 2003 at 01:04:20 PM MST  
([User Info](#))

Your idea of iron is not a problem. First simply make a "half cast" of the chamber, and then forge it twice. On the inside simply weld or braze small iron bars. As many as you can. Next have one of the villagers mix up some clay or ceramic type mix. Simply paint the iron bars and the inside of the chamber as much as you can cover. Do this with the other half as well. Welding shouldn't be a problem if the ceramic has time to harden. Weld the halves together. For your water towers, gravity will be fine. Do not paint them black as you could get too much pressure that it could force open the intake valve prematurely. As for the efficiency. I don't think you can beat pv cells. This machine at MOST will be about 20% efficient. Simply because of the thermal losses of the chamber, the turbine only being pulsed by steam, and not continuous flow. (Probably compansate for this by adding a large flywheel.) The longer the chamber the better. A coil type chamber would be ideal. This is how I made mine. About 2 or 3 turns.

Now on the design....

Put the intake poppet valve right near the water towers (ball valve could work too). Add heat sinks (as much as you could machine or weld, etc.). When the high pressure steam shoots out both directions, it will head toward the chamber. It will approach the valve, and then cool off. It will draw a vacuum when cooling off forcing more water in the chamber. (The neat part about this design is it needs no water towers for pressure, it can intake the water straight up, vertically, which means that instead one could simply put the intake hose in a small pond or lake, etc) If you put the valve right next to the chamber it will not work like this. You WILL need water towers. As for your turbine.... A simple pelton wheel type turbine will be excellent. You will probably need access to a lathe, as balancing this will be a pain. (you are spinning at many tens of thousands of rpm) I got my little pelton wheel to about 22,000 rpm. Everything else looks fine. (if there is anything else)

Re: experiments? (5.00 / 1) (#32)

by Anonymous Hero on Mon Jul 7th, 2003 at 04:50:20 AM MST

I think if he returns to the smaller flash box and stays with solar mirror, it will again be 80% efficiency or higher. Also pulsing a turbine, instead of steady stream, is not going to be a problem for what he intends. You don't need 100,000 rpm, or even 22,000, to generate 1000 watts. At \$3.50 a Watt (Solar Panels) that is roughly \$3,500. If you can make this cheaper by keeping it simple you'll be better off than panels. Any needed valves can be found at a Boiler supply web site. You need nothing in the (small) chamber, no rocks or pipe. The air inside the chamber will be over 600 degrees. The water will not skate anywhere, the air alone will flash steam it. Cheers

-----  
Andrew:  
Your idea of iron is not a problem.  
First simply make a "half cast" of the chamber,  
and then forge it twice.  
On the inside simply weld or braze small iron bars.  
-----

- Hannu

You mean that after twice forged it will be easy  
to weld? I will consult my friends, who work  
for a very big foundry here.

-----  
Andrew:

As many as you can.  
Next have one of the villagers mix up  
some clay or ceramic type mix.  
Simply paint the iron bars and the inside  
of the chamber as much as you can cover.  
Do this with the other half as well.  
Welding shouldn't be a problem  
if the ceramic has time to harden.  
Weld the halves together.  
-----

- Hannu

Don't you think we should fire the whole thing  
in a kiln

after welded together?

-----  
-----  
Andrew:

For your water towers, gravity will be fine.  
Do not paint them black as you could get too  
much pressure that it could force open the intake  
valve prematurely.

-----  
- Hannu

Yes. One of the main problem will be to control the  
pressures.

I'm thinking that we might make the chamber that way  
that the steam starts flowing out fast  
and even creates a bit  
suction. If we make the chamber to expand towards  
the turbine and make it like a spiral inside?

-----  
Andrew:

As for the efficiency. I don't think you can beat pv cells.  
This machine at MOST will be about 20% efficient.  
Simply because of the thermal losses of the chamber,  
the turbine only being pulsed by steam,  
and not continuous flow.

-----  
- Hannu

Yes I think that we have got two possibilities for the  
design:

1. a pulsing steam system or
2. a continuous flow

system.

I'm trying to design this power system to be  
as much as possible 'village technology',  
'self-made'  
so that the cost in money would be low.  
PV cells you cannot make  
in a village easily, so they cost money.  
The cost will then depend heavily on the  
salaries of the local hired people, like blacksmiths.  
I'm thinking that some engineers in India, in Nepal,...  
could try making something like these  
in small villages there.

I agree that concerning how effectively we are using solar radiation, good PV cells are already hard to beat.

---

Andrew:

(Probably compensate for this by adding a large flywheel.) The longer the chamber the better. A coil type chamber would be ideal. This is how I made mine. About 2 or 3 turns.

---

You already made one???  
You seem to be very fast.  
Please describe more!

---

Andrew:

Now on the design....  
Put the intake poppet valve right near the water towers (ball valve could work too).  
Add heat sinks  
(as much as you could machine or weld, etc.).  
When the high pressure steam shoots out both directions, it will head toward the chamber. It will approach the valve, and then cool off. It will draw a vacuum when cooling off forcing more water in the chamber.  
(The neat part about this design is it needs no water towers for pressure, it can intake the water straight up, vertically, which means that instead one could simply put the intake hose in a small pond or lake, etc)  
If you put the valve right next to the chamber it will not work like this.  
You WILL need water towers.

---

- Hannu

I agree that making a pulsing steam flow would be easier to make.

Could you, please describe a bit more your 'heat sinks' concept?

---

Andrew:

As for your turbine....

A simple pelton wheel type turbine will be excellent.  
You will probably need access to a lathe,  
as balancing this will be a pain.  
(you are spinning at many tens of thousands of rpm)  
I got my little pelton wheel to about 22,000 rpm.

-----  
- Hannu

You think that a pelton wheel might work better than  
a simple crossflow?

Are you running your pelton with this  
steam system already???

-----  
Andrew:  
Everything else looks fine. (if there is anything else)

-----  
Thank you a lot  
for your very good contributions!

I've informed about this site some  
of my friends in Nepal and in India , too.  
Maybe some of them would start making  
these things.

- Hannu

Re: Flash steam ([2.00 / 1](#)) ([#2](#))  
by Johnny Cool Pants on Thu Jun 26th, 2003 at 11:16:21 AM MST  
([User Info](#))

## Flash Steam Design by Kevin Charles Perkins

1. Breather if using gravity feed only.
2. Water in
3. Low water warning system
4. Exhaust, Note: If using pressure feed with gravity feed, the exhaust can heat the tank creating some pressure in tank, with breather closed.
5. Valve, works like camera shutter upon piston return.
6. Flash steam chamber heat box.
7. Piston
8. Some kind of piston return mechanism (just drawing a spring for now)
9. Rod with gear teeth driving a clutched flywheel.
10. Clutch gear flywheel.
11. Magnet wheel for generator.
12. Line 'em up!

I was fooling around with a different kind of drive system so the flywheel could spin freely and faster having nothing to do with returning the piston. Only where you see the "spring piston return" I would try to use an air pocket that the piston compressed when fired, thus the air pressure in the air pocket would return the piston when the steam escape through exhaust port.

The thing is, when the air pocket gets hot it may have an expanding mind of it's own, this could be countered by designing it to accomidate a set known running temperature. In anycase, a number of things can be used for piston return but I feel some sort of air pocket could last longer than replaceable springs. Bugs can be refined out of any system.

Johnny Cool Pants.

Re: Flash steam ([2.00 / 1](#)) ([#3](#))  
by Johnny Cool Pants on Thu Jun 26th, 2003 at 11:22:52 AM MST  
([User Info](#))

PS

If you get the flywheel running smooth, this can also be designed to fire the piston only once every ten seconds, with a delay on the shutter, so that even less energy would be needed in keeping the flash box coil at a maintained temperature.

by Johnny Cool Pants on Fri Jun 27th, 2003 at 12:08:52 AM MST  
([User Info](#))

Yeah Xeroid/Bill,

I was in the Midwest not that long ago and while we were there we drove out to Amish country to look foolish with our cameras, but anyway I went off on my own and was watching these guys work in the field right next to the jelly shop and stuff.

And they were using an old steam engine about 3 foot high or so, for threshing, (spelling?) anyway that thing had to be 100 years old, still running. Yeah they burn the cobs, use the husks, whatever, I don't think anything goes to waste on those farms.

E-man,

I thought I had posted something here earlier but don't see it so must have hit "Preview" and bailed. Anyway it was in response to E-man and the steam ball rocket car. 300 MPH in the quarter mile, from a 2 foot round metal ball filled with water and heated.

This means you can launch a heavy weight (aerodynamic so it goes further) up a quarter mile rail, and that heavy weight can slowly come all the way back down the rail geared to spin a fast fly wheel or genny the whole way back down, or pump water, etc.

I know quarter mile rail kits are hard to come by, and the quarter mile flag poles even harder but I'm thinking of the energy used to heat the two foot ball, and how much you would get out of a turbine with the two foot ball, vs. the weight of that rail car geared to slowly roll all the way back down, while spinning a genny fast.

6 of one half a dozen of the other, but when calculating momentum of the launch at 300 miles per hour, that weight is still flying up the rail quite a distance after it has expended it's ball.

That extra distance is generation power all the way back down. It might prove more efficient than using the 2 foot ball of hot water to run a turbine for a short time. Yep.

JCP

Re: Flash steam ([3.00 / 1](#)) ([#12](#))  
by Johnny Cool Pants on Fri Jun 27th, 2003 at 01:46:26 AM MST  
([User Info](#))

I didn't intend to burn corn for this flash steamer but I suppose it could be done. I was thinking electric coil, the hot spot is small enough, maybe even friction heat. A lot of possibilities. Hannu is talking "Solar" The parabolic mirrors he's talking about can focus 1000 degrees, way more than enough. But if you're on a corn farm, use what ya got.

JCP

[ [Parent](#) ]

Re: Flash steam ([2.00 / 1](#)) ([#7](#))  
by hvirtane on Thu Jun 26th, 2003 at 04:54:33 PM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

To make a simple and cheap  
water/solar technology flash steam  
machine.

My general idea is as follows:  
I will later try making a picture of it.  
(At present it is past midnight here.  
Just came back from seeing my friend, who  
is very good at building small steam engines....)

(JCP's picture is really cool.)

1) The water pressure is generated  
by gravity (and maybe air pressure)  
in a water container on the top  
of the valve.  
(Pumped up by solar pumps... or by this machine itself)

2) Water is coming out of the container  
through a small needle valve,  
which can be adjusted and  
can as well close itself from the hot side, by

a big pressure.

3) Water goes into a tube,  
inside of it there is a spiral structure,  
the tube is expanding towards the turbine,  
the tube is made of ceramic.

4. In the ceramic tube flash steam is generated.

5. The flash steam goes into a steam turbine wheel.

(Maybe a simple crossflow 'Banki' turbine.)

6) The ceramic steam tube is heated  
by a solar parabolic trough mirror.  
About 1000 C degrees.

Something quite similar as my drawing here:

<http://www.cc.jyu.fi/~hvirtane/through.jpg>

-----  
So my concept is actually quite near to  
the concept of JCP.  
But instead of a piston engine, a steam turbine.

I think that it is possible to keep the needle  
jet for water flow open all the time.  
No valve closing mechanisms.  
What do you think?

Who would try to build one?

- Hannu

Re: Flash steam (2.00 / 1) (#8)  
by troy on Thu Jun 26th, 2003 at 05:33:02 PM MST  
([User Info](#))

I always liked a nice external combustion machine, less noise, less pollution, and potentially more efficient because the combustion process is both more complete and more controlled. And they'll generally run on anything that combusts nicely.

So this would apply to live steam, flash steam, stirling and other similar external combustion units.

Best Regards,

troy

Re: Flash steam ([2.00 / 1](#)) ([#11](#))  
by Johnny Cool Pants on Fri Jun 27th, 2003 at 01:33:16 AM MST  
([User Info](#))

Okay, here is my "Turbine" version only I'm using a piston AND a turbine in this design, the piston ramming forced air through the turbine instead of steam.

# Flash Steam Design by Kevin Charles Perkins (Piston/turbine) version

Piston rams cool air through the turbine air screw, instead of steam. With good flywheel, the piston need only fire once every 10 seconds. That will allow coil to maintain it's temperature with ease.

1/2 the power to run this machine is the little heat coil. The other 1/2 is the water's reaction (explosion)  
If this machine can keep it's tiny coil hot, it is providing 1/2 it's power source. (Not "Overunity")

Just nothing out of cool pocket.

JCP

Re: Flash steam (3.00 / 1) (#13)  
by Johnny Cool Pants on Fri Jun 27th, 2003 at 01:58:36 AM MST  
(User Info)

Oh yeah, also run a little air tube from somewhere in the ram air turbine action to the main water tank, to provide adequate pressure inside the tank, to maintain a good water injection on the heat coil. build, build, build,

JCP

Re: Flash steam (5.00 / 1) (#25)  
by Johnny Cool Pants on Thu Jul 3rd, 2003 at 04:59:26 PM MST  
(User Info)

Inside, one will have nothing for easy start up, others will have paddles for immediate power (larger machine)

Water tank is plastic too. Everything fits inside of it for transport, including separate bladder and hand air pump in case one is having problems with gravity feed water. When the tank is on the tankstand you can stick the rear end of the Flash Steamer (B) into the camp fire slightly, or use waste oil, a can of sterno, some propane, what ever. The Perkins flash steam will give way more power than a Stirling engine on the same flame. (This is s a generator) These Ecology Friendly Perkins Portables will be different sizes, up to 7 hp.

Does anyone know anything about methane carburator conversions

On this site . I would like to link up with someone who uses methane in their car motor or even a 2 stroke motor if that is even possible Thanks

[methane carburator conversion](#) | 3 comments (3 topical, 0 editorial)

Re: methane carburator conversion ([none / 0](#)) ([#1](#))  
by jubalearly on Tue Jun 17th, 2003 at 09:17:22 AM MST  
([User Info](#))

Do a search for natural gas conversions. Natural gas is mostly methane, and you would want the same carburator and very close to the same settings. In fact, the propane carb should work but it would need different orifice sizes & pressures just like natural gas does in appliances. So your local gas co. or propane distributor may have info on conversions. I'm not doing anything with methane myself, but I am interested at least for information purposes

Re: methane carburator conversion ([none / 0](#)) ([#2](#))  
by DanB on Tue Jun 17th, 2003 at 09:17:38 AM MST  
([User Info](#))

I know very little... so I could be wrong!  
But I think that methane is "natural gas" and it is common especially for large fleets and govt vehicals to run with it!  
So the conversion should be pretty common and straightfoward.

You might also do a Google search for CNG or:

Compressed  
Natural  
Gas

There are quite a number of commercial vehicles like busses, service trucks, delivery vehicle that have been converted. I also went on a boat tour of the riverwalk in San Antonio Texas and was surprised that I didn't smell the typical stink from the outboard. AHA, they were running CNG as well.

Natural gas is methane, but not all methane is natural gas. "Natural gas" per se, must have very little in the way of other gasses like CO2, plus it must have odorant added so you can smell it.

Good luck and have fun!

troy

## [Water engine](#)

By [Demetri](#), Section [Weird Science](#)

Posted on Sun Mar 30th, 2003 at 11:22:35 PM MST [Bio-Fuels](#)

Like a diesel, but water instead of #2.

I've got a wacky idea. We all know how a diesel engine works, right? Heat from compression is used to ignite fuel that is injected into the cylinder at the proper time. Now, I was thinking, what about water? An engine that had such high compression that it created a great enough heat that water could be injected instead of diesel. The water would burst into steam when it hit the incredibly hot air inside the cylinder(s), and force the piston down just like exploding diesel would. Wouldn't it? Sure, I can see several problems(bearings that'd stand up to 30:1 compression, lubricating the injector pump, lubing the injectors themselves, yadda yadda), I'm sure you all can too, but who cares right now. Is the idea sound?

maybe inject water and diesel at the same time

Exothermic vs. Endothermic ([4.00 / 1](#)) ([#4](#))

by Wyomingbob on Mon Mar 31st, 2003 at 01:21:03 AM MST  
([User Info](#))

There's one piece missing from the engine you describe: diesel (or most any hydrocarbon fuel, from coal tar to ethane) generates heat when ignited. Water doesn't. A hydrocarbon is a chain (or in the case of benzene & similar, a ring) of carbon atoms with various doodads hanging off it like legs of a centipede -- mostly hydrogen, a few atoms of oxygen, occasional nitrogen, sulphur, etc. The bonds holding these molecules together are not all that strong: a little external heat applied to them will cause the bonds to break, releasing even more heat, which is a form of energy and can drive a piston. The net reaction is "exothermic," meaning it gives off more energy than it takes on. The hydrocarbon reforms into smaller constituents (NO<sub>2</sub>, SO<sub>2</sub>, CO<sub>2</sub>, CO, etc): it is a \*chemical\* reaction, because the substance changes its identity. Breaking water into H<sub>2</sub> and O<sub>2</sub>, a process called electrolysis, requires vast amounts of energy: the bonds are ionic, not covalent, and quite amazingly difficult to break. The reaction is "endothermic," meaning you put more energy into breaking the bonds than they release

upon breaking. It's a chemical reaction, but a net energy loser. But what you describe is not a chemical reaction at all -- it is a physical one, called phase change (solid to liquid, liquid to gas, solid to gas, gas to plasma, etc). Same chemical composition, just a different form. Turning water into steam is always endothermic: it requires a net input of energy, and quite a lot of it. The engine you describe actually gets the phase change exactly backwards: \*compressing\* water vapor will produce liquid water; placing water in a vacuum will \*generate\* water vapor(steam). Try to compress liquid water, and all you'll do is explode the cylinder head -- because liquids are by definition not compressible. If you try to compress a carburated air/water mist, it will turn to water, not steam. You'd burn a huge amount of energy driving the piston & get nothing in return but a dripping exhaust pipe. See Universal Gas Law, a combination of Boyle's and Charles' Laws.

flash steaming ([none / 0](#)) (#10)  
by Johnny Cool Pants on Fri May 9th, 2003 at  
12:24:15 PM MST  
([User Info](#))

What you describe sounds like "Flash Steaming"

Rather than heating an entire boiler to high degree, you just heat a small coil in a chamber and the water is injected onto the coil, the valve closes as the injected water hits the hot coil and flash steams (driving the piston)

I do it on accident with my coffee maker all the time.

A steam engine might not be able to maintain a piping hot full boiler under it's own power according to the "Can't" Patrol (which is false) but it can deffinatly maintain a small hot coil in the piston chamber under it's own flywheel power while turning a few PM gennys at the same time.

A car battery get's it going, then you disconnect the battery.  
Free or near-free energy is everywhere dude.

Water injection is under it's own gravity weight pressure (just a valve at the bottom of a big full room temperature tank and a filtered breather at the top)

Steam water evaporates back into rain, nothing wasted, no polution. A Steam engine can pull a 100 ton freight train, a scaled down model can spin a few PM gennys easy, one to keep the coil hot, the rest to power you home.  
If you listen to the (Power Company "Can't" Patrol) you'll never try it.

Re: water motor ([none / 0](#)) (#11)  
by Mike G on Mon Jun 16th, 2003 at 03:06:16 PM  
MST  
([User Info](#))

I think that the energy that was used to compress  
the air (creating the heat) prior to water injection  
would be more than that absorbed by the water (and  
turning it to steam). So, the mechanical energy  
created by the expanding steam pushing the piston  
could not be more than that the energy of  
compression, and would be less, overall, due to  
inevitable losses. You'd need to get MORE mechanical  
energy out, somehow, to make it a continuous cycle.  
It was a thought-provoking idea, though, and one I'd  
never heard. I HAD heard of injecting small amounts  
of water into a convention ICE running on gasoline,  
which converted part of the heat into steam.  
Supposed to actually increase the horsepower, but  
I've never seen it verified.

You're on the right track. 26 years ago I had a Monte Carlo that was hard to start in winter cold. I read of and rigged a water bottle with oh what's it called an aerator rock for fish tanks anyway. When I turned the big 8 over, air is drawn thru the fizzrock and a 2nd tube from the bottle cap over to a vacuum plug at the bottom of the carburetor drew the mist into the carburetion. It cost all of \$6 to put together. I used a throwaway 2 litre Coke bottle which subsequently collapsed because it wasn't able to withstand the pressure. But that car that took 15 minutes to warm up to where I could pull out into Chippenham Phy. (Richmond, VA) well it was like having a tiger under the hood. The H2O mist was just enough, didn't lock the engine, and definitely increased horsepower. That was a long time ago. More recently I solved the problem of the LN2000 nitrogen engine. It's on my website [www.newpath4.com](http://www.newpath4.com) and [www.newpath4.com/steamedheatengine.html](http://www.newpath4.com/steamedheatengine.html) . It uses the "Flash Steaming" mentioned also to pre-warm the engine so the directly-injected nitrogen does not freeze the engine, losing power...

Hrm . . . ([none / 0](#)) (#3)  
by Franklin Pierce on Mon Mar 31st, 2003 at 01:01:09 AM  
MST  
([User Info](#))

Curious, but diesel works by (still) an exothermic chemical reaction which is made more efficient via compression. With a water injected "engine", all of the energy of compression is being absorbed into the latent heat of vaporisation for the water, the remainder being lost to the subsequent expansion of the "cumbustion" chamber, although it might make a really groovy vacuum cleaner I'm pretty sure you have a net energy loss from the system. Now, certain high-performance engines DO employ water injection, but only to control combustion temperatures, since the water has a nice, high latent heat of vaporisation.

Love,  
Franklin Pierce

Humphrey Pump ([none / 0](#)) (#5)  
by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Mon Mar 31st,  
2003 at 07:25:31 PM MST  
([User Info](#))

This sounds kinda like a Humphrey pump, and I have to go look up the Newcomb engine now ;~) The Humphrey pump was a water piston engine, but was found to only be efficient on a large scale. They used coal gas, which ignited on one end of a 10 ft dia. tunnel...the entire, monstrous column of water would move, pump some out at high speed and pressure, then fall back -- compressing the coal gas for the next stroke, like a diesel. Interesting -- I think you can still order plans for a small water piston engine out of the back of Popular Mechanics.... DANF

Water Engine ([none / 0](#)) (#8)

by MoonBoy on Fri May 2nd, 2003 at 05:04:15 AM MST  
([User Info](#))

The reason right now that I can't see this being viable is that steam needs great heat to become high pressure...Exactly what source of energy are you gonna hog to accomplish that?

Wacky idea ([none / 0](#)) (#9)

by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Sat May 3rd, 2003 at 10:10:19 PM MST  
([User Info](#))

I was hoping to use the heat of compression as the heat source, but after reading the other posts and thinking on it some more, I realized that as pressure increases, so does the boiling point of water. The heat generated by compression in this engine would not be enough to overcome the pressure, and make the water boil. I talked to a friend about it, and he told me of an engine his dad used when he was a kid to pump water. The engine burned one part kerosene for the heat and four parts water to, along with air. He said that the engine didn't last very long, due to the heat involved, it just burned up, and his dad switched to a normal diesel engine. Always be the lead dog.

Re: Wacky idea ([none / 0](#)) (#12)

by cryonucleator on Wed Jun 25th, 2003 at 05:53:26 PM MST  
([User Info](#)) <http://www.makehydrogen.com>

Still, Demetri, like your thinking. Wonder if you might get added value with a couple of low-power UV lasers, while steam is superheated. This would convert some of it to hydrogen and oxygen. Oh, someone said that liquids "by definition" are not compressible. It's a minor point, but actually all things are compressible, including water and other liquids. But in the practical sense, they're right, since the degree of compressibility is very tiny for water. A simple proof of compressibility is to take a rigid metal container full of water, slide a piston through an opening and slam it with a hammer. Duck! The piston will come flying out with the same force with which it was struck. A cork works too, but everybody would say that was due to the cork's elasticity, not the water's. Any major physics reference has a bulk modulus for water, which tells how much compression of water can be achieved by how much force. Finally, black holes compress everything. Physics requires that everything be compressible- "electrons" are just "fields" that surround "fields" of neutrons and protons, which in turn are just "fields" with "fields" of gluons, quarks, muons, etc. Fields are "by definition" compressible. Not flaming the "incompressible" writer, though, whose point about tearing up the engine was certainly valid.

This is sort of related cause it may be a wacky idea(s).  
Okay we all know how gas powered cars work. They have batteries that power the starter to ignite the gas to power engines that power cars which in turn recharge the batteries.

Then we all know how electric cars work. They have batteries that power the motors to make the car run and you have to recharge them everynight or soon as they run out of charge.

As for Hybrid vehicles, that's foreign to me. But from what I understand, you have a car that has two types of power. It runs on battery but when you need to climb hills or need more power it kicks in the gas, or something. Okay maybe I have no idea how it works.

Then we have Fuel Cell Vehicles. I think, but not sure. They are basically electric cars that run on battery, but is being charged by a Fuel Cell Source at the same time, sort of like how your Laptop works. It runs off the battery and soon as it depletes the battery it will run straight off the energy from teh charger, But in the case of the FCV it will run straight off the Fuel Cell source soon as the battery power is depleted, and same as the Laptop, it will run charge the battery at the same time cause you have it plugged in.

So here is my wacky Idea(s).

#1. Why couldn't an electric car maker, instead of using the Hybrid technology, just use the Fuel Cell (or Laptop)idea. What I mean is, You have the electric car. And just install a Gas generator somewhere on it. When you run out of Power in the battery. Kick on the generator and it

will charge the battery and let you drive the rest of the day. Gas generators supposedly will give you power for an average of 6 hours on 1 gallon. I know driving my car to New York takes six hours but that's 25 gallons later.

#2. Or instead of a gas generator, wouldn't it be nice to see if all cars were electric and were required with some sort of built-on recharging device such as solar panels (not that great of an idea cause the sun isn't always out), so then what about built on wind power generators since they are moving anyway. Why not ass a fan on the fan that will generate power and recharge the battery while it is moving. Means less charging you have to do at night. Why not add a Solar panel to work together on that, and it can be charged while you're at work?

#3. Haven't thought #3 out too much, still working on it in the head, but I gotta go. Email me at [oudone\\_p@hotmail.com](mailto:oudone_p@hotmail.com) if you have any thoughts. Thanks

Re: Water engine ([none / 0](#)) ([#14](#))  
by Nick on Sun Sep 7th, 2003 at 04:59:21 PM MST  
([User Info](#))

Ok, I've been thinking along these lines as well for a while and came across this today. Ok, so it won't work because of the difference in physical and chemical reactions explained above.

How about creating the extra energy needed by using a magnetron to create microwaves? Microwaves are very efficient at turning water in to steam.

Re: Water engine ([none / 0](#)) ([#15](#))  
by charged on Fri Nov 14th, 2003 at 04:39:11 PM MST  
([User Info](#))

No engine will EVER run itself. Self-runners don't exist. There, I got that out of the way. Stop thinking in those terms or you'll just make yourself crazy.

What you CAN do is make your engine ABSORB energy from the environment and convert it to concentrated power for your personal use.

Requirements:

1. heat source that PUTS OUT more heat than the USER must input. Answer: Heat Pump  
Heat pumps have a C.O.P. (coefficient of performance). In other words, YOU put in a small amount of energy to compress a refrigerant. The refrigerant collects that energy PLUS energy from the surrounding ambient space. Then it concentrates and releases BOTH inputs for a combined output MUCH larger than the trivial bit you applied on your own.

Here's how you can do it.

Collect some working automotive AC systems.

Take the "hot" or "high" side of the compressor and feed it

directly into a small "coil" of tubing in the "flash boiler" chamber. This should, ideally, be right at the engine head or even built into it. Insulate the outside of this chamber.

Take the old AC condenser and submerge it in your water supply tank. Run the hot refrigerant line coming out of the flash boiler directly to the condenser. Insulate that line between the two. Also, insulate the water tank.

What you now have is your MAX TEMPERATURE freon right at the boiler. The slightly cooled freon will go to pre-heat the water supply. The closer to boiling you keep the water supply, the less energy that will be needed at the boiler to flash the water into steam.

Now, after the condenser, the line travels out of the tank to the "evaporator". This is where it get's to be fun!

What you want to do is have a VERY LARGE evaporator surface area. Inside the first part of the evaporator is a flow restriction valve. This valve is the dividing line between the high pressure side and the low pressure side. It sprays a very fine stream of liquid refrigerant into the low pressure of the evaporator space. This liquid begins to boil in the lower pressure and it absorbs ambient heat as it boils. This is why your AC can get so cold.

In this case, you'll need to put several evaporators in series with the last one connecting to the low side of the compressor. This is so that the refrigerant can spend a long time wandering around at low pressure. This will give it time to completely boil before it makes it back to the compressor to have the collected btu's squeezed out of it again.

Run the compressor with the steam engine.

For every one unit of input to the compressor, you will collect MANY units of environmental heat to flash-boil your water.

You must start the system by driving it up to speed with another motor until the heat pump reaches the break-over point.

Put a big flywheel on the engine shaft and put some magnets around the outside edge.

Add some stator coils and dump their output into large capacitors.

Then dump the capacitors into your batteries at a regular pulse rate.

Any questions?

Re: Water engine ([none / 0](#)) ([#18](#))  
by newpath4com on Thu Dec 25th, 2003 at 09:42:52 AM

([User Info](#)) <http://www.newpath4.com>

What if the Steam Engine was the right way? And leaving it was the path to damnation? I've crossed the steam engine with the nitrogen engine and it looks REALLY GOOD. [www.newpath4.com/steamedheatengine.html](http://www.newpath4.com/steamedheatengine.html) . I solved the problems with the LN2000 by making the engine into a DUAL-ENERGY ENGINE, instead of following the rest of the pack who kept trying to make just one energy win. I cheated! And I'm proud of it. I found the synergy that was totally missing from everybody else's solutions. And this system is self-sustaining. It's all on my website [www.newpath4.com](http://www.newpath4.com) & [.../info](http://.../info) . The Newcomen steam engine used vacuum but everybody forgot it. I uses vacuum in the solution, in a different way, but it's there and integral to the nitrogen working with great power, explosive power. No pollution. Uses flashed steam in a closed loop, and nitrogen in a closed loop. The steam flashed into each revolution of the engine keeps the nitrogen from slowing the engine to a crawl. I call it my Double Energy Powerhouse Engine altho sometimes I think it should be called the No Waste Engine. Of course, the D.O.E. initially rejected my thesis... but now they visit my website so who knows?

Just for kicks and : )

Twas the night be for Christmas

Just for kicks and : )

Twas the night be for Christmas and across the land

Wind fans were checking a web site built by two guys named Dan

The stocking were hung by the chimney with care in hopes the EPA wouldn't smell them there

The wind fans were all snug in there beds with visions of wind gennys danced in there heads

The folks at Force Field with out flap had just turn in for a long winters nap

Upon the roof arose such a clatter they jump to the window to see what was the matter

Had a blade came off , Had a guy wire busted

And what to there wondering eyes did appear a miniature slay and eight tiny reindeer

And in one shout Santa explained two reindeer had stalled and the nose light was out

The folks at Force Field gave a nod an a wink, and with turn and a tweak had the nose glowing right at its peak

And with out a word they went to there links on how to jump start a reindeer with hamster power I think.

With the job done and high fives all a round Santa jump in to the sled in a single bound.

And he called out as he rose out of sight Merry Christmas to all an to all a good night.

The very best of the holidays to all

Old F

## [High-Gain Cell Phone Antenna For Sale](#)

-- 4 foot 9db Omni

By [ADMIN](#), Section [Classifieds](#)

[Communications](#)

Posted on Thu Nov 6th, 2003 at 09:55:18 AM MST

If you are in a remote location with bad cell reception, this might help! Used only 2 weeks, \$50 off new price.

---

Asking \$100 plus S/H. New cost was \$150.00.

It's the white 4-foot long model 962-C from Digital Antenna with a female N connector on the wall/pole mount base, and you can read their web page about the product:

[http://cellantenna.com/Antennas/900\\_series\\_cellular\\_antennas.htm](http://cellantenna.com/Antennas/900_series_cellular_antennas.htm)

I'll have an article appearing in the next issue of Back Home Magazine regarding cell service in remote areas. I bought this antenna to get more data for writing my article.

As it turns out, a 9db Yagi works better in my location so I'm selling this one....since the omni receives signals from 360 deg. (with a narrowed vertical angle to get the gain) I had problems with scatter signals coming in from all directions, tricking my phone into switching towers constantly. In my location (in the mountains, no line of sight to a tower because of high ridges in the way), the highly directional Yagi rejects these scatter signals better so I chose it.

This Omni antenna would be ideally suited when your biggest problem with cell reception is a long distance to the tower. For example if you are many miles outside of a city that has towers. Also great for a mobile or marine installation where you can't use a Yagi--this Omni does not have to be aimed. In a deep valley, this antenna is probably NOT your best choice. On flat plains or on a ridgetop it could be ideal. Of course I can't guarantee it will work in

your location -- as my article details, cell signals are VERY tricky and unpredictable.

While towers transmit at high power, handheld phones only put out half a watt or so. So keep in mind that while a high-gain antenna will improve both your reception and transmission, if you are too far away the tower still might not be able to hear you....in this case you would have to add a 3 watt booster to your system. This antenna of course works fine with a booster.

Please email me at: Danbob@starband.net if you have questions, need more details, or want to purchase this beauty. It's fiberglass, and extremely well-made and sturdy. This antenna will outperform your typical car cell antenna by 6db!

Cheers  
DANF

## [4 component load control system](#)

By [kww](#), Section [Homebrewed Electricity](#)

Posted on Sat Dec 20th, 2003 at 09:47:35 AM MST

[Controllers](#)

Very cheap, simple, and it actually works very well!

First of all, I give a BIG thanks to "charged" who told me about this setup, it's exactly what I wanted. My turbine now can spin freely with no load until it reaches high enough rpm's to operate efficiently. Then, when the rpm's/voltage is high enough the triac switches the load on. When rpm's drop just a little too much the triac switches the load off. Right now I've just got two separate 4 component circuits which operate two halves of a modified electric heater, due to Radio Shack not having enough triacs :-), but I'm ordering more of them today. :-) Anyway, I highly recommend this to the rest of you out there looking to heat with the wind, but don't currently want to mess with batteries and/or expensive control gizmos. If you want more detail about the circuit just do a search on "4 component load control", it should take you right to the thread in which charged told me about it.

Kevin

Re: 4 component load control system ([none / 0](#)) ([#1](#))

by Dave B on Sat Dec 20th, 2003 at 12:29:37 PM MST

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

More detail please ? I went back to the original post. Which circuit are you using ? What are the part numbers and what are your specs. for turn on - off etc. ? Is your alternator single phase ? Voltage output to the circuit etc. I want to do the exact same thing. My alternator is 18 coils single phase all series and outputs approx. 110 VAC @ 400 RPM. I want to switch on and off 2 hot water heating elements at different RPMs for no load start up and efficiency at higher RPMs. Please help, this has been a hold up. I don't mind experimenting but a place to start will be a great help, I have very little time to play. Thank you to anyone helping me make this happen. Dave B.

Re: 4 component load control system ([none / 0](#)) ([#2](#))

by kww on Sat Dec 20th, 2003 at 07:17:34 PM MST

([User Info](#))

Hi Dave,

The circuit is the one with the triac, two zener diodes, and resistor(s). The triac has three legs, one is the gate terminal, the others are for the hot wires. The triac is just an electrically controlled switch. The hot is split by the two non-gate terminals and the gate terminal is the electric switch. The power for the gate comes from the turbine output's terminal, but a resistor(s) is needed to keep from burning out the gate switch. The diodes, joined cathode to cathode keep current from flowing to the gate too soon. The diodes I got were 5.1v(cat.#276-565, Radio Shack), which I thought would trigger the gate too soon, but with the 2000ohm resistance I had to add the turbine has to make around 14 volts before the diodes see 5.1v so it's working well. The triacs I'm using are cat.#276-1000, but I just found out today Radio Shack is not selling them anymore so I've got to find another source. You may still be able to find them in stores around you, I've cleaned out the ones around here. Anyway, I've got a 3-phase alternator so I'm planning on using 3 of these circuits, one for each phase. You can divide your single phase up into however many circuits you want though. Two will work fine, that's how mine is running now. I think the Radio Shack 12v zener diodes would be the way to go for you, with the voltage your alternator makes. All you do to get the load to come on at different rpms is to add a little(10ohms more on mine) more resistance with the resistor(s). I'm really new at this stuff so I can't really tell you what you'll need exactly, but get some zener diodes(5.1 and 12v, they're only \$.99 for a pack of

two), triacs(6amp, 400v from Radio Shack, if you can find them, about \$2-3 each) and resistors(even cheaper than diodes) that will keep the current down enough at your max. output voltage to not pass the gate's max. current rating, charged tells you how to calculate that in his reply to me. When you get your stuff I'll help you put it together right if you can't figure it out, but it's really not too bad, even for those of us who don't know what they're doing. :-) Good luck.

Good post Kevin,

I'm also interested in doing this. Do you know what current you are putting thru these Triacs?

You said they are rated for 6 amp, if you have more current going thru will they fry?

Keep us posted of your progress.

All the best,  
Hank

That's 6amps at 400volts, which is 2400watts. If you need more triac than that check out jameco.com, I just found them, they've got lot's of triacs, up to 35amps at 1000volts I think it was. Anyway, I have no way of measuring the current my turbine is making, sorry. I can tell you this, heat sink the triac well, it does give off a little heat. Good luck.  
Kevin

by Hank on Sat Dec 20th, 2003 at 09:22:49 PM MST  
([User Info](#))

Thanks Kevin,

Also found Triacs at Digikey.com  
They have them up to 80 amps and possibly higher.

Don't know about 6 amps at 400 volts, my genny won't get up to 400 volts but it sure can pump out 40-50 amps. at 12 volts. I think this would make for some smoke using 6 amp triacs, but I really don't know.

If you are rectifying to DC then you can measure the current quite easily with a digital volt meter.

Tx,  
Hank

Re: 4 component load control system ([none / 0](#)) ([#6](#))  
by kww on Sun Dec 21st, 2003 at 06:44:05 AM MST  
([User Info](#))

Hi Hank,  
50amps at 12volts is just  $50 \times 12 = 600$ watts. Watts is the measure of power with electricity, so those 6amp at 400volt triacs should easily handle it, unless I'm making a mistake in my limited understanding of electronics.

I haven't gotten into rectifying to DC yet, but I've got rectifiers in waiting. :-) This summer I plan on getting a few batteries and an inverter that can run an air conditioner. I just have to find out how to get a triac to turn the ac on when the batteries get fully charged and then turn it off before the batteries lose much of that full charge. I'll basically keep the batteries at about full charge all the time.  
Kevin

by Hank on Sun Dec 21st, 2003 at 09:06:08 AM MST  
([User Info](#))

I'm no wiz on electronics either but I think current is the limiting factor and not necessarily voltage. For instance you have those small glass fuses which, for arguments sake, are rated at 10 amps but 250 volts. They will fry at 10 amps even at 12 volts. I believe it's the internal resistance of the component that limits its current carrying capacity.

I guess another example would be using #14 wire to carry 1200 watts. In one case using 120 volts and 10 amps, in another case 12 volts and 100 amps. Both are 1200 watts but the wire will fry in the case of 12 volts and 100 amps.

But what the hell we will have fun trying and I hope someone else chimes in on this one.

By the way what type of genny do you have? Do you know what voltage it puts out and at what rpm, also your internal resistance of the coils?

([User Info](#))

For the record, this can be "souped up" by using the triac to trigger a mosfet.

This difference will be that you need TWO mosfets and TWO triacs to control the mosfet gate to drive it positive.

OR, even simpler, put a FULL-WAVE rectifier across the generator AC and then use the single triac/transistor circuit to control the pulsed DC signal.

It's the same basic circuit you can use to discharge a capacitor bank. Bipolar transistors work better than mosfets for this application.

Re: 4 component load control system ([none / 0](#)) (#9)  
by kww on Sun Dec 21st, 2003 at 09:31:53 AM MST  
([User Info](#))

I see what you're saying, makes sense to me.

The genny I've been talking about has a 10 ft rotor and a 3-phase alternator. At around 1000rpms it makes 129volts, but I've only seen 52 volts with the 10 ft rotor driving it. The resistance of all the coils that make up each phase is 1.5ohms.

Kevin

Great information and thank you for your replys. Once I get a chance to work with this I'll keep you up to date on how it's all working out. It sounds as if I should be able to get the circuit working, all I need is some more time. I can't wait to get this up and flying, with the weather we have had lately and I'm still working out the details of my tilt up tower it looks like Spring will be a realistic target. This is a great group and I'm having alot of fun. Any other suggestions or modifications to the control circuit as you guys out there work with it would be great to see posted. Thanks again, Dave B.

A cautionary note about this type of energy transfer.

Accurately measuring energy actually being transferred with this kind of circuit is difficult.

DC ammeters are not capable of correctly measuring pulsed currents and an AC ammeter is calibrated to a 60 cycle, true sine current and would return an incorrect reading.

The only proper method is via an oscilloscope across an appropriate current shunt and is a little subjective as to how to read it. The energy in a pulse is interpreted as the "area" above/below the zero threshold and contained within the displayed waveform. (inside the trace)

Pulsed energy delivery systems are notorious for getting people excited about what actually is a less than stellar performance.

True energy transfer is measured not just in "watts" but in "watt time". (WattSeconds, KilowattHours, etc.)

Kevin (kww) made note that his triac can handle 6 amps at 400 volts for a wattage of 2400 watts. My question would then be "What is the duration of that pulse and how often does it refire?"

A 2400 watt pulse that lasts only 10 milliseconds (typical heavy current squarewave pulse) is only 24 wattseconds. If this circuit were pulsing once per second, the time averaged energy transfer would only be 24 watts.

Also, the 400 volts of the specified pulse is only the peak instantaneous voltage of the pulse and is proceeded and followed by the ramping voltages which compose the majority of the pulse. These ramping voltages are obviously lower and therefore these areas of the pulse carry wattage that is correspondingly lower.

Just a couple of notes of caution regarding getting overly excited before the numbers are in. I admit that the concept of transferring full mill energy via a small gauge feed line has me interested.

([User Info](#))

The "numbers are in" when you see the capacitor bank filling with charge between pulses. It also becomes quite evident when you see your batteries fully charged.

The difficulty in power transfer measurement only applies when one wishes to jam a wrench into the system that doesn't belong there. Instead of trying to make measurements on a line carrying electrostatic transients, measure the results at the battery.

The only measurements that count, when the "rubber hits the road" are what you put in at the generator VS the amount of charge in the batteries, nothing more. Taking measurements anywhere else in the system is only useful when you are "tuning" the process. It won't tell you jack about what's really happening. As you said, the resistor and scope produce a "subjective" measurement.

Coulombs built up in the cap bank translate to real power. Keeping the capacitors at a low voltage above battery voltage increases the system efficiency. This is why I've suggested using only a 5v zener for the simple setup.

If you have a 1f capacitor charged to 5v, you have 5 coulombs. Discharging this in 1 second is a 5 coulomb/sec or 5amps. Not rocket-science.

Using a digital pulse control system would allow you to adjust the cap bank pulse voltage down to whatever you like.

As far as the incoming HV pulses TO the cap bank, you'll measure almost no current on the wire UNLESS you draw the cap bank down below the generator voltage that's driving the 1:1 flyback at the generator.

The cap bank converts the pure transient potential back into usable current as it step-charges.

I have two small-scale models of this system running on my bench as I'm typing this. One of them is almost purely mechanical and works like a charm.

Once you really understand how to do it, you'll wonder why it hasn't been used for for the last 100 years since the systems were originally designed.

Keeping the battery bank "load" at a higher voltage than the source generator keeps the input pulse-width to the 1:1 transformer the same at all times. Putting a lower voltage battery or a pure resistive load directly across the caps draws them lower than the source voltage. This puts a "forward loading" on the flyback circuit and makes it draw excessive current. This also translates to hard current on the transmission line until the cap bank rises above the generator voltage again. Then you're back into the pure emf transfer range and the wire stays cold.

Tesla did this over and over again. All the patents are right there for anyone that cares to read them and understand what he was doing. His monster coils were not for his amusement. They were designed for long-distance power transmission. He also worked with lower voltage versions of his impulse systems to drive machinery and charge batteries.

HV transients are pure potential with no current component. This is crossing over into the realm of electrostatics, but in a relatively low voltage range. This is what the 1:1 transformer gives you.

Re: 4 component load control system ([none / 0](#)) ([#13](#))  
by dualsporter on Sun Dec 21st, 2003 at 06:07:09 PM MST  
([User Info](#))

It concerns me somewhat that you so readily dismiss proper engineering analysis in exchange for simple comparative analysis. That kind of comparative analysis can however give a good overview of the systems capability. Such a proper comparison would require, in this case, two identical mills feeding two identical battery banks located side by side for similar wind conditions. One would then compare loading and recovery of the storage batteries. A properly setup benchtop experiment might also be possible, but it must be an honest comparison. (No cheating to get the result you want.)

The "subjective" I spoke of regarding reading an oscilloscope relates to the fact that only a limited number of people invest the time to really learn how to read what they are seeing on the scope. Because of that different people read them differently. Newer scopes (digital) can actually give you a proper analysis of the trace, thus eliminating the human "subjectivity".

Regarding Tesla and his patents... He and his life's work are fascinating and I've spent many hours playing with several of his concepts, but several of them do not work well within the framework of well accepted engineering practices. Deep Tesla believers dismiss this as a "big government" conspiracy to keep his works down, yet have never been even close to properly proving any of these concepts. (When cornered, they will always find someone or something that kept them from succeeding.) Tesla contributed greatly to our current understanding of energy, but as with all great innovators, for every good concept that pays off, there are hundreds of ideas that aren't viable. Tesla does have a great number of patents, but one must keep in mind that at the time he was filing those patents, virtually any concept was allowed a patent and very few were challenged. The patent office does not "go back" and review old patents and cancel them if found unworkable. It truly was the golden age for any "would be" inventor.

I have no doubt this system will transfer energy and given line losses from high amperage, low voltage systems, may be comparable in performance, but for a market viable system a somewhat more scientific approach will be needed.

Re: 4 component load control system ([none / 0](#)) ([#14](#))  
by kww on Sun Dec 21st, 2003 at 07:36:52 PM MST  
([User Info](#))

I don't know what you guys are talking about, but it sounds sort of interesting. :-)

I've got a question about the 4 component circuit. Yesterday the 4 component circuits worked perfect, but today I noticed one of them didn't seem to want to cut off every time when the voltage dropped below the cutoff point. I came to this conclusion because I was getting voltage at the gate and main terminal for the output when it should have been 0, which is how it was working yesterday. Is this an indication that the triacs can't handle the load and they're going bad?

Btw, I tried other diodes, thinking maybe they'd gone bad, but that's not it. The resistors are fine too. I figure I must be drawing too much current with the loads for the triacs to handle, but an opinion from someone who knows would be nice. Thanks.

Kevin

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Kevin, glad you're back to report in on the original topic. There has been a mis-interpretation of what you and I are attempting to do with NO batteries as a controller that switches the load(s) depending on RPM. Our topic has strayed off into charging batteries with pulse charges from caps. and stories about past patents (all interesting I'm sure) but I think that topic was back a few. Anyway, I have purchased 2 solid state relays rated at 50A 240V (no these are not to use as switching pulses to charge batteries) but rather to switch on or off the load (hot water heating elements) depending on RPM. Let me know what you find to be the problem with the original 4 component circuit, I may be on to something with the solid state relays. We may have to start another thread to keep this on subject. Thanks, Dave B.

Re: 4 component load control system ([none / 0](#)) ([#16](#))  
by dualsporter on Sun Dec 21st, 2003 at 11:40:50 PM MST  
([User Info](#))

You may have exceeded the maximum voltage on the triac, but I rather think maybe your seeing some degradation of your gate caused by a parasitic back current. (Is it still pulsing or has that also stopped?)

Some manufacturer's Triacs-SCR's will generate a parasitic back current when cascade occurs (the semiconductor fires) should the circuit allow it. Repeated such firings will cause the gate integrity to degrade.

Any power circuit using a Triac-SCR should have protection designed into the support circuitry to protect against this. The problem circuit here is derived from the zener's ability to flow current either direction. (although only one direction displays the zener threshold for which the diode was selected) The current flow opposite to the zener direction is the problem. To stop this, insert a blocking diode between each of the zeners and the Triac-SCR's primary terminals. Since this is a power circuit a full blown rectifier such as a 1N4004 should be used. These are rated for 400 volt peak inverse voltage. (PIV or PRV) If you use a higher voltage Triac-SCR then use a similarly higher voltage set of rectifiers. 1N4005 - 600V, 1N4006 - 800V, 1N4007 - 1000V

Installing these diodes will raise your trigger threshold approximately 0.7 - 1.0 volts.

I believe the rectifier cathodes (the stripe) should be "away" from the Triac-SCR primary terminals, but if I'm wrong it will be immediately obvious (No... Not ZAP! :) as the circuit will do nothing at all. In that case just reverse them.

By the way... Not certain if the circuit will still pulse, but if you tried this circuit with just the 1N4004's and leave out the zeners,

you're trigger threshold will drop to 1 to 2 volts above your storage voltage and pulse rate will rise considerably. Might be worth an experiment.

Hope this helps.

by charged on Mon Dec 22nd, 2003 at 06:27:14 AM MST  
([User Info](#))

I like that change. You could actually use several HV diodes in "forward" mode to get the desired drop for the triac gate.

Sorry to drag all the other stuff into this thread. It gets really messy in side my head sometimes. heh.

by charged on Mon Dec 22nd, 2003 at 09:11:06 AM MST  
([User Info](#))

I think dualsporter is absolutely correct. The zener won't block the parasitic reversals since they hit it in it's forward mode. Using a series of 1kv diodes in forward mode would certainly block any reversals, just short of a lightning strike.

Re: 4 component load control system ([none / 0](#)) ([#18](#))  
by kww on Mon Dec 22nd, 2003 at 07:10:51 AM MST  
([User Info](#))

You said: ...I rather think maybe your seeing some degradation of your gate caused by a parasitic back current. (Is it still pulsing or has that also stopped?)

kww: That's it exactly I think. Both triacs are still pulsing and the system is still working fine, I can see the difference looking out the window. :-)

You said: ...insert a blocking diode between each of the zeners and the Triac-SCR's primary terminals. Since this is a power circuit a full blown rectifier such as a 1N4004 should be used.

kww: So that's 4 blocking diodes/circuit(triac)? Is the rectifier used for something other than converting to dc electricity in this case?

The idea of hooking rectifiers in place of zeners in this circuit sounds interesting, but those are more complicated than triacs(4 prongs instead of 3 ;- ) and I haven't learned my triacs yet. :- ) I'll look at it though, hook a few wires here, then there... :- ) Sounds like that would be another solution to the parasitic back currents, unless rectifiers also have them occur. Anyway, thanks for all the good info. I can play with.  
Kevin

Kevin & the gang. Sounds like you are working this out and so far I'm learning right behind you. Wish I could help but I'm pretty weak on circuit design, assembly will be no problem at all. I think I see the pulsing thing, wouldn't this be because of the lower AC frequency of your output voltage at your first "turn on" voltage ? I know we are switching AC and if we use a bridge rectifier wouldn't we then be dealing with DC ? Maybe I don't understand where this would be inserted into the circuit. Anyway, I'm rambling and look forward to hearing more on the testing out there. I can't wait to hear that "you got it", I'm trying to do the same thing. Thanks, Dave B.

([User Info](#))

LOL, I think Dualsporter was talking about a rectifier diode/blocking diode/HV diode/1kv diode(charged) instead of a bridge rectifier, which is just a number of rectifier diodes hooked together. Too many names for these things.

Anyway, I need to buy some HV(high voltage I'm assuming) diodes or find them in the small pile of electrical junk I've been saving for around 20 years just for this occasion. :- ) I'll post when I get it together and observe what happens. I think I'm actually starting to enjoy electronics.

LOL  
Kevin

([#24](#))

by dualsporter on Mon Dec 22nd, 2003 at 05:59:40 PM MST  
([User Info](#))

Kevin,

The rectifier I wrote about is a simple, high current, single diode with only two leads. (an Anode and a Cathode - The Cathode is usually indicated by the stripe on the body) They tend to be rather inexpensive (Usually less than \$1.00 USD) compared to your Triac and serve the function of allowing current to flow in only one direction as long as the peak inverse voltage (PIV or PRV) is not exceeded. (Once exceeded, they die, usually in a somewhat spectacular fashion.)

Installation of one these backing up each Zener will stop any parasitic currents. The PIV of the rectifier does not have to exceed the voltage rating of your Triac. If the Triac's peak voltage is exceeded, these rectifiers won't be able to save it. They are there only to protect your gate circuit from stray currents.

Hope this helps.

Side note - After reading DanB's post from last night I realized that I hijacked your thread. Probably caused by typing faster than the speed of thought. Hope I didn't derail the discussion. Deepest apologies.

Variable speed controller rated at 20 amps.

I have a single speed router which is rated at 19 Amps. There are plenty of variable speed controllers rated at 15 Amps. I want either to obtain a 20 amp rated device or make one. I think a triad circuit will do the trick. Has anyone such a circuit or knows where I can get a commercial one at a reasonable price.

19 amps? ([none / 0](#)) (#1)  
by [wdyasq](#) on Thu Dec 18th, 2003 at 06:50:14 PM MST  
([User Info](#))

My big -3 -1/4 HP - Porter Cable says it pulls a bunch mor than either of my two Am-Probes says it does. I have never seen a hand-held router pull more than 10.5 amps. And that was for only a short period of time.

I figure my 3-1/4 HP router actually produces about 1-1/4 HP.

Ron

20 amps ([none / 0](#)) (#2)  
by [JW](#) on Fri Dec 19th, 2003 at 07:45:06 AM MST  
([User Info](#))

mafox,

I did a quick google search on " 20 amp motor speed controller"

Here's what I found  
<http://www.rotronindustrial.com/products.htm>

when you get there to that page click the link for 'controllers" there are two choices for 20 amp controllers. when you hit those links it will automatically download a PDF file. so you will need acrobat reader to veiw details.

I have no idea what these units may cost, but its a start.

Have fun

-JW aka, Jeremy

Re: 19 amps? ([none / 0](#)) ([#3](#))  
by Zack on Fri Dec 19th, 2003 at 10:21:27 AM MST  
([User Info](#))

I don't have any hard data, but I do have many years of observation. I am a carpenter, and it is obvious after buying and using modern power tools that their amp ratings are about as reliable as the "horsepower" ratings on household appliances. How do you run a "3.4 horsepower" vacuum on that 18 gauge cord, plugged into a 15 amp circuit, anyway? Just the other day, another carpenter and I had to share an outlet in a garage. We each have sliding miter saws, rated at 15 amps. We would occasionally each pull the trigger at about the same time, with no effect at all on the 20 amp circuit breaker. That's an alleged 30 amps, at startup, on one ordinary outlet circuit. I have often had to run my operation on a 100 foot extension cord, from a temporary power pole. That's a 3/4 horsepower table saw, air compressor, lights, saws, etc. I have noticed that a couple of halogen work lights will put the amp load over the top, if say, the air compressor starts while some other tool is running, in addition to the lights.

Anyway, I would not hesitate to try any normal hand-held router on the 15 amp device you mention. I have seen a 20 amp version in mail order catalogs, in years past, but they were much more expensive, and required heavy wiring. They did not come with normal power cords installed. A router that actually pulls over 2,000 watts would be an unwieldy thing, at best, I think.

Good luck!  
Zack

Re: 19 amps? ([none / 0](#)) ([#4](#))  
by wdyasq on Fri Dec 19th, 2003 at 03:38:42 PM MST  
([User Info](#))

Zac,

My comments were just on the facts as you stated. I started looking at it when I had a 3.25 hp router, a CNC machine drawing 5 amps and a vacuum- sometimes two, on a 20 amp breaker. I also knew 746 watts = 1 hp. The numbers just didn't add up. So I started measuring what each tool drew as power and found the 3.25 Hp router was 1.25 Hp, the 5.8 Hp vacuum drew 6 amps, 1 Hp, and I could run all of it without tripping the 20 amp breaker.

I have ordered a -Watts up PRO-. When it gets here, I will be tracking the power requirements of a lot of tools and appliances so I may plan my RE electrical system. I hope to have a fairly high voltage abttery bank where I may power many hand tools on pure DC and some on pulsed DC for speed control when I need it.

Ron

I always wondered why manufacturers rate some electrical appliances in Amps. Like almost all Vacuum Cleaners are rated in amps. Some Hoover TV commercial says thiers is 10 Amps. Seems to me that they could just use a badly designed motor and draw 10 amps with very little work being done. It almost promotes inefficent thinking. The consumer thinks that they are getting a more powerful machine by buying More Amps, and manufacturers can use any old Crap motor that pulls that much power.

Simple switching circuit with solid state relays (wind)

My alternator is single phase and outputs approx. 110 VAC @ 425 rpm. with all 18 coils in series. I have purchased 2 solid state relays that are rated at 50A 240 VAC that I plan to control 2 hot water heating elements independently depending on rpm. The trigger voltage is 3-32 volts AC or DC. I have played with this a bit taking the trigger voltage off of 1 coil which seems to work fine switching the main to the load at it's minimum trigger of 3 volts. I am temporarily using a light bulb to view what's happening and there seems to be some fluctuation in the output which I can expect at low frequency. Now the big question, what is the best way to regulate the next "turn on" voltage to my 2nd solid state relay and load ? Resistor in series to limit the voltage or maybe zener diode or what ever. Again I think the best way is to "tap" off one coil. Hope this makes sense, I'm getting a little frustrated with what should be a simple solution. Thank you for everyone's help.

Dave B

Comment and new(?) idea for load control ([none / 0](#)) ([#1](#))

by [kww](#) on Sun Dec 7th, 2003 at 12:50:10 PM MST

[\(User Info\)](#)

Hi Dave,

Glad you're doing it this way so if I can't get what I'm doing to work well I can ask you about your approach. :-)

I thought of a radical new way of controlling loads you may be interested in hearing. You start with a very small light bulb rated at a voltage in which it will glow well when your turbine gets up to speed. This bulb is always connected, but since the wattage is so low it's load is negligible. Near this bulb you have a photo switch that turns on a load when the bulb glows bright enough. Also, this load has a "trigger" bulb hooked in with it that trips another photo switch with another load and trigger bulb, if more steps/loads are needed. Seems like it'd be really simple and work well, but I'm new at this. Maybe it's not new at all even or won't work for some reason, but I figured someone here who knows will comment. Good luck.

Kevin

by [Dave B](#) on Sun Dec 7th, 2003 at 01:05:40 PM MST

[\(User Info\)](#) <http://www.madbbs.com/users/bruggelog>

Between us and anyone else we'll get this figured out. I like the solid state relays but they're kinda pricey at \$30.00 but it sure simplifies things and with no moving parts are extremely reliable. We'll see who else chimes in with suggestions, I can't wait to get things moving again, I haven't had much time to play lately. Dave B

Re: Comment and new(?) idea for load control ([none / 0](#)) ([#4](#))  
by kww on Sun Dec 7th, 2003 at 03:46:25 PM MST  
([User Info](#))

At \$30 a rely the cost will add up fast, I hope what I'm doing works well enough. The triacs, diodes, and resistors were only around \$6 and I got enough to run two different loads, so around \$3 per load control circuit it looks like.

I've been busy building a solar collector and now I'm going to put another one on the house. These things are cheap, easy, and make a lot of heat. I actually heated to and maintained 63 degrees in my old rather poorly insulated 900 sq. foot farm house today. It was windy and cold 30-49 degrees and it wasn't in the high zone for long. My first collector is 6'x 7', made similar to the one pexring made, but this second one will be a transpired collector, even simpler/cheaper as there's no glass. The heat is sucked off the outer surface of the aluminum collection plate through lots of small holes and more heat is collected from the air flowing on the inside past the collection plate. It's all fun. :-)  
Kevin

Re: Comment and new(?) idea for load control ([none / 0](#)) ([#9](#))  
by kww on Mon Dec 8th, 2003 at 09:36:01 PM MST  
([User Info](#))

Pexring is someone who posts here from time to time about his projects, that's about all I really know of the guy.

A transpired collector is what I described above, the thing that pulls air through tiny holes in a collector plate. After doing lot's of net research the other night I've decided it wasn't the one for me after all.

Re: help, ([none / 0](#)) ([#5](#))  
by wpowokal on Sun Dec 7th, 2003 at 05:00:46 PM MST  
([User Info](#))

Dan, from your data each coil develops around 6.1v ac at full speed. Switch the first relay off one coil( effectively @3v switching it in at half generator full volts) then use a voltage divider off the same coil to switch the second, if and when the generator reaches full speed.

Without some hysteresis there definatly will be some high speed switching happening. If this matters I would use a duel op amp or perhaps a LM3917 bar graph driver.

The op amp probally gives the best oportunity to build in hysteresis.

Just my musings, i'm sure someone has a purpose built device just waiting for you to buy.

regards Allan

Re: Load Switching Control ([none / 0](#)) (#6)  
 by Electric Ed on Sun Dec 7th, 2003 at 06:11:57 PM MST  
 (User Info) <http://www.electric-ed.com>

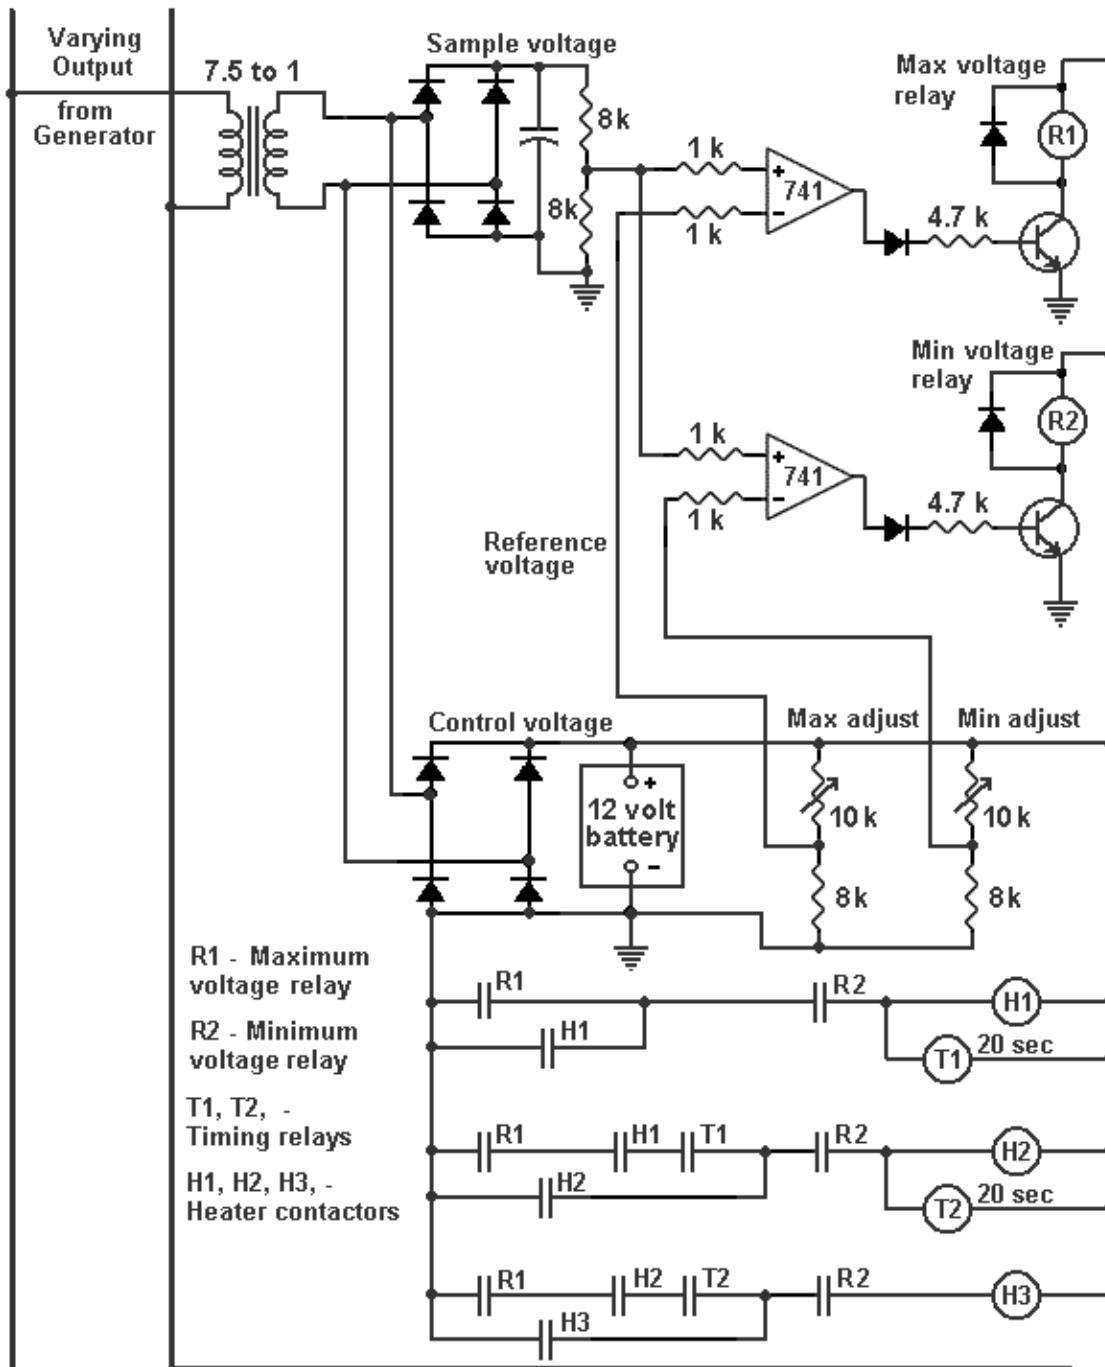

The control will definitely need hysteresis in order to prevent "short cycling".

I'm working on a circuit similar to the sketch below. The basic principles are -

1. A 120 volt heater will produce some heat over a range of voltages, let's say 90 to 120 volts. Turn Load 1 on at 120 volts.
2. This will pull the voltage down some, so if the voltage drops below 90 volts, turn off load 1. But if it stays in the usable range (90 to 120 v) for say, 20-30 seconds, turn on Load 2.
3. This will pull the voltage down further. If the voltage drops below 90 volts, turn off load 2, but if it stays in the usable range with both Load 1 and Load 2 on for 30 seconds, turn on Load 3.

The circuit in the sketch will NOT YET DO what I described above. I may need another relay that operates at the mid-point of the usable voltage range. This is starting to look like a job for a mini PLC.

Electric Ed

Re: Load Switching Control ([none / 0](#)) (#8)  
by Dave B on Mon Dec 8th, 2003 at 07:50:57 PM MST  
([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Boy, I didn't realize I was getting into such an involved circuit. Thank you Ed and anyone else who's been looking at this. It just seems like it should be so simple. I'll have no problem building the circuit from a schematic but I'm not too well versed on circuit design. Maybe a little overkill on the relays I have but it could be (I hope) some pretty serious current to switch and I didn't even want to think about how many times they will trigger. First one to make this simple and reliable using the solid state relays gets my business, I am willing to pay. I'll keep playing when I get the chance but that's the big problem, limited time. Dave B.

### [Four component load control circuit](#)

By [kww](#), Section [Homebrewed Electricity](#)

Posted on Sat Dec 6th, 2003 at 08:40:12 PM MST

[Controllers](#)

I'm missing something, doesn't work.

Someone here ("charged" I think it was) told me of a simple circuit I could make that would work as a load control so I went to Radio Shack the other day and got what I thought would work. I'm rather sure I got everything hooked up right, but I think maybe I don't have the right stuff. Anyway, what I got was two 1k ohm resistors, one 6 amp 400V triac with a gate voltage of 3V and current of 25ma, and two 5.1V Zener diodes. I then took two of the three output wires from the turbine and hooked one right to one screw of a light fixture. The other wire was hooked to one of the main terminals on the triac and on that same wire the resistors were hooked in series to give 2k resistance(calculated by  $R=V/I$ ,  $2k=50(\text{max. alternator voltage})/.025A(\text{gate current, max. I guess})$  and that was hooked in series to the two diodes hooked together cathode to cathode. The last free diode leg was hooked to the gate terminal on the triac. Finally, the second main terminal on the triac was hooked to the other terminal on the light fixture. I hooked it all up to test it and found the thing never seemed to cut on or off, when the turbine made any power it was there, even below the 5.1 volts where I was expecting to see the voltage drop suddenly to 0. An odd thing I saw: I measured voltage(up to 20v, more than enough to see a glow) between the two light fixture terminals but the light bulb never came on. Anyway, please enlighten me somebody. :-) Btw, I tried, about 10 times, to get a usable picture of this test

Kevin

Re: Four component load control circuit ([none / 0](#)) ([#1](#))

by [charged](#) on Sat Dec 6th, 2003 at 10:04:23 PM MST

[\(User Info\)](#)

Is your turbine single-phase or multi-phase output?

The zener-triac circuit will only work correctly with single-phase output. If you have three phase legs coming out of the generator, you'll need one of these circuits on each leg.

Here's the basic circuit. In my haste to scribble it out, I neglected to draw the resistor in series with the zeners. But, I'm sure you get the idea.

The triac will shut off whenever there is a zero-crossing. It can only turn on if the voltage rises high enough to break over the zener and activate the gate.

by kww on Sun Dec 7th, 2003 at 08:02:46 AM MST  
([User Info](#))

I guess the hot wire(not neutral) goes to MT2? If it were the other way around the zeners would never see the voltage to activate? That's what I'm thinking, but I know I don't know enough about electronics to believe in what I think. LOL  
Kevin

Re: Four component load control circuit ([none / 0](#)) (#5)  
by charged on Sun Dec 7th, 2003 at 09:53:52 AM MST  
([User Info](#))

It won't matter which end of the triac is used. Until the triac is "on", the only path for current flow is through the gate. And that's not a path until the voltage rises enough to pass through the zener.

Once the triac is "on", the potential across the zener is less than 1v. The triac shuts off when it hits a zero crossing and then the whole process repeats.

Re: Four component load control circuit ([none / 0](#)) (#7)  
by charged on Mon Dec 8th, 2003 at 05:48:02 AM MST  
([User Info](#))

Sure can.

My local R-shack is pretty weak on small parts. Assuming this was the universal standard for those guys, I suggested the zeners, since they're probably something they keep in stock.

I get cranky whenever I have to order parts via UPS before I can test a circuit.

Re: Four component load control circuit ([none / 0](#)) (#8)  
by Nando on Sun Dec 28th, 2003 at 02:37:22 PM MST  
([User Info](#))

My question is :

What are you trying to do ?

What is the AC voltage range, is it single phase or 3 phase ?

How much power do you need to switch on/off ?

If you have a 3 phase ( rectified) once the triac is triggered it can not be turned off, unless the 3 phase goes to Zero

Nando

Re: Four component load control circuit ([none / 0](#)) ([#9](#))

by kww on Sun Dec 28th, 2003 at 02:43:15 PM MST

[\(User Info\)](#)

What I'm doing is hooking a wind turbine straight to a load control circuit which controls a heater. AC voltage range is around 0-40 and it's 3-phase. Max. total power is around 1000watts I'd guess. Anyway, I've got it working right now and I'm pleased to say it's working very well. :-)

[\(User Info\)](#) <http://www.madbbs.com/users/bruggelog>

Kevin,

I had a chance to play with my solid state relays. The trigger voltage of these is 3-30 vdc. My very simple circuit for each load to turn on at an adjustable RPM is : to tap off any number of the stator coils in series and rectify this AC then run the DC through a pot. Use this adjustable voltage as the trigger voltage for the solid state relay. The relay will trigger at approx. 3 VDC so the pot allows adjusting it up or down depending on the RPM (voltage) you want the load to turn on. The load is then wired in series from the total output of the alternator to the relay. So far so good, I'm switching 2 hot water heating elements on (and off) at different RPM, no load for start up and I'm experimenting with dialing things in with bench testing. If things go according to plan I'd like to see this set up flying 80-90' early Spring. Too little time to play. Dave B.

Re: Four component load control circuit ([none / 0](#)) ([#11](#))

by kww on Mon Dec 29th, 2003 at 07:25:00 AM MST

[\(User Info\)](#)

Hi Dave,

Sounds good. The other day I finally got to radio shack and got those rectifier diodes and hooked them up to the load control circuit.

One triac was still doing fine, but the other didn't want to turn completely off. Once I put in a diode at the triac gate though it started turning off like the other triac. I'm still waiting on new triacs to complete this thing, but two phases are now controlled well. Anyway, I think you should try this circuit as it's dirt cheap(about \$3/circuit for the 500?watt/circuit capacity I'm needing), very simple and compact, and should be very reliable and long lasting. What you're doing sounds good, but I remember you had to pay a bit for those relays, which you may want to save for something else later on. Anyway, I'm going to add a transformer to one output phase, the one going to the hot water heater element, and control it with a triac too. When I've got it all together I'll make a new post and tell you about it.

Here's how the final load control circuit is hooked together: The triac has 3 terminals(the gate and two for the hot interruption). The hots are hooked up to it like you would hook up a light switch(the gate is the switch). Then off one(the one your turbine is hooked to) of the hot terminals you put a resistor to limit current for what your gate can handle. This is also how you control when the gate switches, each circuit should have a little different resistance. To the resistor you add your two zener diodes(5.1v zeners work well). The zeners are hooked together cathode to cathode. To the last zener you add a rectifier diode(number 1N4004 at Radio Shack) and hook the cathode end of it up to the gate, that's it. From the hot(source) terminal all these gizmos are hooked in series to the gate, really easy.

You can get everything you need, except the triacs, from Radio Shack.

Kevin

Kevin,

Sounds great and I look forward to hearing when you get it all wired up. Maybe you could attach a diagram too. My relays were pricey but I don't think I'll ever burn em up, we're pulling a fair amount of current with what we're doing. I've been working on my tower sections that I aquired from a dismantled unit awhile back, that's another project altogether. Keep me posted, thanks. Dave B.

Re: Four component load control circuit ([none / 0](#)) ([#13](#))  
by kww on Tue Dec 30th, 2003 at 09:20:56 AM MST  
([User Info](#))

The control circuit for the hot water heater will be the same as the two circuits for the two stage heater. However, I may use capacitors or a transformer to boost the voltage after the control circuit. Anyway, I don't have a way of posting a diagram. I tried taking a picture, but it's too blurry close up and the stuff's too small far enough away where the picture's clear, sorry.

Kevin

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Kevin,

I think I missed your specs. on your alternator other than 3 phase. Since I am doing something very similar could you enlighten me on voltage, wire size etc. and blade set as well ? I'm crunching numbers trying to figure the best match for specs. on my blade set to carve. What do you estimate your power out to be at what RPM and what value are your load(s) ? Sorry for all the questions, I can't get enough of this stuff. Dave B.

[ [Parent](#) ]

Re: Four component load control circuit ([none / 0](#)) ([#15](#))  
by kww on Tue Dec 30th, 2003 at 08:15:20 PM MST  
([User Info](#))

I've got a 10 foot rotor and I'm guessing my max. rpm's are around 400-500. At that max. rpm I see around 50 volts. The wire size is 18ga., 50 turns/coil, 18 coils total. The magnets are 1x2x.5inch and there's 12 of them. My loads have 8 ohms of resistance, but I think I need to reduce that or increase the voltage with caps. or transformers. I'm guessing it'll make around 1000watts total output. I'm thinking of shortening the rotor to 9 foot, maybe 8, to get higher rpms(voltage) since I have small/18ga. wire. I think I could boost the upper end power output a lot by doing this, but I don't want to hurt the low rpm power so I'm still thinking about it. :-) Too many variables. Whatever you do you'll wish you'd done something different so don't think about it too hard, just do it, watch it, and then do it some more. LOL Eventually you'll get it just like you want, but it's not going to happen the first time around no matter how much thought you put into it I've concluded. Btw, don't put it up high at first and do use one of those \$9.99 1000lb winches for one of the guy wires so you can easily and quickly lower and raise it for changes. Enjoy.

Kevin

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Thanks for the info. We have similar alternators only mine is single phase. 18 magnets (actually 36, these are stacked double) 18 coils 18 guage wire 100 turns per coil all in series and my output is 100 Volts @ 400 RPM. I want the torque and can sacrifice some speed because of my output so I'm thinking 12' rotor possibly tsr-7 should create some heat to my hot water heating elements. I'd rather have my rotor turning more often in lower wind that to wait for higher winds just to get it moving. Should be fun to tweak the controller circuits too, this gives us another option to compensate and dial things in. Like you say, always something to change. Keep me posted, I'll do the same, thanks. Dave B.

([User Info](#))

Thanks for your info. too. Something you should know: I've noticed that when I put a large load on my voltage drops a lot. I'm guessing this is due mostly to the high resistance of the small(18ga.) wire. I think it'd be a good idea if you hooked up your element(s) and ran the alternator at 400rpm to see what kind of voltage you're getting under load. Whatever it is though I think it'll still heat the water just fine, even at 20 volts the 220v water heater element I have will get hot to the touch.

Also, if you did supply 115volts to the element it would put a load of 4500(?) watts on your alternator which would stop it in most winds. The cool thing is, you don't need to run the element at the power it was intended to run at since you'll be supplying power continuously(when the wind's blowing) and not for just a few minutes. The main thing is that you've got enough load. With my alternator's voltage the 220v element I'll be using doesn't provide enough load because my voltage is so low, which is why I'll probably boost the voltage with something. One other thing you may be interested in knowing: The first alternator I made used 14ga. wire. It's similar to this second one, but made around 1/3 the voltage. However, when I put a load on it the voltage hardly dropped. I'm wondering now if the 14ga. wire alternator will make a lot more power, but it's going to be awhile before I get it hooked up so I can compare the two.

([User Info](#))

Try charging a capacitor off the genny and then dumping the cap through your heating element in pulses.

Just shuttle the capacitor back and forth between the two.

This will do away with the mismatched impedance between the genny and heating element.

That's what I want to try. Is there a really simple way to hook this up? Can you throw a diagram at me? I found a diagram of a voltage doubler circuit using 2 diodes and 2 capacitors hooked up to an ac source and load, but seems to me something is missing, something to trigger the capacitors to fire. Maybe they don't need a trigger with this circuit? I don't know and the wind's not blowing for me to play so I've been impatiently waiting. Btw, I took apart an old 400watt microwave oven and I've got a nice big(?) capacitor(1600wac, whatever that is), transformer, and some other cool gizmos which I have no idea what they are, but I'm having fun anyway. LOL Also, the load control circuit you told me about is working perfect since the diode was added to the gate of the triac, thanks again for that circuit idea. Feel free to send more. ;-) Kevin

([User Info](#))

Actually, the SG3524 chip in the patent is less than \$1. The opto-couplers are about \$1 each and the transistors/mosfets are about the same. The only thing the patent doesn't show is the actually pin numbers on the SG3524 flip-flop controller. I believe he chose that particular chip because it's dirt-cheap, internally voltage-regulated, and it can't cause an overlap in the two "on" states for the two transistor banks. I'm trying to work out the pin-outs in the diagram right now. I have a few of those in my "magic junk box" that I plan on using. Not sure where I got them. But then, I've torn apart a lot of stuff over the years. Here's a CHEAP AND DIRTY way to get the non-overlapping "flip-flop" effect. This is one of the basic systems that I've built. Make a simple 50% duty-cycle 555 timer pulse circuit. Drive a tiny, low-power relay with the coil hooked up between pin 3 and ground. Also put a protector diode across the pin 3-grnd connection so the relay coil's emf doesn't zap the chip. Use the relay contacts to alternately connect the transistor base-leads to their respective collector-leads. Place a 3v zener diode across the base and emitter leads of each transistor to keep them from getting an overvoltage and popping. Now your relay is conducting almost nothing since it's just controlling the transistor bases. You can put as many transistors in parallel as you want. A slightly more effective method for further reducing the relay contact wear would be to drive two mosfets from the relay contacts. The mosfets would then control the two large banks of power transistors.

Re: Four component load control circuit ([none / 0](#)) ([#24](#))  
by kww on Fri Jan 2nd, 2004 at 07:22:24 AM MST  
([User Info](#))

Holy cow. :-) If you're interested, how much \$ would it take to get you to make and ship such a thing to me? I could most likely duplicate it once I had it to look at and study. If I can take something apart without destroying it I've always been able to put it back together, that's how I learned to rebuild rotary engines and whole lot of other rather complex things. When it comes to electronics the 4, now 5, component circuit was a "big" step for me. LOL Anyway, I got to looking all over the net for circuits and found a voltage multiplier circuit that's got my interest, nothing but caps. and diodes. Seems to me if I put some of these on my alternator I could step up my voltage output range as high as I wanted to. I'll just arc the power to the house, no wire. ;- ) Kevin

([User Info](#))

Go to Radio Shack and pick up some of their little electronics manuals. They have one dedicated to the 555 timer. It shows, in very plain terms, just how to wire it up to make it do all sorts of things.

One of the best starter books there is called "Getting Started in Electronics". It will take you step-by-step through the use of each basic type of solid-state component.

You really don't want anything that comes out of my "little shop of horrors". I tend to build things that look like rat's nests. Although, they usually work, for some reason.

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

This is great ! Yes, my voltage does drop under load and it is because of the smaller wire and higher resistance. Your 14 gauge wire could carry more current (easier flow) so you noticed less drop. It's all a trade off, bigger wire, fewer turns less room less voltage more current. It's good to hear that even at a lower voltage we are creating substantial heat, I was hoping it would work this way, I am in no rush and don't expect quick recovery on hot water, just would like to supplement if and when the wind blows. I'll keep you informed and thank you for all of your information, this is going to work. Dave

### [Air-X/Solar Panel Conflict](#)

By [dburt](#), Section [Homebrewed Electricity](#)  
 Posted on Wed Nov 19th, 2003 at 05:52:20 AM MST [Controllers](#)  
 Connecting Air-X and solar together...

My neighbor put up a new Air-X wind unit about 3 weeks ago, which has a built-in controller that senses battery voltage and adjusts the charge accordingly. It has a LED that is normally off, on when charging, flashes when the batteries are full or the wind is too fast (over about 30 mph). I don't think the wind has been over 10-12 MPH lately either. He keeps his batteries pretty well charged. He has both Air-X and 30W solar panel wired directly to 4 golf-cart batteries wired up for 12 volts, 10AWG wire about 65 feet down the tower to the battery. There has been NO sun here for several days. He reports:

"I've been watching my windmill, and when it reach's 7mph an red led is suppose to come on and stay on until the system slows down. But what I have seen is, it's been taking much higher winds to turn on the led. But instead of staying on it would blink rapidly. So last night I disconnected the solar panels, and the led came on and stayed on while in a good rotation. No more fast blinking, just a steady charge.

Why do you think the solar panels would confuse the windmill controller system?"

I'm at a loss. Any ideas?

Thanks,  
 Dave in PA

The 403 may be seeing the panels as a load, try adding an isolation diode to the + lead of the panel.

Dr.D

## Homebrew MPPT

By [drgeeforce](#), Section [Homebrewed Electricity](#)  
 Posted on Thu Nov 13th, 2003 at 11:40:44 AM MST [Controllers](#)  
 Trying to squeezing out the last electron.

I have a Xantrex 35D connected to 2-80W 36Vmax, 2.4Isc, BPSolar panels and 1 60W 24Vmax, 3.2Isc, Solatron in parallel hooked up to a 12V battery bank all with 6A diodes. I was considering upgrading to a MPPT controller OutbackMX60 costing \$433. I was wondering if I can create a pseudo-MPPT by connecting a 48Vin 12Vout @ 8A DC-DC converter between the controller and panels. This way the panels can operate at maximum voltage delivering all it can to the converter. The converter can then deliver the 12v load to the controller. The controller cost me \$75 and the converter will cost me \$25. The converter efficiency is rated 85% whereas a straight panel connect to the controller is about 44% at best. Any thoughts on this homebrew setup?

[Homebrew MPPT](#) | 3 comments (3 topical, 0 editorial)

Re: Homebrew MPPT ([none / 0](#)) ([#1](#))  
 by [drgeeforce](#) on Thu Nov 13th, 2003 at 11:55:32 AM MST  
[\(User Info\)](#)

Also, the MX60 is rated at 95% efficiency, but I don't know if the cost, \$433 will offset a 10% difference in efficiency, as compared to \$100 for the converter+controller. I saw a batteryless grid-tie 1500W inverter/MPPT combo for \$995 wholesale/\$2,245 retail. My battery bank is over 8 yrs old and I was considering going batteryless. I figure I would need 10-12 100W panels to make this worth buying. I live in rolling blackouts sunny California, but my electrical needs are not much nor critical.

The problem with a plain dc-dc converter is they won't keep the input constant, soon as you put a heavy load on the output (battery charging) the solar input voltage will drop down close to the battery voltage, so any bonus you would have got has vanished!

You could give it a try I guess, but don't invest too much money in it, and be ready to take the dc converter unit back to the store!

Unfortunately those MPPT controller units cost so much for a reason, very hard to homebrew, I have attempted it and had mixed success:

<http://members.optusnet.com.au/~adiman>

Cheers

Adrian L

Re: Homebrew MPPT ([none / 0](#)) (#3)  
by [charged](#) on Sun Nov 16th, 2003 at 04:07:38 AM MST  
([User Info](#))

Build yourself a direct DC-to-DC capacitive charge transfer system.

<http://www.fieldlines.com/story/2003/10/16/16947/477>

A large capacitance can be nearly 100% efficiently charged with an inductive step-charger until it reaches the required charging voltage for the batteries. Then disconnect the capacitor from the panel and dump the charge into the batteries.

This can be done for the cost of a few power mosfets, a couple of 555 timing chips and a large capacitor rated for at least 200v. You could probably scrounge enough electrolytic caps from old TV sets to make it even cheaper.

## [Dump Load](#)

By [bruce1](#), Section [Homebrewed Electricity](#)

Posted on Thu Nov 13th, 2003 at 10:32:14 AM MST [Controllers](#)

**Can I get excess power from my controller to my house**

My battery bank and tower is about 200'-300' from my house. I will have my inverter and controller at the tower/battery bank. I will bury wire to my house from my inverter. At the tower, I have no use for that extra power from my controller, except to just burn it off as heat. In the winter I could heat the battery shack, but in the summer I wouldnt need that. I know I cant run 24DC that far efficiently, I wonder if I can step up the power the controller is putting out, somehow, send it in a separate cable to the house, so I can use it for something, maybe a preheater to the hot water heater. I doubt I can use a small inverter since the DC voltage will vary and not always be present. I am unfamiliar with any ways of doing this, any help would be very appreciated.

The next thing would be the cost of the equipment and second cable. It may not be cost effective to do so.

Thanks everyone for past,present and future help.

Bruce

by drgeeforce on Thu Nov 13th, 2003 at 10:51:43 AM MST  
([User Info](#))

Distance is your main enemy, I would consider a cooling fan (or a small a/c) for the shed during the summer months, that way the battery banks would benefit. You could possibly shunt the excess to a portable battery, that way you could carry the power to the house.

You could put up a bank of lights on the tower to burn off the excess, and that way you could see if your battery bank is full.

But honestly, I like the winter heating, and summer cooling idea. I suppose your shed roof is good.

Maybe just use the extra to pump water onto the shed roof... maybe that would cool it off a bit in the summer?

Cya,  
Chris

by dburt on Fri Nov 14th, 2003 at 05:41:21 AM MST  
([User Info](#))

Bruce,

How do you keep your inverter from freezing in the winter? Most inverters are only rated for temperatures down to about 30 degrees F (because of the capacitors??).

I have a simular situation (long distance from house to tower), don't know how to handle it short of berming/burying/insulating the battery/inverter shack.

Dave

Re: Dump Load ([none / 0](#)) (#5)  
by laskey on Fri Nov 14th, 2003 at 08:34:22 AM MST  
([User Info](#))

I assume that if it's running it's got heat to spare, and if it's in dump mode he's probably dumping to heaters which will keep it warm in there. Am I right?

Re: Dump Load ([none / 0](#)) (#6)  
by bruce1 on Fri Nov 14th, 2003 at 09:30:41 AM MST  
([User Info](#))

Well, to be honest, I dont even have the shack built, or an inverter. My c35 controller is to be here Tuesday via UPS, and I'm in the process of making some sort of heater for my dump load. I only hoisted my first ever tower 2 wks ago. I like to try to plan ahead, so I'm asking questions about things I havent gotten to yet, so I can understand them better when I do get to that point.

I've got my mill shut down most the time, and run it when I'm home. I have 2 deepcycles at the base right now to serve as a battery bank while messing and experimenting with it. I havent thought about the cold actually, I assumed the inverter and controller would handle it and put out some of their own heat, enough to keep themselves warm at least. Am I wrong on that? I guess heating the shed through a dumpload is where I'm heading with my last experimenting. I have nothing else to do with it out in my pasture.

Allan, can you elaborate, or anyone, on his suggestion? I'm not as electric/electronic literate as most people on this board, but I'm sure learning fast!

Thanks all, Bruce

Re: Dump Load ([none / 0](#)) (#7)  
by wpowokal on Fri Nov 14th, 2003 at 05:11:45 PM MST  
([User Info](#))

Bruce, apologies for my short reply, but if you don't need the excess power at "the shack".

Instead of buying more heavy cable you could run a light cable to send a signal from the charge controller to a switching device (relay/triac) at the inverter end and switch an AC load, like water heating.

regards Allan

[ [Parent](#) ]

Re: Dump Load ([none / 0](#)) (#8)  
by bruce1 on Mon Nov 17th, 2003 at 12:16:19 PM MST  
([User Info](#))

I'm trying to follow you on this, not sure I am. Tell me if I'm right.....

The controller would send DC to a relay inside my house, which would kick on an AC load, drawing more power through my inverter and my grid, thus using more voltage from my battery bank. Using more power from my battery bank would pull down the voltage, and in turn be doing the same thing a dumpload heater would do.

If I'm correct on that, what sort of cable would I use? How much DC voltage can I get into my house, through a light cable, 250' away? Or do I have the relay at my 'shack', send AC through a different cable into my house from the shack.

Sorry if I'm still not following you, but I am interested in your scenario, so if you can step me through it, I would be grateful.

Thanks, Bruce

Re: Dump Load ([none / 0](#)) ([#9](#))  
by wpowokal on Sun Nov 23rd, 2003 at  
02:51:58 AM MST  
([User Info](#))

Bruce, You basically have the idea, staying mechanical ie a relay, you would only need say a 1mm sq cable(aroung 17AWG) + and - run to your house.

Clearly the relay would have to have a coil of the same voltage as your batteries and the contact rating sufficient to switch the proposed load current.

Allan

## [C35 Controller Questions](#)

By [bruce1](#), Section [Homebrewed Electricity](#)

Posted on Mon Nov 10th, 2003 at 01:24:49 PM MST [Controllers](#)

**Making a dump load burner upper thingy**

What ever you call it, something to burn power that is being diverted from your controller. I have my wind setup up and in the wind, now I need to get a controller. I have C35 found for pretty reasonable money I will be ordering. What do I need, something to burn a max of 35A? Should I have something that can burn more, or will 35A all you will ever see come from the controller?

This may not be the ideal thing, but what if I wire a series of taillight bulbs that will burn up to 35A? I wired some up today(boss is gone ;-)), 2 #1157 double filament bulbs in series and hooked them to a 24v battery setup. It burned just over 2.5A. I hooked up 2 sets in parallel and of course burned just alittle over 5A. Could I set up 7 sets of lights in parallel to burn 35A? These bulbs cost me .48 cents each, that would be about \$7, plus some misc. wire and such.

I realize that if one light burns out, I lose a circuit which will lose the ability to burn 2.5A, the others would have to be able to absorb that extra amperage, if/when the controller diverts a full 35A. Should I put in 8 or 9 sets of lights, that can burn 40A or so, and if I lose one, I can still burn in excess of 35A?

I know there are setbacks to this, like not being able to just replace a bulb without doing some soldering, but its something I have easy and cheap access to, so thats the first thing that I thought of.

Thanks for any input anyone has.

Bruce

by [bruce1](#) on Mon Nov 10th, 2003 at 01:31:59 PM MST  
([User Info](#))

I need to correct myself, I would need 28 bulbs, which would make the cost about \$14, and double the soldering as I first thought.

Bruce

Other than the durability issue, bulbs will work. Keep in mind that incandescent bulbs are 5% efficient (or less) at making light. So really what you have in your bank of lights is an air heater that makes 5% light as a by-product. Put it someplace that's a bit cool, and you have a nice little heater.

Using resistance wire from a salvaged heater will also work, keeping in mind that the element from a 120 volt heater will be ten times too long for the resistance you want for a 12 volt setup. So if you were going to convert an element like that for diversion use, snip into ten pieces and run them in parallel to get sufficient capacity for a 12 volt setup.

As mentioned, it's hard to solder that resistance wire, so crimping may work. None of this stuff would pass code or get UL listing, so you are totally on your own for safety. If it burns the house down, your insurance won't cover it without both code and UL approval. What a nuisance...

Good luck and have fun,

troy

Re: C35 Controller Questions ([none / 0](#)) (#2)  
by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Mon Nov 10th, 2003 at 04:27:00 PM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

bulbs are not ideal because they do burn out and their resistance is not linear.

I prefer to use a water heater if I can because then I get some use out of it.

The load should not be much over 35 amps rated or you may burn out the controller.  
Hugh Piggott <http://www.scoraigwind.co.uk>

I do hate the thought of wasting that power that I've worked on generating, but my tower and batteries will be quite a distance from the house, so I think heating water wont help me, but using the heating element may work?

Thanks for the input, Bruce

Re: C35 Controller Questions ([none / 0](#)) (#4)

([User Info](#))

I use a heating element from an old 120vac electric heater that I shortened to 2.8 ohms(if I remember right). I also have a C35 and today it was dumping plenty into my dump load heater, well, plenty meaning 150 watts, not much as compared to most systems here. But the heater was getting warm. It was easy to build the heater although I found you can't solder the heating element and have to use crimp connectors. I don't remember the calculations off hand but I remember seeing it here how to size your dump load. Might try a search for diversion load.

Scott

Thanks everyone. I now have in my possession some old stovetop burners from the salvage yard. I wanted some oven elements so they werent all circular, but found some other straight elements that may work. Cost me nothing, and if they arent exactly what I needed, I will surely learn something working with them. I did also find some formulas on sizing the load from Hugh P. on this board, so I'm loving all the info I'm gaining from the people and past posts.

Thanks again, Bruce

 Watt meter

I bought one of those manual transfer switches used to wire a generator to your electrical panel. This was one with a bad circuit breaker. I have a better one now, so the old one is surplus.

These came with 2 "Watt Meters" to help you monitor power use. Does anyone know if I could use these meters as part of a wind/solar system to monitor use? I really don't know how they work or if they are calibrated only for 120 volt current.

Any thoughts out there?

Bach On!

You can use them on the output of your inverter(s). I would suspect that they have 4 leads, one to the common white and two that splice in to the black ( hot) lead, one will be for the black wire from the inverter and the other for the black wire to the load and lastly a ground.

Dr.D

be careful about using watt meters with "modified sine wave" inverters. they are designed for use with 50/60 hz sine waves. i have a plug in type that shows al sorts of crazy readings from the inverter. works fine on mains.

still having fun  
 bob

I have a pile of old meters including watt meters. I use a 0 - 150watt meter to monitor a small tape drive mill. Hooks up like ampmeter to positive output from mill and also to mill output voltage, amps x volts = watts. I like it, I have a smaller 0 - 50watt meter I might put on my 30W solar panel to see what it's putting out.

Scott

Re: More questions ([none / 0](#)) (#4)  
by Bach On on Sun Nov 9th, 2003 at 07:48:31 PM MST  
([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

Thanks for the responses guys.

These watt meters have a scale ranging to 3,750 watts. They were each wired to monitor 3 of the six circuits for a genset of up to 7,500 watts.

I had considered using them with a modified sine wave converter. I doubted they would be real accurate since they probably aren't RMS. But they might at least get me in the ballpark to determine the power being drawn. I have a volt meter on it already. Why not a wattmeter too?

Does anyone know if these can also be wired to work with DC? Somehow, I doubt it.

Bach On!

This or Trace C40 for controller/dump load of tape drive wind gennie

I fund this on Ebay and was curious if anyonw is familiar with them. I need a controller for my tape drive gennie that I'm building, it's a 40V motor with 2 Jerry blades W/mike mod charging 4 golf cart batteries. My camp only sees occasional use so there will probably be plenty of dump load. I also have a 30W solar panel with controller.

Any opinions?

Thanks  
Scott

Hi Scott,

Coincidentally, I just bought one two weeks ago, got delivery a week ago and hope to hook it up tonight. I can tell you a couple of things already. The insides look pretty professional, but the outside doesn't look as slick as the trace controller. For example, the cooling holes look like they were done with a die, but they don't really line up nicely. The spatter paint on the cover looks ok, but not really professional. Mine did have a loose nut rolling around inside, which I liberated through a cooling slot so as to not short things out on a board, so there could be quality control issues at the factory. Or maybe the UPS guy was practicing his juggling routine...

I'll let you know when I get some actual experience in the next couple of days.

Oh yeah, it's definitely not "UL" listed, so would never pass an electrical inspection unless they do you a favor.

Best regards,

troy

Re: Charge-Max 1500-12/24 controllers ([none / 0](#)) ([#3](#))  
by troy on Mon Sep 29th, 2003 at 11:56:57 AM MST  
([User Info](#))

Hi Scott,

I have everything hooked up and it seems to work as advertised. Hook up is straight forward, and then just set bat voltage with the switch (12/24) and dial in the cutoff voltage to whatever you want to fine tune it to your pack.

Best regards,

troy

[controller circuit with triac](#)

By [bewotec](#), Section [Homebrewed Electricity](#)  
Posted on Thu Sep 18th, 2003 at 08:57:20 AM MST  
nothing

[Controllers](#)

Hello there,

i read the description on <http://homepages.enterprise.net/hugh0piggott/circuits/index.htm>

from Hugh Piggott.

i wonder if the MOC6031 and the BTA06 triac can be a replacement to a relay or not?

i mean in a charge controller circuit when it opens loads at different charge levels by a comparator chip. my original plan was to open the loads via relays, but those consumes quite a lot. this triac offers much less consumption, but i am suspicious a bit, because in my situation the triac would control DC, not AC and it must switch down consumers, which i am not sure if it is capable.

anybody with electronics experience can have an opinion?

i thank for everything.

viktor

Triacs do not work on DC as there is no way to turn them off.

Victor

Re: controller circuit with triac ([none / 0](#)) (#2)  
by laskey on Thu Sep 18th, 2003 at 10:18:02 AM MST  
([User Info](#))

Right... You need a device that can be forced off. Like a power transistor, or a MOSFET.

There is also a device that is SCR and triac like called an SCS (silicon controlled switch) which can be turned on and off, but they are generally used for lower power applications and are pretty rare (since I had to look it up in a textbook).

Cya,

Chris

Actually you can use an SCR but to turn it off you must apply a reverse polarity pulse, this technique was used for DC motor controllers such as used in early electric vehicles. This might be an interesting challenge to build.

Dr.D

<http://timmythy.home.mindspring.com/timmy.htm>

The SCR is the DC version of the Triac which an AC switch (but not DC).

SCRs have the same voltage drop problem as a normal Diode has.

If I'm understanding an SCR correctly, you could call it a switched Diode

I'm even thinking that you could completely replace the diodes that are normally in your charging circuits with SCRs and switch them on and off however you wish.

> my original plan was to open the loads via relays, but those consumes quite a lot

True, but since you're only switching the relays on when your batteries are full and you need to use up some power, is this \*really\* a problem? ;-)

BTH

Re: controller circuit with triac ([none / 0](#)) (#6)  
by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Fri Sep 19th, 2003 at 12:51:43 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

Triacs can only used to switch AC but I do it before the rectifier. I use two triacs to control the 3 phase feed to a rectifier for each load. There is some volt drop across the triac but that's OK for the high voltage loads I use them for.

You can also use relays, but triacs are more robust. Relays are better for low voltage stuff because there is not volt-drop across the contacts.

Most of my efforst to use MOSFETs for charge control have failed. MOSFETs are easily destroyed.  
Hugh Piggott <http://www.scoraigwind.co.uk>

Re: controller circuit with triac ([none / 0](#)) (#8)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Fri Sep 19th, 2003 at 07:17:41 AM MST  
([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

Instead of using Triacs to switch the voltage to your Recifiers.  
Use SCRs in place of the rectifiers and switch them on and off.  
Half the voltage drop . . .

Two SCRs wired in parallel but reversed to each other, equals a Triac

One SCR with the Gate pin enabled, equals a Diode  
-- W o o f

Re: controller circuit with triac ([none / 0](#)) (#7)  
by bewotec on Fri Sep 19th, 2003 at 05:09:30 AM MST  
([User Info](#))

ok, understood. i thought so. so i remain with the relays.

does anybody has experience with a tachometer driven 3p2t relay which switches between star and delta config at a given rpm?

the itdg manual says it is too complicated, but it does not seem so even for me.

thanks for the opinions.

none

Hi guy. This one has bugged me for a while, so I thought I better ask.

It seems like your first machine will only produce a fraction of your required power - as expected. To use that power, the common approaches are to wire into only a few house circuits or to send it back into the grid through some kind of net metering. While both OK, I am looking for an alternative.

Is there a device that takes inputs from both the utility supply and your homebrew source(s) and produce a 120 ac source that goes to your home fuse/breaker box. The aim of this is to use ALL of your alternative source and only suppliment from the utility to meet your current needs. As your alternative sources grow, the utility suppliment will drop as will your electricity bill.

Does such a thing exist?

Martin.

There have been some rumors that some of the commercial mills can be had with an intertie inverter without batteries. That will accomplish what you are after. I'm not sure, but I don't think you can buy anything like that independantly just yet.

Best regards,

troy

I agree with Troy, AFAIK the only way to do this like you are talking is to use an intertie inverter. This normally involves an extra panel box with the critical circuits and their breakers. This would be set up like the transfer switch and panel you would need if you had a generator. But a grid tie inverter can perform the transfer functions.

A grid tie inverter does not always mix with the utility power as you seem to want, however. The problem is that in order to put two 60 cycle (50 or 60 Hz) power sources in parallel they have to be synchronized EXACTLY. A grid tie inverter has the electronics that allow it to synchronize with the utility and could run in parallel with it, and some grid tie systems are set up that way.

There are a lot of advantages to keeping the systems separate, however. But that's not really what you are asking for, so I'll save that for later. Search this web site, Homepower magazine, and the web using some of the key words I've given above along with "solar power", "wind power", etc. & you'll be busy reading up on this for some time...

Re: Does this exist? ([none / 0](#)) ([#5](#))  
by Wolfie1 on Thu Sep 18th, 2003 at 05:55:53 AM  
MST  
([User Info](#))

Which of these is true: -

- 1) It is this something that is possible in theory but no product yet exists.
- 2) Given our current knowledge, such a device isn't possible.
- 3) No one has bothered to make one because the power losses would be too large.
- 4) There is a fundamental flaw in wanting to do this in the first place.

I give number three because it would seem possible (to me at least) to rectify your utility input, add your RE sources (also DC), invert the total and run the house on that. That way seems very inefficient but seems like a contender until something better comes along.

Martin.

Being a newbie, I thought the same way. When my system is charged up and ready to provide power, I thought how great it would be to use my 10%, use 90% from the grid. Everytime my system was ready and charged, it would use all of my power, never having to bury any through regulator. When my system is discharged, go back to the grid 100%. I've been told, for the most part, thats not really how it works, and how am I do disagree. Theres alot I need to learn, but I know where your coming from.

Xantrex SW inverters do exactly this opperation in float mode. It is accomplished by the inverter synchronizing with the grid. any time your battery voltage tries to exceed a user difined set point the inverter suppliments the grid power enough to hold your batteries at that voltage. The Xantrex inverteres also have a LBX mode where loads are transfered from grid to inverter and back at user difined set points.

Outback inverters also have this LBX feature but it is more appropiatly called HBX , high battery transfer, and is more versital and has lower standby losses as the inverter actually turns itself off when batteries are low and you are grid powered.

Make the wind fun!  
Victor

Too expensive? Based on what? OutBack is very competitive with Xantrex but with much newer technology. The OutBack boys designed the Xantrex products you are talking about ten years ago. I'm sure they have learned a thing or two in the meantime  
Robin

Troy,  
Yeah, I've used the 30A capacity model for about 8 months on a small one-panel (64W) system to run my laptop. Bought on eBay. Think these could be repair/returns. Had my doubts cause never heard of company outside of ebay listing. It is a pretty good design. Only noticeable flaw is underbuilt terminal posts (strippable if not careful) that are too closely spaced/poorly located. Can't comment on the charging efficiency cause no way to measure or compare really. Don't know what the algorithm is--they say its is not PWM but then they dont mention anything about MPPT either, so it is something else. But it is still working. The cabinet is not waterproofed and they recommend keeping ventilated (I keep in plastic container which has ventilation). It seems to be ok for a reasonably high capacity (30A) diversion controller with LED's that tell when charging or diverting, but maybe I got lucky on a repair/return that I am not running a lot of current through.

Hope this helpful

Andy

Posted on Sat Aug 16th, 2003 at 11:59:40 PM MST

[Controllers](#)

Curious on some stuff about transfer switches if anyone has one and has installed it themselves

Does anyone have a transfer switch installed? I'm also a little curious how you went about it if you in fact did it yourself, and how long it took. I'm doing a little google'ing on them right now, and says that you need to have an electrical permit to install one and must be installed by a licensed electrician. However, I know that when you're building your own house, you just get the license and you can do all the work yourself. My wife and I were supposed to have our house built this summer by her dad. He has his own construction company but it would have been basically us getting a "build it yourself" permit and he would've done all the work for us. Are there any ways to to do it yourself without being a licensed electrician for something like a transfer switch? Thanks,

Tom

([User Info](#)) <http://oneota.net/~earthsourcespowr/>

Tom;

I'm rural and we don't have too much problem with licenses or inspectors bugging us. We had our manual transfer switch professionally installed. I watched the guy do it it was very straight forward grid in, house feed out and generator in lines.

I could have installed it myself I suppose but crawling up ladders and such is not an option for me anymore. Around here as long as the power company [rural electric co-op] approves the install its OK. Essentially for us, anything beyond the meter is our call and that switch is on my side of the meter.

We had the switch and the install was only around \$100. All my wife can remember about the switch was it was very expensive and that she had bought it several years before we were married for the farm and had just never gotten it installed. When I asked the electrician he said new ones cost \$450 and up but I never checked further on prices. That was in 1999. Our 5KW gasoline generator simply plugs into an outlet on the pole and you throw the switch to switch the grid off and the generator on to the house circuits.

Cheers.

TomW

Hey Tom, thanks for the reply. So you're sayin if you wanted to install it yourself, all you would've had to have done was let your power company know that you were doing it and that's it? If you've seen that post I made a few weeks ago regarding the RE business I want to go into after I graduate, this part is really my main concern because I have never gotten into a house electrical system, let alone after the house is already finished and everything is behind walls! My dad has a generator (unfortuneatly I couldn't talk him into some PV's) and I'd like to at least maybe hook up a transfer switch to get the experience. I don't know, thanks for your reply again!

([User Info](#)) <http://www.electric-ed.com>

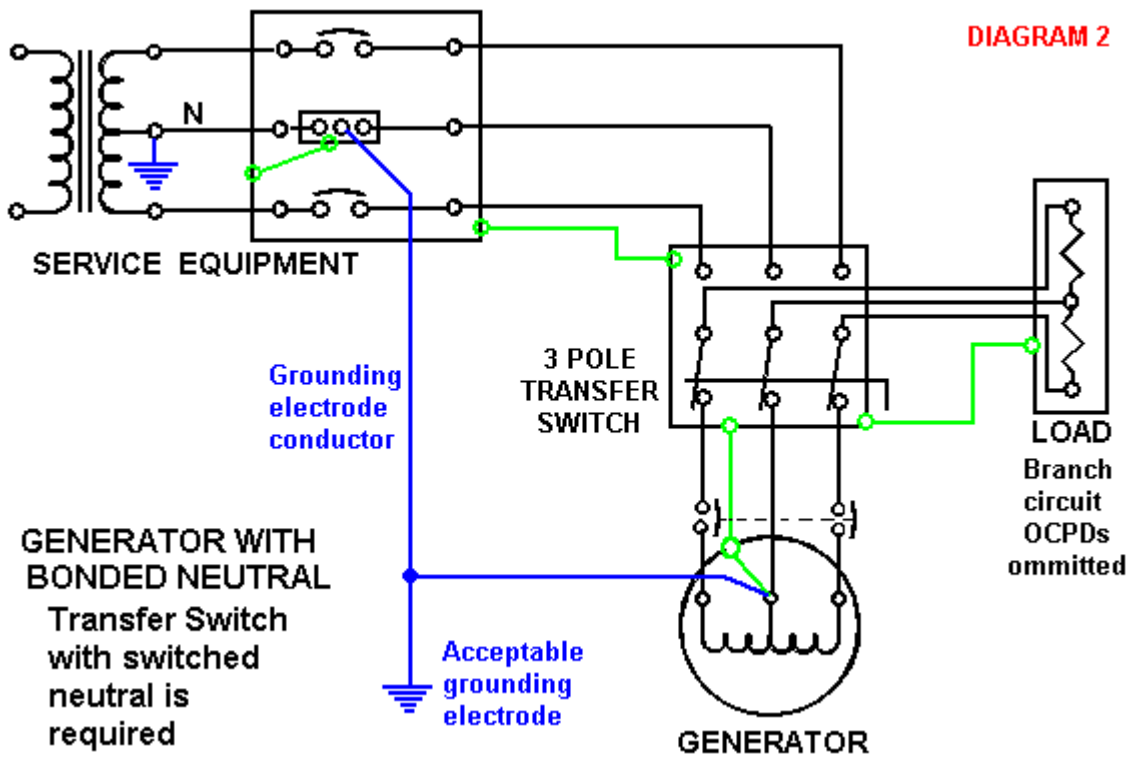

Be very careful with the selection and installation of a transfer switch. The type of switch, that is, whether it switches the neutral conductor or not, depends on the type of generator it is used with.

The "portable" generators that are designed for "stand-alone" use were never intended to be connected to a building wiring system. They are required by code to have the neutral bonded to the frame, and if used with a transfer switch, the switch must open the neutral conductor.

Generators that have a "floating" neutral require a transfer switch that does not switch the neutral conductor.

Electric Ed

by [tleser \(tleser at purdue edu\)](#) on Sun Aug 17th, 2003 at 12:15:23 PM MST  
([User Info](#))

Hey thanks Ed for posting those schematics. That is some good info you posted about and also your site! I will have to look around there, but do you know anything about obtaining the electrical permit to install the switch and the requirement for a licensed electrician? I'll be getting my b.s. in EcET this december and have taken a high power course that went from designing generators, to xfmr's, to sizing fuses and breakers, and even PLC's (Hate those things!). That's why I'm thinking of designing my own transfer switch that will have better automatic features. I'm goin in to talk to the power system prof's this week about it. Do you possibly know any resources?

I'm really just concerned about the licensed electrician bit, would I just have to get the license then? What does that entail too? Thanks again!

Tom

Re: Anyone have a transfer switch? ([none / 0](#)) ([#5](#))  
by [laskey](#) on Sun Aug 17th, 2003 at 05:37:59 PM MST  
([User Info](#))

Let me tell you one very important thing. Designing your own transfer switch may be cool and exciting, BUT in Canada (and I`m sure the states too) if you install it in a house with out CSA (or UL) approval you not only void the house`s fire insurance, but make your self liable for any damages it may cause if it goes faulty. An electrical or building inspector will tell you to remove it if it dosen`t have safety certification sticker on it. Oddly enough CSA isn`t hard to get, but they`re very picky.

I also know of quite a few Dead Electrical Engineers who thought they knew what they were doing instead of having a qualified experienced electrician do the work they specify. It looks easy (and it is), but you need to be trained specifically how to do that work.

Cya,

Chris

([User Info](#))

great tips Chris, definitely something for anyone to follow. I wasn't plannin on goin in without doin it properly. Keep in mind I just started lookin into this, so I guess if I want to be a transfer switch competitor I will have to look up info on getting UL approval. I've learned quite a bit today from the keywords I've gotten from this thread and a couple a couple of email replies from a buddy of mine, who's a LEGALLY unlicensed apprentice electrician. Yep, IN is a weird state where there's no state-wide electrician licensing, his county doesn't require it. Thanks again for the replies.

Tom

## [Need advice on Xantrex charge controller](#)

By [troy](#), Section [Homebrewed Electricity](#) [Controllers](#)

Posted on Sat Aug 16th, 2003 at 03:45:29 PM MST

Will a C35 Xantrex act as a dump load controller?

Will a C35 Xantrex act as a dump load controller?

Here's an excerpt from their advertising:

C35 Charge Controller, 35A, 12 or 24V

Product Datasheet

A Controller for Virtually Any DC Charging Source The C40 has long been the mainstay of our charge controller line-up, its versatility and reliability have made it an industry standard. Now the C40 is joined by two companion controllers, the C35 and C60.

All three of these fully solid state, microprocessor-driven controllers are UL and cUL listed. C Series controllers may be configured for PV battery charging, or DC load control or DC diversion operation. Whatever the charging source, a C Series controller is sure to meet your DC controller needs."

To me, the phrase, "DC diversion operation" sounds like you could hook up a dump load. Anybody have one of these that can say one way or the other?

Thanks a 10^6

troy

([User Info](#))

Hi Troy.

I use the Trace C-40 charge controller, and has been online for over 5 years working perfectly..Highly recommended..

Just wanted to remind you that yes, it can be a load diverter OR a charge controller, but not both at the same time..

Laterz,  
JimU

Re: Need advice on Xantrex charge controller ([none / 0](#)) (#3)  
by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Sun Aug 17th, 2003 at 12:52:20 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

The diversion load mode will control a dump load. It makes a fairly loud buzz as it switches it on and off quite fast. There are two voltage settings, bulk and float. Its a great controller except it does have a bit of a time lag in it so that if the wind is gusty you will see it dumping way above or below the set voltages at times.

The c-40 can be used at 12, 24 or 48 volts but the c35 is only 12 or 24 volts.  
Hugh Piggott <http://www.scoraigwind.co.uk>

Any body ever think of using an old electric heater as a dump load. after rewiring it for 12 volts it should pull a lot of amps / watts.

bobn

[Heater as dump load?](#) | 9 comments (9 topical, 0 editorial)

Re: Heater as dump load? ([none / 0](#)) ([#1](#))  
by laskey on Sun Jul 20th, 2003 at 08:44:27 PM MST  
([User Info](#))

Well... Kinda.

You see it has a set resistance which you can calculate. For example if it's 120volt 1000 watt heater. Then it'll draw 8.33333 amps, and thus it's resistance is 14.4 ohms. Now if you put 12 volt into 14.4 ohms, you draw .83333 amps which gives you about 10 Watts.

You see it's the resistance of the element that drives how much current you draw at a give voltage, and thus how much wattage you can use.

so... Stick an ohm meter across the element. Take the voltage you're going to feed it (say 12 volts) divide by the meter reading (12/14.4 ohms), you'll get the current it draws (.83333amps), multiple the input voltage by the current (12X.8333333= 9.99996 watts) to get the wattage.

I think the saving grace of the thing is that the element can still handle 8 amps (in my example), and when you switch into dump mode you are switching away from your batteries, meaning that your generator voltage can skate up away from what your battery bank was holding it at (say about 12 volts), meaning the you're actually feeding it much more voltage (say 50 volts) meaning it'll eat more wattage

if that makes any sense. :)

Cya,  
Chris

U could always cut the wire in two and X4 the power.....

Re: Heater as dump load? ([none / 0](#)) (#5)  
by Jimbob on Mon Jul 21st, 2003 at 07:14:52 AM MST  
([User Info](#))

I prefer surplus large 1000 watt resistors with say 1/2 ohm resistance to load lower voltage sources with an air heat exchanger. (go to: [www.fairradio.com](http://www.fairradio.com)). I will be using a commercial water heater that can take 6- 1500 watt @ 120 volt elements. At 24 volts, the load would be 1800 watts. Additional load will be the air exchanger heater using the resistors mentioned above. My air heat exchanger is good for 4KW load.

Re: Heater as dump load? ([none / 0](#)) ([#6](#))

by troy on Mon Jul 21st, 2003 at 12:20:19 PM MST

([User Info](#))

As mentioned, resistance is the key. And here is a source for low voltage heating elements to convert a standard 120 or 220 water heater to 12 or 24 volt if you want free hot water out of the excess juice. I've never actually dealt with these people, but their website has been around for several years, which is more than you can say about many of them.

Best regards,

troy

[http://www.kansaswindpower.net/water\\_heaters.htm](http://www.kansaswindpower.net/water_heaters.htm)

Use one or more of these elements as a diversion load with Trace C35, C40, C60, TC60 controllers. They fit most standard water heaters with screw-in elements. An adapter is used for the square flange type element. The dual 12/24 element has two separate 25 elements. It can be wired for 25 amps or 50 amps at 14.5 volts or 25 amps at 29 volts. The dual 24/48 volt element has two separate 30 amp elements. It can be wired for 30 or 60 amps at 29 volts or 30 amps at 58 volts. Order enough elements with a total current draw greater than your charging system's maximum output, but no more than about 75% the maximum amp rating of controller. 150 watt hours will raise 1 gallon of water about 60°.

D380 12/24 volt Dual 25 amp 3 lbs \$65

D381 24/48 volt Dual 30 amp 3 lbs \$65

Square Flange Adapter 1 lb \$20

Re: Heater as dump load? ([none / 0](#)) ([#7](#))

by bobn on Mon Jul 21st, 2003 at 02:14:32 PM MST

([User Info](#))

Well i rewired the heater for lower volts and it draws 25 amps at 12 volts in its current configuration.

bobn

Re: Heater as dump load? ([none / 0](#)) (#8)  
by troy on Tue Jul 22nd, 2003 at 05:23:19 PM MST  
([User Info](#))

Excellent Job!

I always root for the re-users/recylers. And now it's almost fashionable to go dumpster diving because you're saving the environment too. I guess I was cool all these years and didn't even know it.

Best regards,

troy

Re: Transformer/ power supply ([none / 0](#)) (#1)  
 by jubalearly on Mon Jun 23rd, 2003 at 03:30:25 PM MST  
[\(User Info\)](#)

There are several common ways to do this, so I don't think you can find a generic scematic. If you put 12v power supply in a search engine with scematic you'll find a few dozen. I personally like LM317 voltage regulators.

Does this have a chip controlling the voltage? Or is it simply a resistor for each voltage? Older ones might have a couple of transistors for voltage regulation. As cheap as these are, I suppose you are doing this for experience more than money saving. So, I recommend you put on a 10K pot (or whatever you can scrounge) and see what that gets you - HTH, Russ

Re: Transformer/ power supply ([none / 0](#)) (#2)  
 by Anonymous Hero on Wed Jun 25th, 2003 at 12:29:35 PM MST

Russ ( jubalearly), The 10K pot idea is truly excellent. I can then use a VOM to "tune"the correct resistance as I achieve the correct output. Then I can measure that resistance and replace the resistor. PERFECT . THANKYOU !!! Jungle Bill.

[No batteries, heating element load controller ?](#)

By [Dave B](#), Section [Homebrewed Electricity](#)  
Posted on Wed Jun 18th, 2003 at 12:52:10 PM MST  
I'm willing to pay for solution .....

[Controllers](#)

I have designed my alternator to power 120vac 1500 watt hot water heating element(s). 120vac @ approx. 450-500rpm. I do not want to charge batteries but rather run these direct. I am needing a load controller circuit that would vary the load depending on rpm or voltage of the mill. This will allow start up and more power efficiency at various wind speeds. I would also like to adjust the "time-on" and off to help smooth out when the winds are gusty. I can run this alternator up to 400 rpm with plenty of torque for testing with a 2 hp electric motor. I have spun it up to 900 rpm inloaded @ 230 vac with my drill. I am willing to pay for a working schematic or at least a rough circuit drawing to get me started on completing this part of my project. I can wire, build and test it no problem but do not have the time for the design work. I'd really appreciate any feedback (no pun intended) on help with this controller circuit.

Thank you everyone for your support, I'm having a blast. Dave B.

Well, I'll take a stab at it.

This my Blurry Concept Circuit. (remember it`s a concept, and my scanner`s not working.)

WH1 and WH2 (Water heater elements) are put in series so that they can handle 240VAC when your gen gets that high. R1 and VR1 control the turn on voltage for Triac1. It would be set to come on right away. This provides a short across WH2 so that WH1 is the only one on. R2 and VR2 control the turn on for Triac2. It would be set to come on when the incoming AC is up around 150-180VAC (maybe more, or less) and it prevents Triac1 from turning on, thus leaving the 2 loads in series for high voltage times.

Once again it`s a concept. I don`t know if it`ll work with out tinkering. But maybe it`s a starting place. I think it`s pretty good for a cola induced mid-night raving. >:)

Chris,

Thank you very much for your circuit idea. As I mentioned, my circuit design skills are a bit lacking but I am very experienced with assembly and repair of PC boards along with testing. Here's the interesting thing about what I'm trying to do. As the resistance increases the genny will spin more freely so actually I want to have an unloaded or open circuit at low RPM to allow start up. As the rpm increases I want to add a high resistance (possibly several heating elements) This will be a gradual loading of the alternator so as not to "brake" it too soon before it continues to increase in RPM. As the RPM increases I can reduce the resistance (shut off another element) More power at each element as now the voltage will be much higher. Being able to adjust the delay of the on and off switching will be important to try to most efficiently balance the windspeed with the power output. Basically this will automatically load the alternator with the desired resistance and still allow it to turn as easy as possible for the available windspeed. Does this make sense ? Can your circuit be made to work this way ? I understand how your circuit will function as drawn but is this the opposite of what I need ? I sure appreciate your help, this is great fun. Dave B.

Re: your gennie?? (none / 0) (#6)  
by laskey on Sun Jun 22nd, 2003 at 01:07:02 AM MST  
([User Info](#))

Hmmmm, Okay I get it.

You see I was concerned with over voltageing your heating elements at peak time, thus the load adds on in series. You start out with one load and add a second, but I see now. You want to remove the load all together for start up and add it in later.

Try this out for a basis.

The third triac can be set to delay turn on until voltage gets up high enough, as well (with the RC circuit delay the turn on during each cycle so that the load comes on later in the cycle cutting back the power it gets as the voltage goes up this delay should get shorter until there is very little delay.

If you want you could keep adding loads in parallel with R and VR group and a triac in series with the load. and you`d set the load to come on every so many volts. Think of it like this.

It`s getting too late for me to think straight. I`ll look at again tomorrow when I`m fresher.

This is fun isn`t it. :)

Cya,  
Chris

Chris,

I wish I could "read" circuits as easily as you can. I have printed these that you have drawn and they sure seem to make sense even for me. I think you've got the idea, all I need to do is learn more. Are the triacs capable of switching such high current ? Sure seems to me the way to go instead of relays, these will be switching frequently so the reliability and circuit life is very important. Again, the "backward" seeming thing about the load is that the higher the resistance the easier the genny will turn. It's almost like I want to lessen the resistance as the voltage (or speed) of the alternator increases. I'll need a good size blade set for the torque necessary, I believe a 3 blade of at least 10' will be needed, I don't think this is too large to still be able to hit 500 rpm max. in 25-30 mph wind. This will be slightly over 120 vac. I need time to play, I have a bread board and all the tools I need to experiment with the circuit. Do you know of any part numbers for the triacs that could work with this setup ? Thank you again for your time, any further thoughts or ideas to help me get this working is greatly appreciated and I'd be happy to slip you a few bucks for your experience. This is great fun ! Dave B.

Re: No batteries, heating element load controller ([none / 0](#)) (#8)  
by laskey on Sun Jun 22nd, 2003 at 03:24:38 PM MST  
([User Info](#))

Yeah, you should be able to find Triacs that switch this kind of load. A 120 volt element putting out 1500 watts is 12.5 Amps max (figured that out with my solar powered calculator >:)). So to be a good engineer we have to design for that even though I doubt we're going see 1500 watts per element. I'd have to dig for a part number. I'll see what I can come up with at work tomorrow if I get a second.

A triac is one of those strange devices that no one knows much about. I call them zero-cross devices, because they has to be triggered after every time the voltage goes to zero, and what's worse is the trigger voltage have to be the same direction as the way the main current's flowing. Most people find them a pain to work with, but they are real good at controlling AC loads. You can actually trigger the thing in the middle of each AC cycle half somewhere to get reduced apparent power to you load. If you build a variable delay circuit that can delay the Triac's on time from 0 to 8.333 Milliseconds then you can control the apparent load power from 0 to 100%. You actually get that kind of circuit in in most modern day light dimmers. The whole thing falls apart with inductive loads. No simple circuit will serve their needs.

Anyway, I digress, Triac turn on voltages are fairly low, so you need a pretty big voltage divider to get down there (R:VR ratio has to be high)and it'll take some tuning to get them to turn on when you want, but I think the crazy thing might just work. :)

Cya,  
Chris

by Dave B on Sun Jun 22nd, 2003 at 09:12:46 PM MST  
([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Man, this is great stuff. So much to learn and so little time. I guess triacs are magic and it seems like the answer to my continuous switching of the heating elements. Just wish I knew more at the component level and circuit design. If you come up with a component number for triacs that will handle the current that would be great. I'll do a search also and learn what I can about setting up and testing this type of circuit. It sure would be nice if I didn't have to work besides, I really had hoped to have this up and flying sometime before this Winter. Thanks for your help Chris, I'll let you know of any success I may have with testing of this setup. Any other ideas or information you might think could help make this work I sure would appreciate it. Dave B.

regulators for wind gennys

before making my final plans to construct wind genny, i must consider how i am going to regulate this future jewel. i am not sure what voltage output there will be or the amps. can i use an old GM fender mount regulator. what is the voltage range and amp range that i can input. does anyone have a schematic that i can build or adapt. any suggestions or answers will be kindly appreciated. thanks guys.

[how do i make regulator for wind genny](#) | 1 comment (1 topical, 0 editorial)

Re: [how do i make regulator for wind genny](#) ([none / 0](#)) (#1)  
by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Tue Jun 17th, 2003 at 05:57:09 AM MST  
([User Info](#))

Are you building a permanent magnet alternator, or using a vehicle alternator? In any case, the regulator from your GM won't work -- it's made to change the field strength of the electromagnets in the armature.

With a wind genny, you don't ever want the alternator (no matter what type it is) to become unloaded....the mill will overspeed and possibly blow up. Your battery bank basically serves as the regulator for the genny, until the batteries fill up. At that point, you need something that will turn on to use up the extra power.

The simplest way to do that is just a voltage-controlled switch that turns on a 12V heating element (which should draw about the same as what the mill can put out) when your batteries are full, with a little hysteresis thrown in so it doesn't just cycle rapidly on and off. You can use a Trace C-40 solar charge controller for this purpose -- it has a switch setting built-in to turn it into a dump load controller.

Have Fun!

DANF

## [Diode sizing](#)

By [Anonymous Hero](#), Section [Homebrewed Electricity](#) [Controllers](#)  
Posted on Wed Jun 11th, 2003 at 07:14:24 PM MST

What is the smallest size diode I can use... ( Jungle Bill)..

For a one way valve into a battery. I am charging a battery with a PM motor. I am charging 12 volt battery with 15 vdc. About 2 amps is total out put or 25 watts I don't know what actually goes into the battery , I have not tested that yet. Anyway I want safety diode so the power does not reverse and head back to the motor ( generator) incase the water stops running or the thing falls over in an earthquake ,or,or, ,,you know. What size diode could handle this>?? Jungle Bill

Bill;

Well since you probably don't have a Radio Shack nearby I will give you a general opinion.

Almost any general purpose diode will do the trick. Most are rated 1 amp or more. In your case I would use a pair or more side by side.

I have some salvaged diodes and bridge rectifiers I will gladly send you something that will work no charge if i had your address.

Go over here to contact me if you want some:

<http://portslave.oneota.net/~tom/fromail.html>

Cheers.

If you can get to a Radio Shack I think they sell 3Amp 1N5400 to 1N5408 diodes anyone in the series will work. If you can get any schottky diodes the 1N5820 should do fine and they are more efficient.

by Anonymous Hero on Thu Jun 12th, 2003 at 12:06:47 PM MST

Tom , thanks for that very generous offer, however inlight of the distance / postage, I should try to exercise a different option. I have afew small diodes. I don't know the rating , but I have 4 small ones that are the same size as a 1/2 resistor. Would one of these work? OR would several work in parralell to "share "the load. ?? ( I have 4 for a bridge) I also have an old inverter that got toasted ( STATPOWER GARBAGE and they refused to help me one bit when I asked for a schematic in order to repair/ replace the smoked unreadable componenets) The inverter has some fairly large diodes that are similar in size to 3-5 watt diode. But first, do you think those small ones would work? ( Even a few in parrallel)? Thanks for your kind offer and information, gentleman.

Re: Diode sizing ([none / 0](#)) (#4)  
by TomW on Thu Jun 12th, 2003 at 12:53:18 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Bill;

If I was in a remote location with just what you have on hand I would just go aherad and parralel a few of the diodes I had on hand. They will share the load nicely and with several if one opens up the rest are there to keep it working.

On the other hand, that dead inverter may have a couple diodes and a good FET or two in it that can be used in a pinch as blocking diodes and properly heat sinked should handle the load that you are describing. I can't recall exactly how to get a FET to act as a blocking diode just that it has been done. I think it is a matter of tying two legs together.

Maybe someone else has that info onhand.

As far as sending you diodes they are small and would go first class postage in a letter easily.

Cheers.

TomW

## [Hornet as Training Wheels?](#)

By [Coasting Rotor](#), Section [Homebrewed Electricity](#)  
Posted on Sat Jun 7th, 2003 at 09:15:53 PM MST [Controllers](#)

**Will the HTH-3 charge a 48v system in light winds?**

Being new to homebrewed energy I think the Hornet HTH-3 might be a good place to start. I want to set up a 48vdc system using a couple of inverters for loads I cannot or should not build on DC.

I'm trying to **\*\*understand\*\*** what these comments @ <http://www.hydrogenappliances.com/Hornet.html> mean (the e-mail address cited on page bounced).

- HT3H ideas and suggestions:
- Avoid dead batteries! Provides a maintenance charge for 12-24 volt batteries even in calm wind areas. (4 TO 10 MPH)
  - Charges 24 or 48 volt batteries in medium wind conditions. (10 TO 19 MPH)
  - Charges 48 and super charges 90 volt battery systems in high wind conditions with over 12 amps of power! (19 TO 33 MPH)

Does this mean, for example, that at 4-10 mph I can charge ONLY 12v batteries? If so, is it possible to charge a 48v array of 4 12v batteries as individual 12v batteries (without diconnecting the series ties)? I'd want to use all wind capable of spinning the turbine.

I want to go to 48 volts because of less restrictive transmission limits (unless I'm wrong) and smaller wiring. The short question is really 'How would this Hornet work with a 48v system'?

Thanks for any hints and advice. Sorry if I sound stupid to gurus, I am, it's not my expertise (yet).

Chip,

To answer your question you really must consider the amount of wind you have in your area. If you have average wind speeds of 15 mph this will most likely work great for you. If not, you will need to find a turbine more suited for your wind conditions. The only way I know to charge a 48 volt battery bank with 12 volts is to disconnect and wire it in parallel.

Good Luck,

Geek

Always have a dream. Those with out dreams are just waiting to die.

Not really, he could have a switch tied to his charger, that automatically switches them from series to parallel. You might also want to try relays, as they might work too.

Wax ([none / 0](#)) (#1)  
by Johnny Cool Pants on Wed May 28th, 2003 at 12:01:41 AM MST  
([User Info](#))

I know I should probably be minding my own Bees Wax here but they use it for all kinds of things and certain types of Bees Wax are more sought after than others.

Big blocks of it still wash up on the coast here once in a while, (well a little south of here in Oregon, I'm across the state line in Washington) from a ship wreck over 200 years ago.

The Bees Wax was part of a valued cargo on the spanish vessel and it was far North and lost when it ran aground. It like any ship of the day also had some gold and silver for trading.

The wax and honey have health benifits too. Honey is energy food but you can submerge other food in a jar of honey and it will keep for many years, longer than canned goods by far.

Damn The Stingers

hydraulic swith ([none / 0](#)) (#3)

by Anonymous Hero on Wed May 28th, 2003 at 08:58:10 AM MST

I have seen this hydraulic switch to open and close a window in a green house. It automatically expands and contracts in a piston which is connected to the window. Pretty neat. Not sure where to find one , though. Jungle Bill

Expanding ([none / 0](#)) (#4)

by Johnny Cool Pants on Thu May 29th, 2003 at 01:03:09 AM MST

[\(User Info\)](#)

Yeah there are a number of things that could be used for this purpose. Just about anything that expands with heat.

Getting it into a crude piston rod is another story but if you did and experimented with any kind of insulation, you could find the right combo of insulation layers to to get it to expand at the desired temperature of the green house.

Likewise, if it needed to be hotter than the greenhouse to expand, having it in a sealed jar on a steel table might make it hotter than the rest of the greenhouse.

Somewhere I posted something on "Memory Metal"

that is being used for little pistons in battle bots, or something. Same stuff the trick spoon is made out of, stir hot coffee with it and it curls up real fast.

Do you remember if the Beeswax or other greenhouse hydraulic operated on heat alone? both opening and shutting? With no external power source? I'd like to see that myself.

DTT, JCP

wax opener ([none / 0](#)) (#5)  
by Anonymous Hero on Thu May 29th, 2003 at 10:33:03 AM MST

I've got one of those self openers. It's a metal cylinder about as thick as my little finger and a foot long with a metal plunger attached to a lever to multiply it's movement length. It's filled with some type of wax that melts and expands at a temperature range of 60 to 80 degrees. A thread on the cylinder allows adjustment of the opening temperature. I've used mine for the last ten years or so to open up my cold frame. I burst the first one because I had it opening two 3 by 6 windows. Then I counter balanced it to relieve the weight. I think its limited to about 15 pounds thrust. I bought mine from a local greenhouse supply but I've seen them in catalogues and peaceful valley farm supply on the web(you'd have to do a search I can't remember the web address.) These things use no outside energy. I could see someone experimenting with using something like this to automatically opening valves in a solar water system. Chris

wax piston ([none / 0](#)) (#6)  
by Anonymous Hero on Thu May 29th, 2003 at 11:17:02  
AM MST

JCP, As far as I can see the ones for the greenhouses operate purely in the expansion process to open, then the reverse of closing is an action assisted by some hefty (looking) springs. Yep, other feller is right. They are good for a thrust of about 15 lbs. There is a heavy duty one good for 29 lbs. This thing has very interesting applications. The operating temperatures around room of course is what makes this so neat. I am not sure what the propeller heads can use this for, but we'll put it up on the shelf for sure. Some great future idea may use this application . ( Like opening and closing a penstock or something/// who knows) Jungle Bill

Wax ([none / 0](#)) (#9)  
by Johnny Cool Pants on Mon Jun 2nd, 2003 at  
11:54:00 PM MST  
([User Info](#))

Bill do you know how fast it expands? and what the ratio of expansion is? If I could get a 4 foot lift out of 99 degrees heat, with in a minute and a half, I can think of a few good ideas.  
Might even have to put the bowling ball ferris wheel back together (not kidding)

JCP

[ [Parent](#) ]

Maybe ([none / 0](#)) (#10)  
by Anonymous Hero on Tue Jun 3rd, 2003 at  
07:44:33 AM MST

I see what you are thinking , but it is limited to "energy in" and so far that is limited to the bias heating of external vs internal temperatures. That bias pressure is the temp and the flow ( amps) is regulated by the volume of the flux transfer. This unfortunately is only a black plastic piston tube 3/4 inch by maybe 12 inches long. IE small energy. The action is slow and is levered to improve range ( I think based on photos) . Maybe you could build a big one. The medium is called a "Mineral" but further research shows that it is bees wax mixed with brick dust, (Presumably as a stabilizer in super hot conditions) Thats about it. Jungle Bill

[ [Parent](#) ]

ball buster ([none / 0](#)) ([#11](#))  
by Anonymous Hero on Thu Jun 5th,  
2003 at 02:03:49 AM MST

He has one already, he used compressed air to launch the ball back up, with one short little burst of air into what he calls "The Perkins Piston"  
The way it was geared it took a long time for the ball to come back down before another little burst of air was needed.  
Only he had three balls so there was a ball on the wheel at all times.  
He dismantled it after he built something better.  
"The Perkins Perpetual" he calls it. I think he called it a "dogless dog run" here. He said he's given alot of clues and hints on the board.  
Some of you are so sure nothing will ever work and he is so sure anything can work if you keep trying. He is possitive, not negative. So the two wont mix well on the board. Hopefully they can stay clear of eachother. Because he can Bozo a team of them into a little circus car before they know it.  
I know him personally.  
Pod.

### [In need of a voltage regulator](#)

By [Juliang](#), Section [Homebrewed Electricity](#)  
Posted on Sat Apr 12th, 2003 at 08:45:59 AM MST [Controllers](#)

If memory serves me I recall seeing someone selling either a do it yourself voltage regulator kit or an already made one in the range of about \$10.00 to \$25.00

\_\_\_\_\_ somewhere buried down in the old discussion board. I tried doing search but when I get 12000+ hits on voltage regulators I figure asking you all might be a little easier. Does any one recall or know who I can contact on this? Thanks Julian

Sounds interesting, It would have been nicer to see a blade not spinning and up close. I suppose this would give away the design. I imagine If you took some 1/4" thick plywood and laminated them together and jiggged them into the twist you need would make some fairly decent blades. Being plywood and laminated would hold up fairly well as long as it was exterior grade and coated well. Sounds simple enough. Small blades would be quick and simple... not sure I'd try a set of 14ft blades made this way. Possibly using aircraft grade plywood (expensive)... Sounds like a simple project to try for a small unit... Interesting....

Maybe something with your browser ([none / 0](#)) (#6)  
by hvirtane on Thu Apr 10th, 2003 at 04:20:57 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Hi,

your picture is already loaded on the server  
as seen on a note posted.

But if you cannot get it included easily with your post,  
there is maybe something missing or wrong with your  
browser program.

I'm using a Debian GNU/linux operating system and tried  
with two browsers.

- a) With Mozilla 1.0.0. it was OK.
- b) With Konqueror 2.2.2. I had first no success, but  
after putting in the 'preferences' 'java' and 'javascript'  
'included' it started working.

- A) Please have a check, if your browser program supports 'Java'.
- B) If not, please try to update for example latest 'Mozilla' available for your operating system.

- Hannu

Blade Plans on Ebay ([none / 0](#)) (#7)  
by Anonymous Hero on Thu Apr 10th, 2003 at 11:11:26 AM MST

I put the blade plans on ebay. They're cut from pvc pipe (4" for the small ones and 8" for the big ones). I have tested both of them to see that they start and spin, but my generator won't run at a high enough voltage to get meaningful load data. Cutting blades from pipe allows you to build a blade with an angle of attack that remains relatively constant along the blade length for a given wind speed to rpm ratio. As for pvc being brittle, I've heard the same thing but I had a small disaster that seemed to suggest that they aren't. My hub broke (1/4" luan is not a good idea) and one blade out of six came off. The other 5 kept spinning and found the natural frequency of my boom (3/4" pipe). It took about 30 seconds to fatigue the boom to the point that it broke. The generator came crashing to the ground blades first. All of the arms of the hub broke, but all of the blades were fine, and it was about 15 degrees outside at the time. The big blades are cool. Once they start, it's hard to stop watching them. -Dan M

[144,000 pulses and counting.](#)

By [Jerry](#), Section [Homebrewed Electricity](#)

Posted on Wed Dec 31st, 2003 at 07:10:37 PM MST

[Electronics](#)

The testing continuse.

I have 2 Optima deep cycle 12 volt batteries. A freind barowed them for a camping trip last sommer. They were new then. They've been sitting around the shop till now. I tested there voltage and found one to be 10.67v and the other at 8.43v. I'm thinkin this aint good. I don't know if they're good or scrap? So 80 hrs ago I hooked one of these batteries up to the capacitor pulse charging expiriment. I think Charge said the relays wouldn't like doing much more than 100,000 pulses. Right now the relay pulse count is over 144,000 and they are goin strong. I think I'll run them up to 1 million and see if they survive. The 21 volt power supply is just slightly warm and the battery is cold and battery rest voltage is 13.95 and 14.40 when the cap pulse hits them. I'll disconnect this battery and hook up the 8 volt Optima and run a couple 100 thousand more pulses on the relays. I'll let the charged Optima rest over night to see if it holds a charge. Thats all on this test for now. JK TAS Jerry

Jerry, Make sure you don't over heat the batts. They have a one way valve allowing gas buildup to escape and prevent explosion. If the gas escapes the batteries will dry out and be unuseable. RobD

([User Info](#))

Great job Jerry Can i assume you a producing AC and the pulse charge circuit is after the rectifier(s). keep the info coming. Would this idea of Charges be usable as a low wind device and when the wind is strong it can be taken out of circuit or would the high voltage cap bank have to be designed for the highest input foreseeable.

Re: 144,000 pulses and counting. ([none / 0](#)) (#5)  
by Reno on Thu Jan 1st, 2004 at 05:13:26 PM MST  
([User Info](#))

I think Jerry is doing an experiment. Of course it must be scaleable to be of use but the preliminary results look good. If we can turn those 5 and 10 mph winds into stored energy that would be great. I know my mill without the resistance of the battery spins up past charging voltage no problem.

by Jerry on Thu Jan 1st, 2004 at 09:46:11 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Reno Yep this is just playing with caps for fun. Since I have a zillion caps I'll be trying higher voltages and higher UF also. What I really need to do is get the solid state switching thing working. But I like the idea of charging the caps to 20 to 60 volts or higher and then dumping that voltage onto the 12 volt batteries. I guess you could do the same with 24v or 48v also. The battery never got even slightly warm and the charger stayed pretty cool also. The caps were cold. I think however the relay was taking a beating. This is where solid state switching would help. Reno your right about helping the genny in low wind. And then maybe switch over to normal genny operation when the wind speed goes up? At least this will help the genny to make some power in low wind. JK TAS Jerry

Experimenting for fun is good. Pulse circuits are very entertaining. In your case it sounds like you have all the parts setting around which is the perfect situation for playing with an idea any time you want. That's got to be great. I don't have enough room to be able to collect much "stuff".

The life expectancy of any component (relay, SCR, etc.) is directly related to loading. The more energy it has to move, the shorter it's life. (The candle that burns twice as bright, burns half as long.) Things also pretty much work the other way around too. If a component is surviving well beyond it's rated life, then it's not being required to move a heavy energy load. It's also possible you just have a very good quality relay that has not yet met it's rated life expectancy.

Designing and building a circuit to last for 40 years of non-stop operation is not a problem as long as it is designed with an appropriate margin of safety for the components.

The interesting question is how well this circuit transfers energy from your mill as compared to just running a heavy cable and sending low voltage.

A standard heavy copper cable system is somewhat expensive. For that reason, if the pulse concept only moves energy, maybe 2/3 as efficiently as copper cable, it might still have merit because of the comparative prices of the two systems. That's why knowing how well the pulse system transfers energy is the key bit of information someone needs to have before deciding whether it is worth investing in for their final, permanent system.

Also knowing the circuit's efficiency is what tells you if it's worth investing in even for a "starter" circuit for your mill. (followed by switching over to standard cables when wind speed is up) The fact that it's not loading your mill and allowing it to start up in low wind should be telling you something. (The loading on the mill is a direct relationship to how much energy it's trying to move.) "Does the little bit of energy it moves in a low wind condition justify purchasing the parts required?" Also, if it's not loading the mill significantly in lower wind conditions it probably won't in higher wind conditions either setting you up for a runaway self-destruct.

Regarding pulse charging your batteries... Pulse charging borderline batteries does rejuvenate them somewhat. The higher voltage spikes blast the sulfate bridges shorting the plates together. These sulfate bridges form in the sulfate sludge at the bottom of the battery that forms when they are allowed to set uncharged for extended periods of time. The bridges will begin to set up again within a short period of time because the pulse charge does not destroy the sulfate. It just moves it temporarily. It's possible, if you could remove the sludge layer, your battery's life would be pretty much restored.

For all experiments, if it was fun, it was worth the investment.

Dualsporter

Re: 144,000 pulses and counting. ([none / 0](#)) ([#11](#))  
by Jerry on Fri Jan 2nd, 2004 at 09:39:41 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Dualsporter I'm not sure if gell batteries have sludge that settels to the bottom. I've opened one up and the gell guu stuff seems prety stiff. I has a pie dough consistancy but its almost clear. Can't see how much stteling could happin? This is 24 hrs latter and the voltage is still 12.6 v and it still burns the end off the old screwdriver. I hope this works this good on the other battery. JK TAS Jerry

Re: 144,000 pulses and counting. ([none / 0](#)) ([#6](#))  
by Jerry on Thu Jan 1st, 2004 at 09:31:47 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

The 80 hr test was for Relay longevity. I wanted to see how the relays held up in continuous duty. Also the battery I was charging appeared to be no good. That is after charging it in a normal fashion it would lose voltage in just a few hrs. It's been holding 12.67 for 1 1/2 days now. I haven't done a load test yet. But it did burn the end off an old screw driver and after a short time the voltage was still at 12.6. I don't know what the pulse charging did but the battery seems to be back to full capacity. I have a 125 amp load tester at the store shop so I'll load it down tomorrow and see if the battery is still good. I hooked up the other battery it was worse than I thought. It was down to 2.5 volts and the 40 Bosch relay stop working after a couple hrs. I'm going to replace the Bosch with some 100 amp relays and place some 2 uf/ 400 volt mylar caps across their terminals to stop the arcing and pitting. I'll see how long they last. If they hold up this system might just bring this other battery back to life also. Hey Charged could you explain again how this pulse charge helped this otherwise junk battery? If it did? Or maybe this battery wasn't junk? I da no? I guess I'll find out with the really dead battery? JK TAS Jerry

Re: 144,000 pulses and counting. ([none / 0](#)) ([#12](#))  
by charged on Fri Jan 2nd, 2004 at 09:49:50 PM MST  
([User Info](#))

At 21v you're at just about optimum. For desulfating you can use smaller capacitors at higher voltage(100v) for short periods. This "cracks" the sulfate barrier. THEN you discharge to help dissolve the crystals in an orderly manner. Once you fully discharge, then start applying you're standard 21v pulsing.

You might want to build a dedicated charger with two voltage settings specifically for desulfating/reclaiming old batteries. That way you can scavenge batteries here and there and see if they'll come back to life. Some will, some won't, so what.

([User Info](#))

here is also something to check, when you start the next battery pulsing take a voltage reading of the pulses at the battery, I would imagine them to be a higher voltage untill the battery starts to reach a full charge then being around 14.5v. the relays should last upwards of 1 million pulses if the pulse is not near the full current rating of the relay but I would suggest a FET to do the switching, if you let me know what kind of voltage/current source you have available to trigger the relay I could draw up a very simple fet switch for you to use. FET's are much cheaper than relays in the long run unless you have an unlimited supply of course.

Re: 144,000 pulses and counting. ([none / 0](#)) ([#14](#))

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Thanks Budgreen. I'm using a 13.8 volt 3 amp regulated power supply to supply power for the 12 volt flasher unit and the Bosch relay. I would very much like to remove the Bosch relay and replace it with an FET. What FET would I use if I increase voltage to 100 and amperage to 50? Or is that combination not doable or recommended? I did the load test on the battery today. Its a 10 second test and the tester said the battery is a good 770 cold cranking battery. I was surprizes because Optima calls this battery a 750 CCA battery. And this was after burning the end off that old screwdriver a few times. (REDNECK battery tester burning the end off old screwdrivers.) Looking forward to the schimatic. I'll try to hook up the 100 amp relays inplace of the 40 amp Bosch tommorow. This will be to see if I can bring the other Optima battery back to life. Thanks again Budgreen and Charged. You guys are an insperation. JK TAS Jerry

PS. Thanks to Reno, Bsparky and Dualsporter I didn't mean to not thank you guys to. And another ? for you guys. I use an audio generator at work. These things are small and work from 9 v to 15 v. They have square, tryangle and sign wave output from 1 HZ to 1 meg HZ. I guess that would be 60 pulses per min. Could I use this unit to sequence the FETs instead of the 30 pulses per min. flasher unit. You know make this hole thing solid state? JK TAS Jerry

### [Solar Photovoltaic charge controller](#)

By [danny](#), Section [Remote Living](#)

Posted on Tue Dec 30th, 2003 at 08:20:42 AM MST

[Electronics](#)

Hi!<p> I am very interested in solar photovoltaic based power generating units and am a hobbyist but without formal electronics training.

I have a couple of circuits of solar charge controllers designed to work for 12/24 volts DC. Is there any electronic expert who could kindly do me a favour and care to advise me of modifications required to convert this 12/24volt charge controller to work on 48/60V dc input so that four 12v batteries in series can be charged?

I would appreciate any offer of help. My email: [aaditis@iqara.net](mailto:aaditis@iqara.net)

thanks!

danny

Re: Solar Photovoltaic charge controller ([none / 0](#)) ([#1](#))  
by [jubalearly](#) on Tue Dec 30th, 2003 at 01:01:38 PM MST  
([User Info](#))

If you have 2 24v controllers, Then you can probably use them in series for 48v, just like the batteries. If you want more details, you will have to provide some specific information about the particular charge controllers that you have.

Re: Solar Photovoltaic charge controller ([none / 0](#)) ([#4](#))  
by [danny](#) on Sun Jan 4th, 2004 at 07:27:23 AM MST  
([User Info](#))

Thank you for taking the trouble to write in.

As a matter of fact I have not yet built the charge controller. I was planning to use Forest Cook's charge controller featured in <http://www.solorb.com/elec/solarcirc/scc2/index.html> which however works for 12/24 volts whereas I actually have a system where output DC from SPV panels array is 100V(at present driving a DC water pump) and I need to charge 4x12v batteries connected in series and charge current would be 12-15A from this 100V source.

If your circuits are of a switching regulator nature (ie buck, boost or flyback)it should be possible to change the coils/transformer configuration to produce a higher charging voltage. Can you post the circuits so we may have a better look at what you are attempting? I am currently working on a 12 to 48 volt switching design myself, so I can charge my 48 battery bank from more common 12 volt equipment. It seems most everything out there is geared at 12 volt systems.

Re: Solar Photovoltaic charge controller ([none / 0](#)) ([#5](#))  
by danny on Sun Jan 4th, 2004 at 07:33:40 AM MST  
([User Info](#))

Good to know someone is working along the same lines. I had the circuit of Forest Cook posted on <http://www.solorb.com/elec/solarcirc/scc2/index.html> in mind and if this could be modified? I wonder if it is possible and could anyone please help out?

My current array of spv panels gives 100V dc and I have a power inverter running on 4x12v batteries connected in series and my plan is to charge the batteries from the spv panels without disturbing their present configuration as this source is used to run a water pump.

by charged on Wed Dec 31st, 2003 at 01:53:57 PM MST  
([User Info](#))

Here's a DC-to-DC conversion tutorial page. It explains all the basic configurations for building switching regulators.

[http://www.maxim-ic.com/appnotes.cfm/appnote\\_number/710/ln/en](http://www.maxim-ic.com/appnotes.cfm/appnote_number/710/ln/en)

Figure 6, the "flyback" method is probably the best for what you want to do.

## Need strange waveform output

By [CrookedScepter](#), Section [Homebrewed Electricity](#)  
 Posted on Tue Dec 23rd, 2003 at 07:48:37 AM MST [Electronics](#)  
 Please help :)

From what you can see in the image above, I'd like to get an output shaped like that waveform in blue. The circuit shows how currently I have pulsating DC with that diode connected to it. I was wondering what can I do to make a passive filter to produce the waveform in blue? I'm guessing I need some capacitors, but I'm not sure what kind and how to arrange them in the circuit.

The specs on the current setup are that the rotor goes about 250 rpm at max, and the output power is (at max) 1v and 100ma. So That may help in finding out what I need, but again, not sure.

I know this is a bit much to ask, so I really appreciate any help along with this.

Also, are there any freeware programs that use the mic/line input to input the electric signal to an oscilator for display? This would be a great way to confirm the signal that I want.

Thankx

 by [Virgis](#) on Tue Dec 23rd, 2003 at 10:23:43 AM MST  
[\(User Info\)](#)

Hi,  
 let you try this circuit. You need to use germanium diode D1 with low drooping voltage < 0.35 V and triac with low control voltage. Would be better to have a little higher AC voltage (> 1.5V).

Best regards

Virgis

Re: Confusing Schematic... ([none / 0](#)) (#3)  
by CrookedScepter on Wed Dec 24th, 2003 at  
06:30:13 AM MST  
([User Info](#))

I see the drawing and was wondering what the component was between points 'A' and 'B', and I see that the component between 'A' and 'C' is a diode, but its split off weird, does that diode have 2 leads coming off the end of it? or is C just 2 wires connected to the same single lead from that diode?

Thanx-

[ [Parent](#) ]

Re: Confusing Schematic... ([none / 0](#)) (#4)  
by Virgis on Fri Dec 26th, 2003 at 04:35:53  
AM MST  
([User Info](#))

It isn't diode, it is thyristor. The symbol is the same as for diode, but with additional connection, Gate or Knob. Thyristors can be characterised as two transistors connected to each other. Thyristors do not become conductive (ignite) until the knob is connected to a positive voltage and control current  $I_{gt}$  is added. The thyristor will remain ignited irrespective of whether the control current is broken or whether a voltage with negative polarity is connected to the knob. It can be returned to blocking mode by:

- reducing the anode current below the holding current  $I_h$  (this is specified in data sheets),
- breaking the anode current.

Virgis

Re: Need strange waveform output ([none / 0](#)) (#5)  
by Nando on Sun Dec 28th, 2003 at 09:49:04 AM MST  
([User Info](#))

It is a very curious the arrangement that you want.  
Why this arrangement, please give a detailed reason for it.

You can get a lamp dimmer and adding one diode to get the waveform you want and it is capable of about 400 to 1000 watts ( depending on the dimmer).

Let me know if you need assistance, I come to this site not very often, so email direct to: [nando37@comcast.net](mailto:nando37@comcast.net)

Regards

Nando

### [Loop Connectors, revisited](#)

By [drdongle](#), Section [Homebrewed Electricity](#)  
Posted on Sun Dec 21st, 2003 at 01:57:45 PM MST  
Found what I need...on the net

[Electronics](#)

I was doing a bit of surfing and found the two following companies that carry a large variety of loop as well as spade connectors for wire from very small to very large. Prices seem reasonable as well.

<http://nelcoproducts.com/terminals/index.cfm?action=Zrterminals>

<http://trickcableandswitch.com>

### [Where can I find a 3hp 12v electric motor?](#)

By [zmoz](#), Section [Weird Science](#) [Electronics](#)

Posted on Mon Dec 8th, 2003 at 11:22:18 PM MST

Anybody know where I can find a reasonably priced 3hp 12v or 24v motor?

I'm looking for an electric motor of aproximately 3hp that I can run from either 12v (preferably) or 24v. Anybody know where I might be able to find one relatively cheap?

[Where can I find a 3hp 12v electric motor?](#) | 6 comments (6 topical, 0 editorial)

Re: Where can I find a 3hp 12v electric motor? ([none / 0](#)) ([#1](#))

by Jerry on Mon Dec 8th, 2003 at 11:52:53 PM MST ([User Info](#)) <http://www.dplusv.com/Photo-03.html>

You might check the local hydrolic shop. The kinda shop that makes car hop. I bought one of these morors from a catalog place for 60 bux. It looks like a car starter but can handle more on time and it draws less power. If you could do 24 volts try this. I got mine at the local golf cart dealer. He had 2 used Melex carts. I got the pair for \$50. They had 3 hp at 24volt to 4.5 hp at 36 volt motors. These motors work great. I'm using one in a 1978 Ford Curier PU at 32 volts, 4 X 8 volt cart batteries. I made the speed control with 200 amp relays and a small 5 position rotary switch. It selects off, 8v, 16v, 24v or 32 volts works good and its cheap. Did the same thing on one cart. It has 4 speeds and 48 volts. Goes prety fast for a golf cart.

Re: Where can I find a 3hp 12v electric motor?

([none / 0](#)) ([#3](#))

by Jerry on Wed Dec 10th, 2003 at 09:22:29 PM  
MST

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Yep I did.

I freind and I were thinking of building an electric car. Older small PUs are the best for this conversion. They carry the batteries good, have low wind resitance front end, most are manual trans and a guy gave him one.

Well he had a baby on the way and mom to be said get rid of your projects for a while. He gave me the PU. It didn't have a motor.

I was looking at that time for a small vehickel to build a compition car strereo system in. This one was a natural. But it has to move under its own power to go through the competion lains.

I had an extra golf cart motor so we got creative and droped it in. I used a speaker frame or basket to addapt the motor to the transmision. I used a love joy coupler to connect the 2 together. Its a 24 to 36 volt motor. we are using it at 32 volts. Its only purpus is to move the car around parking lots. We don't drive it on the streets.

We've had it up to 20 mph but even that is more speed than we need.

This truck holds the NW Iasca SPL record at near 170 db. We have 54,000 watts on board. We use 4 masive 14,000 watt 15 inch subs in this vehickel. Amp rack wire 4-0 diesle locomotive power cable. We expect to improve preformance in this little pu this winter.

BTW, the world record SPL is 178.9 DB, 5 15s in an Astro van. In my personal astro van I have 8 15s and 12,000 watts. Its ok for a daily driver.

IASCA the sanctioning organization Will not allow you to be in the vehicle while competing. Its done remotely.

I use this analogy for the cars we do listen to at high levels. If its a hot summer day say 110 degrees and you step out side for 1/2 a minute your fine. If you go outside and stand in one stop for an hr. you get burnt. I've been involved with high pressure sound levels since the 70's and my hearing is excellent. However my spelling is bad.

Bottom line short term your fine. Long term your cooked. Just like most exposures.

Our record holding truck is actually quiet on the outside while there is a tremendous pressure on the inside. The NRA folks or drag race people or noise football stadiums create very high noise level also and we listen to those without question?

[Looking for large "ring " connectors](#)

By [drdongle](#), Section [Homebrewed Electricity](#)  
Posted on Mon Dec 8th, 2003 at 09:32:04 PM MST [Electronics](#)  
Auto parts stores are too expensive

Ha guys I'm looking for "ring" or "loop" type connectors for # 8 wire, I have checked all the auto parts stores and they either don't have them or want \$3.00 for two of them! I have also checked Diga-Key, Mouser Electronics and several other electronics suppliers with no success. Has any one got a source for connectors that big and in quantity? I know their made as I have seen them in use on automotive electrical equipment and other industrial electronics.

Thanks

Dr.D

Re: Looking for large "ring " connectors ([none / 0](#)) (#1)  
by TomW on Mon Dec 8th, 2003 at 11:18:08 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Dr. D;

A possible substitute might be a piece of copper tube soldered to the cable with the end flattened and the proper hole drilled in it. Add some shrink tube if you want or some tape and you can duplicate almost any ring connector for very cheap.

Most of my battery interconnects are done this way but with larger cable and tube for ends. Basically free from the copper pipe I have salvaged over the years.

Cheers.

TomW

Hi Dr D.

We use these every day at My car stereo store. The Audio Source in Salem Or.

We have standard nickle plated or the fancy gold plated. 8 ga. in screw hole size #8 up to 1/2 inch.

What size and how many? I'm sure I can help you out a bunch. We buy bulk by the 100s or 1000s depending on size or metal.

If any of you Guys are needing hardware like this. I'll make a partial list.

Ring tungue connectors from very little to very large, 18 ga. to 4-0 ga. golt or nickle, crimp or screw down on some of the big stuff.

Gold or platimun distribution blocks.

Gold or platimun fuse blocks in 2, 3, or 4 gang, for fuse type ATC, AGU, or ANL with amperage ratings from 3 to 250 amps.

Power wire the prety car stereo flexable stuff red, black, rootbear brown, clear and purple all in 10 ga. to 4-0.

Spit loom bunch of sizes, wire ties, gromets ruber, gromets plastic snap in.

Butt conectors 18 ga. to 4 ga. t-taps, mail and feamale spade connectors

And on and on I guess I'd better make a list with prices, YA.

These is so much hardware needed for hi-end car stereo & security. I've just scratched the surface.

I can tell you this all this hardware shure is handy when your doing wind power and such.

You guys need this stuff and I can get you good bulk prices. I'll make a list and you guys pick what would be good items.

Give me a day or 2.

Re: Looking for large "ring " connectors ([none / 0](#)) ([#3](#))  
by drdongle on Tue Dec 9th, 2003 at 06:05:47 AM MST  
([User Info](#))

Thanks, though I would prefer to buy directly from a distributor ( I am a telephone and sound contractor and I am tax exempt). I also generally buy in bulk ( yes, I need 200 surface mount telephone jacks, thank you :)I can get all that stuff from several companies except it seems for the larger wire size loop connectors.  
The number of a national distributor would be what I need.

Thanks

Dr.D

## [Rectifier Question](#)

By [Hank](#), Section [Homebrewed Electricity](#)

Posted on Mon Dec 8th, 2003 at 05:37:39 PM MST [Electronics](#)

Rectifier help

I purchased several Bridge rectifiers rated at 50 amps 400 volts. They have wire lead outs that appear to be to thin (.040" dia) to carry 50 amps. Can any of you electronic experts out there give me some advice as to whether or not this is acceptable. I plan to use these in my PMA which I guesstimate will be putting out up to 40 amps before it furls.

I would not want to fry these rectifiers and have a run away genny.

All comments appreciated,  
Hank

[Rectifier Question](#) | 10 comments (10 topical, 0 editorial)

Re: Rectifier Question ([none / 0](#)) ([#1](#))  
by [DanB](#) on Mon Dec 8th, 2003 at 05:48:02 PM MST  
([User Info](#))

Is it 3 phase?

My only suggestion would be to make sure youve got a very good heat sink, and parallel however many rectifiers it takes so the rating of the whole assembly is at least twice that which you think you'll see. A dead rectifier could mean a wrecked windmill.

Re: Rectifier Question ([none / 0](#)) ([#2](#))  
by [Hank](#) on Mon Dec 8th, 2003 at 06:06:17 PM MST  
([User Info](#))

DanB,

No these are not a 3 phase but rather single phase rectifier. I'm currently using 35 amp rectifiers purchased from WonderMagnet which have spade leads and are much larger. I wanted to beef up my system that's why I bought the 50 amp rectifiers. On paper they should be of higher rating but the size of the leads has me concerned. I always pallel two rectifiers as a safey precaution.

Thanks for the reply,

Hank

Re: Rectifier Question ([none / 0](#)) (#3)  
by Electric Ed on Mon Dec 8th, 2003 at 06:10:41 PM MST  
([User Info](#)) <http://www.electric-ed.com>

A wire of .040" dia. would be #18 AWG and has a continuous current carrying capacity of about 15 amps if exposed to air, about half that if it's in a cable or conduit.

For 50 amps, a #10 AWG (about .10" dia.) would be recommended if exposed, #6 if in a cable or conduit.

Electric Ed

Re: Rectifier Question ([none / 0](#)) (#4)  
by Hank on Mon Dec 8th, 2003 at 06:37:04 PM MST  
([User Info](#))

Thanks for the response Electric Ed,

It is exactly that that has me concerned. The wire leads coming out of the rectifiers appear to be too small for that rating. I would be using a AWG size of 10 or larger wire, but to me it makes no sense to solder these to the .040 dia. lead wires coming out of the rectifiers.

Just curious why they are rated so high yet have such thin wires.

Hank

Re: Rectifier Question ([none / 0](#)) (#6)  
by 5kw on Mon Dec 8th, 2003 at 07:17:04 PM MST  
([User Info](#))

Hank,

The "thin wires" are very short, aren't they. The current capacity of a conductor is very dependant on its heat sinking ability. For example I have a TIG welding torch with a continuous rating of 150 amps. The torch is water cooled and the lead feeding it is run inside the feed water tube, the tube is 1/4" and the conductor can't be larger than #10. The designers of the rectifier are relying on the heat sinking of the device, don't forget the 50 amp rating is for a case temp. of 25 deg. C in the fine print. Also if you over size your leads to the device you can dissipate a lot of heat into the leads themselves. Rectifiers are relatively cheap and paralleling allows you to spread the heat into your heat sink, when I do this I use equal length wires to parallel diodes to aid in the current sharing.

Make the wind fun!

Victor

Re: Rectifier Question ([none / 0](#)) (#5)  
by kell on Mon Dec 8th, 2003 at 07:05:22 PM MST  
([User Info](#))

Are they rated 50 amps continuous? Or surge? Did you get written specs? Look at the power dissipation in watts. A silicon rectifier has a voltage drop of a little less than a volt if it doesn't get too hot. So the watts divided by about 0.7 (nominal) gives you the amps it will conduct and stay within its power rating. Amperage ratings can be very misleading with semiconductors.

Re: Rectifier Question ([none / 0](#)) (#7)  
by Hank on Mon Dec 8th, 2003 at 07:34:59 PM MST  
([User Info](#))

Thanks for all the responses and help,

No wattage specs on these but they are 50 amp continuous with a 400 amp surge rating and with short wire leads

I'll give them a try on a test stand with a very large heatsink first but from the sounds of it they should work just fine.

Hank

Re: Rectifier Question ([none / 0](#)) (#8)  
by laskey on Tue Dec 9th, 2003 at 07:49:33 AM MST  
([User Info](#))

The bridge rectifier you're talking about is designed to be soldered to a PC board, thus the smaller leads. The only reason they'd put bigger lugs on the bridge is to accommodate hooking wire directly to it. You'll notice that those lugs conveniently accept a specific solder-less connector, or in the case of really big bridges, a specific bolt size in the hole.

What you really want to worry about is (as stated above) how hot the bridge itself gets.

Cya,  
Chris

by jimjjnn on Tue Dec 23rd, 2003 at 07:12:14 AM MST  
([User Info](#))

Semi-conductors are current devices. Don't exceed their current ratings by very much unless you heatsink them with large heatsinks.  
you can cool them also with a fan on the heatsink too.  
Voltage ratings are pretty much the same thing. I hope this helps. Great discussions here !!!!  
Jim Nelson

Re: Rectifier Question ([none / 0](#)) (#10)  
by Harry Luubovv on Wed Dec 31st, 2003 at 01:45:23 PM MST  
([User Info](#))

I can think of three things. One, even the wires are small, but since they each is very very short in length, it does not mean too much difference there. Anything less than a 1/4" is Ok when it is smaller than what you are used to seeing. Two, there are Peak Inverse Voltage rating, there are Forward voltage rating, usually they are wide apart from each other with the same rectifier. Three, if you had a rectifier rated at PIV of 400 Volt and 40 amp, you can safety use it at 50 amp if you only use it in a circuit of say, 12 or 24 volts volts.

Thanks for reading mate.  
Luubovv.

by [drdongle](#) on Fri Nov 28th, 2003 at 05:11:51 PM MST  
([User Info](#))

When the turbines output drops enough so will the chargers and you will get no charging of the battery. If you had a rectifier and regulator system from the turbine you could proved, more reliable charging directly to the battery.

Dr.D

Re: What would happen... ([none / 0](#)) ([#2](#))

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

We had a discussion going a while back about a similar idea.

High speed switching power supplies, for computers and such operate 100 volts to 260 volts ac. Some anyway. Some of my motorpma conversions do this kinda voltage swing fairly well. These power supplies are very regulated. Your genny could have a voltage swing all over the place and the power supply would have a rock solid stable output. Within its amperage capability any way. Many of these supplies are 5 volt with bvoltage adjustments so just wire up 3 in saries a dial in 14 volt or so.

We do this at my stereo store. The diferance is the supplies are big and operate off 240 ac grid power. We have the strapped as 3 packs.

One unit is 120 amps at 15 volts. This is 3 5 volts at 120 amps bolted together and wired saries. We've also done this to a 400 amp and a 600 amp.

All together for our instore demo systems we have a 1120 amps at 15 volt power supply. Thats 16,800 watts of power supply. We've can strap this to our RE battery bank to power our deth demo

As I understand it, A wind genny will spin up to the battery voltage, at that point it will encounter drag due to the load that the battery presents for charging and regulate it's speed until your batteries are charged. At that point you need to divert (dump) the load to help control the speed of the genny.

Your Trickle charger attached at the same time is the same as a second wind ginny connected to the same batteries. As long as the batteries are charging it is fine, but once they are charged you will be dumping this load as well.

}=- W o o f -= {

Re: What would happen... ([none / 0](#)) (#4)  
by laskey on Sat Nov 29th, 2003 at 10:27:54 PM MST  
([User Info](#))

A Battery Charger is designed to operate at 60Hz. Running it outside of that frequency will cause all kinds of nasty side-effects. Most of which are heat related.

A cheap battery charger is usually little more than a slightly refined equivalent of your wind gen set-up anyway. Power source, and bridge rectification, maybe a smoothing capacitor. A more expensive one will have a voltage detector circuit that will shut the thing off when the battery is charged.

I agree with the posts above. You want to do your own battery charging.

Cya,  
Chris

## [How many amps does a starter motor use?](#)

By [zmoz](#), Section [Homebrewed Electricity](#) [Electronics](#)

Posted on Tue Nov 25th, 2003 at 08:05:45 PM MST

**How many amps does a starter motor use?**

I've just been kind of curious lately, does anybody know approximately how many amps a starter motor for something like a V8 uses? I know most cheap batteries say they have around 500 CCA, does the motor actually use all of that?

[How many amps does a starter motor use?](#) | 5 comments (5 topical, 0 editorial)

Re: How many amps does a starter motor use? ([none / 0](#)) ([#1](#))  
by [monte350c](#) on Tue Nov 25th, 2003 at 08:22:48 PM MST  
([User Info](#))

Hi zmoz,

A short answer - most likely! For example a GM 27MT starter's test specs are as follows:

(No-Load test at 10 volts)

Amps - min: 120

Amps - max: 210

rpm - min: 9,000

rpm - max: 13,400

Of course under load (like cranking a high compression engine) the current will be a lot higher and the rpm a lot lower. GM suggests a maximum cranking time of 30 seconds for a 27MT.

Hope that helps!

Ted.

by [Budgreen](#) on Wed Nov 26th, 2003 at 09:56:48 PM MST  
([User Info](#))

and if you added a real bearing to the end and some magnets in it would it generate anything? I already have one partially torn apart (was using it to drive something for a test) might be a worthwhile project

([User Info](#))

If you installed magnets in the armature (or just wired up the existing motor right) and spun it fast enough (10,000 + rpm??) you might get a ton of current out. But - like any starter motor, they are not made for continuous operation. It'd heat up fast and melt at 500 amps... either input, or output.

I suspect its a poor choice for a low rpm alternator - Im sure it could be done, but you'd wind up changing everything about the motor (windings, armature, bearings) except maybe the case before you were done I think.

Hi All,

As DanB said, probably not a great choice to make low rpm power. GM's not kidding either about the 30 second duty cycle on heavily loaded starters. After one 'warmed-up' Chevy 350 rebuild I did a few years ago, the 20MT started basically had an internal meltdown after about 2 minutes worth of heavily loaded cranking. Switched to a 27MT and had no more problems - mainly because the 27MT had enough poop to crank the engine fast enough so it started right away. Put another way, 500 amps at 10 volts while cranking is 5KW, or about 6 horsepower. Compare a starter motor with a 6 hp

electric motor. It's pretty small for that output - which is why the short duty cycle!

Ted.

What many of us could really use is a DIY load control kit much like the DIY radio, etc. kits Radio Shack sells.

Those are great kits for people like me who like to do things in which they have no idea what they're doing. LOL I got the idea when I saw those load control system diagrams Hugh mentioned below and knew figuring out what all that meant and trying to find the right parts would give me a major headache.

So, any chance someone would be interested in putting together such kits to sell? I guess I could go buy some Radio Shack kits and learn this stuff in that way, which I prefer as I'm a hands on sort of person.

Kevin

Hi Ed,

I might figure out how to make that one(I'm currently very electronically challenged :-), but I want one that needs no battery, which seem a bit more complicated. Looks like there'd be one simple gizmo that'd connect a load/switch when a certain voltage was reached. That's all I'd need for what I'm doing I think.

Triacs sound like such a thing, but Radio Shack didn't have any the other day. I figured I'd buy one to play around with. What I've got going now seems to work okay, just a heater hooked straight to the alternator. There's very little load until the voltage goes high enough, but I can see two ways it'd be better to have no load until a certain rpm or voltage is reached. Anyway, I'll get more into this area when I finish improving the two turbines I have up. They've endured some hard gusts(60+ mph) and I'm pleased at how tough they appear to be, but they do need to turn better with the wind. Thanks.

Kevin

Would not the device on Hugh Piggots home page be like the one asked for...?? It seems to look at turbine rpm via Hz.... and connect loads in adjustable steps...

If anyone need a pcb layout for the homepower device i have just drawed it (still have not tested if it is correct but i will soon).

Lars A

Re: DIY controller kits ([none / 0](#)) ([#4](#))

by charged on Tue Nov 25th, 2003 at 07:41:04 AM MST

([User Info](#))

Four component method:

1. A triac that's big enough to handle the load.
2. Two zener diodes rated for the MINIMUM required voltage for the load.
3. A current limiting resistor for the gate lead on the triac

The two zener diodes are wired face-to-face (cathode to cathode). This is in series between the gate, the current limiting resistor and either one of the other triac terminals.

The triac is then just wired in series between the generator and load.

When the zener voltage is reached, the gate lead is triggered and the triac begins to conduct until there is no more current flowing through the load. This repeats on each positive and negative voltage peak.

When your generator drops below the zener voltage, the triac won't turn on.

Find the absolute maximum voltage that the generator will produce and use  $R=V/I$  to determine how much resistance you'll need on the triac gate to keep it below it's maximum current rating.

This also works well in some DC applications for discharging a capacitor through a load. In that case, use an SCR and a single zener between the gate and anode. When the capacitor voltage climbs enough to pass the zener, the scr conducts and dumps the capacitor charge. No gate resistor is required in that application.

charged;

You post some very interesting circuit ideas. While I can take the words and draw a schematic to match I am sure lots of the less electronically savvy folks would find a schematic very informative. Any chance you have a way to transform your words to diagrams?

What the internet needs is a good online schematic generator that outputs nice, lean schematics graphics. A picture is worth a few dozen words for sure.

Another great idea, charged, simple and probably cheap too.

Thanks for sharing

Cheers.

Hey Tom W

How about an Other Power Circuits Page? If those of us how are not computer savy could e-mail or even snail mail a coupy of some circuts to one that is computer savy and could aply them the this page we could all benifit.

I think these schimatics could be cretiqued and enhanced by the experts as time progreses.

I'd be willing to through a few of mine in and if they are not correct the experts could give a review and sugjest improvements.

List these as uncertified till tryed or proven. Through in a disclaimer for site protection?

I love looking at diagrams.

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Jerry;

Certainly sounds like a good idea to me.

Some kind of review would be good too.

I see circuits on websites a lot that  
I would not trust to work as represented.

Simply claiming they are untested and presented  
as examples to be evaluated only would probably  
be enough of a disclaimer.

I'm pretty sure I don't want people sending me  
those monster megabyte size .bmp files of a simple  
drawing that takes 10 minutes to download tho.

Never the less a good idea to have a circuits  
section or sub section. I have plenty of web space  
too so I probably could do something there or in  
my diary if I ever start getting motivated again.

Cheers.

TomW

## Mechanical Inverter Again

By [RogerAS](#), Section [Homebrewed Electricity](#)  
 Posted on Wed Nov 19th, 2003 at 03:53:04 PM MST [Electronics](#)  
 all

Greetings,

Here is what I was talking about with a mechanical inverter.

This is an end view of the rotor and brush setup I mentioned in an earlier thread. The colored lines are connections between the commutator positions. As the commutated rotor spins the direct current is redirected in an alternating current fashion. A really small motor could be used to turn this rotor as only the brush resistance is a factor (in my tiny mind anyway :-). The brushes are on the sides and top, no feed or supply wires shown. I think for 60 hertz the RPM would have to be 3600, but it could be half that(it's late in the day). Or with more commutation slots far less RPM.

I think that 12V DC could be fed to this with the addition of the stepup transformer on the AC side. I feel, but don't know, that if the right size motor run capacitors were used on the AC side this could make some pretty good quality AC.

What do you guys think?

RogerAS

Roger

In stead of a transformer you could use a DC to DC converter 12 volts in 120 out.

I don't see why your commutator would not work. Its like a two pole alternator you would find on an engin driven gen set 3600 rpm gives you 60 hz and a good wave form.

Have fun

Old F

([User Info](#))

hello Dr. D. first i will admit that i am not much of an electronics person. i do understand that the ac output will be in the square wave form. if Roger uses a step up transformer ( 12vac-120vac) and two seperate coils in the transformer, would the 120vac coil round off the sine wave somewhat because of the slight lag behind the primary coil? just a hunch. also, could you reply with what items can be succesfully run from a square wave form and what cannot.

thanks--zubbly

Re: Mechanical Inverter Again ([none / 0](#)) (#4)  
by drdongle on Wed Nov 19th, 2003 at 07:10:48 PM MST  
([User Info](#))

While caps can "round off the corners" you need to use them in conjunction with a transformer or inductor. I have built low frequency inverters 20-30 Hz for ringing telephones that I have done this with. Basically I had a 555 timer driving two out put transistors ( 1 NPN and 1 PNP)which in turn drove a transformer connected backwards ( 12 volt secondary became the primary) so that I had a 120 volt square wave output, I would then hook up my scope and try various caps bridged across the secondary to get the best approximation of a sine wave. It was never a perfect sine wave and it had some transient artifacts but it was better than with out the cap. What I had was a "resonant tank circuit" that was tuned to 30 HZ. So if you did build one yes you can approximate a sine wave but you will need to experiment with the caps and you will definitely will need a scope. Note that if the speed and frequency change the "resonance" will be lost and you will no longer have a sine wave output.

Dr.D

Re: Mechanical Inverter Again ([none / 0](#)) (#5)  
by zubbly on Wed Nov 19th, 2003 at 07:22:32 PM MST  
([User Info](#))

hellow Roger. i have sort of been dreaming along the same lines. your idea does seem much more simple than what i was thinking. i was thinking of using a commutator from an old large dc motor, but then couple the connections to a set of slip rings on a common shaft. basically would come out to the same thing i think. the current if from a 12vdc source will be of significant high amps. may i offer the idea of using brushes from an industrial lift truck motor as these are designed for very high current and are often arranged in a row in the brush holder. perhaps you may be able to salvage some parts from a lift truck motor. another source for high current brushes are from the old motor and gas driven Lincoln and Hobart welders. hope this helps and please post your results. i am very interested to here how it goes.

keep having fun--zubbly

by Norm on Wed Nov 19th, 2003 at 08:12:07 PM MST  
([User Info](#))

As for brushes and brush holders wouldn't just plain old parts from car starters be a good source they carry about 300 amps or so....well maybe not probably weren't meant to carry a lot of amps for more than a minute at a time? Norm.

Re: Mechanical Inverter Again ([none / 0](#)) (#8)  
by Simon ([simon@guyo-inc.com](mailto:simon@guyo-inc.com)) on Wed Nov 19th, 2003  
at 11:12:44 PM MST  
([User Info](#)) <http://www.guyo-inc.com/engineering.htm>

Hallo Roger,

I have been thinking about the same thing! A mechanical inverter. The only thing obvious which will result in a pure square wave is the ON-OFF effect of the commutator contacts. Maybe the solution is to use wider contacts on the stationary part of the inverter which have variable resistance. This will sort of create a curve just like on a "potentiometer". You might need a bigger wheel to do this and many contact points to enable 60Hz at lower RPM than 3600! You could try with lower voltages first for this setup. Have fun and tell me when it works.

Simo'

Re: Mechanical Inverter Again ([none / 0](#)) (#9)  
by RogerAS ([rogeras@cei.net](mailto:rogeras@cei.net)) on Thu Nov 20th, 2003 at  
07:11:49 AM MST  
([User Info](#))

Thanks guys,

For the advice and encouragement.

I really don't know when I can find time to build my little idea, so anyone with a little motivation go ahead and try.

I'm building a house, not like on HGTV "build" but rather actually doing the work, all the work! So, little time for anything else.

It seems this could work for a cheapie square wave inverter. Maybe only good for lights or heating, Sure the brushes will wear out and the commutator will go south, but oh well. Thanks for showing me how tuff it would be to approximate a sine none-the-less.

If I used a step up transformer with the square wave output, wouldn't that create another set of problems? I think I read somewhere that trying to setup the output of a square wave inverter was bad, or would the output from my spinner work differently?

DrD? Others?

P.S. I only have net access at work so excuse any delays in responses.

RogerAS

"Put the bunny back in the box!"

Re: Mechanical Inverter Again ([none / 0](#)) ([#10](#))  
by drdongle on Thu Nov 20th, 2003 at 08:26:14 PM MST  
([User Info](#))

Square wave forms tend to saturate a transformer more so than sine waves and induction motors don't really like them either. They can also produce more RF noise, which is bad for radios and such.

Dr.D

Why not use two motors? ([none / 0](#)) ([#11](#))  
by dconn on Fri Nov 21st, 2003 at 06:13:29 AM MST  
([User Info](#))

Why not make an old-fashioned mechanical Inverter and use a universal motor on the DC side and couple it to a induction motor on the other side - you'd get a perfect sine wave output and the only brushes to wear out would be in the universal motor - and at least they are engineered to carry the current.

I've often thought about a mechanical inverter but really I'm [and everyone probably] better off using an off-the-shelf inverter.

Derek

Re: Why not use two motors? ([none / 0](#)) ([#12](#))  
by RogerAS ([rogeras@cei.net](mailto:rogeras@cei.net)) on Fri Nov 21st, 2003  
at 07:12:46 AM MST  
([User Info](#))

Hi Derek,

I'm thinking this might be useful in places where electronic inversion is impractical or outside the budget. In the developing world this little gizmo might come in handy, or in Stone County Arkansas, where I live.

If one had a hydro setup OR maybe a distant VAWT it seems it would be a simple matter to run a take off to drive the spinner. This would make long distance runs to the primary battery bank more efficient, maybe, if run as AC. If one could build a real good rectifier on the storage end.

I dunno, I think I think too much.

I have this set up. I couldn't afford the inverter to power my well pump. I wanted power for the pump if we had a grid power failer. I couldn't afford the big inveter that could start and run my pump.

I did however have some surplus 2 HP dc motors that are rated 180 volts. I had 24 12 volt batteries from a hospital power backup system.

The motors were rated 1750 rpm. I purchased a stand alone belt drive ac generator rated 5000 watts 120/240 v. Its requiered power was listed at 10 hp 3600 rpm.

I used larger pullys on the motors and smaller on the genny. I put a motor on each side of the genny with a double belt pully on the genny.

I used 20 of the batteries (240 volts) and used a 400 amp aircraft relay to swich power to the motors. No load the genny puts out 260 volts and has no truble starting the pump. And while the pump is pumping the voltage is 242. Close enough. These two 2 hp dc motors have no problem meating the 10 hp power requierment for this genny.

I figure the pump wont run continuas so the system is good for back up. I'll post pics.

My small batteries went bad last winter and I've not replaced them yet but the setup is still in the pump house wich is inside my 40X60 shop. Its a small room in the back.

JK TAS Jerry

[How can you check electronic ignition?](#)

By [Norm](#), Section [Magnets & Magnetism](#)

Posted on Wed Nov 19th, 2003 at 03:25:42 PM MST

[Electronics](#)

I used to check the coils on the old lawnmower engines by

hooking neg to the ground of a coil and then briefly touching positive to the tab that goes to the kill switch which would result in a spark at the plug but I don't know what to check on the electronic ignition. Can a multimeter be hooked up some way to check the primary or secondary or the electronic part the sensor perhaps something is shorted out? I'd hate to buy a new coil for this 4.5 hp Lawn Boy since it was given to me investing any money in it just rubs me the wrong way takes some of the fun out of it. I sure wouldn't want to throw it away tho' self propelled looks like new I think they are in the \$300 range when new. Thanks for any help guys! (:>) Norm.

([User Info](#))

Oh...sorry forgot to mention that is what I did first thats why I went to the next step energize the coil. O K...so far that doesn't happen no juice going to it but I thought well maybe that's not so bad maybe because the electronic circuit will not allow it to go into the primary winding. I turn off the lights and in the darkness I see just the barest glimmer of a spark at the point where I make contact to the tab going to the primary (but no spark at the spark plug). I hook up the multimeter probes to the primary windings and can get a reading of about 5 volts when I rock the flywheel past the coil. And so this is as far as I've got for now...Norm.

Re: How can you check electronic ignition? ([none / 0](#)) ([#9](#))  
by Norm on Thu Nov 20th, 2003 at 09:14:31 PM MST  
([User Info](#))

Gameman: Did almost like you said, didn't open the gap anymore than normal (about .030 ) it was laying on the plate that the blower shroud/recoil starter is bolted to plugged in to the coil, kill switch wire disconnected....spun the flywheel with my 14.4v drill and it sparked like it should ....tried it again and again...worked everytime and I was thinking it has to spin faster than a briggs...good old briggs with points...I used to get them so they would fire just by rocking the flywheel mags past the coil. So I tried it with the lawnboy...didn't work ...well I'll spin it with the drill again just to make sure it's going to work....it's stopped working can't get it to work at all! Hooked up the digital multimeter to the primary and spun it with the drill and I get 5 to 7 volts... out of it but can't put juice into it tho'... must have a blocking diode/s . Might be an internal short in the secondary?...moisture? I'm going to try one little trick...put the coil in a warm place for a couple of days...yeah I know they're supposed to be waterproof but its worth a try...couldn't hurt anything. (My dad used to do something like this with Model T coils put 'em in the bun warmer above the cook stove!)  
Have you ever had experience with these 'on again...off again' coils? I imagine you probably have. Hey I don't think it would be any fun if you didn't have any problems to solve (:>) Norm.

by monte350c on Sat Nov 22nd, 2003 at 10:32:02 PM MST  
([User Info](#))

Hi Norm,

I just had a bout of "fun" with ignition troubles - not electronic - but of the on again, off again variety. Tecumseh motor - sometimes would fire right up, other times took a lot of pulling, one day wouldn't start at all. Took off the flywheel, points like new, condenser checked with the Fluke - looked OK. Coil checked out. Reassembled, started first pull. But the problem - I didn't find anything wrong!

One week later, same hard starting problem - and a very weak and intermittent spark. Pulled the flywheel again, and this time when I checked the coil I got about 4 Ohms on the primary, and the secondary was open! (should be something like several k-ohms anyway). So this tricky little sonofa... was a bad secondary on the coil. Sometimes the spark presumably jumped over inside the coil and gave out a bit of spark and sometimes not.

Replaced the coil and it starts first pull every time now. Not sure if the LB coil is 'checkable' like this or not.

Not sure if you can find anything useful at this link:  
<https://lookup2.toro.com/request/request.cfm?xcaller=lawnboy>

Also lots of LB specs and engine ID info here:

<https://lookup2.toro.com/gateway/acrobat/manuals/lball64.pdf>

Good luck with it - LB has always been my favorite. I've got one really neat older model, not sure of exact vintage but it's got a choke combined with the on-off switch, you rotate the switch and pull up for choke.

Ted.

Motor's and Generator's

Alright I know powering a motor with a generator wired to it with the generator being pulled by the motor wont work too much resistance BUT, with you all making your own motor's and generator's can a generator be built into a motor and/or a generator be built on the motor shaft either/or/both powering the motor

[Curiosty](#) | 1 comment (1 topical, 0 editorial)

Re: Curiosty ([none / 0](#)) ([#1](#))  
by Electric Ed on Sat Nov 15th, 2003 at 02:53:14 PM MST  
([User Info](#)) <http://www.electric-ed.com>

There are machines, called rotary converters, that have both motor and generator windings in the same housing.

These are normally used for generating three phase power in a facility where only single phase service exists.

Such a machine could be built to operate from batteries (DC) and produce AC, in lieu of an electronic inverter.

If you are thinking of supplying a motor from a generator driven by the same motor, forget it. That's been tried.

Ed

## [Hot Neutral?](#)

By [storrence](#), Section [Remote Living](#)

Posted on Sat Nov 15th, 2003 at 06:00:23 AM MST

[Electronics](#)

Have installed new service and am getting shocks through what seems to be the neutral line.

Anyone know what could be causing this? I'm using a laptop for example that is plugged into 126v here in Brazil and using the power adapter ac/dc converter and when I'm barefooted on our cement floor I get shocks touching the laptop which has a metal casing. I also get light shocks from touching the metal on some light switches (haven't tried them all). Also I have one of those plug in testers that have 3 LEDs to give the status of the plug and it shows HOT NEUTRAL REVERSAL but I know the neutral is on the right part of the plug. The hot wire is on the shiny screw and marked HOT on the plug and is also the smaller of the 2 holes on the plug. The way our service is set up may be causing the problem though. We have 3 phase (3 126v lines and 1 neutral) coming 350 meters from the street to the house. It looks like the grounded the neutral at the poll where the meter is. So we have 4 wires going 350 meters to the house. All 4 of these go to our siemens breaker box and the neutral is on the neutral bar. We then have a 4mm2 ground wire going from the ground bar on the box outside the house and connected to a 2 meter copper stake in the ground. We are not doing this with the neutral as it was done at the meter 350m from the house. The other thing that is different in how they do things here compared to the U.S. is they seem to share the neutral in some places. For example they run individual wires through plastic conduit and don't always run a separate neutral from the box to a particular circuit. Most of the time yes but I think may be in some cases they are connecting into a neutral from another circuit. Doesn't seem to me though that it would matter since all the neutrals are connecting together. With my limited knowledge of how this works I'm wondering if when something is turned on anywhere it will be sending electricity back through the neutral and it will look to connect to ground. Since our connection to ground is so far away 350M then maybe it's finding a shorter path through my legs!

Anyone have a solution or know what is going on here?

TIA,  
Steve

my guess is that it is getting colder out side, and you are wearing cotton.

Perhaps your computer is on a glass table. Anyway your body builds up an electrical charge from moving. If you could drop set your computer onto a bare electrical wire and the other end which is bare dropped to the floor this may help.

Re: Hot Neutral? ([none / 0](#)) (#2)  
by storrence on Sat Nov 15th, 2003 at 06:24:46 AM MST  
([User Info](#))

My computer is on a glass table but it also happens on a wood (particle board) table. It's a pretty strong shock that builds from weak to strong quickly and then it's impossible to not jerk away. Also what would explain why my little plug in tester is showing HOT NEUTRAL reversal status when they are wired correctly. All of them are testing that way.

on second thought dont send a hot wire to ground because your electric bill will skyrocket. I presume that your wires are reversed from the start at the fusebox.

Re: Hot Neutral? (problem found) ([none / 0](#)) (#4)  
by storrence on Sat Nov 15th, 2003 at 06:39:14 AM MST  
([User Info](#))

I did a little testing at the breaker box and found the problem. When I turn off the 220v breaker to the hot water heater the problem goes away and the tester reads correct on the plugs and I don't get the shock. What I see is that the hot water heater doesn't have a ground wire (Brazil mostly still uses plugs without a ground). So what I did when I hooked up the hot water heater is to take a wire from a screw on the housing and connected it to ground. Now I would think this would not be a problem but it seems that the housing has a fault because it should not be receiving power. It must be touching 1 of the 2 phases somewhere. So I removed my ground wire from the housing of the tank and problem went away. My only concern is that this tells me the housing of the tank is live so it could be a dangerous situation. Correct?

Very possibly dangerous or maybe the thing itself is wired backward

[ [Parent](#) ]

Re: Hot Neutral? (problem found) ([none / 0](#)) (#6)  
by storrence on Sat Nov 15th, 2003 at 07:02:48 AM MST  
([User Info](#))

It can't really be wired backwards because it's a 220v two phase connection. 2 hot wires and no neutral and no ground. It seems though that 1 of the 2 phases is shorting out to ground but not a strong short or otherwise the breaker would have never stayed on when I had the casing connected to the ground on the plug. Still some energy was passing but not enough to trip the 30amp breaker (fuse).

by storrence on Sat Nov 15th, 2003 at 08:23:32 AM MST  
([User Info](#))

The element in it is defective? It only has one element and is functioning. The unit has only been in use for 2 weeks. It seems like one of the phases going to the element is leaking power to the case of the unit. I can't be a low resistance connection because it would have surged to ground and tripped the breaker. I would imagine this might have been wasting power since some of the power would be going to ground instead of the heating element. Possibly even when the thermostat was off. It's possibly still doing that through the feet on the floor. I would have to see what they are made out of. It's surprising that they would sell these units here without ground.

You may have a decayed anode rod or something like that. The heater is in need of inspection by an electrician at any rate. It is very dangerous to have a live hot water heater casing, especially if you have copper pipes.

by storrence on Sat Nov 15th, 2003 at  
11:50:30 AM MST  
([User Info](#))

I have PVC but I agree it's dangerous. It's difficult to get an electrician to my location and even if I did, they would not consider it dangerous. You have no idea how they are with electricy here. Many people just connect wires directly to the overhead street lines so they don't have to pay but that's another story. Since I'm not so courageous to take this risk, is there any tests I can do to confirm I have a problem and what the problem would be? I have a multimeter.

I don't believe the casing is completely hot because it would have tripped the 30amp breaker when I had it's casing connected to ground.

([User Info](#))

If the heater element is partially eaten through this would provide a path through the water to the metal housing and make it "live". If your using metal water pipe this could be a fatal situation. this device needs immediate inspection and repair!!!!

Re: Hot Neutral? ([none / 0](#)) ([#15](#))  
by storrence on Sat Nov 15th, 2003 at 11:55:33 AM MST  
([User Info](#))

The complete unit is only 2 weeks old so I don't suspect that it's eaten through but there should be some way to test this. I am using PVC but wouldn't the water itself provide a path, making taking a shower dangerous?

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

storrence;

I hate to tell you this but "new" does not necessarily mean "good". A lot of manufacturers do not do rigid testing / inspections and simply replace defective units when detected by the consumer because its overall cheaper. A faulty element could quite easily allow the water and you to complete a lethal circuit. An element that looked ok to the person who installed it at the factory could easily have small cracks or other defects that only show up after its cycled a few times, too.

Bottom line seems to be that you need a professional to take a look at it and give you an opinion. Remote troubleshooting something like this is not really a good idea.

Good luck.

Cheers.

TomW

([User Info](#))

Hi Tom,

Being it was built here in Brazil, the quality issues you talk about are not far off the mark. The model I got is:

<http://www.jmsaquecimento.com.br/jmsini.htm>

I don't know if it's possible to get anyone out here because of our location but I have contacted them at their website to see what the procedure is.

Seeing that it's possible to have a defective element or even one that is old, it seems crazy that they would not have a ground wire in the installation. Without the ground wire, the element could come into contact with the water and could that complete a circuit all the way to the shower through me?? Seems it could.

Steve

Re: Hot Neutral? ([none / 0](#)) (#12)  
by WNC on Sat Nov 15th, 2003 at 10:23:03 AM MST  
([User Info](#))

Hi Steve,

You could also possibly have a neutral or hot wire in the breaker box cut or scrapped and resting against something in there. Turn your Mains off and check all your connections on your hot and neutral side. Whoever did the wiring might have skinned up one of the wires coming into the breaker box. If you have a meter, check both the neutral and the hot in relation to ground with the breaker turned off. If you're showing any voltage on a receptacle with the breaker off, you have something touching in the wrong place somewhere.  
Hope you get it fixed:-)

WNC

Re: Hot Neutral? ([none / 0](#)) (#16)  
by storrence on Sat Nov 15th, 2003 at 12:07:38 PM MST  
([User Info](#))

I did all the wiring and my box is a siemens 3 phase box. All the hot wires connect directly to each breaker and there are no problems with the wires that I can see. You said to test it with a meter but I'm not sure how I would go about testing to see if I have a bare wire somewhere. It seems you are saying to turn off the bipole breaker to the hot water heater and test for any voltage on those lines but with the breaker off it would be impossible to have voltage on that plug since the breaker would be cutting voltage to both of those lines and there is no neutral.

What I've tested so far is that the problem completely goes away when I either turn off the bipole breaker to the hot water heater OR I leave it on but disconnect the ground that I connected from the plug to the casing of the heater. So it seems to me that some electricity is passing from one of the 2 phases on the single heater element to the casing either from inside passing through the water or from the point that it mounts to the tank. What is strange is that the unit is only 2 weeks old and the mounting point looks ok.

Re: Hot Neutral? ([none / 0](#)) ([#19](#))  
by ThomasK on Sat Nov 15th, 2003 at 05:11:41 PM MST  
([User Info](#))

Hi Steve,  
Sorry You are in BIG trouble!  
You say You have a meter, so disconnect the Waterboiler and check the lines in and out of the boiler with the OHMmeter in every range of Ohm´s - this both lines to the outside of the tank!! This MUST be in every range No reading of resistance!!  
If not so the Heatelement is BAD!  
IF this happend so NEVER use hot water from the boiler DISCONNECT it immediately until you have replaced it with a new Boiler or element!  
Think about a leakage current protection and a electricially SAFE unit!  
Myself dont want Your Family nor You ELECTROCUTED!!!!!!  
Greez Thomas

Re: Hot Neutral? ([none / 0](#)) ([#21](#))  
by storrence on Sun Nov 16th, 2003 at 03:38:46 AM MST  
([User Info](#))

Hello Greez,

The breaker to the boiler has been off since I started this thread and I don't plan on turning it back on until I solve this problem. I'm not as daring as the locals. I play more on the conservative side which is why I have all my circuits grounded and all my plugs and switches are all from the US. Even all my appliances except the boiler are from the US. So with this boiler now I'm trying to mix Brazilian daring with US conservative :)

Would you mind to give me a little help with testing the resistance. I'm not sure I understand what you are explaining. The points I would think to check would be with the element installed, one terminal of the element to the other terminal. This I guess would see low resistance indicating a good element. Then would I test one terminal of the element and the metal of the boiler looking for 100% resistance on all ohm ranges. Then the other terminal with the metal of the boiler.

Is my thinking correct???

[ [Parent](#) ]

Re: Hot Neutral? ([none / 0](#)) ([#20](#))  
by monte350c on Sat Nov 15th, 2003 at 08:16:42 PM MST  
([User Info](#))

Yikes!

I just moved back to North America from somewhere where there was lots of "interesting" stuff going on with 220 volt power.

The previous suggestion about checking between the power connections and the case of the water heater is good.

If there's a thermostat on this water heater, you should have a look at it, and all of its wiring too to make sure nothing's shorting to the case.

Good luck and I hope you can solve this soon - it's not a good or safe situation at all...

Ted.

Re: Hot Neutral? ([none / 0](#)) ([#22](#))  
by storrence on Sun Nov 16th, 2003 at 04:22:44 AM MST  
([User Info](#))

Hi Ted,

I put up some [pictures](#) to see this better.

BTW, where did you move back from? Here in Rio you can't imagine how the favelas connect to the grid! They all connect directly to the overhead wires and it's a huge spaghetti mess of wires. Completely out of control. I knew 'free energy' was making progress but here they've had it for years ;-)

After I ran the 350M of cable from the meter to my house I was surprised to see how the local checked for neutral. He just touched each wire with one and and put the back of his hand on ground. :)

I'm going to do some testing with my mmeter and post my results here.

Steve

by Michael G on Sun Nov 16th, 2003 at 05:23:42 AM MST  
([User Info](#))

Im no electrician but cant you tie neutral to ground at the circuit panel? Those ground rods need to be in damp ground too. Seems that would fix the problem.

Re: Grounding Neutral ([none / 0](#)) ([#24](#))  
by storrence on Sun Nov 16th, 2003 at 06:25:38 AM MST  
([User Info](#))

Yes I believe so. It's really the same thing and in some boxes you only have one bar to tie your neutral and ground together. I think it's just separated in this box for clarity.

I think I don't even need the 4th neutral wire going back that 350M to the meter. I should be able to just connect it to the ground stake.

Anyone else know about this?

[ [Parent](#) ]

Re: Hot Neutral? ([none / 0](#)) ([#25](#))  
by brock ([nevermab at uwgb dot edu](#)) on Sun Nov 16th, 2003 at 11:17:57 AM MST  
([User Info](#))

You have an open side to the water. One of the two (or really both since they are in the water) are leaking power in to the water. When you add the ground the power is running back up the ground line and leaking in to all the other grounds on you system.

You have two problems.

1. Your water heater element is bad, it could be a defect, it could be worn, no matter the case it is somehow leaking in to the water and it should not be doing that.
2. You need a better ground. Since the power is leaking from the water heater back to the ground and the voltage is raising enough to shock you, your ground isn't doing what it is supposed to do. It should pass all that power back in to the ground but for some reason it isn't.

This is sometimes called a floating neutral or floating ground. In any case make sure you have a good connection to ground in the panel and especially at the water heater itself. As other have noted if you have the heater on and take a shower your likely to get zapped since the power will want to flow from the shower head to the ground (or the drain). As you can imagine, this is a bad thing.

Re: Hot Neutral? ([none / 0](#)) ([#26](#))  
by storrence on Sun Nov 16th, 2003 at 01:03:36 PM MST  
([User Info](#))

I've done some testing on the element while it was still installed and came up with these readings.

I'm wondering also if this unit is really a bi-phase 220v. I'm starting to think it's a single-phase 220v which is strange because I don't know how I would hook it up with my type of service (3 phase, 3 126v lines + neutral).

[Here are the pictures](#) of the element and thermostat:

The markings on the thermostat read:

```
=====
THERMOSTAT
Single Pole
Type R-T-M Water Heater
THERMOWATT
=====
```

Everything in English so maybe it's from the states or the UK.

The markings on the element read:

```
=====
2. 5KW
220. v J-M-S
=====
```

The readings from my ohm meter are:

Connecting to both terminals of the element reads 19?

From the left terminal to the casing (screw hole) reads 4?

From the right terminal to the casing reads 15?

So what I deduce from this is that I the right terminal should really be neutral which is connected to the casing and why I'm seeing a 15? reading.

The left terminal should be a 220v or 110v depending if I was

using a 220v or 110v element. Here I'm getting a 4? reading or should it really be 0? ?

The element seems ok.

Does all this seem correct? If so then how would I wire this to my 3 phase circuit panel without installing a transformer to step up the 110v to 120? I don't have a single 220v phase.

TIA,  
Steve

Re: Hot Neutral? ([none / 0](#)) (#34)  
by drdongle on Sun Nov 16th, 2003 at 08:51:40 PM MST  
([User Info](#))

Your meter readings indicate a short between one side of the heating element and the metal housing I suggest that you replace it ( hopefully under warrenty).

Dr.D

Re: Hot Neutral? ([none / 0](#)) (#27)  
by storrence on Sun Nov 16th, 2003 at 01:36:10 PM MST  
([User Info](#))

Since this now seems to be a uniphase 220v boiler what I've done for now is to take one of the phases going to the biphas breaker in the circuit panel and moved it to the neutral bar. So now I have it set just like a normal 110v circuit except that I'm using a biphas breaker using just one side of it.

It has eliminated the shocks in the ground line and I suppose it will just be less efficient than if I changed the actual element for a 110v.

This makes me wonder though how I could wire it the way it was intended. I don't see how I can get a single 220v phase from my 3 phase service.

Also this has made me think about the safety of grounding.

1. Since I had connected wrong in the first place having 1 of the phases connected to what should have been a neutral terminal which is connected to the casing then why wasn't the shock stronger and why did it not trip the breaker. Was it just because the phase found an easier path into the other phase via the element and this was just the overflow that went to the casing?
2. Connected the way it is now with 1 phase + neutral why would I need a ground hookup for safety? If a dangerous situation occurred like the insulation coming off the hot wire and touching the casing wouldn't it in this case rush the power to the neutral wire since it's in connection with the casing and then trip the breaker?? I don't see how the casing could remain hot in this situation since it would rush electrons through the neutral and build up heat in the wire and trip the breaker.

Why are ground wires needed if neutral is connected to the same thing? Why can't all devices just have the metal casing connected

to the neutral wire for safety? I'm sure there is a reason but I can't figure it out. Why is a neutral AND a ground needed for safety?

TIA,  
Steve

In many cases the ground is redundant and as so normally carries no current, if however there was a situation such as you just had that, that current is redirected to the system ground and hopefully popping the circuit breaker alerting you to the problem and cutting off the current, baring the breaker being tripped that voltage is diverted away from secondary grounds like water pipes and people. Even if you keep the 120 volt set up I highly recommend that you employ a safety ground.

It's simply a matter of safety versus cost, is you life worth more than a few feet of copper wire?

Dr.D

by storrence on Sun Nov 16th, 2003 at 03:34:17 PM MST  
([User Info](#))

All my place is grounded. I'm paranoid about that. :)

Do most appliances in the US that are grounded have the ground and neutral connected together inside the unit? I mean in a toaster for example is the metal frame connected to the neutral on the plug? If not then why not since they end up connecting inside the circuit box anyway. And if the ground pin is connected to the neutral pin then why the redundancy? If it was connected such that the casing of a toaster was connected to the neutral pin which would go to ground at the circuit box and the ground outside the circuit box, if the hot wire got damaged and came into contact with the casing then the power would rush through the casing to the neutral pin to the box and to the ground causing a rise in the wire temperature and shutting off the breaker. The object would never stay in a dangerous situation if the breaker functioned.

I must be confusing something here.

Hi Steve,

Now I'm getting abit confused.

Is it right that the Heater element is/was connected to Two of the phases?

If yes, and your supply/line voltage is 110 Volts so it is very clear that this heater was operated between the phases which gives the element about 209 Volts.

This can be done to uprise the Voltage for a 220 Volts Consumer like this Appliance.

(the missing 11Volts are in the tolerance)-so called Ohmic Consumers

About the readings of the meter - 19 Ohm overall is Ok for a 2.5kW element.

on one side 15 and on other 4 is classical break in the insulation - what happend could be that the heaterwire touches the metal tube were the wire is in .

This is COMPLETELY DANGEROUS for you - NO WAY you connect it to mains!!!!!!

So throw this out, a measure to live longer ... for YOU and OTHERS.

GREETINGS

Thomas

Re: Hot Neutral? ([none / 0](#)) ([#30](#))  
by storrence on Sun Nov 16th, 2003 at 03:22:15 PM MST  
([User Info](#))

Hi Thomas,

The way it WAS connected when I was having the problem was I was connecting 1 phase to one terminal and another phase to the second terminal using a bipolar breaker. No neutral and the ground I rigged up myself to a screw on the casing. I'm utilizing ground on all my plugs and appliances.

Our supply line I tested at 127.7V 60Hz. We have 3 phase and each phase is 127.7V. When we hook up a 220V drill for example we use 2 of the 127V phases and no neutral. I assumed the boiler would be hooked up the same way but now I think not.

Did you see the pictures I put up?  
[homepage.mac.com/stevetorrence/PhotoAlbum4.html](http://homepage.mac.com/stevetorrence/PhotoAlbum4.html)

It really seems that it should be connected with 1 neutral and 1 220V phase but is that possible? With my service I don't think so but how is it in the US when you have a 220V circuit? Are both lines hot or is one a 220V line and one a neutral??? This I would really like to know because I know there are different ways of delivering 3 phase power.

Is it ever correct to wire a unit like this the way I did? The way I see it, the white wire is really intended to be neutral since it seems to be connected to the casing. It seems if it's a single pole unit (the thermostat is marked single-pole) then the white wire or right terminal in the picture would be ok if it was connected to the frame acting as a ground also. I mean even if it didn't have a physical connection to the boiler frame but it did have a ground wire

attached then it would be connected via the circuit box anyway since ground and neutral are one and the same. BUT... I should be seeing a zero ? reading right? But I'm receiving a 15? reading. Would 15 and zero both indicate a good connection? I guess all materials have 'some' resistance?

AND the other problem I see is that the black wire, left terminal (phase as I have it connected now) is getting a 4? reading indicating a better connection to the frame than the right terminal but this should have a very high ? reading since there should be no connection to the frame.

With these readings, is there no question that I have a hot to ground situation, most likely with the element coming into contact with the internal pipe? Any other tests I can do to narrow this down? This has a 3 year tank warranty but I can imagine what the experience will be to get it repaired here.

I just thought of something else. If the element which I suppose is designed with a very long coiled wire inside a metal tube which forms the two terminals. This metal must come into contact with the water which must be ok since I can see no way to avoid it. Why does the electricity not travel through the water to the metal casing and cause an unsafe condition? Is the outside of the element insulated? If so then why does touching the metal pipe create a problem assuming the insulation is still intact?

Maybe the answer is that the water is a conductor but just not a very good one.

Now I'm wishing I had a transparent acrylic boiler :)

Steve

([User Info](#))

Keep in mind that in the US even though we have many 220 VAC appliances they are in fact only single phase, 3 phase is never used for residential installations.

For clarification what we use in the US is a 220 V supply with a grounded ( earth) tap at the center of the transformer on the pole ( or pad). This tap is brought in to the load center ( circuit breaker panel) as one of 3 wires and is tied to the main ground buss, which in turn is connected to the ground rod, all 120 volt circuits and safety grounds are also terminated on the ground buss.

Some 220 volt appliances like stoves ( electric cookers) use 220 V and have a combined neutral/ground lead, newer ones will also have a 4th connection for seperate safety ground. 220 volt circuits like a water heater don't use a or need a neutral connection, but do have ground.

Some appliance like toasters are generally only two wire devices using only a hot and a neutral and have no safety ground, their housings are usually plastic or insulated from the hot and neutral.

If you in fact have 3 phase coming into your house there will be at minimum 4 wires coming from the meter box on the street. 1 for each phase and the neutral/ground (earth), and you can read 120 volts from each phase to the neutral.

Dr.D

([User Info](#))

Thanks Dr. D. for all your help!

We have exactly what you subscribe. 3 phase with 4 wires coming from the box. 1 for neutral and 3 others which each read 127.7V on my true rms multimeter. 60Hz. Here 3 phase seems pretty common. Many hand tools here are 220v but they are 2 phase 220v. I say 220 but I guess it's 127\*2 no neutral. What's crazy is there they use the same plugs so you could blow a 110 appliance if you are not careful what you are plugging into. I'm anxious to do some work with 3 phase motors.

This difference in 220v I had thought a little about before but now you have me thinking.

Is there a difference between a drill for example or a computer that is

designed to run on 220v single compared to dual phase? like in the US with a 220v phase + neutral and/or ground compared to the way it's done here with 2 126V lines and no neutral.

I bought my clothes dryer in the states and have it hooked up to 2 phase (2 126V phases + neutral + separate ground) and it works fine. Should it?

I have a computer that will run on 110-250v. Would it be ok to plug it into a 2 phase 126v \* 2 outlet or would it need to be a US type 220v + neutral?

OR is 2 phase and 1 phase 220v essentially the same to the load device?

Re: Hot Neutral? ([none / 0](#)) ([#42](#))  
by ThomasK on Mon Nov 17th, 2003 at 12:49:45 PM MST  
([User Info](#))

Hi Steve,  
as far as i know it is not applicable to connect a computer to 2\* 126 V (bi phase) better is to connect to one phase plus neutral ( 127V + N )  
The connection between Phases give no neutral so the Voltage difference is only because the phases are 120 degree shifted so this can damage all electronic Devices. Myself have seen a UPS in Venezuela fried by doing so. For Ohmic Loads and Motors there is usually seldom a harm.  
Greetings Thomas

Hello Steve,  
In Poland there is  
220V + N - that is  
single Phase.  
Myself havent  
seen up to now  
computers with  
wide range input  
for mains. Which  
is not saying that  
itis not possible.  
If you have it  
runnig on 127 +  
N it is OK - what  
should it bring to  
run it there on  
220V? Faster?  
more Powerful?  
pls explain.  
greetings Thomas

Re: Hot Neutral? ([none / 0](#)) ([#40](#))  
by ThomasK on Mon Nov 17th, 2003 at  
12:31:48 PM MST  
([User Info](#))

Hi Steve,  
It seems That you have a short to the tank.  
to measure out a Short disconnect all wire at  
the element.  
So you have the bare connectors / no wire on.  
measure from one pole / connector to the  
metal outside of the tank, also the same  
with the other pole /connector.  
This readings must be high Ohm resistance. No  
reading.  
If it is low resistance its a short.

To the element setup -  
yes indeed it is a wire in a metal pipe and to  
insulate the wire (live) to the pipe  
there is some material like quartzsand or a  
stuff similar to avoid contact of the wire to the  
pipe. this bar then is wound to some shape to  
form the element.  
When the wire touches the pipe then its a short  
to the case / tank. to avoid more damage thats  
why a so called Protection Earth is mounted to  
the tank -

Also myself think the line from the meter to  
your house in too long for the diameter of the  
wire. The way your electrical line outlet you  
described is a 3 phase 1 Neutral  
supply where you can obtain about 220 by  
taking it between the Phases, as you said.  
The Ground ( Protection Earth ) has to be take  
near your house.  
To do all this things i suggest to get a skilled  
electrician !

So now you might see more clear,  
Im technician in Germany so I´m cant tell you  
much about electric outlets like in the States  
but as a servicetechnician in worldwide activity  
I´m seen also lots of  
dangerous appliances and wiring, also it took  
me these days to understand what was going

on with your problem by reading the posts.  
So if there was sometimes a unclarity in my explanations its because my english is not the best.

Thankyou for your understanding and ihope you have solved this problem SOON and SAFE!!  
Greetings Thomas

Hi Thomas! I've been a few times to your country and have some friends in Ankara.

I will test the element again. My first test was with the wires still connected.

The cable we have going the 350M is 4 wires and each one is 25mm<sup>2</sup> (read squared). I know the welders that were here recently commented how strong the power was and we haven't experienced any problems other than this heater. Our power seems strong.

Getting a skilled electrician where I'm at is easier said than done :)

Hi Steve,  
Fine that you have been to Germany as well, but Ankara is in Turkey  
- or do you talk about a place in Germany which sound similar which i don't know?  
About the wire / line from the meter to your home it seems to me that 25 sq mmm is OK - i thought that it is only 2.5 sq mm - which could be to less. Possibly thats why i'm thought it is not sufficient.  
Sorry for that!  
greetings Thomas

static electricity shocks ([none / 0](#)) (#35)  
by Simon ([simon@guyo-inc.com](mailto:simon@guyo-inc.com)) on Sun Nov 16th, 2003 at 11:34:50 PM MST  
([User Info](#)) <http://www.guyo-inc.com/engineering.htm>

Working with a heap of manustcripts one day i realised that my body was building charge as i flipped trough page by page. Since my printer is locate in another room i had to go through a door to get more fresh prints. And just when I reach the door handle -- there goes again!!! an electrical sting. I did not realize what was happening for some time until I tried discharging this electrical current by touching the wooden office wall before i go for the door handle. This helped a great deal. There is electricity around us -- its just waiting for us to pick it up!!!

Re: static electricity shocks ([none / 0](#)) (#36)  
by laskey on Mon Nov 17th, 2003 at 07:28:58 AM MST  
([User Info](#))

I went to the manufacture's website, and while my spanish (I pretty sure it was spanish) isn't all that great (actually it's terrible), but a product table is still a product table.

Their 2500 watt electric water heater is indeed 220. Which means it has to be 2-phase.

And that means, you have a bad element, but if I understand the language correctly... you have a 3 year warranty.

Drain the tank, remove the element, take it back, and have it replaced.

Look around that website, you understand the language better than I do, there may just be installation instructions.

Cya,  
Chris

Re: static electricity shocks ([none / 0](#)) (#45)  
by storrence on Mon Nov 17th, 2003 at 01:00:28 PM MST  
([User Info](#))

Is it possible to visually see if an element is bad once I pull it? It's new so what would I be looking for for verification? The only manual that came with it was a sticker on the side of the tank that is now turned against the wall so difficult to see. I will check their site.

I remember that when we ordered it they asked if we wanted 220 or 110 which I guess here is really 126\*2 (should it be called 152V) and 126+neutral. But it only has 1 element and some body here said a 220V has 2 elements in the US. Well I don't see why 1 element wouldn't work if you put 1 phase on each terminal and grounded it. In our case we have some defect but otherwise it seems it doesn't need 2 elements to be a 220v at least not down here.

I'm curious why you say because it's 220v it has to be 2 phase? Aren't the 220V hot water heaters in the states single phase 220v?

Re: Hot Neutral? ([none / 0](#)) (#37)  
by jubalearly on Mon Nov 17th, 2003 at 10:27:34 AM MST  
([User Info](#))

350 meters is plenty far enough to generate a voltage difference between your ground and the grounding electrode conductor (neutral). Also, any imbalance between the 3 phases (unequal loads) causes a current to flow on the neutral which will generate a voltage. In the USA the neutral would be connected to ground in the main panel. I suggest you consult the local code authority (if there is one) or at least talk to an engineer at the power company before you do anything, but it sure sounds like you need the ground and neutral connected at the house. Without it, you will certainly have a voltage difference. It's better if you don't ground the neutral thru your body.

Re: Hot Neutral? ([none / 0](#)) (#43)  
by storrence on Mon Nov 17th, 2003 at 12:49:47 PM MST  
([User Info](#))

Interesting what you say about the balancing of the 3 phases. I was concerned about this when I laid out the circuit board but not for this reason. I was wanting to equal use each of the 3 lines since I knew my distance was a factor. On the positive side we are the only house after the transformer where it drops from what I guess is 7.5kV when we had some welding done on our house recently they commented at how strong the 3 phases were. They were using a 3 phase welder. The problem was it seemed impossible to equal share the load. I was mainly looking at the computers because I have 5 or 6 always on + the dryer, hot water tank, clothes washer and a circuit of outdoor flood lights. But the way the box is laid out has the 3 phases going down the center on copper bars that have pins at each point alternating 1 2 3 1 2 3 on each side of the board. And since the bipole breakers could only be on 12 23 or 31 I just put them the best I could and I don't notice any problems with lights dimming when heavy loads come on. When I just put a test meter on an open plug, I read 127.7V. I've never done readings from the box or our box. I blew my last 10A fuse and need to find another. I don't remember why it blew last time but what is the correct way to test V at the circuit breaker? Don't I need to have some load on? Do I put the jumpers right on one of the phases and neutral?

Here the electrician said it was no problem to connect the

neutral and ground bars together. He said many boxes come with only one bar used for neutral and ground. Is it important the size of the wire I use to connect the ground and neutral bar together? Will a 10AWG or 4mm<sup>2</sup> do it since it's such a short distance?

[ [Parent](#) ]

Re: Hot Neutral? ([none / 0](#)) ([#38](#))  
by jubalearly on Mon Nov 17th, 2003 at 10:35:47 AM MST  
([User Info](#))

I don't know about your water heater, it may cause a load imbalance on your 3 phases. But just the 350 meter run could be your problem. Figure the voltage drop on your wire for that 350 meters. Measure your current in the neutral and find the worst case (whichever appliances on gives you the most neutral current). Figure your voltage drop with that current, round trip, since your neutral to ground connection is a total of 360 meters x 2. You should see that voltage between neutral and ground at the meter (or where ever the ground actually is). The voltage diffence at your house is 1/2 the voltage drop you just figured, and it can easily be enough to shock you

Re: Hot Neutral? ([none / 0](#)) ([#41](#))  
by storrence on Mon Nov 17th, 2003 at 12:38:59 PM MST  
([User Info](#))

I'm not sure I understand how to do this. I don't have much experience with this but have a multimeter. Can you be more specific in how to do these tests? I'm very interested to get these figures to see if we have a potentially dangerous situation here. I'm sure if I asked someone to do this here in Brazil they would give me a puzzled look. I remember them being very impressed with my meter. Not because it was fancy or anything but because they didn't have one! I'm not saying this is true for all places around here but I'm in a rural area so it's worse. I'm learning a lot here though!

Re: Hot Neutral? ([none / 0](#)) ([#47](#))  
by brock ([nevermab at uwgb dot edu](#)) on Mon Nov 17th, 2003 at 01:29:18 PM MST  
([User Info](#))

Again, the more you explain what is going on the more I think it is the element. I would be willing to bet if you pulled it out you would see a worn spot somewhere in the casing.

And to answer your question, the power never touches the water. Think of it like a burner on a stove. You can touch it and not get a shock because it is electrically insulated from the outside part, same situation with a water heater element. Again my guess is some of the insulation has deteriorated away.

Yet you still have a grounding problem that lead you to find this problem in the first place. You need to check where ever the main ground lug is inside and OUTSIDE the home and power box and make sure it is good. Even with the bad water heater element it should have gone out to ground, and tripped the breaker and not through the rest of the grounds in the house.

by monte350c on Tue Nov 18th, 2003 at  
08:20:36 PM MST  
([User Info](#))

Hi again,

If you're disconnecting everything on this hot water tank - I'll go back to the thermostat issue again!

If you're getting readings between either of the thermostat connectors and the case, this very well could be the source of the problems. ie. if you check resistance between each terminal on the 'stat and the case, there should be no conductance at all. If you're showing 4 ohms or whatever it means there's a problem.

220 single phase that's being derived from two 127 volt hots is using two hots for power. That means neither of them can touch anything or there's going to be

problems.

I don't really know for sure but if the 'stat was a U.S. model that was expecting one of the leads to be attached to a neutral/ground that could explain it.

If you DO get a conductance reading between either of the 'stat terminals and its case, you should go shopping for a new thermostat - AND take your ohm meter with you! Check the new ones in the stores and only buy one if it's electrically isolated from its case!

Best of luck - BTW that looks like a really cool spot you have there - I'm envious!

Ted.

## [White LED experiment - failed](#)

By [J Steele](#), Section [Weird Science](#)

Posted on Fri Nov 14th, 2003 at 09:47:31 AM MST [Electronics](#)

**experiment to produce more light didn't work out**

Hello All,  
I've been experimenting with white LED's for use as off-grid home lighting. I wanted to experiment with this idea, If a LED can handle 30 milli-amps of continuous current then could it handle pulses of 60 mA if I gave it time to cool off between pulses and would it be any brighter. I attempted all sorts of pulse lengths and duty cycles and found that the LED was happy as long as the average current did not exceed 30 mA. The failed part of the experiment was that none of the pulsed versions were any brighter than the continuous set up. Oh well, now I know.

If you are wishing to use white LEDs for home lighting consider adding one red and one yellow LED for every 8 white ones. This gives a much more pleasant light.  
Have a good day  
John

J,

I also experiemented with LEDs for indoor back-up lights. The prospect of light with a very low power drain sounded good. I bought a hundred that were billed as WHITE from a guy on e-Bay for just over a buck each.

To be fair, they do put out light. But it is very directional and focused in a very tight area. It was a very cold blue color, not what I would call white. Running it at anything above 35mA only made the color worse. I also tried to experiment with mixing yellows and reds. But the tightly focused area made it difficult to blend the various colors into something that had a warmer feel to it.

I've read that some of the more recent white LEDs are better, but I'm still not convinced. I shifted my focus (pun unintended) over to low voltage fluorescents. It's not as light a battery drain, but a much better quality light output. And it is still better than incandescents.

My conclusion is that LEDs may work for lighting a very small area, but not for general room lighting.

Bach On

Be sure to check out the "LED Museum" (google for it). The site has excellent pictorials of the color and radiation pattern of various LEDs.

Did you try putting lots of mostly white and a few yellow and red LED's bunched up together and behind one of those cloudy white light difussers? Just curious.

At one time I was very interested in making LED lighting because I thought LEDs were more efficient than any other light. After searching and reading I found that LEDs are just more reliable, and in terms of efficiency are rated between Incandescent and Fluorescent. Fluorescents are currently the cost/efficiency leader. Plus they have better color light.

The orange, sodium street lights are probably the most efficient lighting available. With their orange color and slow warm-up time, you won't be finding them as an accepted replacement any time soon.

As some kind of backup lighting or outside, "non-white required" light, they may hold some promise.

Martin.

But it is very directional and focused in a very tight area.

they are made both ways with a focused beam usually 20° or multidirectional like a regular lightbulb just have to order the right ones

White LED's are best applied to small work-light applications where you need to look at things up close. I have one on the electronics bench on a gooseneck holder.

I like them for "guide" lights in the hallways and such too. Since, individually, they consume almost no power, you can mark all your "emergency" items or storage areas in case the power goes out.

That way, you won't really NEED a flashlight to walk through your house and find something like, say, a fire extinguisher, in the dark.

Each marker is just a small rechargeable battery and one LED. If you want to get fancy, run a single length of speaker wire from room to room and connect each battery

to them with a single diode to allow charging from the wire.

At the source, make yourself a small capacitive discharge charger that dumps the capacitor charge across that wire. NiMh and NiCad batteries seem to like type of charging. Make sure you use all the same type, whichever you choose. Stick with something like 150uf and let it rise to about 5v above battery voltage before each pulse.

To battery at lowest voltage will get most of the charge on any given pulse. Just measure the capacitor voltage after any pulse to show the battery charge level for the whole group.

## [Trace Sw4048 Inverter Trouble can anyone help?](#)

By [NeedHelp03](#), Section [Homebrewed Electricity](#) [Electronics](#)

Posted on Fri Nov 7th, 2003 at 09:28:47 AM MST

Trace Sw4048 Inverter troubles

I have a SW4048 Trace Inverter that is out of Warranty, sadly being so expensive it was purchased 3 years ago and never used, until now. It worked great for 2 months. We had some strong winds. I think what happened was the voltage was to high or something, maybe the dump load didn't work, anyway the inverter is configured to put 120V out, the inverter is only pushing 99Volts out, therefore not synching to the grid, or inverting properly. I called Trace they told me I have to take it in, I really don't want to spend more big \$\$\$, it has to be something simple, since the inverter hums, it just won't synch, invert at 120V, or battery charge, because the voltage is only 99 volts instead of 120. Can anyone help? Any ideas, suggestions? Thanks in advance. Battery Volts are 52 Volts presently. One Thing I noticed is if the Inverter Battery volts rise to 55Volts the inverter will push 103Volts.

([User Info](#))

I think the Trace SW's work by using several transformers that combine to make the sine wave. You could have one transformer bad and the unit would work about the way you say. It could have the Mosfets out to that transformer and it would act similarly.  
Just my thoughts on it.  
RobD

We had a 4048 smoke FET board for no apparent reason several years ago a little beyond the warranty. Trace replaced it for free but because they had recently revised the design.

The description above of how it works is accurate but that's as deep as I understand it myself. Its a good product but it is complex. Its probably not a transformer but possible. Its probably a FET, especially if there's any chance the lightning got in and let the smoke out (arrestors on the AC and DC sides are a really good idea). Some chance there's something wrong upstream but my money's on the transistors.

Good luck.

Re: Trace Sw4048 Inverter Trouble can anyone help? ([none / 0](#)) ([#4](#))  
by NeedHelp03 on Fri Nov 7th, 2003 at 01:54:24 PM MST  
([User Info](#))

I did a volt meter test, no fluke meter, just a cheam dvm, and on the output of the 120V I get 181Volts, The inverter registers 99Volts on the menu, when transistors smoke, do they leave a black circle, or burned smell? I don't see any evidence of burned circuitry, or any odd smells. But it very well could be a transistor, I'll probably end taking it in for service in about 2 weeks.

Also can anyone show me a url where I can get some ac and dc lightning arrestors?

Finding a blown FET can be a problem because you are working with low transformer resistances. You almost have to remove the xistor to check it even with a Fluke. you can take a shot and check across the coils to see if one is less than the rest or open but after this it starts to get technical so you might want to send it in especially if Trace has an update on the board.

Testing components in  
circuits like this ( and in audio  
amps, which are similar) can  
be tedious and frustrating,  
often you need to remove all  
the output transistors so as  
to facilitate accurate testing  
and to avoid interaction  
between the various  
components in the circuit, so  
I guess I'm saying "yes".

I have a gadget I built when  
I was in the Navy that when  
used with an O-scope is great  
for testing solid state  
components. We called it an  
"octopus" ( I'm not sure of the  
origins of it's name, except  
that it probably had a bunch  
of wires coming out of it).  
Any way it gives a visual  
display of the junctions in any  
solid state devices on the

screen and allows you to quickly determine there quality.  
If any one is interested I'll (try to) post the circuit.

Dr.D

I have had similar experiences where I work. We employ Trace SW4048 type invertors for Remote radio Transmitter site power controllers . You know charge and maintain the batteries -start and exercise the generators and be the psuedo UPS. I have on more than one occasion thought we have blown the outputs on the unit, We removed and replaced the unit with a brand new one . Once the bad unit was repowered up on the test bench in reset itself and worked fine once again... the next two times we only removed the battery leads and all power leads to the unit for a few Minutes (not seconds). Reapplied the batteries and power and like magic it somehow lost some internal bias and started functioning normally again.  
This may nor be your problem ...but what could it hurt.  
If it does help I would guess your Fets are bad on the output. If you change them- do it in pairs..if one is bad it's partner will be badly wounded too.

Good Luck

by VermontMaple on Wed Nov 26th, 2003 at 06:51:59 AM MST  
([User Info](#))

I meant to say "if this doesn't help", you probably have bad output FETS - they should be changes in pairs.

([User Info](#))

I tried this, machined the rotating part out to fit in some magnets, and bolted on blades. The frustrating part was that the original coils were of really tiny wire, varnished so it was near impossible to change the way the coils were connected (they were all in series to begin with). At any rate, I found that the thing clogged pretty bad, takes a stiff breeze to get it spinning. I decided that my time would be better spent building a dual rotor axial machine similar to DanB's.

([User Info](#))

I rewired and add magnets to a ceilingfan, it had two phase 14 poles in a waded wound, i use 100 turns of about 0,5 mm wire, and add ceramic magnets. I have 12 v at about 120 rpm with to phase rectified and then in series, and the max. amp. i have seen is 1,5 amps, with neos sure can be more; with ceramic magnets its low cogging, but with neos can be higger; probably if you put a diferent number of magnets than poles diminish cogging.

Daystrom Weston

Hello Folks,

I have a qty of single purpose meters forsale. These are made by Daystrom Weston, Singer, Sensitive Instruments Corp. These units are from the 1960's. Each has a leather handle and is about 4" X4" square. I use a pair of these to monitor the current and voltage into my battery pack from the solar panels. All are in excellent condition.

Email me with your requests as there are AC or DC meters, volts Amps, millivolts, milliamps of all different ranges. Most of the meters have several scale. made of almost indestructable bakelite.

I have pix of some so you can get a look at the meter.

prices

QTY

1. \$24.00 ea.
2. \$22.00 ea.
3. or more \$20.00 ea. plus shipping from 06791

Thank you

PauLC

## [switching regulator](#)

By [kell](#), Section [Homebrewed Electricity](#)  
 Posted on Mon Nov 3rd, 2003 at 09:55:42 AM MST [Electronics](#)  
 looking for circuit diagrams etc.

I have a charging situation where I need a regulator that will pass about 10 amps. The voltage drop is variable, up to about 40 volts. Tried making my own linear regulator with a bunch of 2N3055 pass transistors, because I know how to build the circuit, but have come to understand that the power dissipation is just too much. Now I would like to find info about how to build a switching regulator.

Something based on a N-Channel MOSFET would be convenient because I have some IRF540N's. But all knowledge is useful. If I could find out how to introduce hysteresis into a linear regulator I could probably work it out how to build the circuit on my own, now.

[switching regulator](#) | 5 comments (5 topical, 0 editorial)

Re: switching regulator ([none / 0](#)) ([#1](#))  
 by [N9WOS](#) on Mon Nov 3rd, 2003 at 11:53:51 AM MST  
[\(User Info\)](#)

Here is one thing that may give you an idea or so.

<http://n9wossolar.home.att.net/schem/bpwm/bpwm.html>

The best way to introduce hysteresis in the circuit or send it into a switching operation is to modify the control element or to increase the regulating element gain then increase the response time of the control system and put inductance in the circuit to produce time lag. The output voltage will always be out of phase with the Drive voltage. That will keep the current control elements in a full On, or off condition.

Switching frequency will not be controllable, but it has a lot lower loss than a linear regulator.

Recently I came up with a better idea. I should just use an off-the-shelf automotive voltage regulator. I won't have to try to design, test and build a switching regulator from scratch. I know how hard it is. My power in this project comes from a generator, and I have a plan to regulate the output by controlling the generator's field current (electromagnets). An alternator regulator will do this, I just have to connect the field coils of the generator to the regulator's field connections. I found a schematic of the Delco SI regulator and understand how it works and have figured out how wire it with the generator I have. Here's the challenge: how do I go into an auto parts store and just ask for a voltage regulator for the 12 volt Delco SI alternator, without having an answer for their inevitable question, "What kind of car is that from?" Any suggestions?

([User Info](#))

Take a look at the ACE catalog for Delco 10SI alternators here:

<http://www.aceelectric.com/PDF/Altpage.htm>

Otherwise the parts place should have an electronic regulator that is a 'universal' replacement for the old mechanic regulators. But in my opinion the regulators for a starting battery don't have the proper charge characteristics for deep cycle batteries. Richard Perez had an excellent article in Homepower magazine with a circuit for a better charge controller. It's been mentioned on this site a few times or you could look for it on the Homepower site. HTH,  
-RussH

## PC Oscilloscope

By [ChrisW](#), Section [Homebrewed Electricity](#)

Posted on Sat Nov 1st, 2003 at 08:55:01 AM MST [Electronics](#)  
freebies!

For all the electronics wizards out there:

I was surfing the 'net for PC-based oscilloscopes and was horrified by the prices for new and even used equipment. After refining my Google search a bit, I came upon a freebie oscilloscope program that uses the PC's sound card for input. My intuition told me that it'd be great for very low voltage signals, but the risk of frying a perfectly good sound card seemed quite high when checking PMA coil voltages. After searching a bit further, I found a buffer circuit to protect the sound card. I haven't built this circuit yet, but it's on my To Do list. For anyone interested, you can download all the files I collected via this link:

<ftp://ftp.greatspiritsoftware.com/pub/misc/oscope.zip>

The zip file contains the oscilloscope program as distributed by its author, along with a text file explaining the buffer circuit and a JPEG of the schematic (long story here -- the schematic was originally in PostScript format; after downloading about 10 megs of stuff, I was finally able to convert it to JPEG format). If anyone builds and tests the buffer circuit and scope program, please post your results here. I'm in the process of moving (arrgh!) so it'll be a while before I can warm up my soldering iron!

Cheers,  
ChrisW

P.S. The board's code for handling A HREF tags is unbelievably strict!

[PC Oscilloscope](#) | 1 comment (1 topical, 0 editorial)

by [Insomnian](#) on Mon Nov 3rd, 2003 at 02:40:31 PM MST  
([User Info](#))

Hi, I've used some free DSO programs, using the soundcard as the input channel. I've posted a screenshot. Here I was testing the squarewave output of a 555 timer circuit I'm planning on using in a PWM. I didn't build a buffer circuit as such. I just used a potential divider setup, to divide the signal voltage by 10. Figured I'd be safe upto 12V signal/10=1.2V It took less than a minute to build. For a higher signal voltage I'd use a higher divider. Best to check signal voltage with a DMM before calculating the required divider, and also before hooking up to the soundcard.

## [Rectifier usage](#)

By [bruce1](#), Section [Homebrewed Electricity](#)  
 Posted on Thu Oct 30th, 2003 at 02:04:15 PM MST [Electronics](#)  
 Using a rectifier as a blocking diode.

Can you use a rectifier for a blocking diode? Isn't that all a rectifier is anyway, just 2 diodes in a heat sink? I have been using a rectifier off of a charging system from an old model Mercury Outboard motor, about a 70's vintage. Is is an aluminum block about 1.5 inches by 4 inches, has a mounting flange, has 3 terminals sticking out of the black potting material, 2 yellow and one red. The yellows are the AC in , the red is the 12vdc hookup. I've been using this as a diode while messing around, was wondering if I can use it for permanent? I could even split the incoming DC between the 2 yellows to spread out the amperage. The casing is not electrified, I can bolt it to the side of my battery box( metal medicine cabinet), and use that to distribute heat. I looked up some specs in an old Merc manual, it says 'gross amps output at rectifier' 12-14 amps. It doesnt tell the output of the stator. The newer ones, when you do a cranking test, you should have about 200acv with a peak reading meter. I'm telling you this so maybe you can guess how this would hold up.

I would be running 24-28vdc into the rectifier from my wind charger, amps could be anywhere between 1 and 20-50 on the top side, really not sure yet. Since it was on a 12v system, will it work with 24vdc hooked to the red terminal where there was meant to be 12vdc? I had it hooked up as 12vdc before, so there was no 24vdc there.

Any guestimates would be great, thanks everyone!

Bruce

It's best to use a bridge rectifier which is really 4 diodes hooked together in a square configuration. This type of rectifier will recover power from both the positive and negative swings of the your source voltage.

Also , don't use things made for 12vdc with 24vdc feeding them.

([User Info](#))

Don't forget to heatsink your bridge rectifier, those ratings only apply if device is kept below 25 deg.C  
Make the wind fun!

Sounds a little like you have a seliem (I think thats how its spelt) rectifier.

As others have advised simply buy a bridge rectifier of sufficient voltage and current, cheep and effective.

regards Allan

Re: Rectifier usage ([none / 0](#)) (#4)

([User Info](#))

If you've really got AC coming in from the gen you want a bridge rectifier rated for your maximum voltage and maximum current, any thing else and you run the risk of burning it out. Remember, a bridge rectifier has didoes pointing both directions for each half of the AC cycle, so using one in a DC application is the electrical equivalent of using nothing at all.

If you've really got DC coming from the gen then you'll only need a single rectifier, and the same voltage and current rules apply.

Cya,  
Chris

That's Selenium - it's an element. Where is the 12vdc negative if it isn't the case? You won't get much current thru this until you have a complete circuit.

[Electronics](#)

Help help help help...

Hi Everyone, I'm back again. I finally recieved a Surplus Center catalog and in it I'm trying to find the ideal motor/generator for my little wind turbine. I've never dealt with the company before but I've seen them mentioned on this board so I assume they're ok. All the PM alternators I've looked at are simply way too expensive. For \$2,000 I could just buy a complete system.

I'm looking, in my ignorant way, at the DC motors on pp.131-133 of the catalog. All the ones I'm considering are permanent magnet, reversibile of course. I'm shooting for reasonably cheap, maximum efficiency, and the most minimal maintenance possible. The motors vary annoyingly in what information is given about them, so I'll start with this confusion:

1. Only one of the motor descriptions mentions brushes. If the description doesn't actually say brushless, do I assume that the motor has brushes? I'd really prefer brushless, of course, but maybe I'm being too picky. Are brushes a big enough pain as far as expense, maintenance, replacement, or anything to the point that I would be wise to just completely avoid them?
2. Must a motor be 12 volts or a multiple thereof to work for battery charging? In other words, a variable speed motor (0-6750 RPM) rated 95-130 VDC would not work for charging a 12 volt battery even at very very low RPMs?? It is incapable of producing voltages lower than 95? I see that the motor they recommend for "experiments with wind, water power, etc" says 10,000 RPM, 120 volts-- which would suggest to me that voltage output varies with speed and therefore if one were working only in a low range of RPMs the voltage would correspondingly be lower than rated. I do plan to get a charge controller...
3. Speaking of RPM, if my turbine works like it should, it will be turning only at very low to moderate wind speeds due to the design of the vanes which utilizes air pressure instead of air speed. Therefore I'm looking at motors that have very low RPM ratings. If a motor is 12 volts and 3600 RPM, does this mean that it will not produce even a trickle charge at, for example, 40 RPMs? It must reach 3600 RPMs to produce any charge, or it must reach 3600 RPMs to produce 12 volts? I guess this is pretty much the same question as above...trying to figure out if I need to base my motor choice on voltage, RPMs, or both.
4. For people who have built a vertical axis turbine, how did you attatch your vanes to the central axle so they didn't flap around, and how did you attatch that axle to the motor's shaft? None of the shafts on the motors I'm looking at have keyways...a few are threaded. I've got PVC pipe for my axle and I can't figure out how I'm going to fasten it securely to the motor.
5. Most of the motors are open, or unsealed. Is it fairly easy to build a little shelter for them for

protection from the elements?

6. I'm still a bit foggy on how HP enters into the whole thing. One of the motors is 1.5 to 2.5 HP, one is 0.2 HP, and several don't have the HP listed. What should I know about this, or does it even matter for generator use?
7. Are sleeve bearings liable to wear out more rapidly than ball bearings, and can they be replaced cheaply and easily? Should I avoid them?
8. Must dual shaft motors be driven from both shafts, or can one be used and the other ignored?
9. Does a high torque rating mean that it's going to take more effort to start the shaft turning than a lower torque rating?

OK, that's all for now. Thank you for your wisdom on this...truly couldn't do it without you guys. :D

by Norm on Mon Oct 27th, 2003 at 06:59:29 AM MST  
([User Info](#))

Okay I don't know that much about it, have yet to test it for rpm to get a charging voltage of about 13-14 volts load. I have a Leeson 1hp. 10 amp. 1800RPM 110volt.DC. motor. Someone else with a 2HP Leeson motor rated at 3600RPM (I think) has suggested that 600rpm would be sufficient to reach charging voltage...Mine a little less, I guess the lower the rpm rating ... (the better?) Hope this helps in some small way. Don't start out too big on this. A bargain for some may not be a bargain for you. Mileage may vary....have fun! (:>) Norm.

Re: Choosing a DC motor from Surplus Center ([none / 0](#)) ([#2](#))  
by Scott on Mon Oct 27th, 2003 at 05:28:00 PM MST  
([User Info](#))

I'm new but I'll give it a shot

1. I wouldn't worry about the brushes in a tape drive motor. I heard they last awhile and it's a good way to get your feet wet.
2. No, but it won't start charging until it hits 12V so it should be rated over 12V.
3. I suspect you may have trouble getting a tape drive or similar motor up to cut in speed with a VAWT. Although I've read hear of using capacitors to charge at low rpm's and volts, could be a possibility. I'm using a 40V Ametek tape drive motor like the one in the link below and it likes to spin fast. I'm getting close to 10 amps in a good wind with 2 jerry blades.

<http://www.surpluscenter.com/item.asp?UID=2003051913523979&item=10-1563&catname=electric>

4. don't know
5. Tape drive motors seam pretty well sealed.
6. I suppose as hp increases so does the physical size of the motor as well as it's power generating potential.
7. I would think so.
8. No, yes
9. Not sure,

I have no experience with VAWT and only a little with HAWT but to me the tape drive motor was a great way to get my feet wet and I learned quite a bit. The biggest thing I learned is how important tower height and location is.

Scott

[watt/hour meter ?](#)

By [44toy](#), Section [Homebrewed Electricity](#)  
Posted on Wed Oct 22nd, 2003 at 04:19:52 PM MST [Electronics](#)  
constructing a watt hour meter.

Want to test the output of my experiments with a meter that would tell me at least how many watts or any other measure the generators put out in a days time. With hydro I can pretty well figure but wind is not constant, and will be trying wind power. Have been looking at used watt/hour meters from electric company but not sure since mine is a 12volt system and they are for 120 ac

If you have made one or know any tricks to collect info beside setting there for a few days with a volt meter let me know. Sorry for beeing dumb and-----thanks in advance.

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

44toy;

I have been logging solar data with an RS232 meter and a computer.

JImU is doing the same. He wrote the perl scripts to interpret the data. I think he is about to go live with it.

This just graphs battery voltage but in and out current is being added at some point in the near future. It runs on a grid connected full size PC now but hopefully this weekend it will maybe get transfered to a laptop running off the batteries.

Being the R&D graph there are gaps and inconsistencies.

This setup will work on ac or dc and volts or amps . I got the meter for around \$20 on ebay I have the PC anyway, all the software is free which runs on Linux which is also free. Using perl you can combine multiple data samples to calculate watts and the graphs make a nice visual so you can see whats going on at a glance.

Cheers.

TomW

**Converting ac amp draws to dc amps**

O.k. I am trying to get my first system going, and no body around here can tell me if I am figuring my load correctly.

Lets say these are the specs on an item. .72 amps (read with amp clamp,) 120 volts ac (read with my meter.)

I was using the following formula-

$$\frac{P}{I \times V} = \frac{A \times v}{.72 \times 120} = 86.4 \text{ watts}$$

$$\frac{P}{V} = A \quad \frac{86.4 \text{ W}}{12 \text{ v}}$$

dc = 7.2 amps dc

I am using The total of the (basic items) dc amp loads + a 50% cushion for additions etc, to figure the amps my hydro powered generator will need to put out.

This may be confussing the electronic teachers at my college look at me funny and will not stand firm. My questions are--

1. Will this work to figure the amount of power I will need? I know I could simplify the process and any better conversion formulas would be nice
2. Will there be any drop other than the loss to the inverter? the main thing I am unsure of is using the formula to convert from dc to ac.
3. If you guys look at this and just have a funny look on your face, You can get the idea of what I am trying to figure and please HELP.

Re: new with ?s ([none / 0](#)) ([#1](#))  
 by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Fri Oct 17th, 2003 at 03:50:38 PM MST  
[\(User Info\)](#)  
<http://timmythy.home.mindspring.com/timmy.htm>

when converting amps between 120v and 12v, I just multiply by 10

1 amp at 120v will be 10 amps at 12v

or using your formula  
 .72 X 120= 86.4 watts  
 7.2 X 12v= 86.4 watts

. >-- W o o f --<

Thanks for the reply, I posted this here by accident and then in homebrewed electricity also, please repond there. I cant figure how to delete this post.

Re: new with ?s ([none / 0](#)) (#3)  
by drdongle on Mon Oct 20th, 2003 at 03:00:55 PM MST  
([User Info](#))

Don't forget to account for loss of energy when converting from 120 V to 12 V, in other words you wont get the 7.2 amps that the formula leads you to expect, probably more like 5 amps.

Dr.D

## [electrical switch](#)

By [Homebrewed12vdc](#), Section [Remote Living](#)  
Posted on Wed Oct 15th, 2003 at 03:03:08 PM MST [Electronics](#)  
forced hot air furnace

I have a good ? for those electrically inclined ones, I have a nice big wood furnace with a blower on it, the heat activated switch that turns the blower on, is there any way I can run 12v dc through this switch to turn on a 12v dc motor on that I bolted to the squirrel cage fan. Thanks in advance for your help. From Mike

[electrical switch](#) | 6 comments (6 topical, 0 editorial)

Re: electrical switch ([none / 0](#)) (#1)  
by 12volt dan ([dan12v@hotmail.com](mailto:dan12v@hotmail.com)) on Wed Oct 15th, 2003 at 04:34:42 PM MST  
([User Info](#))

Honywell makes a machanical fan swich (or they used to) that should work fine.

One drawback though is that it has a rather long stinger. There's probably smaller more better suited swiches out there  
7 years off the grid and counting

Re: electrical switch ([none / 0](#)) (#2)  
by jubalearly on Thu Oct 16th, 2003 at 08:24:18 AM MST  
([User Info](#))

You can probably find a 12v switch in the Grainger catalog (they have a web site). If not, I'd use a 12vdc relay, 120vac activated (or whatever it is now). Most furnaces (actually the controls) have several voltages that can be used. But this approach means you have to continue to supply 120vac or whatever the current control voltage is. Note that RV and marine applications often require 12vdc (optional 24vdc?) ONLY - you might try West Marine or search under RV heaters.

The switch is basically a relay activated by a thermocouple, usually also controlled by a 12vdc, 24vac(or dc), or 120vac thermostat. You probably will have a hard time figuring out which of the dozens of models you can find will fit.

Ok, Mike, I just want to make sure I understand your problem. You want to turn on a 12 Volt blower motor when the temperature is at a certain level. Is the correct? Do you have anything else in the circuit?

RobD

Re: electrical switch ([none / 0](#)) (#4)  
by Homebrewed12vdc on Fri Oct 17th, 2003 at 02:50:53 PM MST  
([User Info](#))

Yes that is correct, I put a 12v dc motor on the squirrel cage, and I want to set it up so when the wood furnace comes up to a certain temp, the motor comes on, and when the temp drops to a certain point the motor is shut off. Basically just looking for a heat activated switch that well handle 12vdc at about 4 amps.

[ [Parent](#) ]

Re: electrical switch ([none / 0](#)) (#5)  
by RobD on Fri Oct 17th, 2003 at 03:48:14 PM MST  
([User Info](#))

The best way to do this is with an LM339 comparator and a MOSFET. The mosfet takes the place of a relay so you have no mechanicals to break down. I have a similar circuit around here somewhere. Can you build your own board? If you can I'll try to dig it up and get it too you. How many amps is the motor?

RobD

### [more than 3 phases?](#)

By [Budgreen](#), Section [Homebrewed Electricity](#)  
Posted on Wed Oct 15th, 2003 at 08:14:13 AM MST [Electronics](#)  
what if I...

just out of curiosity, has anyone here ever experimented with multiple phases (more than 3) in a stator? I would imagine that having say 6 phases could boost voltges higher for better power outputs and smother waveorms for filtering, possibly better efficiency. or even 2 3phase outputs to charge multiple banks of batteries. if anyone could point out some information or experience along these lines it would be much appreciated

Josh

[more than 3 phases?](#) | 4 comments (4 topical, 0 editorial)

Re: more than 3 phases? ([none / 0](#)) (#1)  
by [DanB](#) on Wed Oct 15th, 2003 at 08:31:58 AM MST  
([User Info](#))

Hughs plans are for a 5 phase alternator.

The only thing that worries me a bit about more than 3 phases, is that youll have more rectifiers, and theyll need tto be up on the windmill unless you want to run lots of wires down. 3 phase can come down on 3 wires.

The advantage to having rectifiers on the tower is that theyll cool better, and DC will cover distance with slightly lower losses than AC.

The disadvantage is that... if they burn out, youll have to drop the tower! And... if you want to have a brake switch, youll have to also have a blocking diode (no big deal), and if you throw the brake switch, youd want to be sure the machine was turning slowly when you did or else I think you'd run the risk of blowing the rectifiers (just guessing).

But - basicly, if you don't mind having rectifiers on top of the tower - the more phases the better! Although I think the advantages gained with more phases than 3 would be very small....

other disadvantage is that a star/delta switch cannot be used or only with more relays.

if you compare the sinewaves for 3 phase and 5 phase, you can see the voltage gain. i dont think it is more that 5%, because the sinewave on the top half is quite low.

viktor

Re: more than 3 phases? ([none / 0](#)) ([#3](#))  
by troy on Sat Oct 18th, 2003 at 11:14:54 AM MST  
([User Info](#))

Plus, keep in mind that every rectifier drops the voltage. Lots of rectifiers means lots of voltage loss, so eventually, more phases leads to less efficiency.

Best regards,

troy

by Jerry on Sat Oct 18th, 2003 at 08:36:26 PM MST  
([User Info](#))  
<http://www.dplusv.com/Photo-03.html>

Hi Troy, I think there would be a voltage lose if the diodes were in siriess but the are in some what of a perelell configuration. The only diferance is the peak voltage of each phase arives at a slightly diferant time. So there is only voltage lose equal to that of one phase or diode bridge no matter how many phases you have. This is my take on it anyway. Lets try it this way. Lets say phse 1 through its diode bridge has 1/2 volt drop and its producing 10 volts and phase 2 has a 1/2 volt drop when you perelell these 2 phases the voltage won't be 9 it will still be 10 and the same when phase 3 is added. I can see the volage drop idea in star but not in delta. Someone steer me straight if I'm all wet here. JK TAS Jerry

Yes it is.. im using one right now... wanted to see the power draw of my puter...

And i was suprised... it only draws 110W, 140W When burning a cd... was lower than what i exspected.... 117W under full cpu load running S.E.T.I. at home....

by Adrian L on Wed Oct 15th, 2003 at 07:30:46 AM MST  
([User Info](#))

I believe these great little units are \$40ish dollars, commonly advertised in HomePower magazine adverts. They also reviewed the unit and loved it.

If only they made one of those that cheap down here in Australia...cheapest you will find here is like \$130US!

Cheers,  
Adrian L

## [Full wave rectifier](#)

By [Norm](#), Section [Homebrewed Electricity](#)

Posted on Wed Sep 24th, 2003 at 08:56:04 PM MST [Electronics](#)

I stopped in at RadioShack today...just browsing

and was surprised to see a full wave rectifier specifications said 50volts 25 amp for \$2.99, really? Would this little gadget be able to handle over a 1000 watts? It looked like it had an aluminum heat sink about the size of a postage stamp and about 1/4 inch thick. Would this be big enough to charge a 12 volt battery at about 10 or 15 amps? Well anyway just havin fun ...finally had a good wind here this afternoon the kind that slams shed doors back and forth!(Just gotta finish building that anemometer with the bike speedometer so I know what kinda wind that is!) (:>) Norm.

([User Info](#))

I have bought several of those from various surplus electronics places over the past several years. The RS price isn't bad. You should attach it to a larger heat sink if you run it at higher currents. I can't tell you just what currents will need a bigger heat sink, maybe 20% of rating or more. If it gets too hot to touch then you need a bigger heat sink. The heat sink that is made on it is no where near 1/4 in. thick (maybe 1/16?), take a closer look at the bolt hole and you can see how thick it is. The diode bridge is epoxied into that little block & to the aluminum which is there to provide a good surface for heat transfer to a large heat.

The 50 volt ones are OK for 12 volt systems, but I usually pay a few cents more & get the 200v, or for a 120v application, I use 400v or 1000v. When you rectify AC often you are dealing with higher voltages than you think. For example, one battery charger I built had 21v RMS AC at the transformer. That means it was 30v peak AC, and the rectifier would also see 30v reverse voltage on the other half cycle.

I like to go to the "Ham Fest" at the local exhibit center. It's a Ham Radio flea market. I bought the 2" x 2" x 1/2" ferrit magnets that I'm using for 50cents each. I bought \$20 worth, incredibly strong.

At the last show I got some 25amp diodes at 1 for \$1 or 11 for \$10. well thats not as good as the RS prices but still the deals abound.

([User Info](#))

Those magnets sure sound like a pretty good deal, they probably are quite a bit stronger than the domino sized ceramic magnets that I have at \$1 each? I guess I'll have to find a good flea market...sure is fun shoppin around for bargains like that...isn't it? (:>) Norm.

([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

McKee,

I think the lack of response may partly be because of concern over shipping charges from Portland. I also believe that many on this board are looking for generators that can run on alternative fuels.

The unit you have sounds like a good one. But the Briggs or Tecumseh engines aren't always that long-lived. Plus, they usually have to run at 3,600 RPMs. That often means a louder unit than on the 1,800 RPM units. I do have to tell you that \$3,100 sounds a bit high for only 6.5 Kw.

eBay may be your best route on this unit.

Bach On

[India built Lister slow speed engines](#)

By [MrLister](#), Section [Classifieds](#)

Posted on Sat Nov 29th, 2003 at 11:13:59 AM MST

[For Sale](#)

Lister type diesel engines

I am importing the "Lister" type engines from India. They come in sizes from 6hp 8hp and 10hp in the single cylinder model and sizes from 12hp 16hp and 20hp in the 2 cylinder model. The prices for the 6hp w\ tapered roller bearings are \$950. The 8hp are \$1000 and the 10hp models are \$1100. The 2cyl 12hp models are \$1400, 16hp are \$1500, and the 20hp are \$1650. These are water cooled engines so you can build a cooling tank out of a old hot water heater or the like. Or you can buy one with a factory mounted automotive style radiator w\ water pump for an additional \$235. These engines are built to run for 100,000 hours that is 11 years 24 hours a day. They run on diesel, you can run them on cooking oil! I have run one of these in my shop for over a year with just about every kind of cooking oil I could find. All of my engines have an oil pump. I have these engines shipped after I receive payment. The reason I do this is I simply do not have enuf room to store them. It takes about 90 days to ship from Bombay India to my shop in Tulsa Oklahoma. At this time the customers can pick them up here or I can arrange having them trucked. If you just have any questions about these great engines feel free to drop me an email [WesternStar66@aol.com](mailto:WesternStar66@aol.com) I can also email pictures of these engines. Thanks!

## Turns Counter

By [Jerry](#), Section [Classifieds](#)

Posted on Sun Nov 16th, 2003 at 09:12:54 PM MST

[For Sale](#)

Small coil turns counter.

Hellow fellow coil winders.

I found a neat little numerical counter at the local surplus store the other day.

It has a 1"X1.25" face X 2" deep. It has 9 digets. Wow thats lots of turns. But siriusly though. It operates on a 24 volt pulse. Each time you pulse it it counts one then 2 ECT. up to 9 digits. I don't see a reset so just write the face # down when you start winding.

I'm going to use it on my coil winder. I'll just make a little bump or cam or something to hit a small micro swich.

I'm concerned when I try to wind coils I'll be interupted and loose my count. Or maybe just forget. I'm getting old you know.

Anyway the store has a factory PKG of 20 or so. If anyone wants one I'll pick up a few more befor there gone.

\$5 and the shipping should doit. If not thats OK to. Just thought this might be a little helper.

JK TAS Jerry

Re: Turns Counter ([none / 0](#)) (#4)  
by NJ JOHN on Wed Nov 19th, 2003 at 06:45:56 AM MST  
([User Info](#))

Hi  
New to this board and this is my first comment. Here's a way I made a counter/tach with a Dollar Store calculator. What I did was soldered 2 wires to the leads going to the EQUAL key and the other ends to an earphone jack and mounted this to the case of the calculator. To make a sensor I connected a normally open micro switch (or magnetic switch) through a toggle switch in parallel with a normally open pushbutton switch. This was then wired to a jack.

To use this setup just plug the jack in when needed and remove when being used as a calculator.

To use as a counter just turn on the calculator enter + 1 on the keypad and each time the switch is closed the calculator increases by 1 until you reach your desired count. If you put in a starting number and enter - 1 on the keyboard and when the display reads -1 you have completed your count.

To use as a tach open the toggle switch and push the push button switch for 15 seconds then multiply by 4 for RPM.

I hope this helps.

John

Re: Turns Counter ([none / 0](#)) (#5)  
by 5kw on Wed Nov 19th, 2003 at 10:55:23 AM MST  
([User Info](#))

I prefer a mechanical counter so you can back up, it happens. also no double counts if you dwell or stutter at the trip position.  
Make the wind fun!  
Victor

[SALE: 50 lbs #10 GUAGE 0.1051" DIA. ESSEX ALLEX 240 DEGREES C MAGNET WIRE : \\$6/lb](#)

[For Sale](#)

By [Christina](#), Section [Classifieds](#)

Posted on Fri Nov 7th, 2003 at 12:09:06 PM MST

SALE: 50 lbs #10 GUAGE 0.1051

Hi Everyone,

I have for sale 50 lbs of #10 Guage (0.1051" Inches Diameter) Essex Allex High Temperature 240 Degrees C Magnet Wire. Price: \$6 per pound (lb).

This type of magnet wire is used in applications where temperature specific requirements are paramount and is ultra high quality stuff with proprietary insulation methodology being used from Essex. It is their highest temperature rated magnet wire that they sell. Here is a URL to Essex's Website for more information on this magnet wire: [<http://www.essexwire.com/oem/products/magnet/allex.htm>].

Will accept Paypal, or any other payment method including Escrow, USPS Money Order, Cash, etc. You can come and pick this up also for free if you are in the area (Zip 33147, Miami, FL).

Please note shipping would be whatever method you choose including your own FEDEX or UPS Account Number (insurance option must be used with these methods) and will be based on the exact amount of what is quoted to me from the Carriers. Please note I only use World Class Trackable Carriers/Shippers so that when product ships you will be emailed a Tracking #.

Will also be willing to sell this batch on a per pound basis.

I am a verified user of Paypal with paypal email being [[cyrix333\\_1999@yahoo.com](mailto:cyrix333_1999@yahoo.com)]. Also note that for Paypal payments sent online I will not ship to unconfirmed addresses for reasons relating to fraud. I am aware that someone might just want to have their stuff drop shipped to another location but as Paypal have it and to protect you and me it cannot be done.

Thanx a lot for your patience reading this.

Respectfully Yours,

Christina

Christina;

In my opinion it was highly inappropriate of you to spam this board by posting this to every section on the board.

I moved it here where it should be just like the first one you posted several days ago:

<http://www.fieldlines.com/story/2003/10/28/01540/999>

I hid the other multiple copies. This board is not intended as your personal billboard.

Cheers.

TomW

[Heat Sink for sale.](#)

By [Jerry](#), Section [Classifieds](#)

Posted on Thu Nov 6th, 2003 at 10:56:34 PM MST

[For Sale](#)

Small heat sink for sale.

Hi group

For those of you who might need a heat sink for your fullwave bridge diode/rectifiers.

I have about 70 of these left over from a 10,000 watt audio amplifier I was manufacturing 7 years ago. We would use a bank of 20 of these with 4 fans in a tunel for cooling the amp. It was a clas A/B.

They measure 3 1/8 in. long, 1 3/4 in. wide, and fin plus deck highth is 1 inch. Fin hight 7/8 in. and there are 13 fins in the lngth spaced 3/16 in. apart. There is room for 2 of the fullwave bridges to fit with room to spare. They are black and have no holes. \$2.00 each plus shipping. hope this ends up in the right spot this time. Clasifides?

## [5hp Honda engine](#)

By [windstuffnow](#), Section [Classifieds](#)

Posted on Sun Nov 2nd, 2003 at 08:26:23 AM MST

[For Sale](#)

For Sale....

I have a fairly new 5hp Honda engine for sale. It was used for misc set ups and testing. It has about 5 hours run time on it. I'm switching things around a bit and the engine is no longer needed. I'm asking 250.00 plus shipping. Smooth running and very quiet. Great for light weight power. It has a 4 inch pulley installed on the output shaft for driving a car alternator or belt driven gen head. If no-one needs it here it'll go to ebay. Let me know...

Have Fun  
Ed

I must appologize, I found my reciept from when I purchased it 2 years ago and found the price I placed on it was close to what I paid for it. I bought it for 259.00. So with that being said and only having about 5 hours use on it I'll let it go for 200.00 + shipping.

Have Fun  
Ed

[early Bergey generator for sale](#)

By [5kw](#), Section [Classifieds](#)

Posted on Sun Oct 26th, 2003 at 03:55:58 AM  
MST

[For Sale](#)

The generator for this wind turbine is rated at 13 amps at 120 volts and could be configured for 26 amps at 48 volts

The generator consists of two three phase delta wound alternators, mechanically offset 60 electrical degrees to reduce cogging. The outputs are individually rectified and then wired in series inside the nacelle at the tower top. They could easily be paralleled at this point for lower voltage higher current. The generator, rectifiers, nacelle cover, mainframe, and tower stub are in good condition both electrically and mechanically. The plastic ( nylon?) yaw bushings need to be replaced and the sliprings and brushes need some work. The original blades are unusable except as patterns. The tail is missing. Asking \$400.

Make the wind fun!  
Victor

Hi Victor... sounds like a good deal!  
Just out of curiosity... what was the original swept area of the machine? Does Bergey still sell replacement blades for it, and if so ... how much? Were the originals wooden, or extruded plastic like the new ones?

The original diameter was 10' , it was the predecessor to the Bergey 1500 sn# 00145. I'm not certain that 1500 blades fit , if they do they are aprox \$ 600 for the set. The original blades are wood with a thin fibreglass coating. these blades have the passive Powerflex tm pitch weights near the tips. The machine is in Lafayette Colorado USA 303-665-3991

I am keenly interested in your Bergey generator. I just bought an XL.1 and expect to be happy with it, but need more power (two will come much closer to my needs) I would like the damaged blades to attempt to resurrect them, or at least use one for a pattern. I will pay your price plus shipping.

[For Sale](#)

Neo's for sale

Hello Folks,

I have a quantity of 1" X 1/8" Neo's for sale. I bought these about a year to build a dual rotor axial alternator. I no longer have the time to build one so these are up for sale. I believe these are grade 40's or 42's The magnets stack nicely so you can build what ever height magnet you need. N/S poles are on the faces.

I have approx 200 of these magnets to sell.

\$1.25 ea plus shipping

respond to

[Paulc@snet.net](mailto:Paulc@snet.net)

Thank you

PaulC

### [Batteries Inverters for sale](#)

By [Garry](#), Section [Classifieds](#)

Posted on Wed Sep 17th, 2003 at 06:24:40 AM MST [For Sale](#)

24 volt components for sale

I have 24 Trojan L-16 6 volt batteries for sale. These have been connected as two banks of 24 volts each. They are three years old and in very good condition. I will include the 4-0 connections and the copper bus bar. I also have two Trace modified square wave inverters DR 2424 ( 24vdc and 2400 watts ), two Trace C-40 charge controllers, and a 24 vdc 1000 watt Statpower sine wave inverter, all in excellent condition. Any reasonable offer on any of the above will be entertained. The batteries are located in north central Oklahoma and will have to be picked up. I have acquired a 22kw propane backup generator and am buying a new grid tie inverter for my solar cells and wind generator.

I will be happy to answer any questions.

Hey i want a C-40,... i have a C-60 to give up too....

I want to go to 48V... and the c-60 wont handle that kind of voltage

Re: Batteries Inverters for sale ([none / 0](#)) ([#6](#))  
by Garry on Wed Sep 17th, 2003 at 06:00:12 PM  
MST  
([User Info](#))

Seth,

I paid \$145. each for them. I won't let them go until I sell either the Batts or one of the inverters. Make me an offer. I'm easy.

By the way, for anyone else looking. The two inverters I paid \$952. for but the best price I can find on the net now is \$852. Again if you're interested make me an offer. I am grid connected and would rather back up my meter than divert the extra to heat.

[For Sale](#)

[Link 10 Amhr/Voltage/Current monitor](#)

One barely used Link 10 battery monitor for sale 100\$

Description

Link 10

Single Battery Bank Monitors

Provides Battery Status Information At-A-Glance

The Link 10 (part#84-2016-01) uses sophisticated microprocessor technology to provide complete battery status information for one and two battery banks, respectively. Simple and easy-to-use multicolor displays show volts, amps, amp hours consumed, and operating time remaining. The Link 10 allows you to select Automatic, Sleep and Scanning modes and automatically calculate and display charging efficiency. By adding an optional prescaler, Link 10 can monitor single battery banks up to 500 volts.

Product Features

- Digital Numeric Display - LED display shows numeric read out of volts, amps, amp-hours and time remaining
- Easy to read multi-color LED bar graph
- Splash proof panels allow for outdoor mounting and hands free operation
- Displays key historical battery information such as charge efficiency, deepest discharge, and average discharge
- Compatible with 12 and 24 volt DC systems
- Works with any battery type

This version does have the RS-232 port.

Winchargerman, Dave B. here outside Frewsburg. I recently met up with Dave at Royal Welding and he had dropped your name. Reason being, I am building an axial alternator and the connection was made. I also know L J as he has cleared out for my future tower location. I plan to pre-heat water and recent testing shows all positive results. I got started in this adicting hobby about a year ago and have many questions that I'm sure you can help me with, towers, blades, furling systems etc. I'll contact you by e-mail or call very soon. Visit my website at [www.madbbs.com/users/bruggelog](http://www.madbbs.com/users/bruggelog) Great to know you're out there. Dave B.

## [So you want to build a waste oil heater, eh bunky?](#)

By [robotmaker](#), Section [Rants & Opinion](#)

[Fossil Fuels](#)

Posted on Fri Dec 19th, 2003 at 03:47:34 PM MST

New designs, variations on old designs, and idea swapping...

I was an old subscriber to the MEN (mother earth news) back when the rag first started. This is where I learned about savonious rotors, digesters and a whole bunch of alternate energy stuff.. Well, I moved to Florida back in 1980, and really didn't need all that then, but now I live in Arkansas and let me tell ya...it's a bit colder here. Well, still being into the alternate energy stuff, I got tired of cutting the tree, chopping the tree, splitting the logs, carrying the logs, stacking the logs, carting in the logs, burning the logs, and emptying the stove. Not to mention having to sit around in yer jockey shorts and having a boiling pan of water on the stove because you can't regulate the heat output worth a hoot without alot of expense and besides...cleaning the chimney isn't all that much fun either. Well... along came the idea of making the waste oil burning stove. Since I was already making my wood stoves out of old hot water heaters, I had a source for them. I downloaded that brief article from the old MEN article and built my version of that stove. Let me tell ya, I'm STILL sitting around in my jocky shorts cause it gets so hot, but have learned a few things from it as well. First, that burner design lends itself to oil being splashed out into the sand bed and it clogs up the holes in the burner. It doesn't go too long before you have to rip it apart and clean it up to get it working again. The longer you let it go, the more fuel it uses and smokes like hell. Well, I looked for other designs without any luck. I saw a few variations on the subject, but for the most part found lots of professionally made devices for sale, but the price tag was way above what I wanted to spend. I'm kind of a cheapskake when it comes to this stuff. I figure if I can't build it out of bailing wire and bubble gum wrappers, it ain't worth building. I have done a small windplant using a servomotor, but the wind quality around here is the reason my sailboat is still in Florida. But I still like to tinker with it. Seems that when you need the heat the most in the winter is when the wind starts to howl...

(Imagine that) So now, when it howls, I put the output across some heating coils with a little muffin fan blowing the hot air out. Anyway, back to oil...I came up with a much better design on that burner, but the only downside to it is that it needs forced air. Want to know how many GM cars that are in my local junk yard without the heater motors in them now? (Heh heh) They work perfectly!!! This design starts up without smoking, and runs without smoking, and burns extremely hot. The original intent of just sipping oil has been kept foremost in my design also. I get my oil at the local jiffy lube for next to nothing, and with this design, am burning some old peanut oil in it too! Smells so good you want to keep the door open.

Bottom line is to see if anyone wants to share designs on this variation, and see if anyone else had trouble with that original MEN design, and if anyone else modified it? you can reach me at robotmavr@aol.com or.. i'll be watching this board.

Thanx... rj

Robotmakr, huh?

I build robots, too, and am also into RE, and I also live in AR.

Wierd, huh?

I'd like to see your waste oil heater, or at least some plans for it. . .

May want to build one. . .

DS

I built one of these back in the early 80's and experienced similar problems with the burner unit which I had to disassemble every few days and beat with a hammer to remove the baked in oil sludge. But did it keep the house warm!! It was the one thing that kept my first marriage together as long as it did! My then wife told me that it was the only time in her life that that house had been warm.

To answer DS, where in Arkansas are you? I am in the Fort Smith area. Maybe we should share a few notes.

To answer Ron, I knew about the modifications to the MEN article, and yes, I tried that too. That guy explained how he added a down tube and dripped the oil AND the air flow down to make it run hotter etc. Yes indeed, it did burn hotter, I think I went one better and added a 6" deep cast iron vessel in the bottom. I continued to get the clogging tho, and not only in the burner, but in the down tube as well. I thought that the air should go UP from the assembly, not down into it. The next modification I did was to make a burner assembly out of two electric motor casings, one 8" in diameter and one 6" in diameter that were about 8" tall. I drilled about 16 - 1/4" holes in the inside piece about two inches above the bottom, placed one inside the other and welded it to a bottom plate. Next, cut out a 1" ring and welded it to the top of this assembly. Cut a 1 1/2" hole to accept a piece of tailpipe near the bottom and use this to blow the air into. Now the only way the air can get inside this weldment is to go thru the 1/4" holes. Drip the oil in as before with the down tube extending to just about the top of this assembly, and this thing heats up fast, burns clean, and sips fuel. I still have a problem with buildup tho, and get a ring of unburned oil deposits all around the ring of holes, from the holes down to the bottom. So I changed the design from holes about 2" above the bottom to holes at about 1/2" above the bottom. I can also see that mild steel isn't going to last very long, so I scrounged a couple of motor cans made out of stainless steel. The down tube keeps clogging up also, so I changed it to a 3" diameter tube, and now there isn't any clogging in the tube anymore. But.. it STILL get residue in the bottom of this burner assembly. How come I don't hear anyone ELSE complaining about this? I will try and get some drawings posted as soon as I figure out what format I can put them in. That is, if there is any interest...and I would like to see anyone ELSE'S attempts at getting this clogging phenomenon down to a minimum too..

## [Multiple generators](#)

By [wdyasq](#), Section [Homebrewed Electricity](#)  
 Posted on Sun Nov 9th, 2003 at 06:45:29 PM MST [Fossil Fuels](#)  
 Will generators "Sync"

Thinking of a theoretical situation in a shop where one might need - say 15 kW of energy, but not often. Most of the time, this shop would use 5 kW at the most. Could one run an 8 kW generator and then when more power is needed crank up another 8 kW? These would be 3 Phase units running both single and 3 Phase tools.

My mind says it will work - the second generator will immediately synchronize with the first one and they will run happily together. The reason two identical generators would be used is to switch the running of them so there would always be a spare or at least spare parts. But, in this scenario, one might use a 5 kW and a 10 kW unit to achieve the needed level of power.

I'd like to hear the opinions - even if they are wrong and don't agree with me....

Ron

Re: Multiple generators ([none / 0](#)) (#1)  
 by Electric Ed on Sun Nov 9th, 2003 at 07:27:42 PM MST  
[\(User Info\)](#) <http://www.electric-ed.com>

The alternators will not automatically synchronize. They can be manually synchronized and paralleled by using a system of "synchronizing lights" or an instrument called a synchroscope.

When operating in parallel, they will divide the load equally only if their prime movers are running at the same speed.

In other words, to operate alternators successfully in parallel, their prime movers speed must be precisely governed.

Electric Ed

I'm afraid that Ed is right, and as wind can be extremely variable even over a small area, there is no practical way to sync two 3 phase or even single phase alternators. I might suggest that you divide the shop into two "zones" one on each alternator and independent of each other. This also has the advantage of being redundant.

Dr.D

Re: Multiple generators ([none / 0](#)) ([#3](#))  
by wdyasq on Sun Nov 9th, 2003 at 08:11:51 PM MST  
([User Info](#))

These will be diesel motor driven generators - I KNOW if one hooks a generator to a power system, the generator will - lock in - on the cycles of the grid. I'm wondering if two generators will synchronize like mechanical devices.

I have also been told a 3 phase motor - hookes up to the grid and 'overdriven' will actually generate electricity. If so, could one generate electricity and then 'overdrive' a standard 3 phase motor and produce enough power - on a temperary basis, to run the additional machinery.

Ron

Re: Multiple generators ([none / 0](#)) ([#4](#))  
by laskey on Sun Nov 9th, 2003 at 08:46:28 PM MST  
([User Info](#))

You're right its called "infinite bus" synchronization. The grid is so large an powerful that the generators conform to the Grid, because they can be "forced" into sync by the grid, the main problem for you would be if the grid went down. In free running mode those two gens would fight each other and likely do damage to each other. You'd be well off to build yourself a synching setup so that you can match them to the grid and each other.

As a side note, the "infinite bus" effect is exactly the same reason that a non-grid-tie inverter will explode if you hook it straight to the grid. Inverters don't normally have the ability to synch to the grid, and if you try to force them something will burn out.

Re: Multiple generators ([none / 0](#)) ([#10](#))  
by troy on Wed Nov 12th, 2003 at 11:44:35 AM MST  
([User Info](#))

Not all types of generators will automatically sync with grid phase. Approach with caution. Overdriven induction motor/generators generally will, but there are lots of other types of gennies out there which can produce spectacular failure if hooked up directly to the grid or each other.

Good luck and have fun.

troy

Re: Multiple generators ([none / 0](#)) (#5)  
by kurt on Mon Nov 10th, 2003 at 06:18:57 AM MST  
([User Info](#))

copy pasted from  
[http://www.3e-co.com/onsite\\_power.html](http://www.3e-co.com/onsite_power.html)

KOHLER switchgear is designed to manage your power needs by carefully monitoring and adjusting the load between generators that have been installed to work in tandem. The paralleling of multiple generator sets is a long accepted technique for increasing the amount of available electrical power required for variable load conditions.

The switchgear will automatically synchronize, parallel, and match the electrical power from a number of generators, to the size of the load requirement.

Multipule inputs vs. multipule generators ([none / 0](#)) (#7)  
by Norm on Mon Nov 10th, 2003 at 07:37:08 AM MST  
([User Info](#))

One interesting setup is to have a large electric motor turning the main generator coupled with a large flywheel, the split-second there is the slightest hint of an interruption in power from the grid a large diesel is instantly engaged to the flywheel on the generator, the diesel is up and running with no problems. Actually what I'm leading up to as in this case is one generator with alternate multiple inputs. Seems like it would be easier to just add more power to a generator when needed (same speed...just add more torque) Norm.

Re: Multiple generators ([none / 0](#)) (#6)  
by wpowokal on Mon Nov 10th, 2003 at 07:11:24 AM MST  
([User Info](#))

Ron, All of the above adresses your theoretical situation and all are correct, however none individually solve your question.

So with 29 years of main stream power generation behind me diesel and thermal albiet in OZ I suggest the following.

The advice to split your shop is the most aproprate, cost effective way to aproach this proposal. Coupled with aproprate switches it will give you the redundancy we all need.

I could bore all with tails of being back-up station and having to use synchronizing light as opposed to the syncroscope to add in diesel plant, cause the frequency had fallen so low, but I won't, it's potentialy very damaging to the generators.

Split your shop load and start the back when needed, it will save much heart ache, cost etc. Ohhh one day I may write a book. Ops sorry one of those days, old farts should just fade away.

regards Allan

Re: Multiple generators ([none / 0](#)) (#8)  
by gps on Mon Nov 10th, 2003 at 10:18:02 AM MST  
([User Info](#))

Not quite what you asked but IIRC a Trace SW series inverter can 'back up' a generator, adding its own capacity to the generator's (4 or 5kw continuous, 10kw surge).

[Homemade fuel stabilizer?](#)

By [zmoz](#), Section [Remote Living](#)  
 Posted on Wed Sep 10th, 2003 at 03:07:15 PM MST [Fossil Fuels](#)  
 Anybody know how to make some fuel stabilizer?

I used to know a guy a few years ago that made his own fuel stabilizer - I thought he was nuts! Anyway...I have recently learned that most fuel stabilizers are made with a high percentage if isopropyl alcohol. (rubbing alcohol) Anybody have any thoughts on making my own? I already have about 20 gallons of 99% pure isopropyl that I use for other things. Probably would only be slightly cheaper to make my own...but I think it would be pretty damn cool...:-D

[Homemade fuel stabilizer?](#) | 1 comment (1 topical, 0 editorial)

Re: Homemade fuel stabilizer? ([none / 0](#)) ([#1](#))  
 by [jubalearly](#) on Thu Sep 11th, 2003 at 08:22:09 AM MST  
[\(User Info\)](#)

These stabilizers work by breaking down the heavier molecules into lighter fractions at a more or less slow but constant rate. Gasoline is made up of a mixture of hydrocarbon molecules with various chemical formulas, and it is the lighter ones that evaporate. Breaking up some of the heavier ones that otherwise become gum or varnish replaces the lighter ones so that the gasoline will burn properly.

The isopropyl alcohol is just a carrier for whatever small amount of chemical accomplishes the above. Call a chemical engineer at a refinery near you & ask him what could do that. Or, get the MSDS for Sta-Bil or better yet whatever the military uses (it's much better than Stabil) and see what chemicals it lists.....And be sure & let us know how it works.  
 Russ

### [More power for portable generator?](#)

By [petegresser](#), Section [Homebrewed Electricity](#)  
 Posted on Tue Aug 26th, 2003 at 11:24:34 AM MST [Fossil Fuels](#)  
 I need help with this line of thought

I have a portable generator rated at 2200 watts powered by a 5 HP Briggs and Stratton engine, My question is this. Is it the HP of the engine that determines the maximum output of the unit? I realise the generator itself must have a bearing on this, but if I were to install a drive motor of considerably more power would I be able to make a substantial increase in generating capacity? My line of thought is that if I were to drive it with a modern, small fuel injected car engine I could connect it at a 4-1 ratio, govern the engine at 650 rpm to maintain the desired 3400 rpm at the generator and have a more fuel efficient unit that would also be capable of running a good size 12 v alternator to charge my battery bank at the same time. In cold weather the coolant could be routed to provide heating for living areas. I have not done any testing yet but I figure a 1500 cc Honda Car engine running at 650 rpm is going to consume less fuel than the Briggs running at full boogie, not to mention quieter, remote start, etc. I really need brainpower input on this, and all comments would be greatly appreciated Thanks Pete

[More power for portable generator?](#) | 7 comments (7 topical, 0 editorial)

Re: More power for portable generator? ([none / 0](#)) (#1)  
 by [laskey](#) on Tue Aug 26th, 2003 at 12:45:48 PM MST ([User Info](#))

Well... Look at it this way. A HP = 746 Watts (power wise) meaning you so your 5HP motor is capable of 3730 Watts, or just over 58% efficient. There is no way you're going to get that with a car motor.

Plus a generator is design to hit a maximum somewhere. Give it more horsepower than that and you'll just be wasting it. (mostly as heat into the generator)

It's worth a try if you're going to use the car engine to feed other stuff as well. It's going to give you the most bang for the buck "loaded well".

Cya,  
 Chris

Most commercial engines have a fuel/HP/hour chart or graph available. Study of these charts will show which engine produces the most horsepower from a gallon of fuel. The "old" industry standards showed Gas engines would produce 12-15 HP from a gallon of gasoline. Many diesel engines will get 18-22 HP from a fuel that is less dangerous to handle and was less expensive.

If you do the research you will find some types of engines are much more efficient than others; there is a particular range in which an engine is most efficient and with the proper enclosure, an engine can be made quiet.

You will also find the quiet, efficient generators are not cheap and they are not found at discount tool and food stores or other "consumer" type businesses.

Ron

Re: More power for portable generator? ([none / 0](#))  
(#3)  
by petegresser on Tue Aug 26th, 2003 at 03:29:09 PM  
MST  
([User Info](#))

I guess I didn't explain myself very clearly in my original post, sorry guys. When I am using this generator and am pulling near maximum power from it the Briggs will load down and lose RPM. As this happens the voltage drops off and the throttle is wide open. If I had a more powerful drive motor that would maintain the 3400 RPM would the voltage remain at 120 even if I were attempting to pull more than the rated 2200 watts from the unit? Seems to me like the limiting factor here is the ability to keep the generator up to speed.

Thanks again  
Pete

Re: More power for portable generator? ([none / 0](#))  
(#4)  
by drdongle on Tue Aug 26th, 2003 at 04:24:42 PM MST  
([User Info](#))

A larger engine will be able to handle peak demands better than your current 5 HP unit. As to whether it's more efficient I can't say, the ability of the small car engine to perform several tasks may be a plus that negates the efficiency issue. If you have a workshop you could also connect a compressor for air tools, or even a water pump depending on your needs. Don't forget that not only the coolant but air from around the engine can be used to heat your house or the workshop or whatever.

Dr.D

You won't be able to get much more than the 2200 watts the generator is rated for no matter what engine you drive it with. You can't get something for nothing. In this case, you have a voltage and a maximum amps that the alternator can output without overheating. Maybe you could increase the output 10-15% at the expense of engine/alternator life.

It also sounds like your existing engine is a little tired, and no longer producing rated horsepower. It is rare for a lawnmower engine to actually produce rated power for any length of time. You might try changing pulley ratio's so that the engine turns faster, and (maybe) can put out more power.

But lawn mower engines wear out very fast when they are run over 3000RPM. I'd use a bigger engine at lower speed (1800-2400 RPM would give you 3-5 times the life of one running at 3000+ RPM).

Using a small car motor for a co-generation scheme could be a good idea. But you don't want to run it at idle. Idle means that the engine is not only barely running, but barely able to run. The fuel mileage will SUCK and the engine will run terribly, and the whole thing will wear out quickly. You really want them in the 1800-2400RPM range where they can make useful power efficiently.

No matter what you do, a gasoline engine is not a cheap way to produce electricity. A good setup might cost \$.80 a kwh. By using the heat that normally is wasted, you could get about half of that back (get \$.40 of heat, if you can use it).

Re: More power for portable generator? ([none / 0](#)) (#7)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Thu Aug 28th, 2003 at 06:34:16 AM MST  
([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

The wire inside of the generator will only handle the amount of power the generator was designed for. If it's a 2400 watt generator it is probably wound with 12 gage wire whis is generally rated at 2400 watts and would start overheating if you tried to pull more power from it. I suppose if you could cool the generator coils. then you could put a stronger engine on there and get more power.

How fast do you have to turn it to get 12 volts ?

.

 100+ mpg and 250mpg cars now

Although back in the 70's there were cars that achieved between 50 and 100 mpg today's cars have the potential to get much better. The engines are getting smaller and more powerful... ever wonder why?

Toyota has a prototype that gets 104 mpg but by their own admission will never go into production. Look up the Toyota ES3 (Eco Sprint cubic). This is a hybrid/diesel combination. Or better yet how about a 265 mpg VW... although a bit awkward, is a tandem 2 seat with a 1 liter diesel. What do you suppose Ford, GM, and Daimler-Chrysler is up to? I believe they have more to do with trying to keep them out as opposed to trying to compete with them. Just think of the money being spent on marketing these big expensive low mileage vehicles.

See even the government promotes gas guzzlers by giving tax breaks for those that own them... are they really concerned about the environment? Probably more concerned with their pocket books. It's not technology that's to blame here it's Politics. Actually the average mpg now is lower than it was in the 80's. The government wants to set standards for fuel economy of 35mpg by 2010... 35mpg? The US is only 5% of the world population and accounts for 25% of the world's energy use ... AND contributes 36% of all greenhouse gasses!

The technology is already here... multivalve engine for better flow, change valve timing during light loads and close the exhaust valve sooner (6% increase in efficiency), let the computer set up lean burn for light loads as in cruising down the highway (another 6% in efficiency)... Optimize the transmission with better gearing (up to 9% increase in efficiency). The list continues including materials other than steel, better tires, low friction lubricants, aerodynamics, more efficient pumps, alternators that work from the motion of the car (free recovery of lost energy), more efficient power steering units and on and on and on....

You see the point any way... whew... I feel better... But I've only touched on a very small and tiny tip of what could be... and in all reality should be.

Have Fun  
Ed

I agree Ed . I see those gas guzzlers every day at work and it's not only the bad fuel economy that hurts. The government controls the taxes on the fuel we put in our vehicles. What do you think will happen if all vehicles got 50,60 mpg or more. Less gas being bought, less taxes the government collects, less pocket money for the energy companies pencil pushers. Not to mention the political effects of all this. I'm not even going to go there. I heard a story on our local news about taxing electric vehicles based on the mileage on the odometer. Come on give me a break. It's obvious the old saying still holds true. The two things in life gurrenteed, Death and taxes. All this neggaitve, Government, control stuff is one of the reasons I escape in my workshop to build things out of the ordinary. Its my way of keeping my sanity.

have fun.

I do the same thing go to my workshop instead of driving the car, there I try to use hand tools to save using electricity. All the time I'm spending in the shop, is time spent off the road where I don't have to watch someone trying to hurry up and get to the red light so they can slam on the brakes and stop before it changes back to green. The sad part of what I just said is that this will be read by someone that won't understand (what the \*9#! is he talking about?) Well I got that off my chest and I feel better too. Norm.

Yes it's a very sad situation those at the top only care about stuffing their pockets. I doubt anything will change untill the oil is gone or we can no longer get it. I believe the technology for change is here to day like Ed said but nothings going to change as long as there is plenty of oil. I am also sorry to say that I don't believe any of us can make a change in the big picture. We could sent a man like us to Washington but he would be eaten alive before he got to first base.

I believe we can make a difference.  
Maybe not in the big picture of Politics but possibly of a secret society of tinkerer's that share devices that work.  
I'm not talking about perpetual motion machines or anything outlandish (although in my heart I would like to believe its possible for such a device to work). The Dan's have provided a window to those tinkerer's.

I don't drive much either and try to consolidate all my trips into one outing.  
If I could get groceries online.. I probably would. Some things such as materials for my projects can't be ordered online so I'm stuck with having to go and get them. My vehical already gets above the government standard for 2010 but its my right to complain about it... since I was getting better mileage in 1970. I believe there are millions of people out there that would opt for devices that would cut their utility bill, increase their mileage or simply reduce the cost of living.

Granted if one of the car manufacture's did release one of these prototypes and fuel consumption was cut in half, there would be no savings whatsoever. They would simply increase the cost to match the loss and we would be no farther ahead than when we started although we may breath much easier and storms would digress.

Enough complaining... back to the shop...

Have Fun  
Ed

It's funny that my '30 model A gets upwards of 30mpg... I think a BIG part of good fuel milage - at least in my case, is lousy brakes :-). If the brakes are not so good, it kind of forces a person to drive in a very defensive and predictable way. Driving this way actually makes things even safer than if I had good brakes I think, and it helps fuel economy greatly!

I go to my workshop, build things out of the ordinary and it hasn't helped my sanity one bit.  
My vehicle gets 125 mpgs. My other vehicle gets about 170 mpgs. They are both mopeds.  
My Honda 150 scooter (not one of those cheapo tiny things) gets 55 to 60 mpgs but it will do 60 mph. It's the gas guzzler of the group. The new mopeds are coming out in 4 cycle now, I'm thinking of retrofitting. I shouldn't be telling you guys (sorry ladies it's just to much of a machine for you) about the secret world of mopeds, low cost (I buy mine used with adds in the local papers), zero insurance, high mileage and the chicks you'll pick and heads you'll turn on a 'cool' moped cause there just aren't enough to go around and besides I don't want to be the one to slow the oil flow down when we just got our own oil rich country to keep the SUVs rolling along.  
Now that I'm entering 'geezerdom', well that's what Nancy says anyway, 35 mph on a moped is about right, although I do kick up the speed on the 150.  
Ed, I think you need a moped. Maybe two. Let that breeze run through your hair, chill out and thumb your nose up at Uncle Exxon.

Still there but I think the specs are generous.  
Figure 125-150 to the gallon and a lower top  
speed. Check Ebay. Don't want to go gas?  
Check out the electrics, charge them from your  
mill. I'm not crazy about the little scooters. Get  
the larger wheeled mopeds, they're more  
stable. Good brands are Honda, Yamaha,  
Tomos, Puch and Vespa. Nancy likes the Velo  
solex, it's claimed to have over 200 mpgs.  
Tomos sells new mopeds in the USA and in  
Europe you can still get the great names. You  
might be surprised to know that some mopeds  
have run 40 and 50 thousand miles. I'll take  
some pics and post them.

Elvin, sounds like you need a moped too!

([User Info](#))

Here's my take on it, for better or worse, wrong or right:

Automakers build what people will buy, and a tiny, gutless  
120mpg vehicle isn't it. Personally, I like having the  
horsepower to pull a hill without downshifting, pass the  
slower folks when I need to, and haul a load/pull a trailer.  
Fossil fuels are going to run out, whether our group does  
our part to save them or not; others won't. In the mean  
time, I want a vehicle fast enough to keep up with traffic in  
general, and still have a good bit of metal around me too.  
There's gonna be all kinds of hell breaking loose when  
fossil fuels do go down, and it will probably calm down  
after a decent alternative is found. I would rather that  
happens sooner, and gets over quicker, rather than later.  
Another consideration: I can only afford to own/operate  
one vehicle. The insurance and maintenance for second are  
beyond my means. I must be able to haul things and tow  
trailers, so I need a truck, and it's not possible to build a

high mileage truck that'll still get work done. Unloaded and driving it easy, I regularly pull 22 mpg from my truck. That's nothing compared to what you people are talking about, but I consider it a great step up from the 6 mpg my Nova got. I think a lot of people are in the same boat as me, they can only afford one vehicle, a big truck or the like may be it for the same reasons I have my truck, and hence they have nothing else to get groceries with. Though this argument does not work for the soccer mom driving the Escalade or the Navigator. Those vehicles just disgust me.

Ok, I'm getting off my soapbox now.

Demetri

Re: Fuel economy- The Rant continues ([none / 0](#)) (#11)  
by Dave B on Wed Aug 13th, 2003 at 11:49:18 AM MST  
([User Info](#))  
<http://www.madbbs.com/users/bruggelog>

The technology is always available to do much better. Politics regulates the release of much of this technology to a great extent and therefore the availability of current product. We will see (and are seeing) solutions to our energy needs only as it becomes critical, funny how this happens. I'm not fooled into thinking that the people on top don't care about our energy situation, quite the contrary. Milking the dollar for what it's worth demonstrates a total understanding, unfortunately these rules frustrate some (most) of us on this board who care more for prompt solutions to our environmental issues than stalling to line our pockets. Our concern and involvement in AE is the "fuel" that eventually releases either the old or our new technology (one way or the other) that will solve many of our energy problems. I don't totally agree with the system but I'm not a pot calling the kettle black either. I'm happy with my gas guzzler, I'm also happy being a part of this great group and learning AE ways because the issues are important to me and the real kicker is that it is fun. Just had to voice my opinion also. Dave B

Takers, anyone?

GREAT magneto, jumps a bright blue spark 1/4 inch. I rebuilt the carb, I replaced the spark plug, and the thing won't even cough. Had fuel, had spark, checked the compression. 15 psi. Put oil in the cylinder, came up to 25 psi. I was forced to come to the conclusion that the saw was dead. It's a Craftsman/Paulan model 358.

Everything's in good shape, the bar and chain are already spoken for. I can post carb numbers if anyone's interested (maybe to cross reference to a different engine), but I'll let the whole thing, or pieces, go for the cost of shipping.

Two things. Check the reed valve, usually these things have them. Sounds like rings to me. Easy job and cheap. 2 cycle engines are mean little varmints if you ask me. That's why I like the new Honda 1.5 hp 4 cycle. Small, quiet, dependable and it doesn't shake like the diesels.

Thanks for the response, RobD. There's no reed valve in this engine, just a port. The way I understand it, a faulty reed valve would allow the charge to flow back out of the carburetor from the crank case when the piston is on it's down stroke, but the compression would still be fine(correct me if I'm wrong). The cylinder walls are pretty scored up, not worth the hassle or expense to have it bored(we're talking .080" here), get oversized rings and piston, all that. If you think it's worth it to you, you know the offer. Carrying case comes too.

Demetri

([User Info](#)) <http://www.livetheword.info>

Demetri, One thing you can try (which I have to do on just about every 2 Cycle I do a carb rebuild on)is - take an oil can (you know the type you put oil in and squeeze a handle on when you want oil) and put some gas in it with a little bit of oil (or some of your mixed Gas/oil). Remove the breather and open the choke with the throttle wide open squirt a little of the mixed gas down the carb (one to two is plenty). Now try to crank it (with throttle open full and choke closed). You will probably have to do this a couple of times before it will run for more than a few seconds at a time. When it seems it may have warmed up a little you can then try to adjust the high side adjustment screw while it is running (for those brief seconds and make sure throttle is open full). 2 cycles can be tricky after a carb clean and rebuild. If you still don't want it or just don't want to mess with it, could you get me a quote for shipping to 75474.

Good Luck!

Be blessed! Gary

Re: Chainsaw parts ([none / 0](#)) (#5)

Sorry Gorrilla, I know about priming the engine to get it to crank up. Fuel was dripping off the spark plug. I already yanked the carb and the flywheel and the magneto and tossed the rest. If any of you have a saw like this, come up with a better air cleaner. The unoled foam is junk. And no, it's not supposed to be oiled. I tried, and the saw got warmer than I like it to, and I shut it down before it over heated. That was also the case after I'd readjusted the air/fuel mix to match the lower air flow. The manufacturer does not recomend oil either.

## [Ethanol Engine \(Updates once again\)](#)

By [Andrew](#), Section [Homebrewed Electricity](#) [Fossil Fuels](#)  
Posted on Thu Jul 10th, 2003 at 11:24:10 AM MST  
**Engines coming along perfectly**

Hi,  
Brian asked how the engine was coming along.  
Well, I got the reamers 2 days ago, so now I up and back to production.  
I have most of the parts machined, but I'm rinning into some problems....  
How do I make or get rings that small?????

Also, I cannot drill and tap the top of the cylinder, until I buy a glow plug, because of the chance that I might get the thread wrong.

Its stainless piston, aluminum head, and crankcase, and I'm still working on the carburator, so that might be aluminum too.

-Andrew

Re: Etanol Engine (Updates once again) ([none / 0](#)) (#1)  
by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Thu Jul 10th, 2003 at 12:17:28 PM MST  
([User Info](#))

Hey Andrew, great to hear things are coming along! Most engines that size (and slightly larger, like my Magnum) don't use rings at all. The piston tapers towards the crown, so the diameter at the skirt is bigger than the diameter at the crown. As the engine runs and heats, the crown gets hotter than the skirt, and expands more, bringing the piston out to fit the cylinder. I'm sorry if you know all this already, but maybe you could do something similar? Good luck.

Demetri

Andrew;

May I suggest that you post future updates on this ethanol engine to your diary rather than the front page?

It just seems to me that is a better place for it rather than posting it to the front page every time it gets down the queue a ways. After all this is exactly the kind of thing the diaries are for.

Cheers.

TomW

Re: Ethanol Engine (Updates once again) ([none / 0](#)) (#4)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Fri Jul 11th, 2003 at 04:34:59 AM MST  
([User Info](#))

Well demitri,  
I used your idea.

YESSSS!!!!

I put the tapered piston into the head, and.... I made a gas spring!  
No leaks!!!!  
It will work beautifully in the engine.

I'm leaving for Wisconsin tomorrow, so I won't be able to machine or make any progress on the engine until I come back on Tuesday.

From now on, I will post my progress on the diaries page.

For the glow plug, I'll wait until Brian gets back to me on the heat range.

Until then,

All is good!

Everything is panning out perfectly!

I expect this engine to be sputtering along late next week!!!!

It should make an interesting battery charger (probably only like 10 watts),  
I picked out a hoover vacuum motor that is 6v at 10.5A, and should work beautifully for this application.

Thanks!

-Andrew

by Brian on Sun Jul 13th, 2003 at 12:35:19 AM MST  
([User Info](#))

I agree a tapered piston would work well, but we all know metal expands as it heats up. If the clearance between the skirt and the cylinder wall is too tight when the engine is cold, you could end up with a seized piston and a busted crankshaft if the thermal expansion isn't taken into account. If you know the exact composition of the metal you're dealing with, it's possible to calculate the thermal expansion of the piston so you can machine for the proper clearances at normal operating temperatures to ensure the engine will operate at temperature without excessive wear...or worse. The one good thing about burning ethanol as opposed to gasoline is the fact that the engine should run close to 40 degrees cooler which could lessen the thermal effects.

I would hate to see your hard work go down the drain, so just something to think about.

Regarding the temp calculations, you haven't given me the exact dynamic compression ratio so any numbers would not be accurate. Have you actually machined the intake and exhaust ports yet? I can't run the numbers without it!! :-)

I didn't see any intake or exhaust ports in your drawings, nor did I see an internal passage which would allow the pressurized fuel to flow from the

crankcase to the intake. How will the fuel get from the crankcase to the cylinder?

Brian

Re: Ethanol Engine (Updates once again) ([none / 0](#)) (#7)  
by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Mon Jul 14th, 2003 at 10:00:39 PM MST ([User Info](#))

I'm sorry Andrew, I had it backwards. The cylinder in the engine I spoke of is tapered, the piston is straight. The top of the cylinder is ever so slightly smaller than the bottom, and when cold the piston actually binds a little at tdc. The best way I can think of to achieve this would be to heat the cylinder on one end to operating temperature, bore straight, and let it contract as it cools. Hope I didn't goof up things too badly. You might try running that piston anyway, I believe aluminum would expand more than stainless steel, your cylinder would pull itself away from the piston, probably allowing excess blow by but I doubt it will ruin anything. I'm really sorry, good luck.

Demetri

Always be the lead dog.

Re: Ethanol Engine (Updates once again) ([none / 0](#)) (#8)  
by Brian on Tue Jul 15th, 2003 at 08:22:52 PM MST ([User Info](#))

Yes, aluminum does expand thermally more than steel does. Mild steel has a thermal expansion coefficient of around 0.0000126/deg C and aluminum is around 0.0000240/deg C. These numbers will obviously change depending on the exact composition of the steel and aluminum. The above numbers have no unit of length associated with them either. Here's a sample calculation of how you would calculate the expansion of a mild steel rod.

Length of rod= 50 mm  
Change in temperature= 200 deg C  
Thermal expansion= 50mm x 0.0000126/deg C x 200 deg C= .126 mm expansion in all directions.

Andrew, I noticed you said you used an aluminum head and steel piston. Did you sleeve the cylinder? The steel piston against the aluminum will cause it to wear out pretty quick.

Good luck, Brian.

[ [Parent](#) ]

Re: Ethanol Engine (Updates once again)  
([none / 0](#)) ([#9](#))  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on  
Wed Jul 16th, 2003 at 04:06:26 PM MST  
([User Info](#))

I'm back!

No, I do not have a sleeve.

It would wear pretty quickly now that I think about it.

I'm going to have to machine the cylinder head. I'll make the piston out of aluminum, and a slightly taper piston, top being biggest, and then have the head machined out of stainless. Since the aluminum will expand about twice as much as the steel, I'll have large heat sinks machined on the side of the head. The aluminum should expand ever so slightly in the cylinder, thus the top being a perfect seal, and the bottom expanding to fit. About the seizing, I'll probably have to heat up the engine a bit before I start it, just so I avoid this problem.

I'll get back to you on where the intake and the exhaust ports will be.

Thanks!

-Andrew

[Fossil Fuels](#)

Ethanol powered lawn boy.

---

Hi,  
I just got a old stihl weed eater motor. The thing was trashed! After an afternoon of fixing up the piston, the recoil unit, I got it running! Just need to adjust the carb to allow lower idling speeds. The nasty oily smoke though just screamed for the engine to be converted to ethanol. (I know one distributor down here in Colorado Springs, on 8th street I think) So, I was told that I need to adjust the carb for a richer mixture of ethanol/oil mix. How do I go about this.  
Finally, anyone know a alcohol soluble oil for 2 cycles. If so, what proportions should I mix?

Thanks  
-Andrew

P.S.  
The Machining process of the tiny ethanol engine is progressing! Got the pistons and the crankcase done. But when I went to machine the head I found out I have a chipped reamer! Looks like I'll have to take it in the shorts and buy a 3/8ths reamer and a 1/2 one too. (Anyone know any good machine tool places for internet order?) (3/8 needed for valve assembly) I'll keep you posted as both projects progress.

-Andrew

Castor works, and there are a couple synthetics and synthetic/castor blends, though I don't know if they'll offer enough protection for the weed eater motor. Most model airplane engines burning the same stuff use 10-30% oil <I'm not a small engine mechanic, nor a fuel chemist, try at your own risk>. You might find it sold separately from the fuel at hobby shops(or buy the fuel pre-mixed, with nitro!) for those who like to mix their own fuel. Good luck. Demetri

Re: Ethanol Engine (updated) ([none / 0](#)) (#2)  
by Brian on Sat Jun 28th, 2003 at 01:07:01 AM MST  
([User Info](#))

Sorry I took so long but I have been busy with other projects. That weedeater will run just fine on ethanol. Adjust for about a 9:1 air/fuel ratio which is richer compared to the 12:1 mixture used in gasoline engines. Just find the mixture adjusting screw on the carb and back it out to richen it up. Run it for a while and be sure the plugs arent white. If they are, the fuel mixture is too lean and it will run hot. As far as the fuel/oil mixture, try to mess with the fuel/oil mixture ratio until it smokes just a LITTLE while on the throttle to be on the safe side. Now for the temps for your other project....I believe you said u were going for a 12:1 compression ratio. How did you figure this is what you will end up at? Dynamic compression ratio will be lower than the static compression ratio. I would have to see the intake and exhaust design to know what volumes to use to figure out the CR you will be running at. If you want, send me your latest drawing and I'll take a look and tell you what to use to compute the actual compression ratio. It doesn't make much sense to do the math on the temps until I have that. If you're sure it's 12:1, let me know and I'll figure the temps using that ratio. Keep us posted of your progress. I expect it will run just fine using a glow plug setup!

Re: Ethanol Engine (updated) ([none / 0](#)) (#3)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Sat Jun 28th, 2003 at 01:26:27 AM MST  
([User Info](#))

This is static I believe. I did it by just checking the heights. I'll send you the dxfs. I'll post them asap. Thanks for your help.  
I can change the compression ration if this is a problem.  
-Andrew

Re: Ethanol Engine (updated) ([none / 0](#)) (#4)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Sat Jun 28th, 2003 at 02:59:10 AM MST  
([User Info](#))

Well here is a pic of the rendered pattern but showing the hidden lines to reveal the piston and the crankshaft.

Sorry, it is big, admin could you reduce it again.

You can also see the glow plug and the coil at the top of the cylinder.  
I do not have the exhaust or intake on this. I will do this upon request.

Keep in mind that this thing is a two cylinder machine, and I have only drawn up one cylinder to keep it simple.

Here is the dxfs of this...

["http://www.otherpower.com/images/scimages/248/crankcase\\_and\\_cylinderhead.dxf"](http://www.otherpower.com/images/scimages/248/crankcase_and_cylinderhead.dxf)

just right click it and hit "save link target as" or some thing similar.

It should start downloading. Open it with autocad or similar.

I can also put up a 3d cadkey pattern if yall want to do cool stuff with it (like spin the rendered model at any angle, etc. just another reason to get cadkey)

-Andrew

(Brian, the total stroke length is 0.4 the and the the cylinder depth is 0.43 excluding the height of the piston (which if included the total height would equal 0.83) and the volume in the glow plug. I look forward to seeing the temp ranges. If you need the exhaust and intake, I will add them asap THANKS!)

Re: Ethanol Engine (updated) ([none / 0](#)) (#7)  
by Brian on Mon Jun 30th, 2003 at 02:42:05 PM MST  
([User Info](#))

Sorry I haven't replied sooner. In order to figure out the dynamic compression, you need to take some measurements. How did you design the intake and exhaust?? The dynamic compression will vary greatly depending on how you set it up. Go ahead and post a description of your design and I'll tell you where to take your measurements from to figure the ratio.

BTW, if you want the picture to show up the same size on everyone's computer regardless of the resolution they're running at, use the HTML formatted option when posting and use the tag below. I'll use the filename engine.jpg but you can change it depending on your file name and server addy.

```

```

This will make the picture take up 80% of the screen width no matter what size monitor the person viewing it is using!! No more scrolling sideways!

by RobD on Mon Jun 30th, 2003 at 08:00:58 AM MST  
([User Info](#))

Nice Job! I have a Stihl chain saw that has run great for years. The fuel oil ratio is 50/1. You shouldn't get that much smoke out of it, I don't. Also 2 cycle engines are more prone to ceasure when the oil is RICH in the mixture. These engines also run on Hi-test gas. For those of you not familiar the difference in hi-test and regular is the speed of burning. Hi-test burns SLOWER than regular this prevents ugly things like pinging that can eventually burn a hole in your piston. I don't know the octane of ethanol but you might want to play with your timing if it is on the low side. RobD

Re: Ethanol Engine (updated) ([none / 0](#)) ([#8](#))  
by Brian on Mon Jun 30th, 2003 at 02:51:44 PM MST  
([User Info](#))

Ethanol has a higher octane rating that gasoline does so he shouldn't have any problem with pre-ignition.

You're right about the speed of combustion. Many people confuse a high octane rating for high volatility which is wrong. The octane rating is the fuels ability to resist knock, AKA pinging or preignition. The slower the fuel burns, the better it is at resisting preignition. The higher the octane rating of the fuel, the higher one can raise the compression ratio without preignition. A higher compression ratio creates more power!!

It will be interesting so see what fuel/oil ratio will end up working the best for this application. This is definitely a guess and check type experiment!! All very good points though! Brian

Re: Ethanol Engine (updated) ([none / 0](#)) ([#10](#))  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Mon Jun 30th, 2003 at 04:06:33 PM MST  
([User Info](#))

I make the intake/exhaust on the drawing. I'm not really sure where to put them other than the exhaust should be a little bit higher in the cycle than the intake.  
I think one problem with high octane fuel though is the fact that with lean fuel mixures you will get detonation. I believe this you will also hear a "ping" because its the speed of the engine slamming down so fast that it get hit against the side of the cylinder. This is probably why most engines run on a rather rich fuel/air mix like 10: 1  
I think pinging starts for normal gasoline at about 18-22: 1

-Andrew

(Could you post why and where the intake/exhaust is where they are.)

Re: Ethanol Engine (updated) ([none / 0](#)) ([#12](#))  
by Brian on Mon Jun 30th, 2003 at 05:08:00 PM MST  
([User Info](#))

Hi, I'm guessing you meant that the intake and exhaust are labeled on the drawing file you posted. I wasn't able to open it so I can't comment!! Does Cadkey allow you to save it as a \*.dwg file?

Regarding the intake and exhaust design....in a 2-cycle engine the fuel/air mixture is forced into the combustion chamber during the down stroke of the piston. During the upstroke the mixture is compressed. When the piston gets close to TDC, the glow plug ignites the mixture.....forcing the piston back down. As the piston moves back down, exhaust gases escape through the exhaust port while the fuel mixture re-enters the cylinder.

Regarding pre-ignition, you are correct for the most part. High octane fuels do not vaporize as well as lower octane fuels do. This lack of vaporization causes much of the mixture to remain as a liquid instead of the dry vapor necessary for efficient combustion. Since there is less fuel in the fuel/air mixture, the mixture is often way too lean....causing detonation and internal damage!! So in the case of higher octane fuels, it is the octane rating iteself that often causes the lean mixture, resulting in detonation. This is the reason you need to richen the mixture when burning ethanol.

However, most gasoline engines do not run at a fuel/air ratio of 10:1. Between 11.5 and 12:1 is the norm for most 4 stroke gasoline engines.

Hope this helps, Brian.

[ [Parent](#) ]

Re: Ethanol Engine (updated) ([none / 0](#)) ([#16](#))  
by Brian on Thu Jul 3rd, 2003 at 12:47:43 AM MST  
([User Info](#))

Yes, I have been busy....Sorry about that. I have been working on a prototype solar collector for OREC. Fun stuff!!

Regarding your drawings....very nice. The conversion worked just fine. How does Cadkey work for coil/spring drawings like those used for your glow plug drawing? Just curious if it's easier than the method used in AutoCAD. In AutoCAD, you have to use an AutoLISP to extrude a 2D object about the spring path to create the 3D solid drawing of the coil. Kind of a pain.....

Ok, now for the intake and exhaust. The exhaust port will need to be slightly higher than the intake port to allow the exhaust gases to escape just before the fresh fuel mixture enters the cylinder. You will want the intake port to be fully open just as the piston hits bottom dead center. When the piston reaches BDC, the pressurized fuel mixture will flow through the intake port into the combustion chamber for the power/exhaust stroke.

In order to make this work, you need to incorporate a reed valve into your design. It's essentially a one way valve that allows the upward motion of the piston to suck fuel in from the carb but not allow it to leave when the piston begins its downward motion....pressurizing the mixture for injection once the piston moves past the intake port.

In your design, I see no intake port that will utilize the downward motion of the piston to pressurize the fuel. The fuel MUST enter the crankcase in a 2 stroke design, not through the top of the cylinder head.

I'll try to make some time in the next few days to tinker with your drawing and post the required design features.

Hope this helps. Brian

Re: Ethanol Engine (updated) ([none / 0](#)) ([#18](#))  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Thu Jul 3rd, 2003 at 01:09:12 AM MST  
([User Info](#))

First, its easy for the springs. Just go over to draftpak (a part of cadkey package) and select spring. It will ask how many windings, and the thickness of the wire.

Here are the images of the valve I was talking about.

Sorry if they are big.

Thanks  
-Andrew

[ [Parent](#) ]

Re: Ethanol Engine (updated) ([none / 0](#)) ([#19](#))  
by Brian on Thu Jul 3rd, 2003 at 11:19:04 AM MST  
([User Info](#))

LOL, I saw your valve on the side of the crankcase. I'm not that blind!! What I didn't see is how the pressurized fuel/air mixture is going to flow from the crankcase to the cylinder!!! There is normally an internal passage from the crankcase to the cylinder that is opened when the piston passes a certain part of the stroke, allowing the fuel/air to flow into the cylinder to be burned on the next intake/combustion stroke.....somewhere near BDC.

How will you accomplish this???

Regarding the solar collector, it's not as bad as one would think. We're working on a new design that will maximize efficiency without tracking regardless of the time of day. The design is meant to concentrate the rays in order to quickly heat water while also generating electricity. It's the first of it's kind design wise, and we hope to have refined the design by next summer for testing. Preliminary data look very promising, but only time will tell.

[ [Parent](#) ]

I was thinking on just using an endmill, and buzz the side a bit at the appropriate length. I just ordered a couple of reamers yesterday, so production should be up and running by next week. (I can't wait to get the new swivel vice for my mill) Also, I'm having trouble figuring this out, how do such tiny engines use rings, and how does one go about manufacturing them. I was thinking on using a cobalt or tungsten disc the right size, and very slowly drill out a hole, and then grind a tiny slot on the side to allow compression against the walls of the cylinder. -Andrew

Does anyone know the differences.....

Hi,  
 I'm drawing up some dxfs for a 2 cycle alcohol engine, but i'm running into trouble.  
 First, I have been researching on the web, and nobody really has a site explaining the differences between a gasoline, and a alcohol 2 stroke engines.  
 I plan to make this a diesel cycle.  
 Second, one problem I have, is I don't want to mix lubricant with the alcohol, as it totally voids all reasons for using alcohol in the first place.  
 Third, the only solution I can come up with is designing an otto cycle engine. (sealed crankcase) this would prevent the mixing between oil, and alcohol.  
 Finally, I would like to stay away from otto cyles, until I get some experieance machining engines.  
 Thanks.  
 -Andrew  
 (p.s., is there any funky carborator I need to machine to run a ethanol otto cycle?)

Re: Ethanol Engines ([none / 0](#)) ([#1](#))  
 by [Brian](#) on Wed Jun 18th, 2003 at 05:59:21 PM MST  
[\(User Info\)](#)

That'll be a tough one for sure. You could just as easily set up an oiling system similar to a 4 stroke engine while burning ethanol to lubricate your cylinders, bearings, etc. Sounds like you're building the engine from scratch so that shouldn't be a problem in your 2 stroke.

If I had to choose I would go with the Otto over the diesel or any two stroke cycle any day for burning ethanol. Otto cycles are more efficient IF you can up the compression without pre-ignition. Ethanol or ethanol blends(gas/ethanol mix) allow you to increase the compression ratio substantially which increases efficiency.

Is this just an experiment to see what can be done or is it going to be used for something? If it's actually going to be used just pick up a used 2 stroke engine about the size you need and make the convesion over to ethanol. It's just a matter of changing the jets to accomodate a richer mixture. Increasing the compression ratio is not required, although it will aid in increasing the efficiency and power output of your engine.

Ethanol is definitely a much cleaner burning fuel so I can see why you woudn't want to mix it with 2 stroke oil for lubrication. You're machining the engine yourself so add an oil pump and oil galleries to splash lube the cylinder, rings, and get some decent oil pressure to the bearings.

Hope this helps! Brian

It is an experierment, but it will be used for something. The one i'm machining will fit in the palm of your hand. I plan to build a much larger one after this (probably otto cycle) to power a small battery charger. I'm confused. Do I need a much larger compression stroke than a normal gas burning one? How do I prevent preignition on an ethanol engine? The reason I'm leaning towards a diesel cycle is It would be a much simpler design, and I wouldn't need a sparkplug. Now, I'm not sure about the compression ratios of ethanol, and what point does it ignite? I'm not trying to sound stupid, I just never worked with ethanol before.

Re: Ethanol Engines ([none / 0](#)) (#4)  
by Brian on Wed Jun 18th, 2003 at 08:48:05 PM MST  
([User Info](#))

Wow, that's tiny!! Given the extreme compression ratios of a compression ignition engine, I'd be worried about it holding together. It's definitely easier than trying to set up a spark ignition system for an engine of that size though. Timing it would be a pain.

Regarding the compression ratio.....you DO NOT have to increase the compression ratio over common Otto cycle pressures as it will run regardless. 8.5-9.5:1 is perfectly fine for ethanol although not ideal for power output.

Ethanol has a higher octane rating which allows you to run a higher compression without pre-ignition problems which increases power. However, since you're planning on making this a compression ignition engine, the compression ratio needs to be much higher to ignite the ethanol without a spark.

I'll look in my books to see if I can find the info on what compression ratio is required to ignite ethanol and post back later tonight or tomorrow.

([User Info](#))

I'm not sure you can use alcohol to diesel. It has to ignite and BURN CORRECTLY under the compression you can apply. I think you can go to about an 18:1 compression with ethanol, but it won't diesel (it will knock or detonate first, just like gasoline does when the octane (or cetane) is too low. See if there is a Cetane number for alcohol - if there ain't it isn't a sane diesel fuel.....

How about a Wankel rather than a 2-cycle?

Russ

Andrew

a 2 stroke motor has to have oil in the fuel  
an alcohol motor uses castor oil [regular oil will not mix with alcohol].  
Needs a much higher compression ratio to work well  
[won't run on gas it will melt down].  
It will have to have larger jet's in the carb  
than a gas motor [much larger].  
have fun  
Elvin

Re: Ethanol Engines ([none / 0](#)) (#5)  
by Brian on Wed Jun 18th, 2003 at 08:54:58 PM MST  
([User Info](#))

Just another thought.....most RC engines are two stroke and run on an alcohol/oil blend.  
If you can get your hands on one of those, just rig up an adaptor to connect a  
compression tester to it to get an idea of the kind of pressure you'll need to have to ignite  
the fuel and just go ahead and burn RC fuel. 20% or so would be great. Using the  
pressure reading from the RC car, you can easily calculate the compression ratio you'll  
need to achieve that pressure. You will have to run a glow plug though.....

Re: Ethanol Engines ([none / 0](#)) (#6)  
by Anonymous Hero on Thu Jun 19th, 2003 at 02:02:47 AM MST

Andrew, just like brian sayed you will need to mix the alchol. Your best bet is to talk  
to some model airplane flyers. they have experience with cox engines and be able to  
tell you what compression ratios you need and what percentage alcohol blend you  
need.

Re: Ethanol Engines ([none / 0](#)) (#7)  
by Gordy on Thu Jun 19th, 2003 at 11:22:41 AM MST  
([User Info](#))

Andrew,

As a fomer R/C (remote control) junky I can add that as you go from spark to glow to  
diesel the compresion goes up. The R/C diesels use a specal blend of feul, containing a  
certain amount of either (starting fluid) to lower ignition presure.

You might want to try checking out Dasvis Diesels , they advertize in the back of most  
R/C mags. And are probably on the net too. What they offer is a diesel conversion kit,  
which is prety much an adjustable compression head. The head is a little over sized than  
the original contianing a cylinder, a piston, and a set screw. The set screw alows you to  
adjust the heads piston up or down to control ignition timing.

Don't forget that the higher the compresion ratio the heavier duty every thing has to  
be. I found this out after boring , stroking, ect..... my Harly . It goes like hell , but it just  
isn't lasting like a stock one would.

Hope some of this helps,  
Gordy

Thats a novel idea. Adjusting the height for optimum compression. I'll try that. Now.... What is the different between a glow plug and a diesel? I'm currently machining heat sinks and the head, how hot do you think this thing will run? Also, I have a small poppet valve as the fuel intake to the crankcase. will this be a problem for the fuel inlet? Finally, I saw a design on the net a while ago, and it was an alcohol burning engine, that was 2 cycle, but had a completely seal crankcase, so the fuel was injected into the cylender when the piston reached a certain height. It worked on the principle, that when you first started it, there would be alcohol vapor in the intake. when you started it, it would heat up and heat up the coils of small copper wire around the head. this would then vaporize the alcohol, and it would be ready to be injected into the cylender. It would have a weird type of carbtorator, in which the alcohol vapor would blow by a tube with air inlets, (kinda like a propane torch) to get the right fuel/air mixture, right before it reached the cylender. Does this sound at all possible?

[ [Parent](#) ]

Re: Ethanol Engines ([none / 0](#)) (#9)  
by Brian on Thu Jun 19th, 2003 at 04:23:44 PM MST  
([User Info](#))

There is no difference. Diesels have glow plugs that get the engine started. Once the engine is running, the compression alone is enough to ignite the fuel. Believe it or not, Ethanol has a higher self ignition temperature diesel does. The auto ignition temperature of ethanol is between 365-425 degrees C which is around 750 deg F. Diesel self ignites at temps of around 480 deg F which makes it much more ideal to use in a compression ignition engine.

You're going to have trouble starting the engine on ethanol without a glow plug. Once the engine is warmed up, take the glow starter off the glow plug and it should remain running on compression ignition alone assuming the compression is high enough. Preheating the alcohol using exhaust gases would be optimal to ensure proper vaporization and combustion.

Regarding the fuel/air mixture, around 9:1 is optimal for ethanol. I would use a needle valve type carb like those found on small RC engines for simplicity and ease of adjustment. Throttle and mixture control is simple and easy to adjust.

I'll crunch the numbers and post them to give you an idea of what compression ratio you'll need to ignite the ethanol on compression alone. It won't run if you don't have it right.....

Thanks! That would be a great help, as I can now get the heights, and the compression ratios right on my design. The head is the only thing I have to finish, and I'm done. I'll give you the cadkey files if you want them (autocad dxfs if you dont want to download the cadkey viewer) Its looking very impressive! Especially in solids 99, it is amazing what it looks like in 3D! Now, how much of a vacuum do you think the piston will pull in the case as it is compressing (intake, letting fuel in the crankcase via the valve) Do you think it will be enough to open a poppet valve? (probably, considering the fuel on the otherside is probably under pressure.) For the compression ratios, what do you think would be easier to control for timing: Octane percentage, fuel/air ratio, or height of stroke/ compression ratio. (within reason)

Re: Ethanol Engines ([none / 0](#)) ([#12](#))  
by Gordy on Fri Jun 20th, 2003 at 11:34:11 AM MST  
([User Info](#))

Andrew,

Gordy here, the differences between glow and diesel are

1. compression ratio, the diesel being higher.
2. is the ignition process once running. The glow plug engine does not create enough heat to start with out energizing the glow plug . Once running the combustion process keeps the element in the glow plug red hot so the power can be disconnected from the plug. I read (years ago) that the element is coated with platinum to give it a catalitic efect to keep it hot.

The diesel does'nt need a glow plug to start, because of the higher compression ratio. Exept in cold whether it does make it easier to start them. As witnessed by my 84 suburbine with a 6.2 diesel it will start easily in temps down to 25 or 30 degrees with out engaging the glow plugs. Also for the 5 or 6 years I've been driving dump trucks, tankers ect none of them have glow plugs. At 10 degrees and below it's a good idea to have a can of starting fluid on hand, though use it sparingly to much can make things go boom in a bad way!!!

3. the feul is also a different recipe or blend if you will.

An interesting note one of the trucks I drive (a 50,000# gross tanker) has a 300 somthing two strock Detroit diesel. This engine has a standard oil type crank case and a gear driven blower mounted to the side of the engine. At 60 mph the engine turns 2,200 rpms, and is screaming so loud I wear ear plugs.

Good luck,  
Gordy

Re: Ethanol Engines ([none / 0](#)) ([#11](#))  
by Anonymous Hero on Fri Jun 20th, 2003 at 11:07:09 AM MST

diesel engines commonly have around 450 plus psi of compression other problems you will encounter with you design will be preignition, as you cannot have a diesel cycle with carburation, the fuel mix will ignite too early as the engine warms up and this will quickly melt it down, destroying it you will need some form of injection system to get the methanal into the chamber at the precise time needed. smaller engines are more tolerant of detonation or preignition. the larger the bore size the less tolerant they become. other concerns with diesel engines are they have to be made heavier as vibration is a problem and a small 2 cycle engine converted to diesel operation would not last very long, in my opinion. glow plugs in diesel engines serve a different purpose to that of a RC engine, in a diesel they heat the intake air charge to get the engine running, and then they are shut down. in a RC engine they not only start the engine but they also retain heat from the previous ignition cycle to ignite the next cycle. the RC engines are not running as diesels when you disconnect the glow plug. bob g

([User Info](#))

Very strange.... So the glow plug is the ignitor for the next cycle? It doesn't make sense, wouldn't you get pre-ignition before the piston reached the top of the stroke? Also I read somewhere, that normal "diesel" glow plugs were made out of tungsten, I thought that sparkplugs were always plated in platinum at the spark gap. -Andrew

[ [Parent](#) ]

Re: Ethanol Engines ([none / 0](#)) ([#16](#))  
by Anonymous Hero on Fri Jun 20th, 2003 at 08:58:50 PM MST

preignition on these tiny engines, as most all of the RC versions are is of little consequence, the chambers ability to dissipate heat is much greater than in larger displacement engines, also one might note that the life span of an RC engine is quite small in comparision to the 10 of thousands of hours larger diesels are designed to run. first spark plugs were mostly a steel electrode as they still are on the cheaper ones at least on the negative electrode or strap, then as time went on tungsten was used to increase life span of the plug and more recently platinum has been used on both center and ground electrodes, to further increase lifespan bob gayle

Calculations..... ([none / 0](#)) ([#17](#))  
by Brian on Sat Jun 21st, 2003 at 01:24:47 AM MST  
([User Info](#))

Ok, I'll run the numbers IF you want to run on compression ignition alone and let you make the choice on what's best for your design.

State 1 will be piston at bottom dead center and state 2 will be the piston at top dead center. We'll use a relatively cold outside air temperature to ensure the engine will fire even on colder days.

$$(P2)/(P1) = (Pr2)/(Pr1)$$

$$---P1 = 14.7 \text{ psi}$$

Pr1 = relative pressure of state 1

Interpolation from relative pressure table at T1 = 45 deg F yields:

$$---Pr1 = 1.0954$$

P2 = cylinder pressure required to ignite ethanol

Pr2 = relative pressure at temp required for auto ignition of ethanol

Interpolation from aforementioned table at T2 = 797 deg F yields:

$$---Pr2 = 28.555$$

Simple algebra to solve the first equation for P2 yields:

$$---P2 = 383.2 \text{ psi}$$

So, to ignite the ethanol on compression ALONE will require a PRESSURE RATIO of 26:1

At those pressures and temperatures, I think it would be difficult to hold an engine of that size together.

In my opinion, you would be better off machining a hole in the top of your head for a glow plug with the correct heat range. You can cut the required cylinder pressures WAY down to reduce wear and tear and make it a whole lot easier to start. Turning over an engine of that size at those cylinder pressures would not be easy!!!

You also mentioned CAD files. I use AutoCAD2000 for my drafting, so if you can save them in that format I would be very interested in seeing your plans. You using CNC???

In any case, Good luck!! Brian

Re: Calculations..... ([none / 0](#)) (#18)  
by Anonymous Hero on Sat Jun 21st, 2003 at 09:11:36 AM MST

what you have calculated is static compression ratio, the dynamic compression ration could end up being much higher or much lower,, lower and the engine would not run at all as a diesel, higher and it only exacerbates the detonation problem unless some sort of direct fuel injection is incorporated,

direct injection of ethanol will be very difficult as it has no lubrication qualities to aid in injector and pump plunger operation.

i would be leaning toward a glow plug fired engine too,, i think it is the only way of making this scheme work. short of spark ignition.

there are so many factors involved in this design, and if one is to go to all the time and trouble to build one i think i would research very well..

i have a 2 volume set on internal combustion engine , engineering,, i think they were 85 bucks for the pair soft bound..

if you are interested i will get the name and isbn number for you, i think one would be well served to get this set if you are serious about engine design.

another option may be the conversion of an old lawn boy 2 stroke engine to glow plug operation, this would leave you with redesigning a head possibly, and the carburation is already in place.

just more thoughts,, good luck with the project

bob g

Re: Calculations..... ([none / 0](#)) (#19)  
by Brian on Sat Jun 21st, 2003 at 01:07:59 PM MST  
([User Info](#))

You're right, that is a static compressio ratio. I should have mentioned that those calculations assume no intake and exhaust valves opening and closing, as with an engine of that size it would be nearly impossible to set up a cam/pushrod/rocker/valve or overhead cam setup. If it were an Otto cycle, I would have to account for that but since this is a two stroke without valves, it's a pretty close estimation \*\*without actually having the engine in my hand to get the actual numbers.\*\* Hope that clears it up, Brian.

Re: Calculations..... (none / 0) (#25)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Sun Jun 22nd, 2003 at 12:38:57 AM MST  
([User Info](#))

Ok,  
So it looks like glow plug or spark ignition for me.

I have never worked with glow plugs before.  
I assume that the compression ratios for a glow plug would be fairly similar to a spark igiton. So...  
about 10-1 compression ratio sound reasonable?  
If so, how do I machine a glow plug, and how do I make it the right temp ranges for my engine. I would think all it is a piece of metal, that has a certain specific amount of heat sinks on it, so i will always be at the right temp. maybe I'm wrong.

Any advise on this would be great.

[ [Parent](#) ]

Re: Calculations..... (none / 0) (#26)  
by Brian on Sun Jun 22nd, 2003 at 03:37:04 PM MST  
([User Info](#))

Ok, I'm not the expert on RC glow plugs so this link will be a great place to start. They have a lot of great info on how they work, etc.

<http://www.rcnitro.com/rn/articles/glowplugs.asp>

You can go to a hobby shop and pick up the correct glow plug for your application. You'll have to read about them and decide what temp. range would be best as I really couldn't tell you. Then you can go ahead and machine the hole in your cylinder head with the correct threads. Hopefully you haven't gotten too far along making your head, as the glow plug could contact the piston if you're not careful. I have done quite a bit of RC stuff messing around with my MP-6 but that's about it so that's all the help I can offer on this one.

## [From old board -- Gaseous VS liquid fuel](#)

By [John](#), Section [Rants & Opinion](#)

[Fossil Fuels](#)

Posted on Thu Jun 12th, 2003 at 05:42:00 AM MST

This is copied over from the old board so I can answer it here:

-----  
I guess I can't really add anything to the debate about whether the fuel is or should be fully vaporized but can someone tell me if burning a gas (say propane) gets more MPG than gasoline. I know that propane has a lower energy density than gasoline but if vaporization is that much better, then propane should still get more MPG. So, does propane get more MPG?

Martin.  
-----

Not really. Propane burns cleaner than gasoline as gasoline is now normally used. The mileage is about the same or a little less for propane, but performance can be improved for either fuel. If gasoline is totally gaseous and when enough oxygen is provided for a clean burn then gasoline will give many more MPG than propane. The problems with using totally gaseous gasoline are greater heat (burnt valves), and explosion and fire danger. I'm sure that the heat problem could be handled, but the explosion and fire danger is so great that no manufacturer wants to touch it.

John

What's this? For once we agree on something? Nah.

Propane does indeed burn cleaner in the real world as it gets closer to complete combustion than gasoline does. Here's the equation for complete combustion of propane with air:

You can see the only byproducts of combustion given complete combustion of propane are carbon dioxide, water, and nitrogen. The exact same byproducts, but in different quantities, result from the complete combustion of octane:

Unfortunately all the stabilizers, additives, etc. they add to gasoline make it a lot "dirtier" fuel to burn. Gasoline isn't pure octane either. The exact chemical composition of gasoline is tough to track down as the seasonal changes made to aid in vaporization effect the composition of the fuel. Neither propane nor gasoline completely combust, but propane gets closer to it so it doesn't indeed burn cleaner than gasoline.

90% combustion of gasoline will yield more carbon monoxide and unburned hydrocarbons than 95% combustion of propane will. More of the propane is burnt, so it burns cleaner.

Re: From old board -- Gaseous VS liquid fuel  
([none / 0](#)) ([#4](#))  
by John on Thu Jun 12th, 2003 at 02:36:34 PM MST  
([User Info](#))

No argument here! All the additives do hinder truly clean and complete combustion. All combustion has some byproduct, so "clean" really is a relative term.

E-man here. My password may not be working just yet.

In the 1950's there was one fellow willing to take on the mechanical challenges associated with using a very lean fuel mixture. His name was Russell Bourke, and he developed a very ingenious engine that ran on a 1000 to 1 air/fuel ratio. His first commercially available engine came out in 1954. The basic layout was an opposed two cylinder engine having pistons arranged on opposite ends of a straight rod connected by a Scotch yoke drive mechanism in the center.

The exhaust temp was cool enough to put your hand near due to the almost complete combustion of fuel (including the hydrogen which favors an oxygen rich environment and high heat). Also, the fuel burned so quickly, driven by the hydrogen flame propagation, that the end of the piston stroke during expansion was actually a refrigeration cycle which cooled the spent gasses before exhausting them. The combustion "event" is very much like a sharp detonation and only the in-line piston design saves the engine from becoming a pile of aluminum sand. The traditional Bourke engine has no flywheel and reaches ungodly rpm's. The torque vs. rpm plotted curve looks similar to that of a turbine.

It's a real treat to study Bourke's engine if you've never been introduced. They are still being produced by enthusiasts; here's a url:  
<http://bourke-engine.com/index1.htm>

Re: From old board -- Gaseous VS liquid fuel ([none / 0](#)) (#6)  
by Wolfie1 on Mon Jun 16th, 2003 at 05:43:31 AM MST  
([User Info](#))

That's right Mr On :) If it is claimed that a gasoline engine can be converted to 100+ MPG through just vaporization of the fuel, a propane fueled engine should be able to get close to that number. So where is this super efficient engine? Martin.

"The oil companies have it under a sheet in their garages!"

Please know: I'm not taking pot shots at this particular comment. But I've seen and heard charges like this for years from a number of sources. I wonder if everybody thinks this is really true?

If they are true, how could it be proven?

Seems like a patent would have been filed for the engine. Then it seems like the inventor's name would be listed. Somebody could then contact the inventor and ask. I suspect that has not been done. Or if the patent was sold, does the patent office maintain the current owners of a patent? Sure would make for an interesting research project.

I wouldn't put this tactic by the oil companies, but I doubt we can really prove it.

Bach On

- I'm just as happy as if I had good sense! -

True!! Propane does generate less power when compared to the burning the same amount of gasoline.

Ethanol is the way to go anyway. Burning ethanol greatly reduces emissions while making us free from our dependance on crude oil. It also allows you to increase the compression of the engine to 15 or 16 to 1 which increases efficiency.

Ethanol is fairly easy to come by as well. While you will get roughly the same fuel economy and about the same power when not pulling a load when compared to gasoline, the increase in compression and efficiency actually maintains the fuel economy at a constant level while towing, etc. I wish my truck did that....

Diesel engines are more efficient than current gasoline engines in that they run a higher compression ratio, but if it were possible to increase the compression of a gasoline engine (Otto cycle) the efficiency would be greater than that of a diesel engine operating at the same compression ratio. The Otto cycle is simply a more efficient process.'

You would lower emissions, maintain fuel economy, and generate the same amount of power, all without any crude oil!!

## [Woodstoves Poll](#)

By [ADMIN](#), Section [Remote Living](#)

Posted on Sat Mar 29th, 2003 at 07:16:40 AM MST

[Fossil Fuels](#)

This section of the board is devoted to to folks who live way back in the sticks, where the topic is NOT related to generating electricity. Read on...

So questions about woodstoves, passive solar home construction, water pumping, guns, water heating, and a bunch of other topics are quite appropriate here. I heat almost entirely with wood (plus a propane backup), as do DanB and Matt from Forcefield. We love our woodstoves. What kind do you use? We already filled the answers from our neighbors up here near Otherpower HQ.

[Woodstoves Poll](#) | 10 comments (10 topical, 0 editorial)

replying to someones post, I think? ([none / 0](#)) ([#2](#))  
by Anonymous Hero on Sat Mar 29th, 2003 at 04:08:02 PM MST

Not sure how to use this new area yet, so I'm just replying to you. Put a little steam engine on that wood stove to power up that Lava Lamp while you're watching Dr. Who.

by Wyomingbob on Sat Mar 29th, 2003 at 09:35:49 PM MST  
([User Info](#))

I'm currently browsing little woodstoves, trying to find a 'kicker' unit that will heat my new house when the passive and active (hot water) solar aren't doing enuf. The house is roughly 1500 sq. feet and will be extremely well-insulated, and the stove will be backed by a concave brick wall (interior wall). Right now, I'm looking at Jotul and Vermont Castings. Model recommendations? Are they worth the sick money they command? I'd prefer non-catalytic stoves, and the thing must have a glass door: no television, so watching logs burn qualifies as entertainment around here. The floors in this house are concrete and/or tile; is anything gained by raising the stove onto a hearth, or should I sit it right on the floor?

this what i was looking into getting.... ([none / 0](#)) ([#7](#))

this rocks: I used to live in the cold. 8 months a year burning. Crappy old house , with an excellent Pacific Energy wood stove. I built two copper manifolds and mounted them on the top and back of the stove. 1/2 "copper. poured concrete on them right on the top of the stove. This water pipe was then lead to the bathroom floor full of 120 feet of pex pipe and poured 3 inches of concrete and a tile surface. The system was circualted by a TYCO 50 watts circ pump which operated 24/7. Fianlly using clack valves I tapped into my water system and exited into the hot water tank ( electric. Every time I used hot water , the system drained 120 F water into the hot water tank. Meanwhile the bathroom floor was wonderfully warm to hot. I no longer needed to use the electric heater in the bathroom. I saved about 60 -70 % on my power bill. U-HUH! Plus the bathroom was super hot ( floor) . This system pushed about 2-3000 watts of energy into the water and circulated about 40 -60 degree celcius water. Smooth as silk. Jungle Bill

wood boiler ([none / 0](#)) (#8)

by ROSCOE ([roscoe.s@sympatico.ca](mailto:roscoe.s@sympatico.ca)) on Sat Apr 5th, 2003 at 07:48:26 AM MST

([User Info](#))

I built a wood fired boiler last fall. I used 3/8" high carbon checker plate for the fire box, and 1/4" plate for the water jacket. 2 annodes from hot water tanks (to keep the corrosion down).the fire box measures 59" x 36" wide x 42" high. I used catch basin grates for the bottom (they'll never rotout)with a cleanout tray onder neath. I took the water off the top back with an armstrong pump,and returned it to the bottom front. I pumped the water to the house (from my shop where the boiler sits) through 3/4" poly pipe that has been wrapped with closed cell insulation, then boxed with 2" S M ,then wrapped with plastic before being burried. Iused 3 airconditioning condensers from full size chevys in the plenum of my forced air furnace. I installer a seconed thermostat and wired this through a second honeywell controler to the furnace fan. I burn hard wood slabwood which I can buy for \$10.00 a bundle. cut in half these slabs work great.

My kind of adapting ([none / 0](#)) ([#9](#))

[How to fix a 'bad' lawnmower coil...\(maybe\)](#)

By [Norm](#), Section [Magnets & Magnetism](#)

[High Voltage](#)

Posted on Fri Dec 5th, 2003 at 01:57:40 PM MST

If you don't get a spark after you've tested the coil...

Some people would assume the coil is bad and replace it . If they're like me.. I would simply get one of my used coils that I have readily available, but there comes a time when that isn't all that easy...about a week or so ago I had a lawnboy with electronic ignition ...a '94 model...now this is a different story! Had it been a Briggs with points... A new coil for this Lawnboy cost about \$50.

If the primary is putting out a few volts, why isn't the secondary working? Burnt out? Possible...but I doubted it...doesn't take much for high voltage to find a different unintended path...a little moisture? Of course! It had been sitting around outside for a couple of years(only a Briggs can tolerate something like that according to some actual personal experience) on closer inspection...what some people think of as being waterproof...really isn't that much...just because the coil is encased in plastic...that just makes it water-resistant...over time the plastic can peel away from the metal laminations or moisture can seep between the laminates and inside to short out the coil.(my theory anyway )

So I let the coil lay around in the sun for a day, set it on top of the water heater for a couple of days, then just to make sure I put a hair dryer on it.. I'm not sure which of the three had done the trick... but I put it back on the engine and WE HAVE IGNITION! and I saved about \$50. After making sure it was going to keep on working I took it off and sprayed a couple of coats of clear (polyurethane or whatever) on it. Maybe this might work for someone else someday! I always have fun when I see that I've saved some money...money for another new battery, wire, magnets, or another inverter etc. (:>) Norm.

Hi Norm!

Woo - hoo!! (as Homer would say!)

That's a great tip and may very well come in useful some day.

I got a free lawnmower last week with a Briggs 3.5 Classic on it. I was looking for something to load test alternators - and this just showed up. Took the head off and decarbonized it and the piston top - no scores in the bore. The old owner complained it was hard to start and wouldn't rev up. The choke plate was completely missing from the carb (!), and the control cable was all jammed up. Fixed the control cable, got a new choke plate from our local small engine shop, put in a new carb diaphragm while I was at it, and now this thing runs like new. Total: \$10

Here are another couple of small engine links I've found useful:

For good exploded views of engines, plus part numbers and prices (haven't actually ordered anything from here yet):

<http://www.partsandservice.com/index.html#home>

and a good general forum for small engines:

<http://forums2.gardenweb.com/forums/lmower/nph-ind.cgi?n=60>

Both links probably good for folks looking for generator engine parts or troubleshooting tips.

Lots of fun!

Ted.

on decarbonizing a Briggs ([none / 0](#)) ([#2](#))  
by Norm on Fri Dec 5th, 2003 at 09:04:02 PM MST  
([User Info](#))

Yeah I used to get them all the time one time one was so bad it lost compression got a chunk of carbon lodged under the exhaust...now that's carbon!

Another time saw this lawnmower in the junk...looked like new after taking it home wouldn't turn over...took the head off the cylinder wall had a deep gouge in it about 1/8" deep the owner tipped it over to check the blade gas from the carb had washed all the oil from the cylinder wall. ...still I had a lot of like new parts. Lot of fun almost unbelievable what some people do to lawnmowers. Norm.

by monte350c on Fri Dec 5th, 2003 at 09:30:52 PM MST  
([User Info](#))

Hi Norm,

Yeah, it's pretty unbelievable what people expect out of their small engine products. If you took a car, only used it at full throttle, stored it for 6 months at a time, and never changed the oil or otherwise maintained it, I suspect it wouldn't last half as well as most Briggs last.

Hats off to the Briggs company - where else can you buy a brand new source of 3.75 hp for \$60?

Ted.

Hi Norm,

Makes me wonder just how long those 3,600 rpm generators will really last. Seems to me it might be better to use a larger engine and make it 4-pole to run at 1,800 rpm instead. 3,600 is really honking for most stock 1 cyl. engines.

Ted

Where are you getting 120 volts DC from ?  
if you rectify the voltage from your wall outlet with a filter  
capacitor across it, you will get voltage closer to 170 volts  
DC

. >=- W o o f -=<

Re: DC converters ([none / 0](#)) ([#5](#))  
by Joseph Turrisi on Sat Oct 11th, 2003 at 04:02:26  
PM MST  
([User Info](#))

The 120 volt DC comes from my welder for running  
AC/DC power tools. I converted it to electric start and  
need some way to charge the battery. I would add an  
alternator but that would be another pulley on the  
crank shaft a add more load to the engine. since it all  
ready produces DC it would be nice to step it down  
for battery charging and forget the price of an alt.,  
pulley, and home made brackets.

Re: DC converters ([none / 0](#)) ([#6](#))  
by drdongle on Sun Oct 12th, 2003 at  
08:19:07 AM MST  
([User Info](#))

I was looking over a used "Power One" brand  
switching converter that I have and it occurred  
to me that as the AC input is rectified, filtered  
and then is converted to a high frequency AC  
voltage to drive a small ferrite transformer, one  
could feed it DC directly, the rectifiers are  
superfluous in this case, but as long as the unit  
receives enough voltage to make it happy it will  
still work. Many of these units are available for  
85 to 120 volts AC. 85 volt ac in reality peaks  
at about 145 volts, I have no idea how tolerant  
these units are, so there is the possibility that  
it might not start up and run. Experimentation  
is obviously in order.

#### [question about transformer winding](#)

When ya wind a transformer, do you have to have the wire wrap around an iron core from north to south? Would just winding the iron core without thought of north to south windings still work(am assuming not as well)?

## [220 V Converter](#)

By [Stillen](#), Section [Homebrewed Electricity](#)  
 Posted on Mon Sep 8th, 2003 at 10:06:11 AM MST [High Voltage](#)

I wish to plug in my hairdryer from the US which has the polarized pin on it. The converter I am using to plug into 220 does not have the distinction for polarized plugs...meaning, you could plug it in both ways. On the rear of the converter, each pin is labeled. The two horizontal pins are labeled L and N, and the "ground" pin is labeled "E." How can I distinguish these and what do they mean?

[220 V Converter](#) | 1 comment (1 topical, 0 editorial)

Re: 220 V Converter ([none / 0](#)) ([#1](#))  
 by [laskey](#) on Mon Sep 8th, 2003 at 10:45:17 AM MST  
[\(User Info\)](#)

Well. Here you go.

L= Live  
 N= Neutral  
 E= Earth (which the same as Ground)

Your polarized plug goes:  
 Thin= Line  
 Wide= Neutral  
 And of course the U shaped one is the ground (if present)

**BUT!!!!** It really doesn't matter. Your hairdryer will run either way. That's why your converter isn't polarized.

Cya,  
 Chris

Homebrew Use?

Has anyone found a good use for the high voltage capacitors salvaged from microwave ovens? Those that I have range from .8 to 1.2 microfarads with WVAC ranging from 2100 to 2400.

last time i played with a HV cap I hooked it in wrong and blew a hole through a door (electrolitic cap)

you could hook it up to a solar cell and a LED and have a light that will last a few min after the sun isnt on the sell .. sorry cant think of anything usefull right now :(

Nasher

Go find some of Tesla's old patents. There's lots of uses for HV caps in those. Especially after around 1890.

Not a big deal Xray. I was just having a rough time with the new board. im self taught on this computer stuff and most things in life. sometimes I think im better without a computer, dont know how to cut and paster and post on the new board and a lot of other puter stuff but I usually get by. When patience takes over frustation ill try this p??p scoop thing again but not right away. its ate my password twice already and i aint got the time and patience right now to dink around with it. I think just cause things are free and hitech doesnt always mean they are worth a darn unless you want to be a slave to it. The simpler the better for me. Oh well nuff of this bs. I got to make a dollar and get things done . Buy this book for your Savinorus type genny. You wont regret it Technicians And Experimenters guide to Sun Wind and water power by Richard Pierson. Im glad I did. Take er ez up there in Canada. My apologies. JB Dayton Nevada

Hi JB.

Maybe the thing to do is to go to the FAQ section to see if there is something you're doing (or not doing) to cause your passwords to get eaten. Failing that, send an e-mail to the admin. They're a good couple of guys, and always willing to help.

I agree you can be a slave to technology. I don't even own a decent computer. The one I post from is at work (shhhhh!).

The book you mentioned sounds interesting. When funds allow, I'll see if I can track down a copy. I have written it down and filed it in my pocket file folder (wallet) where I keep all kinds of interesting bits of info for later reference. Thanks.

Xeroid.

Well thats simple to fix ([none / 0](#)) ([#1](#))  
by TomW on Sun Apr 27th, 2003 at 09:30:21 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

JB;

Simply go to the next text window. You are trying to put it all in the "intro" text window. By next window i mean further down on the post message page is a second window that is for the story itself and as far as I know there is no limit on length of that text. Its dead simple but may not be obvious at first.

Might be time for the admins to eliminate the intro text altogether anyway its confusing and it clutters the main page.

Cheers.

TomW

[Hydrogen](#)

Has anyone ever seen a regular internal combustion engine to run on hydrogen?<br>

Has anyone ever seen a regular internal combustion engine to run on hydrogen? I am thinking of trying this and was wondering if anyone on the board has tried.

I plan on testing by remote since hydrogen likes to go boom but I think with the proper precautions it could be a viable way to use home made fuel for low wind periods.

Geek

vacuum ([none / 0](#)) ([#1](#))

by [wdyasq](#) on Tue Dec 9th, 2003 at 07:08:36 PM MST

[\(User Info\)](#)

One of the problems of running and Internal Combustion engine on hydrogen is the by-product is pure steam. Until the engine becomes hot enough to were the steam will not condense, the vacuum caused by ignition will not produce power.

Been there, done that..... unfortunately, I didn't have an accountant good enough to even dedcut the cost of the game from my income. And, it was "prior art", meaning I was not the only one stupid enough to try it.

Ron

Re: vacuum ([none / 0](#)) ([#3](#))

by [Geek](#) on Wed Dec 10th, 2003 at 09:56:09 AM MST

[\(User Info\)](#)

I'm thinking about a almost constant run genset so even if I had to heat the engine to 150 degrees C to start it really would not be a big deal. I hope to take a motor and run it a very low rpm (like 200 rpm) with the addition of a large flywheel. to produce around 3 HP for charging a battery bank. I plan on making the hydrogen by from solar and wind resources and storing it in a 1000 gal. propane tank. My goal it to have enough hydrogen stored up to run the place for a month if I run into a low wind low light situation. I plan on using the waste heat to supplement a outside wood burner. Check out this link for using hydrogen in ICM.

As a fuel, pure hydrogen works beautifully, similar to propane but with less pollution. Expensive to make and store though.

Good luck, have fun, don't blow anything up that's attached to your body.

The indications are that hydrogen is a good fuel for gasoline engines with no modifications to the gas carburetion system is from [hydrogenappliances.com](http://hydrogenappliances.com)  
Perhaps starting them on gasoline and then suppling the hydrogen is workable.

Geek

Running a engin on hydrogen should not be any harder than running one on propane.

I think all you would need is a demand regulator for propane and a supply of hydrogen at 12 psi to feed the regulator .

I did a duel fuel conversion on my back up generator this summer I can run ether propane or gasoline starts easy in cold weather on propane .

Check out this post  
<http://www.fieldlines.com/story/2003/9/1/82526/70829>  
It not hard to do.

Old F

Have so much fun it should be illegal

Hi IFred,

Enjoyed your web!

Wonder if anyone has any direct experience with that Aqua-fuel or whatever they're calling the gas that comes off the underwater arc thing. It would be interesting to make a bit, capture it, and have it properly analysed. If it's safe to store it might be a way to use wind energy and save it for times when the wind's not blowing.

It would be especially good if it was compressible like propane - where 90 psi or so will get you a liquid.

But I've read so many of these that claim this and that I must admit I'm a little sceptical!!

Lots of fun!

Ted.

by J Steele ([JvsinThai@yahoo.com](mailto:JvsinThai@yahoo.com)) on Wed Nov 19th, 2003  
at 10:23:31 AM MST  
([User Info](#))

I can find no mention of COH<sub>2</sub> in any of my chemistry books so I rather doubt it is a stable or possible compound. I suspect he's getting a mixture of H<sub>2</sub> O<sub>2</sub> CO<sub>2</sub> and CO. Even I'd be careful with this one.  
John

[ [Parent](#) ]

Re: Someone asked about generating hydrogen ([none / 0](#)) (#5)  
by Tom in NH on Wed Nov 19th, 2003 at 09:15:37 PM MST  
([User Info](#))

There is information about COH<sub>2</sub> on the web. For instance:  
<http://www.21stcenturyradio.com/futureenergytech-11.24.00.htm>  
Biomass Gasification

quotation begins . . . . .

Figure 5. Biomass Gasification

Clean fuels are difficult to find today. One example that satisfies a limited definition of "clean" is the carbo-hydrogen gas produced from biomass. David Wallman has patented the process for producing COH<sub>2</sub> from a high voltage discharge through any biomass solution (Pat. #5,417,817). This gas burns cleanly, producing water vapor and only the amount of CO<sub>2</sub> that was originally absorbed by the biological mass when it was growing in the ground.

/Tom

Re: Someone asked about generating hydrogen ([none / 0](#)) ([#6](#))  
by J Steele ([JvsinThai@yahoo.com](mailto:JvsinThai@yahoo.com)) on Thu Nov 20th, 2003 at 10:32:37  
AM MST  
([User Info](#))

I found the reaction responsible for "aqua fuel" in the book General Chemistry by Ralph Petrucci. Solid Carbon exposed to high temperature steam yields Carbon Monoxide, Carbon Dioxide and Hydrogen gas. This process is very old and was common in the early days of metal processing. Our fore fathers would inject steam into hot coke and then burn the resulting gas. It was called "Water Gas." So the "aqua fuel" is just a modern version of "water gas." Oh well. Any chemist out there? If COH<sub>2</sub> did exist, would it be a type of sugar?  
John

Re: Someone asked about generating hydrogen ([none / 0](#)) ([#7](#))  
by monte350c on Thu Nov 20th, 2003 at 08:40:06 PM MST  
([User Info](#))

Yup!

I did a little looking around too. Just do a google search on "Town Gas" and you'll find lots of info about this gas combo. You can get it by blowing steam over red hot coal, or coke.

But I am still not too convinced that this is what's happening in the underwater arc apparatus.

I suppose the only way to know for sure is to either present the experiment to a qualified chemical engineer - or make a very small quantity and have it assayed to find out what is actually in it.

My suspicions are that it still contains lots of oxygen and therefore would be impractical to store....

Ted.

Re: Someone asked about generating hydrogen ([none / 0](#)) ([#8](#))  
by charged on Sun Nov 23rd, 2003 at 04:31:24 AM MST  
([User Info](#))

If the water is "jetted" through the arc you get something quite different from "town gas" or the like.

Here are the folks that are holding all the U.S. and international patents on this process.

<http://www.usmagnegas.com/news/>

Re: Someone asked about generating hydrogen ([none / 0](#)) ([#9](#))  
by monte350c on Mon Nov 24th, 2003 at 08:39:48 PM MST  
([User Info](#))

Hi charged,

Spent some more time reading about Aqua fuel, MagnaFuel, Bingo fuel, GEET, etc. etc. - I still have my original questions unfortunately. I'm not at all convinced that any of these gases are over-unity as some of these guys claim, nor that there are any 'unexplained' contents of any of them.

I think, though, that if there's a safe way to make some kind of gas using electricity that might be a good way to store energy in a really usable way. Then you could decide later whether to use it to make heat, or even generate electricity with a genset on demand.

But the key(s) to the whole thing are - is it compressible, or I should say, can it be stored fairly efficiently like propane, and what exactly is in the mixture? It's important to know, for example, if the process makes a lot of hydrogen mixed with oxygen, then it's "Look out Scout" if you're thinking about storing it!

So I guess once my current project(s) are finished up I should make some of this gas - outdoors - and send it out for an assay. There are a few labs close by that will do that for about \$100. They will tell you exactly what's in your sample - then suitability can be determined from there.

Ted.

## [Homemade hydrogen?](#)

By [zmoz](#), Section [Remote Living](#)

Posted on Thu Nov 13th, 2003 at 05:09:35 PM MST

[Hydrogen](#)

What's the best way to make it?

I want to do a little experimenting with running an engine on hydrogen. I know I won't end up making very much hydrogen, but I would like to make the most that I can. I know you need to run some electricity through salty water, but what do I need to do to make the most? Should it be high volts or amps to make alot? Is there something better to use in the water besides salt? Should the wires be close together or far apart? And is it the + or - that makes the hydrogen?

Thanks :)

[Homemade hydrogen?](#) | 11 comments (11 topical, 0 editorial)

Re: Homemade hydrogen? ([none / 0](#)) ([#1](#))  
by [kww](#) on Thu Nov 13th, 2003 at 07:38:58 PM MST  
([User Info](#))

Use high quality stainless steel for the electrodes and just a little baking soda in distilled water for a long lasting generator. I think it's simply the amount of power supplied that determines output. Also, the neg. attracts the hydrogen I'm rather sure, but a simple match can show you the light. ;-) Be careful, hydrogen needs no containment to explode, only some mixing with air(oxygen). A plastic gallon milk jug half full of hydrogen and mixed with air explodes like a 12ga. shotgun going off(I don't really know that. ;-). Kevin

Ya at one suggestion I used a pepsi bottle and water as a flame arrestor for a torch GLAD I did, flame backed up split the bottle right down the side. Not much hydrogen either ( 12oz bottle half full of water. Big bang!!! Wife says if Dr Frankinstien is going to do more experiments she wants better life insurance and laboratory outside on other end of property. I guess I go back to wind for now.

Yeah...just a test tube full that I made tonight made a pretty loud noise. :-) In terms of more power, do I need more amps or volts...or both?

([User Info](#))

Today I tried some stainless steel nails in a peice of PVC pipe with some salt water. (didn't have any baking soda) After about an hour running @ 12v and about an amp, the positive nail was completely liquified! Also there didn't appear to be any bubbles coming off of the positive. (oxygen) Why?? And what can I do to make this thing last a little longer than an hour?

Re: Homemade hydrogen? ([none / 0](#)) (#8)  
by kww on Fri Nov 14th, 2003 at 08:25:01 PM MST  
([User Info](#))

You were making some chlorine gas at the positive nail, that's what happened to it. :-) That stuff will eat about everything and will do major damage to your skin and lungs in large enough amounts. That's another reason to use baking soda.

Since water is H<sub>2</sub>O there's only half the O molecules so there's less gas at the positive electrode. Also, the O bubbles are very small and aren't very noticable unless you've got lots of it being produced. Btw, stainless steel pipe in varying sizes makes a great generator used with large 2-4" diam. rubber pipe caps. I have a little unit that will make one liter of H and O gas in about a minute, I think it was.

Re: Homemade hydrogen? ([none / 0](#)) (#10)  
by charged on Sun Nov 23rd, 2003 at 05:35:14 AM MST  
([User Info](#))

Electrolysis is driven SOLELY by the current flowing through the cell. The lower the resistance of the cell, the lower the voltage required to produce a given amount of current.

For maximum efficiency you DO NOT want the cell to produce heat. This means that you'll need lot's of electrode surface-area in each cell.

You'll also need a GOOD electrolyte. A light Lye solution (sodium hydroxide) will work just fine.

You can make a simple cell by using two large stainless plates of equal size with a separator membrane (artificial chamois from the autoparts store). Leave about 1/8" of space between each plate and the membrane. You'll end up with about 3/8" overall distance between the plates.

The two plates must vent at the top into two different gas outlets that are isolated from eachother.

Place about 400uf (electrolytic) of capacitance across the two plates in that cell.

You can push about 10amps per square inch MAX before you start making heat and reducing the efficiency.

Your power supply, for the best outcome, should be a pulsed DC supply. A standard PWM chip is used to control a power transistor to produce what you need.

The transistor emitter is connected to a heavy inductor. The other end of the inductor goes to the positive on the cell capacitor. A heavy current recifier diode is connected in reverse-bias mode with it's cathode connected to the transistor emitter and it's anode connected to the cell capacitor negative.

The negative lead from your power-supply is also connected directly to the cell-capacitor negative.

The power supply voltage is not critical in this instance, but using higher voltages will allow greater flexibility when you build the system larger.

Here's how you adjust it. Make all your initial adjustments with your scope across the inductor.

1. Set your PWM duty-cycle and frequency to their minimum settings.
2. Gradually turn your duty-cycle (ON time per pulse) up until you reach the point where you see the top of the waveform becoming a DC "flat-line". Then back off the duty-cycle to get rid of that DC line. This is your ABSOLUTE MAXIMUM position for duty-cycle before the system starts wasting power. Mark it and don't ever exceed it.
3. Leaving the duty-cycle at the max setting, turn your frequency up gradually reduce the space between the pulses on the scope. Get the frequency as high as you can without letting the pulses overlap. This is your ABSOLUTE MAXIMUM frequency setting. Mark it and don't exceed it.

You should now see some gas being generated. You can place an ammeter in series between the capacitor and the cell plate to monitor cell amperage. If your cell is getting hot, back off on the frequency a little. Keep backing off until you don't see any cell temp increase. This is the most efficient gas production point.

If you want to further increase your gas production efficiency, find a way to introduce EXTERNAL warming of the cell(s) while they are running in this thermal "sweet spot".

4. Don't automatically believe most of what you read on the web about hydrogen production.

Try it this way and you'll see that most of those so-called hydrogen "experts" are overlooking some very basic principles in their haste.

For expanding the system, make more cells just like the first, with a single capacitor across the plates. Wire the cells in SERIES. Connect the positive pulse-supply output to the topmost cell positive and the supply-negative to the bottom-most cell negative.

Each cell needs a minimum of about 2 volts. So, for a 12v supply, use a max of 5 cells in series. This gives you a tiny bit of voltage overhead to account for resistance anomalies that might crop up from time to time in the cells.

Most important, don't blow yourself up. Homemade hydrogen and oxygen are dangerous toys.

I still believe you're better off just buying lots of batteries and storing your power in a relatively safe ionic solution. Easier to use this way too.

[Hydrogen](#)

Why do only the big guys get to hydrogen fuel cell?

Hydrogen fuel cells are quite the buzz. I like the idea of having water coming out the tail pipe at home or on the road. I am learning about hydrogen fuel cells now and the first thing I have learned is they cost too much. This problem of the right kind of electrolyte for the cell seems to me just couldn't really be THAT big a deal. But it is stopping the show. Can anybody out there help?

I am an injection molder with time on his hands ( made in china has helped that! ). If a polymer with a Ph around 14 can be formulated it could be a start. If that polymer could be compounded into a thermoplastic we could make plastic batteries. It is time to get the thinking cap on.

Chirp

([User Info](#))

yes, they are exciting, and damned expensive.  
And that's not counting the cost of the hydrogen, ahh but they don't have to run on hydrogen alone, the different types of fuel cells (FCs) can run on a variety of fuels, including a quite common fuels. And at the time of the impending shortage of crude, and natural gas, we will be able to change the fuel. Hate to say it, but FCs should be used for baseline power generation way before they will effectively be used in mobile applications (something about the various materials expanding and contracting as the FC is turned on and off). The increase of efficiency (FC = 70%+ ) over coal (40%) and NG (50-60%) powered generation will be the driving force behind adaptation.

the earth has finite resources, let our legacy not be of stupidly using them!

Hi All,

Dont really want to burst anyones bubble, but lets face it the Hydrogen economy is Quite laughable... Ya water coming from the tail pipe is nice, but at what price? lets just drain the oceans... its not like water is more important than Oil or anything... Besides what about the residues from electrolsis? thats pollution isnt it? By the way, has anyone really contimplated how much energy is required to liquify gassious hydrogen to liguid, anyone really know how cold liguid hydrogen gets? what about energy for electrolsis??? You can use the stuff all you want, but I wont..

I want to make it clear this is my own opinion....

by TomW on Mon Nov 3rd, 2003 at 09:33:13 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

its not like water is more important than Oil or anything

Amen to that.

Hydrogen is kinda neat but it does not spontaneously appear in the tank. Energy is used to make it. Its great stuff for, say, a space station where power density is important but on earth and for day to day power needs its well in the future. In general you still need to use carbon based fuels to get hydrogen so its just s different way to use the same resources.

In the future water will be far more difficult to find in a usable form than fuel and quite a bit more essential to life as we know it. Better to invest in stillsuits than hydrogen generators.

Again just one mans opinion.

Cheers.

TomW

by DDT77 on Mon Nov 3rd, 2003 at 10:46:55 AM MST  
([User Info](#))

guys,

its not like the "conventional" energy sources don't require water for conversion into usable sources.

ex:

[http://www.fhrpinebend.com/refinery/raw\\_materials\\_detail.asp](http://www.fhrpinebend.com/refinery/raw_materials_detail.asp)

I would have to argue that use of 2/3 of a gallon of water per gallon of crude oil is significant.

A lengthy report of the current state of fuel cells (and associated technology) can be found at:

<http://www.seca.doe.gov/tutorial/pdf/FCHandbook6.pdf> (451 pages, ~6.5MB)

this will show that FCs are still in their infancy, and that they don't have to run on H2 alone.

And for baseline generation- condense the water and the cycle begins anew.

regards,

darren

([#5](#))  
by JW on Mon Nov 3rd, 2003 at 01:01:53 PM MST  
([User Info](#))

Tom W,

I could'nt agree with you more. Water is indeed a precious resource.

DDT,

/and for baseline generation- condense the water and the cycle begins anew./

Indeed water is the major by product of fuel cells. However for a fuel cell to work effectively, water as humidity must also be introduced to the fuel cell. I am certian this allows the actual figures to be fudged somewhat. I guess what im trying to say is when you "crack" water molecules it is an irreversible process. The actual "subtraction factor" is like 95%, so if you start out with 100 gallons of water then electrolisize it you get so much hydrogen, take this hydrogen pump it into your fuel cell, minus the "whole" water introduced for humidification, and you get some thing like five gallons water back. DDT, you are infering the cycle approaches perpetualablity, this is just not true. there is no such thing as a free lunch. By the way yes they do use water for refinment purposes, however it should be confused with "cracking" the water molecule, as is done to produce hydrogen. Lets not forget about sticometry here, all fossil fuels release water and carbon dioxide thru proper combustion. So, how much water is in a gallon of propane, the only way to release this water is thru combustion.

I do recognize the advantages of reformer technology, and thru this methodology the mean efficiency may be increased over what is currently possible with internal

combustion technology(IC) so there you go, both will emit water as an emission.

Re: fuel cell and hydrogen generation ([none / 0](#)) (#6)  
by DDT77 on Mon Nov 3rd, 2003 at 11:09:55 PM MST  
([User Info](#))

JW,

What you seem to be saying is that stoichiometry doesn't apply for FCs but does in combustion. When you say that we get say 5 gallons back from the 100 gallons of electrolyzed water, where did the other 95% go?

Irreversible process? What is combustion of  $2H_2 + O_2$ ? I would have to argue that this is the reversal of the process of electrolysis, and fuel cells use an electrochemical instead of the chemical reaction of combustion.

And the 2/3 of gallon used per gallon of crude oil I wrote was just that (the amount of water that is used in the process of refining crude oil) not that of the equivalent water content of the crude oil. What the point of that was that when we look at the amount of water that is used in electrolysis to generate  $H_2$  (and have to take a step back) we should also be aware of the amounts of water that is used elsewhere in other (competing?) technologies and processes that are used to transfer mechanical <---> electrical <---> chemical energy(ies) to their more convenient forms.

If I understand you correctly, what you are referring to is the use of water in the reformation of whatever (non-  $H_2$ ) fuel may be used.

What I was trying to get across was that especially for the more promising technologies (SOFC) the fuel is broken down into the components that are usable by the FC at the high temperature of FC operation.

hell, in a couple more posts we might even be on the same page,

hope this clarifies my previous posts,

darren

Re: fuel cell and hydrogen generation ([none / 0](#)) (#7)  
by JW on Tue Nov 4th, 2003 at 07:45:19 AM MST  
([User Info](#))

DDT77,

Ya, I was referring to "PEM" type fuel cells. However you are correct the "SOFC" fuel cells do show much promise. I am especially exited about about the hybredization process thats occuring now, with them, regarding the adapation of thermopiles, utilizing the "SeeBeck Effect" and the "Pyroelectric Effect". Believe me I'd love nothing more, than to see some large cooling fins, or water jackets, and radiators on these proposed new units.

Just as I would'nt want someone stifling my research, I dont want to do this to someone else's. But at times we must be critical.

Any experimenters out there?

Is anyone out there doing anything with do-it-yourself hydrogen generation and storage? I've built a small electrolyzer that runs off a solar panel. It bubbles away quite nicely, but I'd like to talk with people who have figured out some good ways to store it.

Tom

Hi Tom,

I've played around some with hydrogen generation. The best way (electrically) I know to make it uses stainless steel pipe in varying diam. all inside each other, but insulated from each other (I used short pieces of vacume tube for spacers). Then there's the center electrode (also stainless) and the baking soda (sodium bicarbonate) water solution.

Big rubber pipe caps (at Lowes, etc.) make great top and bottom. About 4 neg. electrodes (the outer pipe is also an electrode and where the neg. wire goes) seems to give the best efficiency. Seems like such a unit would make about 1-2 liters/min. of hydrogen and oxygen gas from 12 volt dc at 7 amps input and will run continuously for days, weeks? at this output. As for storing it, Mazda has a tank with something in it that absorbs hydrogen, but takes a little heating to get it to release.

Kevin

by wpowokal on Mon Oct 6th, 2003 at 06:17:21 AM MST  
([User Info](#))

what you need is a large blader, like a weather baloon.

Hydrogen's ability to escape is relative to the fact that it is some 50 times less dense than air, that is all.

Re: Hydrogen Generation ([none / 0](#)) (#7)  
by troy on Mon Oct 6th, 2003 at 02:52:02 PM MST  
([User Info](#))

Storing H2 is interesting for a number of reasons.

1. very light buoyant molecule
2. very small molecule, 16 times smaller than O2 molecule. it can leak through the pores of sheet metal unless special precautions are taken. If you think metal doesn't have much pore structure, ask a welder who is trying to heliarc a piece of oil soaked aluminum. Oil molecules are enormous compared to H2, yet they manage to penetrate aluminum for some distance.
3. the range of flamability of H2 is amazing. Methane (natural gas) by comparison has a very narrow range, it has to be a very particular fuel/Oxygen ratio range or it won't burn. H2 will burn at almost any fuel/oxygen ratio. That's what makes electrolysis fussy, it's hard to trap the liberated hydrogen without getting a little oxygen in there also, thus making the mixture explosive.

Not that it can't be done, it just wants to be done right.

www.homepower.com has several back issues with very detailed descriptions of H2 setups.

Good luck and don't blow anything up you don't mean to!

troy

A weather balloon would be fairly inexpensive. It's time to check out eBay, I guess. One thing that's becoming apparent is that H2 production is a good thing to do with solar panels because it occurs even when it is cloudy.

I think low pressure and short-term storage will help cut down on the losses. The idea is to use H2 as an energy storage medium instead of a battery.

When I was a kid, my parents wouldn't buy me a dog so I turned to a life of making Hydrogen. One of the best ways to store the stuff is trapped under water. Hydrogen has a hard time penetrating water.

John

Re: Hydrogen Generation ([none / 0](#)) (#10)  
by troy on Tue Oct 7th, 2003 at 04:39:39 PM MST  
([User Info](#))

I have seen photos of two different low pressure methods:

Big truck inner tubes, all tied together with a weighted board on top to provide a few inches water column pressure to feed it to the stove. The other system used a cylinder shaped tank, closed at the top, open at the bottom. This fits inside a second tank that holds water. As the H<sub>2</sub> enters the movable tank, it rises and provides modest pressurization. It had several weights on the top to provide more/less pressure and a cable/pulley attached to the top to adjust the counterweight and keep it nice and vertical.

Good luck and have fun.

troy

by TomW on Tue Oct 7th, 2003 at 07:28:26 PM MST  
([User Info](#))  
<http://oneota.net/~earthsourcepowr/>

Troy;

I tried both of those methods on my methane digester and both worked pretty well. That was very long ago. I adjusted the weight to get a good burn on the range we burned it in. Admittedly methane is not hydrogen but the principle is the same. Took forever to turn pigstuff into burnable gas in any quantity but it did work. The tractor tube developed leaks pretty quickly but was not new. The inverted water heater tank in a barrel of water seemed better long term and never gave any problems. Plus, if I recall correctly the bubbling the gas through water acted to purify it of some ugliness like sulphur or??

The first question to be asked will be how big / how much gas etc. All I can remember was about a 300 gallon stainless steel milk bulk tank as the digester and adding pig manure as it reduced in volume. Once it got working good it made enough gas to use it a couple times a day to cook with. Had pigs right on the place and all the waste I wanted to haul from the

manure pit under the confinement building. If you have the "feedstock" I think methane is pretty easy to pull off and seems to work fine in gas equipment set up for propane. I simply scaled plans I found in a Mother Earth News circa 1972 or something.

Cheers.

([User Info](#))

I remember that Mother Earth News article. I was thinking about an inverted drum for hydrogen storage, but I'd want to keep it outside and I'd somehow have to keep it from freezing in the winter.

I've read how methane can be produced using hydrogen and carbon monoxide and offers several advantages over pure H2. Hopefully it would be a little less noxious than the original method that used chicken or pig sh--.

## [Water wheel and 12 or 220 volt?](#)

By [Anonymous Hero](#), Section [Homebrewed Electricity](#)  
 Posted on Wed Jun 25th, 2003 at 07:06:45 PM MST [Hydrogen](#)  
**Water wheel and 12 or 220 volt?**

Greetings People,

I have a fishing camp on the banks of the Zambezi river in Africa. We want to put in a water wheel to drive an alternator or similar. Could anyone give me some ideas on what would be best. The speed of the water is approx 5 kilometers an hour but there is tons of it, the river is about half a mile wide :-). Revolution speed of the water wheel will be slow but we can make the paddles any size and therefore generate any amount of torque. However, we don't want to build a monstrosity. Lastly, i don't have any idea on what size wheel i would need to build so that we could drive a 1Kva 220 volt alternator. If anyone has experience with this, any help or clever ideas would be greatly appreciated.

Thanks

Dave Adams

Homepower magazine has published a couple of articles describing similar installations. You might find the info on their website:

[www.homepower.com](http://www.homepower.com)

(it's a great website anyway by the way)

or you might have to purchase a back issue on cd to get all the details.

Best of luck,

troy

There's a micro turbine group on Yahoo, if I recall correctly that can probably refer to a web page that would answer your question. If you only need 1kw (1000w), it shouldn't need to be very big (I'm thinking 6 ft. diameter, not very wide, just off the top of my head). I've been looking other types of water powered generators, so I don't have the formulas for your situation, but they are out on the web.

If you need 1kva, you'll probably need to generate 1500-2000w to allow for losses. Do you have the 220v alternator? If you don't need 12v, then I would generate at 220v - you can use much smaller wires or make much longer runs from source to load. HTH, Russ

12 v pump or inverter

Hi there,  
I`m living in the north of Germany building my first genny.  
My question is is there a 12or 24 V DC Water Pump for my well (26 ft deep)wich give me water pressure for garden watering.  
Or is it better to use a 220 V inverter (really pricy).

Thanks a lot Armin

simple is always best, given my choice of the three I would pick 24V.

Dr.D

How many and where?

My question for everyone is with a completely off grid system in central maine how many surge suppressors and where do i need them for lightning protection? I have a dc disconnect for the panels and charge controller i figured one there. and i have a main 120 panel and i also have a 240 volt panel from the generator that ties into the inverter should there be one there or is it overkill? and i also have a auto transformer for a deep well pump i was told i should have one there to? what is everyones opinion?

[Lightning protection](#) | 3 comments (3 topical, 0 editorial)

Re: Lightning protection ([none / 0](#)) ([#1](#))  
by [drdongle](#) on Sun Dec 21st, 2003 at 11:20:39 AM MST  
([User Info](#))

If you have a wind turbine there you definitely want to ground the tower, and add arrestors to the incoming lines. Any equipment that is exposed out side, particularly if it is elevated or near high objects needs to be grounded, if possible and have arrestors.

Dr.D

Re: Lightning protection ([none / 0](#)) ([#2](#))  
by [charged](#) on Sun Dec 21st, 2003 at 11:57:34 AM MST  
([User Info](#))

As another addition, just for the sake of greater system integrity, consider a heavy DPDT flip switch with the incoming power tied to the center. "Up" goes to your charging system, "down" shunts the outside genny line into a low impedance liquid dead-load with a good earth-ground.

That way you can completely isolate your system when thunderbangers come through and still have some loading on the generator.

I Have a Trace inverter it is a sw2524 my question is

I Have a Trace inverter it is a sw2524 my question is it has a generator input and i was wondering if you could tie that int a modified sine wave inverter to charge the batteries? the reasin i ask this is i spend a lot of time on the road and my truck has 4 deep cycle batteries and a xantrex inverter set up that charges right from the high output alternator. seemed like seing that it runs a lot of miles anyhow i could use some of that power for my house? what do you think sound feasible or hal brained?

[Inverter Questions?](#) | 2 comments (2 topical, 0 editorial)

Re: Inverter Questions? ([none / 0](#)) ([#1](#))  
by [gps](#) on Mon Nov 24th, 2003 at 06:53:26 AM MST  
([User Info](#))

I've tried that with a UPS and a SW4048. The AC2 in light flashed indicating it recognized the input but never went solid, which would indicate it had synchronized with and was happy with the input. I don't know why it didn't work but it didn't. Your mileage may vary.

Maybe someone else will have more info.

Re: Inverter Questions? ([none / 0](#)) ([#2](#))  
by [troy](#) on Wed Nov 26th, 2003 at 12:36:26 PM MST  
([User Info](#))

The real problem is not technical, but economics. Any electricity you make from your truck, even if diesel, will cost you more in mileage than the grid will charge you per kilowatt hour. If you're off grid, and you make all your electricity, then your idea has some good potential.

Good luck and have fun!

troy

## [Possible Inverter](#)

By [RogerAS](#), Section [Homebrewed Electricity](#)  
Posted on Mon Nov 17th, 2003 at 10:46:45 AM MST

[Inverters](#)

Hi All,

Recently there was a thread here where someone was using mechanical switching and a stepup transformer to make an inverter.

Couldn't one use a battery bank, series wired, to get 120V DC to start with, and thus eliminate the stepup transformer. Then all one would have to do is switch polarity on a 60Hz basis. It seems that with the right balance of capacitance it would be fairly simple to achive sine wave output to the AC side.

Now, it seems to me that if a 4 brushed common shaft were spun at the right speed the iversion could be done with a very small motor. I mean the spinning could be set up to direct power one way then the other. I must be missing something.

RogerAS

Re: Possible Inverter ([none / 0](#)) ([#1](#))  
by [Budgreen](#) on Mon Nov 17th, 2003 at 11:28:24 AM MST  
([User Info](#))

series wires 120v dc battery banks are quite common for large inverters. I know a person with one that's a 10Kva ups that uses 120Vdc for the input.

as for that form of switching (chopping) is quite easy in theory, but the voltage will drop from 120v under load.. plus the switching would need to handle X ammount of amps which is usually not a small task.

Re: Possible Inverter ([none / 0](#)) ([#2](#))  
by [bob golding](#) ([yubba at clara dot net](#)) on Mon Nov 17th, 2003 at 12:59:20 PM MST  
([User Info](#))

if you not trying to change voltage it is fairly easy to do dc to conversion using silicon. a h bridge inverter using IGBTs would work and is 99% effcient.

bob

Hi Bob,

What the heck is an IGBT? Also I've never heard of an H bridge, but then again I'm pretty ignorant!

RogerAS

([User Info](#))

IGBT Insulated Gate Bipolar Transistor  
it's similar to a fet, basically a transistor with an insulated base, they can handle up to multiple kilowatts of power

and H bridge is a configuration of FET's or IGBT's usually that form an H, I don't have a picture handy but a quick google of it should turn one up fairly fast.

## [Mechanical DC - AC convertor experiment](#)

By [Junkie](#), Section [Homebrewed Electricity](#)

Posted on Sun Nov 16th, 2003 at 03:20:43 AM MST

[Inverters](#)

DC - AC convertor using a solenoid oscillator

See my page:

<http://www.akuma.dsl.pipex.com/chris/dctoac.html>

It makes a quit hum, and some really small sparks across the solenoid switch. Ouput voltage was measured at 241 Vac.

It should have really been in a closed box but...

Have fun,

-Chris

[Mechanical DC - AC convertor experiment](#) | 16 comments (16 topical, 0 editorial)

Re: Mechanical DC - AC convertor experiment ([none / 0](#)) ([#1](#))  
by Norm on Sun Nov 16th, 2003 at 07:59:54 AM MST  
([User Info](#))

It's neat, now just add a switch on each end that sends current thru the transformer one way then reverses polarity at the other end of the stroke have some adjusting screws so you can adjust the frequency to about 60 cycles.

Back in '56 they had power inverters with a oscillator in fact even car radios had ocllators to step up the voltage to about 45vdc for part of the tubes a little later they came out with 12vdc tubes to eliminate the ocllator in cars.

I got one of those power inverters to run my 45rpm record player (110vac.) figured where to put the input into my push-button, non-station-seeking radio and had the only '56 Chevy around with a record player in it!  
Watch the bumps, worse than a cd player without anti-skip!  
the power inverter had a schematic(wish I had even just kept that)  
Its a nice project tho' I like the stirling engine project even better.Please don't take any of this as sarcasm....just an old man reminising about the 'good ol days' (:>) Norm.

Norm

Throes were the days Real radios glowed in the dark.  
And a fellow could make a good living repairing just car radios.  
As most repair men did not want to mess with them.

We called them multi vibrators. I still have one or two in a junk box some where.

Old F

Ah, ok that is one way of doing it... Another would be to hook a  
transistor to where the solenoid/switch is now and you would have  
no noise or interference and no arcs... But it's a good starting point  
and shows how to convert that DC to AC easily.  
I wish you good luck and keep up the experimentin...

iFred wrote : "Another would be to hook a transistor to where the solenoid/switch is now and you would have no noise or interference and no arcs"

I'm not sure its possible to make an oscillator with a single transistor.

Anyway I built that just to see if its possible to build a cheapo inverter without transistors, oh and I like sparks too :)

Sure you can, just apply a little feedback from the secondary ( with appropriate resistance to reduce the voltage) and you'll have a fine 1 transistor oscillator/upverter.

Very close though I would add an additional resistor between the base and ground then ground the top lead on the transformer secondary. Your current resistor should be fairly large and the grounded one fairly small ( so as to form a voltage divider) something on the order of 100K ohms and 1K ohms so as to give a 100:1 ratio. You may also have to try reversing polarity of one winding and fiddle with the resistor values. too much voltage on the transistor will destroy it. Also keep in mind that the transformer primary will determine how much current the circuit passes so chose a transistor with the appropriate power handling capabilities.  
IE:  $I = E/R$  and  $E \times I = P$  ( watts)

Dr.D

I'm certainly no expert in the field of electronics but it seems to me I remember playing with something in that form using a capacitor, resistor and a center tapped transformer. I'd have to dig out some papers to find it but I was driving flourescents with it. One of those fun things to do...

by RobD on Mon Nov 17th, 2003 at 06:23:44 AM MST  
([User Info](#))

The limitation is that the transformer saturates with a low frequency square wave but it's a good start. Go to MOSFETs or IGBTs next and then use different core material. E77 from Amidon is good.  
RobD

([User Info](#))

I personally haven't found any easy ones Ray. I was going to design one myself but now the prices seem to be falling so I'll wait on it. The technology is out there and getting better everyday. If you can program AVR microcontrollers go to the Atmel web site. You'll see it's quite extensive and costly. For what it's worth I think you can build a 'stepped' inverter with about 8 steps in each half wave that will work close to the pure sine ones with a lot less electronics. I may do one of those and post the circuits.

I wondered if 'magic sine waves' as promoted by Don Lancaster @ <http://tinaja.com/magsn01.asp> might be an easier approach. They are supposed to be microprocessor friendly and suitable for inverters.

Here's a brief description taken from Don's psge: "Magic sinewaves" are repeating long sequences of ones and zeros. They can get created from ordinary but extremely carefully chosen digitally switched pulses.

Digital sinewaves with precisely controlled amplitudes and amazingly low distortions. Compared to traditional PWM, magic sinewaves can offer far higher efficiencies and lower distortions. With circuitry that is elegantly simple and microcontroller friendly.

([User Info](#))

I've been thinking that this approach--Magic Sine Waves--would be awesome for inverters, but have never seen it implemented. The I2K inverter I previously posted is the closest, but all he is really doing is lengthening the pulses to do power factor compensation. Wish someone would develop one.

maybe <http://www.technology.niagarac.on.ca/people/mcsele/i2k.htm>

not a true sine-wave inverter

Re: Sine wave inverter ([none / 0](#)) (#3)  
by RobD on Mon Nov 3rd, 2003 at 06:06:52 AM MST  
([User Info](#))

Thanks Kmitchel,  
I have just looked at this page and the inverter. It is basically a low frequency square wave inverter. The two transformers are driven at 60 Hz in much the same manner as a class AB audio amplifier. There is nothing wrong with this approach excepting that AB amps have relatively low efficiency (75% at best). The low internal resistance of the MOSFETS (rds(on)) save the inverter from some real heat problems. Obtaining the transformers might also be a problem and I imagine they are quite expensive.

Re: Sine wave inverter ([none / 0](#)) (#7)  
by kmitchel on Mon Nov 3rd, 2003 at 05:02:31 PM MST  
([User Info](#))

I believe it's more like a class D amp. The MOSFET's are either on or off. It would be nice to see this inverter further developed, but I am grateful the author posted the work he did do. As far as the transformers, maybe...<http://members.tripod.com/~schematics/xform/xformer4.htm>  
I was kind of surprised he used two in parallel. I think in any homemade high VA inverter transformers would be a problem. I kind of question how cost effective a homebrewed inverter is, and whether it's better in the long run to buy a commercial inverter. Maybe multiple small (cheap) inverters tasked to specific applications. And get a smaller true sine wave inverter just for the stuff that really needs it.

Re: Sine wave inverter ([none / 0](#)) (#9)  
by Budgreen on Tue Nov 4th, 2003 at 10:57:35 AM MST  
([User Info](#))

it could be fairly hard and not worth the time.. most inverter ups systems that have non-square wave outputs normally use a microprocessor to create the waveforms and do the rest of the inverter control. if you could read the software off it and recode it would be very possible but quite time consuming :)

on another note you could start and make a dc-dc converter first say 24vin 170v out.. pwm controlled, take a rectified 170v out and run it to an H-bridge, control the H bridge with a 10-25khz pwm signal modulated by a 60hz stable sine wave, then filter the output of the H-bridge to remove the 10-25khz pwm frequency and your left with a nice sine wave output at a high efficiency.

I have been trying to come up with a good dc-dc converter information to try and design a 24v-170v converter (that in itself is easy, just getting it to put out 10-20A is the hard part) so if anyone could help in this arena I may have schematics available by the end of the year :)

Didn't see this option mentioned: ([none / 0](#)) (#10)  
by TomW on Tue Nov 4th, 2003 at 12:10:01 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Folks;

This is not new at all but have any of you considered just driving an induction motor at its generating speed [with caps added] by using a dc motor from your batteries perhaps with some form of speed regulation?

The output from an induction motor would be the purest of sinewaves.

Just another way although mechanical it would work.

Cheers.

TomW

Re: Didn't see this option mentioned: ([none / 0](#)) ([#11](#))  
by Budgreen on Tue Nov 4th, 2003 at 12:47:05 PM MST  
([User Info](#))

that is indeed a feasible idea..

but the concern would be how efficient would (say a 5hp) dc motor be? plus the current draw of the motor unloaded to spin the induction motor with relatively little load?

using 250W of power to spin a motor to run a 50W ac load might not be reasonable

(wattages just guesimated as I have no source to back it up)

National makes a CLASS D amp chipset that I am going to base my Sinewave Inverter off of ,and I have a chip to make the 60hz sine , this will drive the CLASS D amp which will drive H-Bridge modules that will handle 5k watt each, need another 5k just add another module and mine will put out 220v just like the power co , when I am done I want to be able to do 40k watt also the controller will turn on output modules based on need, only need one running , then only one will be on , turn on something that needs 2 then it will enable 2

I could also make them on 1k modules

Jim Thank you for the info I'm new at this wind & solar system. I'm going to use 8 ga wire to the battery bank, it will about 30 ft from the battery bank

[ [Parent](#) ]

Re: inverter ([none / 0](#)) (#3)  
by [jimu](#) on Sat Nov 1st, 2003 at 04:20:27 PM MST  
([User Info](#))

Ok..Now I have a bit more to work with..

Since we have no idea of the size of your inverter, and the capacity of your bank, I will go with what I have set up..

I use a Trace DR1512 inverter, which is 1500 watts at 12 volts, and the inverter is mounted directly above my battery bank , which consists of 6 Trojan T-105's.

I use two 3.5 foot lengths of 00 guage cable to connect to the bank from the inverter..

Unless your inverter is going to be under, say 600 watts, I wouldnt use 8 ga. and definely not 30 feet from the bank..your losses would be tremendous..

You want the absouletly shortest length from the inverter to the batts, and the largest

guage wire you can afford or work with.

Now, there is an exception to this rule, and that is some people use small inverters for each room, running large guage DC runs from a central battery bank to each inverter

in the house..I have done this some years ago with some small inported inverters, one in the bedroom, and one in my living room, and work fine for the small loads.

There is quite a bit of info out there on the net, and a google search of "inverter wiring" yielded over 400 hits, some of which will answer your questions in more depth.

Hope this helps,

JimU

Re: inverter ([none / 0](#)) (#5)  
by DanB on Mon Nov 3rd, 2003 at  
01:06:28 PM MST  
([User Info](#))

30' of AWG 8 wire is not good for a 3000 watt inverter.... not good at all!  
You need lots less distance and very heavy wire! Keep in mind, your inverter could draw over 200 amps from the batteries!  
What you have there now is good for about 1/10 that..  
Your inverter will almost surely shut down if you put a significant load on it, and that wire might get dangerously warm.

[ [Parent](#) ]

Amen to that! ([none / 0](#)) ([#6](#))  
by TomW on Tue Nov 4th, 2003 at  
08:41:04 AM MST  
([User Info](#))  
<http://oneota.net/~earthsourcepowr/>

Dan is absolutely correct. Inverter to battery wiring needs to be relatively massive wire to be safe and efficient or even work at all in some cases and certainly if more than a few feet between the batteries and the inverter.

Cheers.

TomW

### [Question about dc to ac inverters](#)

By [camp185](#), Section [Homebrewed Electricity](#)  
Posted on Thu Oct 30th, 2003 at 12:33:14 AM MST [Inverters](#)  
[Question about dc to ac inverters](#)

Howdy,

I have a question about DC to AC inverters...When I finally connected my inverter to my battery I came across something that I never calculated. That when my inverter is on it uses energy whether something is plugged into it or not. My question is this. Is this the case with most small inverters, say under 1000 watts? I have a 400 watt with 800 watt max, and according to the directions it uses .6 amps while it is on. Seems kind of like a lot to me...it has a fan. Are there some that use 0 amps while left on?

The reason I ask is because I have a bunch of itmes that run on timers that I would love to plug into an inverter. Sucking up over 14 amps a day just to leave it on doesn't sound to practical. Any help?

Rob

there are inverters that have no load amp draws lower than .6A some also have a "sleep mode" which reduces the amount of power the inverter requires when nothing is running ever further.

Re: Question about dc to ac inverters ([none / 0](#)) (#3)  
by Adrian L on Thu Oct 30th, 2003 at 05:35:07 AM MST  
([User Info](#))

Just to let you know, The no load current draw on inverters varies a lot, some cheap chinese inverters can use 2 amps at 12 volts when not powering anything...

Normally the bigger the inverter capacity the higher the no load current will be, I believe this is due to more higher powered components needing to be 'powered' ready to go all the time, and stray inductance in the higher powered transformers.

The more expensive ones have automatic shut down, and automatic restart when a larger load is detected, but this will not suit your situation with the timers because the timers will stop timing!

Inverters I've owned for reference:

a 1200 watt modified sinewave inverter, it had high load triggered fans, so it only used 0.3amps while on and not powering anything....

a 250 watt pure sinewave inverter, it was a 24 volt model, and also had load triggered fans(heavy load triggered), uses 0.16 amps when not powering anything (I used to leave this on day and night)

a 330 watt 12 volt modified sinewave inverter, this one ran it's fan constantly and used about 0.35 amps

Cheers,

Adrian L

Re: Question about dc to ac inverters ([none / 0](#)) (#4)  
by veewee77 on Thu Oct 30th, 2003 at 05:46:53 AM MST  
([User Info](#))

You could make a small circuit that puts the fan on a temperature switch that nly turns the fan on if the heatsink gets above a certain temp. That would lower the "dead" current. Or you could add a current level sensor on the output line and make the fan come on only with a certain amount or more of output current. The inverter won't get hot unless it is driving a load above a certain amount. With trial and error, you could figure out the level where the fan needs to come on.

just my \$.02 and worth every penny!

DS

Worth a lot more than 2 cents to me....

Knowing my wonderful ability to take things apart and DESTROY I thought twice about your idea. Then it gave me a great idea, or at least I think, it's one I can handle anyhow. Simply install a toggle switch for the fan. I am sure the inverter can keep cool enough while cranking out the power for a digital timer, and when the timer goes off the units only need high power for a few seconds (sprinkler system). Then when I want to crank on the lights or computer I just flip the switch and the fan kicks on keeping it nice and cool.

Thanks!

Anyone out their...let me know if this is a bad idea...

Rob

Re: Question about dc to ac inverters ([none / 0](#)) (#5)  
by Norm on Thu Oct 30th, 2003 at 07:11:04 AM MST  
([User Info](#))

Aren't the timers using 110 volt electricity anyway, (unless it's a quartz battery operated timer) or if you had a mechanical wind up timer that would turn on the inverter and whatever at the same time.....  
Ever notice how much a 'wall wart' uses times 4-8 ?(:>)  
Norm.

(Just a glance back.)At one time they had spring-wound clocks for cars whereupon every few minutes a 6-volt solenoid would rewind the clock. ('38 Chevy Special Deluxe)  
Wonder how much of an amp. that used in 24 hrs.?

Re: Question about dc to ac inverters ([none / 0](#)) (#8)  
by RobD on Thu Oct 30th, 2003 at 03:27:53 PM MST  
([User Info](#))

What you're talking about is idle current and inverter manufacturers usually state this in their specs. .6 amps idle current is about normal and when you think that a 12 volt 1500 watt inverter is drawing 125 amps at full load that's not bad.  
RobD

Re: Question about dc to ac inverters ([none / 0](#)) (#9)  
by Adrian L on Thu Oct 30th, 2003 at 07:56:19 PM MST  
([User Info](#))

Yeah i've added a switch inline with the wires to the fans on my 330 watt unit, worked just fine with it switched off, and would not even get warm without the fan up to about a 100 watt load!

Cheers,

Adrian L

DC Timer? ([none / 0](#)) (#10)

([User Info](#))

One of my -future projects- is a stand-alone Solar powered freezer. The -brain- of the system will be the low-voltage thermostat. This thermostat will turn the inverter on until the freezer reaches a particular temperature. It will then shut-off and wait for a time interval. If the freezer needs to be turned on - the upper limit switch, it will turn the inverter back on. If not, it will go back to -sleep-.

There could be more instructions to the system, such as add more intermittent machines and cycle them so only one large one or several smaller ones would run at the same time. System conditions could be monitored so non-essential items would only be run when the reserves were available.

I know one of the new small low power chips could do all of this on a few milliamps. I guess I'll have to learn how to make them work.

Ron

### [Cobra Power Inverters for sale](#)

By [onyx](#), Section [Classifieds](#)

Posted on Sun Oct 26th, 2003 at 07:02:49 PM MST [Inverters](#)

For Sale: Cobra Power Inverters, 1500 watt, and 2500 watt Continuous

I have the following Cobra Power Inverters for sale, Brand new, in box, factory sealed, never used:

CPI 2500: 2500 watt continuous, 5000 watt peak. New improved model. For more details go to product website, [CPI 2500 at Cobra.com](#). Selling for \$220, plus \$15 shipping to anywhere in the continental US.

CPI 1500: 1500 watt continuous, 3000 watt peak. This is also a new model that has been improved. Again, for more details go to product website, [CPI 1500 at Cobra.com](#). Selling for \$130, plus \$10 shipping to anywhere in the continental US.

[?s about converting dc to ac](#)

By [44toy](#), Section [Homebrewed Electricity](#)  
 Posted on Fri Oct 17th, 2003 at 03:56:35 PM MST [Inverters](#)  
 Posted this on the wrong board so I posted here to ( will try delete copy in magnets section)

O.k. I am trying to get my first system going, and no body around here can tell me if I am figuring my load correctly. Lets say these are the specs on an item. .72 amps (read with amp clamp,) 120 volts ac (read with my meter.)

I was using the following formula-

$$\frac{P}{I \mid V} \text{ ----- } A \times v = P$$

.72 X 120= 86.4 watts

then to covert this to a 12 volt dc amp draw --  $P / V = A$

$$86.4 W / 12 v$$

dc = 7.2 amps dc

I am using The total of the (basic items) dc amp loads + a 50% cushion for additions etc, to figure the amps my hydro powered generator will need to put out.

This may be confussing the electronic teachers at my college look at me funny and will not stand firm. My questions are--

1. Will this work to figure the amount of power I will need? I know I could simplify the process and any better conversion formulas would be nice
2. Will there be any drop other than the loss to the inverter? the main thing I am unsure of is using the formula to convert from dc to ac.
3. If you guys look at this and just have a funny look on your face, You can get the idea of what I am trying to figure and please HELP.

Re: ?s about converting dc to ac ([none / 0](#)) ([#1](#))  
 by [RobD](#) on Fri Oct 17th, 2003 at 04:28:11 PM MST  
[\(User Info\)](#)

The first problem I see is that you are mixing AC power from your meter that is not RMS and then figuring DC from it.

RMS power is the amount of AC that will heat a resistor to the equivalent DC power.

The formula  $P = E I$  gives the power and this is correct. You might want to measure the resistance of your load IF the load doesn't vary excessively when it is under a dynamic load. Once you know the resistance you can get the current by  $I = E/R$  and  $P = E I$  or  $P = I^2 R$  to get your power for your working voltage.

Your method will get you in the ball park though.

RobD

([User Info](#))

I believe I am with you on the statement (Once you know the resistance you can get the current by  $I=E/R$  and  $P=E I$  or  $P=I^2 R$  to get your power for your working voltage.)

But alot of the loads I measured are computer, television, vcr and other dumb stuff. And I dont think I can measure resistance on them? So all I have to go on is the amp clamp, and my measured voltage of the supply 120 volts ac.

All I need is a Ballpark since I am Trying to figure a 40% buffer and have no help local. -----thanks for all advice.

why not use an AC ammeter to determine your current draw? Or if you only wanted to be 'in the ballpark' you could just read the wattage on the back of the appliance that is in question. It is usually listed. RoyR

Re: ?s about converting dc to ac ([none / 0](#)) (#6)  
by 44toy on Sun Oct 19th, 2003 at 07:51:30 AM MST  
([User Info](#))

I am using a fieldpiece sc76 voltmeter with ampclamp to check the current draw of the loads i will be pulling (clamped on one wire of my test cord). I measured the volts by inserting the probes into the house outlet.

Readings for one load were .72 amps at 120 volts

I am trying to figure how many dc amps I will need power the loads. I am not sure The above formula is right because I have a limited undrsanding of power.

Re: ?s about converting dc to ac ([none / 0](#)) (#5)  
by wdyasq on Sun Oct 19th, 2003 at 07:45:11 AM MST  
([User Info](#))

I have found a few meters that might help. The Kill a WATT ; Watts and Watts up PRO and AC cost control all measure watts of 120 volt AC current. The Watts up and Watts up PRO record the surges. The Watts Up PRO has a computer interface so one can play with a spreadsheet and figure out just how much energy the tool or toy uses and how much it is going to cost to build a system to handle it.

The lesser meters run in the ~ \$30-\$40 range while the Watts Up is ~\$100 and the Watts up PRO is ~\$150.

For you mountain guys, the unit is only rated -Altitude up to 2000 meters - I guess one would need to drag the tools off the mountain to test them or - heaven forbid, risk breaking -UL listing-!

Ron

Re: ?s about converting dc to ac ([none / 0](#)) (#7)  
by jubalearly on Mon Oct 20th, 2003 at 09:02:44 AM MST  
([User Info](#))

The kill-a-watt meter works up to 15 amps and as long as you are close to 60Hz. Otherwise, your meter (DMM?) and clamp ammeter should be measuring RMS as long as you are close to 60Hz. It depends on the meter design and original calibration to give you RMS @60Hz & your meter may not be accurate.

I really like my kill-o-watt meter. I had to replace one that was used on a generator, tho. I think I can repair it. But, my point is that they increased the size of the input resistor (that burned up) from 5 watt to 10 ohm, 10 watt.

Re: ?s about converting dc to ac ([none / 0](#)) (#8)  
by charged on Thu Nov 13th, 2003 at 11:50:09 AM MST  
([User Info](#))

Call me crazy. But, why not just do the following..

1. power up your inverter with no load and measure it's "idle" power drawn from a battery.
2. Plug in each appliance and measure the increase in power drawn on the battery side.
3. Add up all the appliance power measurements and you'll have better-than-ballpark measurements.

All D.C. all the time.

Enjoy!

[use for ups's](#)

By [Budgreen](#), Section [Homebrewed Electricity](#)  
 Posted on Fri Sep 26th, 2003 at 09:03:57 AM MST [Inverters](#)  
 what can be done here....

Before to long I will be getting some old ups's (660va and 720va) and either the charging section or scr controller in these units is bad and basically unrepairible but the actual inverter section is good, what good use could I put these units to work doing? I do have a large battery bank but that is reserved for future use at the moment. within the next month I will have up a small windmill to provide power for them, just loking for an interesting use.

[use for ups's](#) | 3 comments (3 topical, 0 editorial)

I use[d] one as an inverter for a long time.. ([none / 0](#)) (#1)

[\(User Info\)](#) <http://oneota.net/~earthsourcepowr/>

Budgreen;

I used an APC brand 650 UPS very successfully for several hours a day for about a year as an inverter. It worked beautifully but finally died a couple weeks ago.

One note that i will make is that it got awfully hot when drawing 20 to 25 amps continuously which more than likely contributed to its failure and also is wasted power.

They are not designed for anything but intermittent short term use. You will want heavier cable from the batteries to the internal cable than they use from the factory to connect to the batteries also.

Add a cooling fan if at all possible such as a computer fan.

I had to trick out the buzzer and you need to press the "test" button to get it to fire up without grid. Considering it was a dumpster find I felt it did well as an inverter. I have used them for years when camping in the RV where there was no juice bush, too.

Cheers.

Folks;

That comment reminded me to dig that UPS out and look into the problem.

What I found is a first for me that I can remember in 30+ years of electronic work.

2 of the power resistors had gotten so hot [no cooling fan] that they became unsoldered and were lying in the bottom of the case. Pretty darned weird. If i can get to it I will be soldering them back in and adding a cooling fan to get rid of that heat. The PC board in there is at the top of the case with all the components hanging down and the traces up with about 3/8th inch clearance to the cover.

Considering they are only designed for intermittent short term use it is amazing it lasted this long running about 5 hours regularly at pretty much full load plus.

Again it was a dumpster find so no loss if I can't get it working again plus its a goldmine of parts too.

Just passing on the experience. If you intend to use one as an inverter I highly recommend a fan that kicks on when its running. You could modify the battery door to hold a fan easily without even pulling the cover. I will modify the top of the case for a fan because its off already.

Cheers.

TomW

([User Info](#))

Hi Budgreen,

I have two APC ups'es here and I did a bit of playing around to see what I could do with them. They are rated at 650VA and 800VA. I was hoping to dedicate one to running a fridge.

I had no problem at all connecting directly to the UPS battery wires from a big battery bank and then switching on. They made a little beep every now and then but I didn't mind that (it was in the battery shed). It was also great that I was able to connect a serial cable to the UPS'es and read battery voltage (and lots of other not-so-useful stuff) - (I used apcupsd to read the UPS details).

I gave up though because when I switched on the fridge the ups would switch with over-current protection. Ok - I know that an induction motor draws a lot of current starting up but I think the computer UPS units are, perhaps, over-protected. Another thing to note is that VA does NOT equal watts in APC UPS land (maybe the VA is battery draw/charging and watts is AC output? I dont know) so a 800VA UPS only gives around 600 watts.

As usual I've found that the answer is to somehow get the cash and buy a new Inverter.

All the best,

Derek

## [12v-240v](#)

By [morgs](#), Section [Remote Living](#)

Posted on Sun Sep 21st, 2003 at 05:17:41 PM MST

[Inverters](#)

Current draw.

Hi all

I need to know what current draw I will have through a 12v-240v inverter. e.g 240v 100w light through a 800w 12v-240v inverter. Am I better off using 12v or 240v lights with energy efficient globes. I am building a remote home using solar and wind for power. I will have about a 600 amphr battery bank when I first start out. Will 240v lights, fridge, microwave oven,TV/video/DVD work properly off a modified sign wave inverter.

Thanks

Re: 12v-240v ([none / 0](#)) ([#1](#))

by [laskey](#) on Sun Sep 21st, 2003 at 06:04:32 PM MST

[\(User Info\)](#)

Well, you're always better off going through as few electronics as possible. Everything has losses associated with it. You're better off using DC devices, and only using an inverter when you have no other choice.

Of course, things change if you have high draw rates and long distances to run. In that case you're better off inverting near the battery and running the 240 to the high consumption device. For example, say your fridge consumes 1500 watts (it won't be that high, but say it is) at 12 Volts that 125 amps. You`d need some really expensive (and BIG) wire to deliver that to your kitchen.

Not practical. At 240 Volts AC the same 1500 watts is only 6.25 amps which will run on the same wire your house is already wired with. (for 240VAC I`m assuming you`re somewhere in the UK) Cheap, and easy. BUT, with an inverter you only get up to 95% effcient, so to deliver your 1500 watts you actually need to generate in excess of 1575 Watts.

As for the actual lights you asked about. Use the energy effcent ones whether you go AC or DC they use about a quarter of the power for the same light as the incandecent type.

Hope that helps some.

Cya,  
Chris

Good advice in the previous post, use as few "conversion" steps as you can between the batteries and the loads, It helps to place the batteries and load as close as possible to one another. Consider automotive florescent lighting, and 12VDC entertainment equipment, ( TV, VCR, Radio, etc). Consider a car stereo for you sound system ( already set up for 12VDC), Consider doing with out energy hogs like a microwave, and look into gas powered refige ( propane/ butane or natural gas)and and a gas cooker (stove) . As you talking about 240 V appliances I take it that your in the UK.

Dr.D

([User Info](#))

Thanks for the info. I'm actually from Australia and I haven't been able to find many energy efficient 12v globes here. The ones I have found have been quite expensive compared to the 240v ones. I'll keep an eye out for them though. I'd like to keep using an 240v electric fridge so I'll have to work out my power supply to suit.  
thanks again.

([User Info](#))

I don't think anyone makes any good 12v appliances. So I prefer the 120v ones. I usually multiply the amps by 11 (120/12= 10, & add 10% for losses). If you have a device that does not list the amps, it will at least have watts. Divide watts by volts to get amps & then calculate. Watts are the same for either voltage. For 240 volts, you would want to figure 21-22 times the 240v amps to get what you would have at 12v. So your 1 amp, 240v appliance will need 10 gauge wire (until you get to the inverter) on 12v (24 + amps!). Gee, why does my coffee maker run my battery down so fast? It only draws 10 amps....

by [jubalearly](#) on Fri Sep 19th, 2003 at 09:21:43 AM MST  
([User Info](#))

What kind of lightning protection do you have? Whatever it is you can probably improve your protection considerably. Do you have a lightning rod on the roof? I'll have to dig around but I had a couple of good references for lightning protection companies that had a great deal of information on the internet. Try a search on google. You may need several properly installed lightning rods.

Re: Lightning strikes again ([none / 0](#)) ([#3](#))  
by [reecko](#) on Fri Sep 19th, 2003 at 11:38:21 AM MST  
([User Info](#))

But will installing a lightning rod on the roof keep me from getting strikes that are coming up my ground line? If we get a strike close by it is coming up the ground from what we can tell.  
Reecko

Re: Lightning strikes again ([none / 0](#)) ([#8](#))  
by [jubalearly](#) on Mon Sep 22nd, 2003 at 01:25:31 PM MST  
([User Info](#))

All lightning comes from the ground up - that's the source of the electrons. Actually there is an initial flow from the cloud that establishes the channel. I think most lightning gets into the equipment from the AC lines so unplugging it should help. Unless you need to use it during a storm.

Take a look here:

<http://www.lightning.org/protect.htm>

<http://www.harger.com/>

could try winding a coil of thickish wire around the leads about 5 turns and grounding one end. this will take out the HF spikes and still appear transparant to the inverter. dont know if it will work with inverters works fine for H.F antennas.

keep having fun

bob

I use Varisters.

A varister is something like a Zener diode except it works on AC current as well. When the voltage goes up to the rated voltage of the varister it becomes almost a dead short and loads down the overvoltage. The normal 120vac line is a sine wave with the peaks at about 170 volts so you will need a varister rated at 175 or 180 volts, very common at RadioShack. While the peaks are 170 volts, the RMS average is 120 volts. If you wanna use one on the phone line you need a varister rated at 90 volts to accommodate the ring voltage which is much higher than the talking voltage.

I have them all over the place: Circuit breaker box, Extension cords, box on house where phone wire comes in, computer power distribution. When properly done you will use 3 varisters for each AC Line. One will go between the 3 wires of the line...

Hot - Neutral

Neutral - Ground

Ground - Hot

This forms a little circle of varisters which will short out the voltage spikes, no matter which lead of the AC line that they come in on. I have read where, if you parallel 2 or more together, that the protection goes up by a factor bigger than the total number of varisters that were used.

Re: Lightning strikes again ([none / 0](#)) (#6)  
by DanB on Sat Sep 20th, 2003 at 09:29:56 AM MST  
([User Info](#))

Rough...

There have been 3 inverters killed here and a few more in the neighborhood.

This sounds tedious, but now days... when I suspect lightning when Im gone, or if it gets near - I simply unhook the inverter. The most important part to unhook I think is the AC side.

Most inverters that have died up here are killed not by a direct strike - it could be some distance! But most of the fried inverters had long AC lines plugged into them, like... 2 story houses, or places with outside shops and lines running to those. The long AC line I think is dangerous... a near strike will induce a voltage in in the line - enough to fry the inveter!

Especially dangerous are lines in the air - the first one that died here was hooked up to an outbuilding via a powerline running through the air on insulators. Better is to bury the line. - at least, thats my "theory"!

Knock on wood... but I've had no problems since I started unhooking the AC side of my inverter in storms. Perhaps time will tell!

Re: Lightning strikes again ([none / 0](#)) (#7)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Sun Sep 21st, 2003 at 08:52:40 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

Have you ever tried MOV lightning protection?  
The things will soak 10,000 amps before exploding  
still cheaper than an inverter...

about inverters

[Inverters](#)

Now I finally think I have it I need one of these  
<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=3046353843&category=294&rd=1>  
and then I can hook up my waterwheel generator to it and I can have plug in power. But I was wondering because I have a 40vdc generator and I wanted to know how I can keep it into the 9-15vdc range. can it be done using a battery dead or alive?

[need help](#) | 2 comments (2 topical, 0 editorial)

Re: need help (none / 0) (#1)  
by DanB on Mon Sep 15th, 2003 at 08:23:08 AM MST  
([User Info](#))

That sort of inverter would offer your 120 AC nicely (only 400 watts but...)... you couldnt hook it directly to the generator though. You'd need a battery in there - a good, "alive" battery.

Re: need help (none / 0) (#2)  
by shane on Mon Sep 15th, 2003 at 08:27:45 PM MST  
([User Info](#))

man that sucks, so what I need a diode or a bridge rectifier?

just throwing this out here for any one fresh out of projects:)

### Portable power

just throwing this out here for any one fresh out of projects : )

Ok here it is take an old push mower remove the engine . On the mower deck bolt a box to hold two deep cycle 12V batteries.

Bolt a piece of plywood across the lower part of the push handle and mount a battery charger Inverter and reel type extension cord.

In the summer this could be used to power electric hedge trimmer or weed eater or other lawn care items. Or where ever you need a bit of ac power but don't want fire up a generator or run long cords.

Using it regularly means that it will be better maintained. And if the grid goes down it will keep some things going for you.

And if the engine that came off the mower runs use it with a car alternator to charge the batteries during longer power outages. I have had mowers given to me that took only a little TLC to get them running again .

Old F

So many projects so much fun : )

[Inverters](#)

none

After blowing up a Canadian Tire 700 series inverter by placing the rated 500 watt cont. load on it and lasting 3 minutes it went back.

Since I live in a small city I will have to order or travel to get one.

I was looking at the Power Bright Inverters,

[http://www.dcacpowerinverters.com/12\\_volt\\_power\\_inverters.html](http://www.dcacpowerinverters.com/12_volt_power_inverters.html)

but they ship out of the US and charge GST and PST. They state prices are in US funds and all orders from US I was always billed afterward by rev Can for the Taxes.

This this makes no sense to me.

I also considered the Vector inverter

[http://www.donrowe.com/inverters/vector\\_1200.html](http://www.donrowe.com/inverters/vector_1200.html)

but they use a broker and the fee is 30.00 US even though the price even with exchange is good all the service charges cost almost as much as the inverter.

Any suggestion

thanks

by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Wed Sep 3rd, 2003 at 06:49:26 AM MST

([User Info](#)) <http://www.internetfred.com>

I purchased a "uberex" standard 600 watt inverter from costco. Seems to work well.

As far as tax's go. All merchandise made in Canada is charged PST and GST. both imported and exported if it is new, if not new then it is under a product catagory and gets charged differently... Don't ask. Our tax system is screwy at best and everyone knows it.

Hi Reno,

Try [www.vectormfg.com](http://www.vectormfg.com) then go to the remanufactured web-sales section of there website. They do sell the 3000w model (VEC051) there for \$435.00 us plus shipping. Bear in mind this is a remanufactured unit. but it still carrys the full two year warranty. I just bought one there myself, it works just as good as a new unit. I was able to compare a new one against a reman, they both seem to work equally well.

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

LTW;

I have to point a couple things out with regard to that inverter.

I can't imagine it has much frequency stability. What I mean by that is while it will certainly put out AC the output hertz [frequency] will vary wildly with the load it has on it.

Pretty much the same thing goes for output voltage and current. I would never attach that to anything i cared much about. However, for lights or heaters or something like a wall wart it would probably be OK.

Just felt that should be said before someone thinks they can build one to run their house off of. Modern inverters incorporate several layers of control on frequency, current and voltage in order to stay within rated specs over varying loading and supply conditions.

By all means experiment, learn and try one out but be aware of its limitations before you plug in your new Widescreen HDTV.

I tend to see things from the angle of "Whats wrong with this picture" viewpoint which comes from years of troubleshooting. I never believed anyone else much so I experimented and you should too. I have seen some spectacular failures over time trying circuits i found in some obscure place including a tesla coil that nearly fried me because i doubled the windings for some windage.

I am certainly not an expert in electronics circuit design just a guy who has worked with electronics and computers for a longer time than he cares to admit.

Cheers.

TomW

by thebbqguy on Fri Sep 5th, 2003 at 08:09:22 AM MST  
([User Info](#))

Hi Reno ( original poster of this topic )

Are you saying the Canadian Tire model was rated at 700 but you were able to blow it out at 500 ?

If so, did you get your money back from them ? .... I'm curious. I find Canadian Tire are not so quick to refund money.

I have always wondered about the quality of their inverters. I thought they may not be of the highest quality, and your story seems to back this up.

Anyway from what you say you were well within the specs of the product and it blew anyway, - that's pretty scary and depressing.

Mark

Re: Canadians where/which inverters ([none / 0](#)) ([#15](#))  
by thebbqguy on Fri Sep 5th, 2003 at 02:44:52 PM MST  
([User Info](#))

Hi Reno,

By the way, I see many of the people who responded to your original post, posting prices of power converters that are MUCH higher priced than the \$99 model you bought, - I'm wondering if the low price of \$99 for a 700 watt power inverter tells the tale - that indeed it's a piece of crap ? ... not sure, but from what I see here, it must be. I'm glad of your post because I will steer clear of that brand, that's for darned sure. If in the States you buy a 700 watt inverter for \$400, ( about \$500 Canadian) then it's for sure that they are much better quality than the piece of junk our local Canadian Tire store sells.

Is this by chance the model you bought ? it sells for \$99.99 at CanadianTire ... <http://www.canadiantire.ca>

The bottom line, if the thing was rated at 700 watts which it is, and their website even states it has a 1000 watt surge, then it should never had blown with what you were using ... - this product is indeed a POC.

[ [Parent](#) ]

Re: Canadians where/which inverters ([none / 0](#)) ([#16](#))  
by Reno on Fri Sep 5th, 2003 at 04:34:44 PM MST  
([User Info](#))

yeah thats the one  
But not my problem Canadian Tire owns it again.  
Actually was thinking of blowing up another  
just for fun  
It does come with a 2 year warranty.  
Why is that Canadian companies list prices  
in US Dollars and did you know that provinces  
do not collect each others sales taxes  
PowerBright ships out of quebec and wants to  
charge me PST. I told them Que doesn't collect PST for Ontario  
and Quebec doesn't have a PST anymore.  
The price you quoted for a 700 watt inverter is a little high  
though  
PowerBright - 159.00  
Vector - 129.00 on sale normally 189.00

[ [Parent](#) ]

Re: Canadians where/which inverters ([none / 0](#)) ([#17](#))  
by Reno on Fri Sep 5th, 2003 at 04:38:40 PM MST  
([User Info](#))

It went back  
Canadian Tire is great for taking thing back  
A buddies bought one of those Mosquito Magnets  
back in June he is returning now with no box and  
no questions asked (Told them it didn't work)  
Actually it was rated fot 500 watts continuous  
so that is what I put on it.

[ [Parent](#) ]

### [What would happen if.....?](#)

By [waldo](#), Section [Homebrewed Electricity](#)  
Posted on Thu Aug 21st, 2003 at 02:31:13 PM MST [Inverters](#)

**What would happen if you plugged a normal inverter into your house wiring?**

What would happen if you plugged a normal inverter (not grid tie) into your house wiring. Would it feed power back into the grid/ your house. Would it be out of phase with the house current? Or would it just blow up.

I don't plan on trying this. I try to stay away from electricity, but I am just curious.

That's pretty much what I thought. I had overheard some guy saying, "why not just hook it up..." I thought to myself that it might be a recipe for disaster, but not being the expert, I thought I would find out.

Maybe I should find where this guy lives, so I can watch the fireworks.

Re: What would happen if.....? ([none / 0](#)) (#5)  
by boB on Thu Aug 21st, 2003 at 04:33:47 PM MST  
([User Info](#))

Actually, there is a ~very slight~ chance that the inverter would be in phase in which case it might not blow up right away IF the voltages were the same and the frequency and phase did not drift. This is a very remote possibility though... Most likely it would go:

```
##### # # # ##### ###
# # # # # # # # # ###
# # # # # # # # # ###
##### # # # # # ##### #
# # ##### # # # # #
# # # # # # # # # ###
##### # # # # ##### ###
```

Or at least... POP !

Re: What would happen if.....? ([none / 0](#)) (#6)  
by laskey on Thu Aug 21st, 2003 at 05:15:40 PM MST  
([User Info](#))

Yeah maybe, but your average inverter isn't a true sinewave , and the frequency isn't controlled dead on.... so I'd opt for boom myself. But mostly because the grid forces the inverter to run at it's voltage, frequency and wave shape, and I doubt highly that the inverter would like that at all.

cya,  
Chris

Guy's don't be ridiculous.  
The inverter would spark when you plug it in,  
and heat up a lot. No booms about it. (Might  
hear some fets poppin) Might see some smoke.  
It would be more depressing then impressive.

-Andrew

OF course, the Trace SW series grid tie  
inverter is just an inverter plugged  
into the grid, with special control  
software of course... And a voltage  
source inverter at that !  
Also, generators are connected to the  
grid too.

It ~can~ be done..., but in general,  
sparks and bangs are most likely  
to occur.

Let's set up a money pool to buy one of those cheap inverters at Val-Mart. Then we can plug it in and see if it blows...post pics. I'd pay \$5 bucks for that! Hey, this could be a regularly featured segment: "What Would Happen If"... We could even vote on what wacky thing to destroy next. Hhhmmmm, as I rub my chin thoughtfully in mock concentration.

OK,

I new a guy who had a generator driven from the PTO on a tractor, and he would just plug it into his electrical box when the grid went down.

I imagine while the grid was down there ouldn't be a problem, but when the power came back on, shouldn't there have been a bang, pop, sizzle or something else?

As far as I know he didn't have an automatic transfer switch, but he could have had a manual one, and I guess that could explain it.

[Inverters](#)

More Amps?

This may be an absurd question.

I guess the only dumb question is the one you don't ask, But..

Can you parrallel the output of two or more 12v-DC to 115v-AC

inverters for more amperage?

[Multiple Inverters](#) | 7 comments (7 topical, 0 editorial)

Re: Multiple Inverters ([none / 0](#)) ([#1](#))  
by [wpowokal](#) on Thu Aug 14th, 2003 at 06:14:08 AM MST  
([User Info](#))

Generally no, unless they are designed for paralelling. Reason is the time base 60 hz needs to be in sync, that is zero crossing point ie the point between positive and negative so to speek must be the same for both inverters.

regars Allan

Re: Multiple Inverters ([none / 0](#)) ([#2](#))  
by [jubalearly](#) on Thu Aug 14th, 2003 at 08:11:48 AM MST  
([User Info](#))

Allan has it right, it's complicated trying to get these to synchronize. In addition to matching the frequency exactly, the waveforms would have to be identical. It's much simpler just to keep the circuits seperate.

This is a good reason to buy a bigger inverter than you actually need. But 15 amps @ 120v is only 1800w. So, unless you have a dedicated circuit (usually for motors) or other uncommon application, 1800w is all you need for any circuit. Actually, you'll be hard pressed to find a 120v appliance that requires more than 1380w, so a 1500w inverter will cover almost anything you are likely to need.

A few of the more expensive sine wave inverters have built in electronics to allow them to be synchronized. It's generally available only on the largest (highest KW output) at each input voltage level so you can get more amps if necessary. A 3HP well pump is the type of application that might require this. But a more common requirement is if you want to get 240v from two 120v inverters.

([User Info](#))

OutBack Power inverters can stack multiple inverters and Trace SW inverters have some provisions for this.

Line Tie inverters for selling back to the grid also will inherently parallel. The grid is their reference signal of course.

by LowTechWreck on Thu Aug 14th, 2003 at 03:38:46 PM MST  
([User Info](#))

These things are pretty expensive.  
They have LARGE heat sinks, the whole out side of the case is an aluminum heat sink isn't it. I know that can't be cheap.  
What would stop someone from getting schematic and ordering the parts from Digikey or a local parts company. Unless it is highly technical involving oscilloscopes and other equipment that someone might not have.

[Inverters](#)

Selecting an inverter, continuous runtime question

I have a small beginner system that I am putting together and have a couple elementary questions. Question 1, what can I expect to run from a 97 amphour battery. If power is calculated as watts = volts \* amps, then an AC device that pulls 5 amps requires 600 watts (120v\*5a). Assuming that the inverter were 100% efficient, does this mean that the AC device would actually draw 50 amps from the 12V battery (600 watts= 12v\*50a)? And I could therefore expect slightly less than 2 hours of runtime, before I fully discharged them....bad idea I know, just trying to understand some basic concepts.

2nd question: some of the cheaper 800 watt inverters claim to run for 5 hours, does this mean that there are some inverters that can not be run for long periods of time, for instance 30 minutes?

I searched the baJesus out of the old and new boards and couldn't find these answers, sorry if they have been answered before.  
bye, -Pete

thats about the sum of it.. if you ignore the losses... like only get 75% of input power into bats,.... inverters are never 100% effecient... ect

Re: DC to AC power inversion ([none / 0](#)) (#2)  
by troy on Tue Aug 5th, 2003 at 04:59:05 PM MST  
([User Info](#))

Yes, you have the general idea down pat. Golf cart batteries are an inexpensive way to add lots of amp hours to your storage.

I think some of the less expensive inverters may be a bit generous on their output capacity. Yeah maybe it'll do 14000 watts but only for six milliseconds and then the fire starts.

No seriously, most of them are reasonably close to rated capacity, but I just prefer not to push their limits.

Best regards,

troy

I used to use a Wagan (inexpensive Taiwan inverter) 2500 watt inverter and it worked well... it was reasonably efficient. I changed to a Trace 2500 watt sine wave inverter, which is actually a bit less efficient especially at lower outputs, but it is interesting how much stronger the trace is when it comes to starting motors and running large loads! I was barely able to weld off the Wagan with my small 120V mig welder. The trace does a better job of running my welder than my 6500 watt Honda generator!

([User Info](#)) <http://www.windstuffnow.com/main>

I also have a trace 12/2500 and it works very well. I think it surges to around 5500 watts. I used to have a Vector which seemed to work well but as you said it didn't handle the surges very well... thank goodness for a reset button. I wish now that I had purchased a 24V trace... live and learn.

by DanB on Wed Aug 6th, 2003 at 09:23:56 AM MST  
([User Info](#))

Yep... I'd have gone 24, except for me... the cost of the batteries, the fact that I got this inverter used for a real good price, and the fact that all the lights in our house are 12 V made it a no-brainer to stick w/12 volts for now. Even though the wire costs more and the inverter is only 2500 watts, I think the 24V version of the same inverter is 4500W which would be nice... (I could kill my batteries a LOT faster!)

So Im stuck at 12 volts for a while....

([User Info](#)) <http://www.windstuffnow.com/main>

I like the inverter and the 12V stuff really isn't a big problem. One of the problems I have is my well pump is 220VAC. I thought of adding a second 12/2500 and tie them together.. I think that option is open on mine.. there is a link between the two that matches the hz. But the expence is rather high. Right now all my 220 stuff is from the grid ( stove, water heater and 4" well pump) and about 70% of the main house is on batteries... still not good enough.

We really don't have super winds around here in the summer and there are times when there is no wind for several days in a row which puts me back on the grid charging batteries.

I guess partial dependency is still better than total dependency... especially when the grid goes down.

Havin' fun as usual  
Ed

I've seen that you've built some working small stirlings.

Do you think that it would be possible to build  
a stirling (a combination of several small ones)  
to make 50 W constant power, when the sun is shining?

To make it using less than 200 \$ for the parts?

What about making a solar chimney of 50 W power?

What about a producer gas generator using just  
firewood to power a Brigg & Stratton?

([User Info](#)) <http://www.windstuffnow.com/main>

The stirlings are fascinating machines but to get any real  
power from them they become quite complex. Unless of  
course you build them very large. All the idea's are do-able  
depending on how involved you want to get. I'm currently  
working on a prototype engine to do just that. Its basically  
a linear diesel engine to power the alternator. The stirling  
system had crossed my mind with this one but would  
become more involved than I wanted. The model is a small  
300 watt unit and its almost operational, there are a few  
details that have to be finished up. My goal with this one is  
to be able to run it for 50 hours on 1 gal of diesel fuel. The  
linear diesel isn't new nor is the alternator but the torque  
drive is the kicker. This was a spin off of a torque  
enhancement system that I designed for a magnetic rotary  
engine I built several years back. It really didn't sink in until  
recently that it could be used by itself for other applications.  
I should really write a book on all the odd gageets I've built  
while experimenting with different things. Alot of them were  
only good for conversation or junk art when done but  
interesting just the same.

More fun stuff...

Ed

Thu Aug 7th, 2003 at 09:07:17 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Hi Rob...

The linear diesel is basically 2 pistons inline connected by a rod with no crankshaft. I believe its considered a "Free piston" engine. Not a new concept but quite interesting. Basically trying to regain the inherent 25% automatic loss going through the crankshaft. Once the buggs are worked out should make a great little engine for powering Hybrid set ups. Here is a site that is working on generator and compressor versions of the unit.

[http://www.innas.com/Chiron\\_wp.html](http://www.innas.com/Chiron_wp.html)

There are a bunch of sites describing them.

I needed 40 pounds of linear thrust to drive the torque system which delivers 32 ft lbs output on the rotary drive. In order to achieve 40 lbs thrust you only need a piston that is 5/16" in diameter. I'm working through some problems of controlling it at this point as well as the injection system. A few other bugs need to be worked out also. I believe it could run longer than the 50 hours on a gallon once the inefficiency's are worked out. There is 147000 BTU in a gallon of diesel. At 50% efficiency it should run for around 70 hours with a 300 watt load.

Its another one of those strange Ideas I always have cluttering up my brain... If nothing else its definately fun and challenging...

Have Fun  
Ed

Re: DC to AC power inversion  
([none / 0](#)) ([#12](#))  
by windstuffnow  
([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Thu  
Aug 7th, 2003 at 04:06:40 PM MST  
([User Info](#))  
<http://www.windstuffnow.com/main>

I'm hoping to get away from the rings unless absolutely necessary. I figure with a 1.5" stroke plus the extra length of the cylinder and close tolerances the blowby will be minimul. Once it's at running temp it shouldn't leak or at least the leaking will be insignificant. If all else fails its not that difficult to make the rings

Having fun...

([#19](#))  
by Gordy on Sun Aug 10th, 2003 at 12:01:10  
PM MST  
([User Info](#))

ED,

This is a pile driver, we are currently driving 12in. dia. x.250 pipe with a 3/4 inch plate welded across the bottom (to plug the pipe). Using a 220,000 lb crane a 60 foot frame is hoisted up, the frame holds the power head and pipe. The crane uses two cables, one to support the frame and one to control the power head. Once set in place the power head cable is lowered and a catch hooks the bottom of the piston, then the cable is raised when the piston reaches the top of its stroke the catch releases and the piston falls. As it reaches the bottom of its stroke it fires throwing the piston back to the top of its stroke and at the same time pushing the pipe down into the ground. Using splices when nessesary we are driving these pipe down 50 to 90 feet. The pipe are the cut off 2.5 feet above ground and filled with concrete, then forms are built around them and filled with concrete to make footings for a bridge.

The power head has not been on the ground where I can make measurements. But the cylinder is open at the top so I can see the piston stroking about 36 inch. into the air. And looks about 10 inch in dia. To deliver the force it does the piston has to be solid steel. The power head works on the 2 cycle princeple and fires 48 times per minute.

It is a trip to watch the pipe hit mush 10 feet down and suddenly go into freefall for another 10 or 20 feet down into the ground.

I will try and get a few pics. But we are on 12 hour days (plus 2.5 hours drive time) so it will be next week end before I can try to send them.

Regards,

Gordy

linear? ([none / 0](#)) (#17)  
by hvirtane on Sun Aug 10th, 2003 at 03:37:38 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

1)  
The discussion about linear engines reminds me of Beale free piston Stirling engines.

Anybody has tried any of them?

<http://www.sunpower.com/products/index.html>

2)  
And then:

anybody has tried to make a free piston steam engine?

A cylinder very hot, a small hole lets water coming in, when the piston is in a suitable position... flashing steam pushes quickly the piston to move... a coil around the magnet connected to the piston produces current when the piston moves, another magnet opposite that pushes the piston back when it is far enough, and the steam is coming out from another hole, which the piston opens inside the cylinder wall, when the piston is far enough... the cycle repeats.

- Hannu

Re: linear? ([none / 0](#)) (#18)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Sun Aug 10th, 2003 at 08:33:38 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've never attempted to build a free piston stirling although the idea is quite interesting. The idea for the free piston steam also sounds interesting, but instead of a magnet use another flash steam piston to push it back into position for the next flash. I think this would utilize the power more efficiently. Using a magnet, a portion of the power would be used in compressing the field and power would be lost. Similar to a spring.

I chose diesel fuel because of the amount of energy stored in the fuel. I've been tossing other ideas around but the main objective is reducing the amount conversions to get the end result. Diesel fuel contains 43,108 watts of stored energy, obviously we won't get 100% conversion factor, but if we could convert it at 50% or better (preferably better) our energy problems would be reduced considerably ( or at least by 1/2). The standard 4 stroke engine is only around 20% efficient ( 2 strokes are even worse because we are cooling the piston with wasted fuel). The biggest inefficiency is the design of the crankshaft which contributes to 25% of all losses.

If its there use it to its best possible potential, why waste it?

Enough of my pet peeves...  
Have Fun  
Ed

([User Info](#))

Hi,

I did once think about trying to build an inverter but quickly realised that 1) much cheaper and easier to buy one and 2) the waveform from poorly designed inverters is very far from sinewave (normally only squarewave) - not good for running CFL bulbs.

If you are really interested in building an inverter there is a guy named madhav\_chowdhary ([madhav\\_chowdhary@yahoo.co.in](mailto:madhav_chowdhary@yahoo.co.in)) who has details of a board he sells to make a 800W or 1500W pure sine wave inverter. The details are viewable in the files section of the AWEA-Wind-Home yahoo group (I think - otherwise you could email him).

I'd still recommend that you just buy an Inverter off-the-shelf - if you use CLF bulbs you would probably get away with a lower wattage requirement and a smaller and cheaper inverter.

Best regards,

Derek Conniffe

by wpowokal on Mon Jul 28th, 2003 at 10:29:31 PM MST  
([User Info](#))

Simon, here is a link to a simple inverter which uses transistors not mosfets.

<http://www.uoguelph.ca/~antoon/circ/555dcac.html>

Have you thought about DC lighting or is this a project for the experience of building it.

I have found one using MOSFETS and when I re-find it I will post the link, in all probabily the transistors could be replaced with MOSFETs,with maybe some driver mods.

regards Allan

I am like a proud daddy. Fedx delivered it today : )

It's a Statpower portawattz 3000, 2400 watts continuous 3000 surge.

I took it out to the shop to try it out all I had to run it was a old 12 volt RV battery better than 50% discharged and light jumper cables but it started and ran the 1/3 hp cap start motor on my ban saw no problem it was cutting a 3inch by 1/2 inch steel bar stock for a load .

I will be using it for stand by power for some things in the house using a transfer switch. The AC out put can be hard wired no cords to mess with. It will have a 900 amp hour battery bank with grid powered for now 3 stage charger.

Having so much fun it should be illegal : )

## [Portawattz 3000 inverter any one have one?](#)

By [Old F](#), Section [Homebrewed Electricity](#)

[Inverters](#)

Posted on Sun Jul 20th, 2003 at 09:05:01 AM MST

Are they worth the money ?

---

Portawattz 3000 inverter any one have one?

I am putting together a UPS for my furnace blower an water pump on my wood stove.

And want to know if there worth the money and how well they hold up.

I know that some of you out there have done some thing similar , inverter battery bank and transfer switch. Any hints or tips or things you would do different looking back on it now?

Many thanks

Old F

Not directly answering your question, I am using a 1-hp 24 vdc motor for my well pump as an alternate to the inverter/AC motor package. Besides the inexpensive replacement of brushes every few years, I like the immunity to nearby lightning strike surges. Being cheap in general, I am going to buy 10 2kw computer UPS units for my other 120vac needs. I heat with wood & have a backup hot water system. It uses a small 1/6hp circulation pump.

Jimbob;

Just want to mention that while I have used consumer grade computer UPSs as inverters you can expect short life and the occasional shutdown from high surge like turning on a TV or motor starts or thermal problems. They are not intended for continuous duty at all.

Having said that I will also note that you really don't need to buy them. They get tossed in dumpsters daily for failed batteries. I have used up 3 free ones over the past couple years and they were all discards with fried SLA batteries. I just hook them to my bank of batteries and use them as is. They also have somewhat horrible efficiency too with a high standby current while idling. There is a trick to getting them to start without ac on the plug too which is easy on older ones but on newer ones i have not figured out how to do it without modifications to the UPS.

Just my real world experience with them.

Cheers.

TomW

You are correct on the cheap UPS units. I derate to 50% and had success without a problem. I also know not all UPS units are built equal in durability.

I forgot to add, a computer UPS is not for starting an electric motor. I would limit use to simple lighting, and small inductive loads such as a window fan. I have operated a toaster, iron, skillet & other high wattage resistive loads without incident on a part time (ICAS) basis. I have not experienced a problem running a TV, however the UPS I played with was industrial quality. I do not recommend for everyone, but I am comfortable with the better designed UPS units.

Cheap inverters ([none / 0](#)) (#5)

([User Info](#))

I cannot speak for portawatt, but often times you'll find the same inexpensive inverter with lots of different brand names on it as I'm sure you know!

There are lots of very inexpensive inverters getting used up here and there have been no problems. The very small ones, in my experience - where the fan runs all the time, have "fan" problems... they wear out because I do not think they were ever intended for continuous use, but the larger ones (over 1500 watts) have all worked out fine so far!

I used an inexpensive 2500 watt "Wagan" (which may be the same thing) for 2 years w/no problems, it did well starting 1 hp motors, it ran our washing machine etc... with no problems. I took it out of service recently only because a neighbor gave me a good deal on his used Trace SW2512, which does seem a bit more powerful and makes a little less hum in amplifiers. One gripe I have with the Trace inverters (and the thing I like about the more inexpensive ones) is the trace is always "buzzing" - which is a bit annoying if it's inside the house like ours is! The more inexpensive ones are quieter, at least in my experience.

([User Info](#)) <http://www.oldf.homestead.com>

I know what you mean Dan.

One assembly line 3 colors of paint and 26 different name labels : )

The one I am looking at is 3000 watt continues and 5000 surge.

I will be using it with a manual transfer switch to keep some things running in the house when the power goes off .

Thanks for the Feedback. ( Huge UPS INVERTER)

After printing out the responses to my questions about this extremely large UPS , Inverter .... i was able to get a 24 Hr. 800 No.and the person I spoke with was very helpfull especially with the Info .... and Ideas I received from the site... Seems this Company is still around and the reason this Machine was retired after only 10 years .... a New one with the same specs is less than 1/3 the weight and 1/4 the size ....and does more. The UPS I have tips the scales at about 1800 Lbs. stands 5 Ft tall ... 36 In. deep and 36 In. Wide. When asked what I was useing it for I told him to power my home from stored wind energy ... Guess he is interested in such things and asked to stop by . 2 Hr. Drive from Seattle.He is going to show me exactly how to convert this . I will in turn show him several Machines and tell him what I can about starting out . This UPS has a 5000 Watt True Sine Wave Inverter. Oh Joy! I will Post all I've learned from him for those who may have one of these or might be thinking about picking one up. I gave 30.00 for this.. Yahoooo.

Good job Windnutone,

I always try to contact the OEM first. And if that does not work then try other alteratives. I hope you have lots of fun. Just remember to be careful because that inverter is like messing with an open breaker panel.

JW-

## [Grid Tie](#)

By [wdyasq](#), Section [Homebrewed Electricity](#)  
 Posted on Thu Jul 10th, 2003 at 09:04:12 PM MST [Inverters](#)  
 Wouldn't post on Myke thresd - too long?

Myke,

An old friend of mine decided to switch from one of the "Baby Bells" to the old parent company here in Texas. He knew one of the higher up in the old parent company and was assured it could be done painlessly.

After 6 months of wrangling, the fellow's credit rating had been ruined due to the "Baby Bell" continuing to charge him for a phone service he wasn't getting. He also could not get them to release this phone number as required by state law.

The short story is it was a mess and he is having more trouble than one could think. I personally believe dealing with an electrical company will result in more trouble than it will be worth.

Here, the "buy back" price is \$.06 kWh. If a man had 4 - 100 Watt panels cooking 10 hours a day, it still hasn't netted a quarter. A fight over "this ain't right, get an electrical engineer to approve it" and "you'll have to have somebody here" and "We're sorry, we couldn't make it the day we scheduled, can you make it ...", "the inverter you just paid \$2500 for is no loner acceptable". I could go on for weeks.

Of course, while you are steaming over the lack of cooperation, you will read in the Sunday paper (your electricity has been cut off for weeks so you can't read it on your monitor and your system requires the inner-tie to work), about how folks are able to sell surplus power back to the local utility and how the local utility encourages home owners to.....

## [Cheap photovoltaic system DC TO 120 V AC inverter](#)

By [myke](#), Section [Homebrewed Electricity](#) [Inverters](#)

Posted on Thu Jul 10th, 2003 at 12:00:25 AM MST

How do I cheaply hook up a quad of PV panels to my house 120V AC system?

I need some help. I've acquired 4 PV panels (85 W 17V) at a great price, and want to hook them up through an inverter into my house system - which is on grid - at a good price. Sunny Boy et al inverters are VERY expensive, and I want to put this quad to work safely and cheaply.

Any ideas? MYKE

[Cheap photovoltaic system DC TO 120 V AC inverter](#) | 6 comments

Myke,

Check out Home Power mag [CLICK HERE](#) . Check out their classified ads they list a seller for the small inverters. Also check out their Guerilla Solar section, these people are doing what you want to. But with out the power company's OK.

this helps,

Hope

Gordy

What, exactly do you want to do? The National Electrical Code has a number of requirements for adding power sources, outside the utilities, to your home. You can't just hook such power sources (generators, solar panels with inverter, etc.) up and go. That's one reason why grid tie inverters are expensive.

But, 4 panels is not likely enough to run your entire house, so I assume one circuit (15amp?) is all you currently require. The cheapest approach is to use an extension cord & plug in the appliances you need (floor lamp for light). Also, you make no mention of batteries. It seems unlikely that you only want to use this on sunny days. Do you have the rest of the system figured out?  
Russ

([none / 0](#)) ([#4](#))  
by myke on Thu Jul 10th, 2003 at 11:28:24 AM MST  
([User Info](#))

Thank you all for your replies/input. Russ, my goal is simply to lower my monthly electric utility bill and learn more about solar power in an economic fashion.

I have always been fascinated by all things science. I am a novice in this area, and hoping to learn more. I may have, in the future, access to a few more out of the box PV panels at a very good price (local municipality gave up on PV bus stop project mid-way). What I want to do is safely apply the electricity generated by these panels to my in house wiring with an eye on saving some money - realizing that it will take months or years for the system to pay for itself. My house is in the suburbs, and the panels would not be visible from the street, and in a location for 8hrs/day average sun exposure. I am not interested in breaking any utility codes, and am not selfish such that "anything goes as long as I benefit" - that mentality is self defeating. I welcome your advice, and if you need any more info to give solid direction to my fledgling enterprise, please let me know. As of this moment, the ONLY components I have are the 4 panels. MYKE

Re: Cheap photovoltaic system DC TO 120 V AC ([none / 0](#)) (#6)  
by troy on Sat Jul 12th, 2003 at 10:57:45 AM MST  
([User Info](#))

Dear Myke,

Here's a brief overview:

The big advantage of a pure intertie system is that you don't need batteries. The grid IS your battery. There are several drawbacks to this system. 1. Your inverter MUST be an intertie inverter to match the wave form and phase of the grid electricity, or things will blow up and/or catch on fire. 2. So far as I know, there are no cheap intertie inverters. 3. When the grid goes down, you automatically go down also. 4. Most utilities don't make it easy or cheap to set up intertie. Many require a special accessible disconnect and a second meter, with two sets of monthly "reading fees".

If you add a bank of batteries, then you can run a circuit from your mini system and be completely independent from the grid. The big advantage here is that when the grid goes down, you still have (limited) power. Plus, the

utility has no control over your system then.  
You can also start out with any little cheapie square wave inverter which will run most things within their wattage rating. Not as efficiently as full sine wave inverter, but not terrible.

By all means, go to [www.homepower.com](http://www.homepower.com) and download the most recent issue. It's the best home brew power periodical on the planet and it's FREE.

Good luck and have fun!

troy

## [Monster UPS ... Inverter ...](#)

By [Windnutone](#), Section [Homebrewed Electricity](#)

Posted on Tue Jul 8th, 2003 at 07:21:06 PM MST

[Inverters](#)

Hello everyone ,,, new to board. Have aquired a UPS ..  
Input Voltage is 480 .... can this be changed to 120 AC ?

I bought a Huge UPS from the Local Hospital .... 10 Years old . Its weight alone is about 1800 Lbs.Wanting to know if this input voltage of 480 could be changed by a Pro.

Or how could I get a 480 line out of my house? I only need to start it up a while.

Just long enough so it than shuts down and thinks there is an outage.Than will kick over to Batts.Any Ideas will be most welcome.Thank-You

Well well,

I ran across such a thing once before. This company I work for, bought this building and it had a uninterruptible power supply. Which sounds very similar to what you describe. This thing was built into the building's 460v three phase service. And had a switching capability of less than a second. I guess this system was designed to accommodate the "fire up time " for the 500kw diesel gen-set. It wasn't designed to run the maximum output for anytime more than an half-an-hour, from what I understand about the nature of the UPS system.

From what I remember about the system it has some kind of 386 controlling it. It had a classic "green screen" from the 80's.

If you can isolate the charging system, I'm sure you can charge it with what you want "ie" 120vac. You charging circuit may require more charging time to fill the batt bank, but you can have theoretically the full rated output for the "monster inverter" for the given time of output. Possibly less output for a longer period of time.

I just want to remark here that I wasn't allowed to play with such a thing, so consider yourself lucky.

JW

I feel that it is rare to acquire one of these UPS systems. That's why I remarked that your lucky.

I think that you could run several houses off one of these units. The first thing I would do is contact the OEM for the unit. Then try to get the factory schematics for it. After looking at that for a while, you will figure out what your up against technically. Since you probably don't need three phase for your home, unless you have some machine tools that have three phase motors. You might be able to reconfigure it a little and make a nice 220 service, then have an extra 120 line. It seems to me the computer that controls the whole thing switch's the inverter on. The first thing I would do is try to get that computer back up. Then see what it has to say and go from there.

one thing you could try is to activate unit with control transformer. it is very possible that 3phase 480 volt is not required. you could try using 50-100va control transformer-480v primary-120v secondary. connect 120vac to the secondary and you will have 480 volt on the primary. attach the primary transformer leads to any of the 3 3phase input leads and see what happens. if it does not work, interchange in put with the other remaining lead. you have 3 possibilities here. phases ab,ac, or bc. i am hoping that your unit only has to see the voltage on two of the three phases to trigger. also, please make sure that you use a fuse ( not more than 1 amp ) between control transformer and your ups unit. if none of that works, attach your control transformer to your ups unit, connect from one of the 480v transformer leads to a 5mfd capacitor and from the other side of the capacitor to the remaining input lead of the ups unit. the capacitor will create a third leg so to speak, a little out of phase, but maybe just enough to activate ups unit. **DON'T FORGET THAT YOU RUN A GOOD CHANCE OF BLOWING UP YOUR UNIT OR YOUR SELF. WEAR SAFTEY GLASSES. PLEASE WAIT FOR OTHER COMMENTS AS SOMEONE ELSE MAY HAVE A BETTER IDEA-I HOPE.**  
have fun. Zubbly

Hey Zubbly,

Personally, I never thought of that. It sounds good, give the input source what it wants. The controller shouldn't need more power than you describe supplying. Unless it has an old CRT. Ten years ago sounds pretty new to me, maybe display output won't require more power than that. Excellent suggestion with the fuse. Instead of the capacitor you could use a small phase converter. That uses 220 two phase and a three phase motor to make the third leg. I've seen "phase converters" use 220 to run three phase motors, with some efficiency loss of-course. Not quite sure how you would step up to 460 from 240, but I run some small PLC's off 460 three phase through a small delta wound transformer, and just pick up the 120v I need to run the PLC from a leg of the transformer and neutral. Actually If the UPS uses such a step down transformer configuration to pick up power to run the controller. You could tap into that with 120v and not need to energize the "main phases input/output's.

JW,

Somewhere, I read an article or post about using a three-phase 230/460 Volt motor to get 460 3 Phase. I always wondered if that one motor could be used as a "phase converter" at the same time.

While we are at it, power a small device off it too and get some return.....

Ron

Hi Ron,

I first heard that it was possible to make a three phase service from two phase from my uncle. He had a small warehouse with only a two phase service. He acquired a big air compressor from a friend. And that needed three phase to operate. Anyway there was an old ten horse three phase motor laying around the shop, and you guessed it he had a brain storm. So he connected 220 to the motor, and left one of the legs "open". Low and behold the motor ran. Then he tested the open leg of the circuit and there was a good enough reading there. So he decided to parallel the two motors and try to run the air compressor. and as long as he let the first motor freewheel the air compressor ran ok. I remarked too him they got phase converters you know. He said ya I know, but all this is free. Then I asked him how long did you run it that way, and how much more was the electric bill. He said I ran it for about two months till I couldn't afford the electric bill anymore. I asked how much more was it? he said about twice the usual.

As far as getting extra power back, I think it worked the other way around, at least in this example. But I have heard story's about people getting some mystery extra power from VARIACS which are variable transformers. I'm not sure if they were rectifying the output or what. But it has been reported a couple of times that way.

JW-

230v inverter to 120v

Hi to all, new to posting on this board and I lost the first post so will try again. I have a 24vdc in 230v 60hz out inverter at 1700 watt. Can I use a transformer to drop it down to 120 volts and if so how do I wire this up to work. The inverter has no ground on the three prong plugs. I removed the cover and there is no wires connected to the ground terminal. Thanks for any help.

Yes.. i do believe that trace(now Xantrex) sells a 240 to 120V transformer.... or some body does....

Re: Inverter Question ([none / 0](#)) (#2)  
by RobD on Mon Jul 7th, 2003 at 10:00:24 AM MST  
([User Info](#))

Hi Larry, There are problems doing this if your inverter is a modified sine. At 60Hz most AC sine wave transformers will saturate. This leads to over heating. Also unless your converting very low power (under say, 100 watts) you will need a very substantial transformer. I'm not sure how your inverter is set up but it is possible, on some inverters to tap off two legs and this will be your 120 volts. Check it with a meter to be sure. If this works you should also see 120 across the other leg. (You should have one common leg) When you use your inverter remember you can't pull all the inverter power off just one leg. you'll have to share between the two to balance your power as each leg will only give you half the inverter power. RobD

RobD: The problem is I have no common wire. The Fluke says 230v between the two output prongs but the neutral or common has no connection inside of the inverter. I can get 115v from each of the two legs to case ground, but have been afraid to try a load that way. It looks as there has never been a wire connected to the neutral inside the unit. Thanks  
Larry755

Hi Larry, It sounds like your going to be ok if you tap from one side to ground on the case. Ungrounding a supply is usually not done if the engineer wants to pass UL. From what your saying it looks like the mod. sine wave is being developed from a zero center point. This is why you see 120 on each leg. Of course the best thing to do is look at it with a scope but if you don't have one open the case and find the ground leg on the circuit board with your meter going between the case and what you think is ground on the board. When you get ground you should see zero ohms or close to it. When you find the trace see if it is very wide indicating that it can take current ( you can compare it to the output traces in diameter which you can find by going from one of the output pins to the trace on the PC board you think is output). I would say if its wide that your ground is left floating and the company has a 120 inverter where they run the ground to the 120 socket. If this is ok it should work for you. You can try hooking a low wattage (say 25 or 40 watt) bulb across your circuit from the new ground to one leg. Se if the bulb looks about right in brightness and check the voltage across it with your meter. Good luck, RobD

[Inverters](#)

48 volts? New industry standard?

Hi,

Any of you ponder what the future of automotive operating and off-grid power equipment?

I heard from a friend that he is absolutly convinced that the new systems for inverters and others is 48 volts. He claims it is the easiest by far to step up to usable "grid" voltages. I tend to agree with him, because I have seen it in many backup and ups systems. Also since the automotive companies are switching their systems to 48 volts, it is sure to have an impact on the inverter market. Just wondering what your 2 cents worth is about this. Agree? Disagree? This could be interesting on what actually will happen.

-Andrew

[\(User Info\)](#)

Odd there Andrew,

I thought all I read was "42 Volt" automotive systems. SAE, Dupont, Sanyo and others are using 42 Volts and there is a pdf on "42 Volt Automotive Electrical System Standards".

There are some real innovations in the 43 volt systems, PM alternator/starters in the flywheel, all electric A/C systems, electric brakes and power steering and even electric valve trains.

<http://www.sae.org/42volt/bookstore.htm>

It will be nice when one can purchase "off the shelf" products for the alternative energy uses we dream up....

Ron

by [Seth](#) on Fri Jul 4th, 2003 at 08:02:00 PM MST

[\(User Info\)](#)

I do agree.... at 12V the currnet is large for the amount of power compared to 42V, Wire is expensive..... 24V is what im looking for right now..... Id like to know if you can compose a list of UPS's that operarte on 24V and 48V .....

A note on the 42 volt auto systems. They are actually 36 volt nominal systems ie 18 lead acid cells and run at 42 volts when the car is running, like saying present autos are 14 volt systems.

Re: 48 volts ([none / 0](#)) (#4)  
by wdyasq on Sat Jul 5th, 2003 at 06:00:20 PM MST  
([User Info](#))

Good Point on the "42 = 36" 5kw. Also, the "new and improved" batteries may be Lithium based to reduce weight. Pre-packaged "heat-pumps" in the new car AC units will be a scrounger's delight.

Ron

A few years ago we were able to get our grubby little hands on a 120vdc/120vac inverter from beneath a railroad coach car. It was great on the current demand side but the idle current was too much for for for only 10 auto batts. We solved the problem by parrelling two more banks. Haven't talked to the fellow in years but he didn't have any problems for the 18 months I was around..

[Inverters](#)

How long they last, etc....

Hi,  
I was just wondering if people were using ups inverters as their main source? It wouldn't seem like they would handle well to continuous duty.

Also,  
I have a junked ups here, but there is something horribly wrong with it. I would put in the 30v and what it would do was when I turned it on it would make a loud click (sounds like a big relay) Also, I plugged it in the wall, and it was only putting out about 3v AC from the battery leads. STRANGE! Sounds like the circuit opened up myself. Or a fuse popped. It is one of those huge 4000watt type ones. It has a huge transformer in it too. I've seen smaller ones on welders. What do you think is going on?

-Andrew

[Ups inverters](#) | 3 comments (3 topical, 0 editorial)

Re: Ups inverters ([none / 0](#)) ([#1](#))  
by [wpowokal](#) on Wed Jul 2nd, 2003 at 06:35:03 AM MST  
([User Info](#))

Andrew, While I do not use an UPS myself, they are frequently in continuous service in commercial installations. The quality will have a bearing, so can you post details on your unit?

The 3v AC sound like mutual inductance to me, so I agree the circuit is not complete. There was a posting on the old board some time back (months) someone posted how to trick them into believing the power had failed.

regards allan

3V ac on the battery terminals.... with batteries conected.. or not... , then your measuring the wrong electric mode... batteries are DC, feel silly dont u. My 300VA UPS does that too... actually it has 3 sererate clicks.... on mine i get it to go by holding the push on/off button ---- when i dont have it coneted to the mains..... U have a 4KW modle.... cool.. what vantage is the battery bank on it.. im looking for a 24V banked UPS in that power range....

I'm not THAT ignorant. Just because I'm 15 doesn't mean I know nothing about electronics. I know batteries are dc. The batteries were disconnected. I was just getting some strange inductance from the transformer. That's what I was saying was wrong with it. I think that either the transformer blew a winding or I transistor opened up on me. (probably the drive circuit fet) Its gonna be tough trying to track down which particular one it is. I think the relay thing is happening because of the transformer not being hit with a frequency thus making it practically a small resistor. I'm almost POSITIVE its a transistor problem. It has it written all over it. If the circuit opened up the relay wouldn't fire at all would it. The relay fires even when the ups is plugged into 120vac. This ups might not be recoverable. (On a lighter note the ups manufacturer must deal with xilinx because I found a programmable xilinx chip wired on for the interface between the ups and the computer. It was cool! There were little thermistors and other goodies wired up to it. It sounds like it would be a pretty sophisticated ups when it was working.)

[Levitation](#)

Some of the Otherpower.com board folks may not have seen our levitation experiments yet -- Read on, cool PICS!

In 1842 Earnshaw determined that a permanent magnet could levitate, but would only be stable in one axis. An external force is needed to stabilize in the other axis. In these experiments of ours, the external force is provided by the levitating magnet's reaction to a diamagnetic material, like carbon-graphite or Bismuth.

All matter is charged with a natural ositive charge. What you did was charged the bottom plate which also field charged the items and created force internally to equal the items mass that forced the smaller portion of the same mass to equal it's adjacent mass causing a more magnetic force externally causing a repelling action. As for it's positioning on the plate is another matter and the best reference is many Ancient systems have prodused anti-gravity: See two Water Work jdolci: Ed Leed and Flower Show, James Dyson/Wrong Garden water flowing up hill. If you can find on a drawing the pyramid angles of the great pyramid: The angles which have been surveyed are in error and have not been constructed properly. Take it from two people who know of course Ed Leed is dead and old old man me!!!!!! jdolci@ij.net

Present Diameter ([none / 0](#)) (#5)

by Anonymous Hero on Wed May 28th, 2003 at 02:09:10 PM MST

Some more Ancient talk. If you draw a one inch diameter you canot truely find the hypotenuse of a square tanjent to the drawn diameter. Yes I know you can calculate the triangle to the corner of the square9 (45\*), but who is to say that one is rite although we are presently useing it. All engineer have been climbing for many centuries all over the Great Pyramid's allusive Pyramid cubit's inch. When sombody many years ago thought of the present inch the erson came to the conclusion that he can cheat when manufacturing and filling the vases he can cheat with the ONE INCH which is a short count. To the thinking many just a crack pot!!!!!! jdolci@ij.net

([User Info](#))

Is it posible to levitate large diameters using this science?  
if so I have an application for it.

I saw that too in the latest issue, and will be ordering it.

Quite a few years back, Mother Earth News was turned into a rich yuppie outdoor magazine, with articles about helicopter salmon fishing in New Zealand and such; I cancelled my subscription then. They lost thousands of subscribers from this, and many staffers. Some of the ex-staffers and readers went on to start Back Home Magazine, to which I have been a contributing author twice now. That's actually my house on the cover of the latest issue of Back Home, with the remote communications article ;~) I do highly recommend Back Home....lots of organic gardening, home cooking, home business success stories, livestock tips, renewable energy, homesteading info....

Then someone at TMEN realized that, hmmm, maybe this was a bad idea. The new TMEN magazine is more back to the roots of the original. My only complaint is they don't run much about renewable energy systems anymore.

In fact, there's not even much about homebrew RE systems anywhere anymore, not even in Home Power.....they seem to focus on mostly big, expensive commercial systems now. It's a void we are considering trying to fill. Just a thought for now, but who knows?

Cheers!  
DANF

maybe not

[http://story.news.yahoo.com/news?tmpl=story&cid=573&ncid=573&e=9&u=/nm/20031114/od\\_nm/environment\\_redford\\_dc](http://story.news.yahoo.com/news?tmpl=story&cid=573&ncid=573&e=9&u=/nm/20031114/od_nm/environment_redford_dc)

The building's exterior appears to be wood but is made of a fiber and cement material. Much of the interior is lit with skylights and solar cells that provide about a fifth of its energy. Cool sea breezes augment the air conditioning and special towers draw off heat.

The structure uses about 60 percent less water than most buildings because it captures rainwater from the roof, showers and sinks and uses it to water the plants and flush the low-flow toilets. The urinals use a special cartridge to funnel away wastewater.

## [Vortex Anemometer Review](#)

By [ADMIN](#), Section [Homebrewed Electricity](#)

Posted on Mon Nov 3rd, 2003 at 12:24:54 PM MST

[Reviews](#)

It's a slick and inexpensive unit based on a bicycle speedometer.

[InSpeed](#) was kind enough to send us one of their Vortex anemometers to fly and test. It's a nice, well-made unit, and costs only US\$65.00.

The cup assembly comes assembled and is a solid plastic piece. The hub uses a bushing and the company suggests lubricating with graphite, not oil. It spins very freely and starts up at walking speed. The magnet and sensor are contained inside the hub. You can disassemble the hub unit for cleaning and lubrication. We got the pole-mount version, with an aluminum bracket for mounting. It came with 20

feet of wire; we have to run it over 100 hundred feet and just spliced in more 2-conductor wire. You can special order the Vortex preassembled with longer wire.

The digital bicycle speedometer computer shows instantaneous windspeed, and also tracks maximum windspeed, and totalizes (plus other features I haven't tried yet -- averaging, etc.). The builder rates it accurate within 4%. We did not test the accuracy -- we don't have an expensive reference anemometer up here for comparison, and it's been windy here for weeks, which prevents truck testing. The display updates about once a second.

We have it flying on DanB's windmill mast. This is probably one of the harshest locations we could fly it at -- there's high winds and lots of turbulence. It's hard to tell in the picture below, but the anemometer is flying a couple feet below the blade, on a "foot" that sticks out toward the direction our prevailing winds come from -- most of the time, there won't be a wind "shadow" from the pole on the anemometer. Our anemometer will get slammed hard all winter. We'll report back on how it holds up..

If you are looking for an inexpensive anemometer and don't want to build one, this is a slick, well-made unit from a very friendly company.

It looks nice and the price can't be much better from what I can see.

However, the disclaimer they have on the web site is important. It doesn't calculate in times with 0 wind speed, so this won't be good for averaging wind speed (and lack thereof) over time. Should be fine for instantaneous measurements though.

Chuck

Re: Vortex Anemometer Review ([none / 0](#)) ([#2](#))  
by DanB on Mon Nov 3rd, 2003 at 05:51:41 PM MST  
([User Info](#))

yes, that's always the case it seems with these bike speedo anemometers. It does a good job of "average" on a windy day though... many times on windy days itll never stop- so in those cases the average is accurate.

Wind miles is an interesting one though.. for long term data aquisition.

Re: Vortex Anemometer Review ([none / 0](#)) ([#3](#))  
by 5kw on Mon Nov 3rd, 2003 at 09:03:29 PM MST  
([User Info](#))

Hi Dan,

If it totalizes miles of wind run you can simply divide the wind run by the number of hours since the last reading. Por ejemplo if the odometer neted 1680 miles in one week divided by 168 hours = 10 mph ave.

I have always heard that reed switch type anamometers, I'm assuming this one uses a reed switch as most bicycle speedometers do, fail rather quickly . Even though the reed switch is rated for millions of cycles the cups chalk up millions of revs in a matter of months. Time will tell!

Make the wind fun!

Victor

## [motor/generator review](#)

By [Chuck](#), Section [Homebrewed Electricity](#)

Posted on Mon Oct 13th, 2003 at 03:50:10 PM MST

[Reviews](#)

After a few months testing

This is a brief look at a low speed DC motor I've been testing as a generator for the last few months. It is available used at Surplus Center in Nebraska for about \$50(US) plus shipping.

This motor has a face plate rating of 24 volts at 194 rpm and 13 amps. It is rated as a 1/4hp motor. It comes in 3/4" and 5/8" shaft sizes. The shell is formed from 1/8" sheet steel and contains four large ceramic magnets. There are four small brushes contacting the commutator, although not at 90 degree angles as one might suspect. The coils appear to be awg 14 wire. without pulling things apart I can't tell what the winding pattern is.

I purchased a few of these and have been working on finding the issues one might encounter attempting to use these in wind applications. In the tests referred to below, I used the motors as they arrived, without refurbishing or replacing parts. I expected (correctly it turns out) that I would destroy some of these in tests.

Matching a rotor to your generator is important in getting satisfactory results. I tested this motor as a generator in a 24v system with two different sets of blades; a 3 blade, 7.5' diameter rotor of carved wood, and a 2 blade 8' diameter cast nylon rotor. In both cases I observed voltage and current during low (under 20mph) winds and high (over 35mph) wind events. In both cases I used high capacity batteries as the load.

For 12 volt systems the 3 blade rotor is a good fit in low winds, charging as soon as the rotor spun up. Start up speeds seemed a little high, but motors of this type (dynamos) tend to have a fairly high resistance to moving due to heavy armatures and pressure from brushes. A four blade rotor may be a better 12 volt fit as the cut-in speed is a low 100rpm and four blades should provide more low end torque.

For 24 volt systems the 3 blade rotor is disappointing in lower wind regimes. I watched for quite a while as the output voltage bounced between 15 and 20 volts. In a similar wind the output of the 2 blade rotor was much more satisfying, charging up to 5 amps in the same conditions. Startup with 2 blades is lousy for all the reasons given above. Even in a 20mph wind startup is slow.

In stronger winds both rotors provided good results, although the 2 blade rotor gave consistantly higher amperage as long as it was already spinning.

Not knowing the actual limitations of the motor (as generator) I set the furl very stiff with the 2 blade rotor and watched to see how high I could get the current before things got nasty. As happens in Colorado in the fall, nature was eager to grant my desire for high winds. In winds over 40 mph I watched this motor put out over 500 watts before the fiery end.

The weakest link appears to be the brushes, which burned up within a few hours at 20 amps (500 + watts). The brush pigtails, a strong smell and black dust were all that remained. There was evidence of high heat and melted wire insulation.

Higher current replacement brushes might help boost the durability of these units somewhat. But that may not take care of overheating issues. These motors, like most, are totally sealed. They have a removeable band for accessing and servicing the brush connections. Leaving off the service band or allowing airflow through the generator in some creative way that keeps water out could help aleviate heat issues and gain a few amps.

Conclusion:

For 24 volt systems these motors can be used to produce 300 watts and for 12 volt systems, 150 watts. If you decide to use one of these motors in a wind generating application, adjust the tail to furl at the rated 13 amps. Remember that this is a cheap and quick way to get a few watts out of the wind. Design to account for it's limitations and you can get good use of your investment.

If you want more, you'll need to address the heat issue. Don't skimp on replacing the bearings if you intend on leaving it up for a while.

Chuck

Great report, in paragraph 6 you described one unit in terms of volts output and the other in terms of amps output, could you clarify by applying the same standard to both?  
again a great report.

Dr.D

Re: motor/generator review ([none / 0](#)) ([#2](#))  
by Chuck on Tue Oct 14th, 2003 at 08:39:24 AM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

Hi Dr.D,

Thanks for the kind words.

Regarding paragraph 6, for the 24v system there were no amps with the 3 blade rotor because it didn't reach cut-in speed. Voltage is all that could be measured. With the 2 Blade rotor cut-in was reached and amps (up to 5) were being produced. Voltage for the 2 blade test was battery voltage, roughly 26 volts.

Chuck

For reviewing equipment, parts, components, anything related to this board.

Chuck M wanted to post some equipment reviews so here's the place for them! Everyone, let us know if you want more topics added. They are easy to do and aid greatly in searching.

How about a topic for Heat or Thermal

I have tried to place posts for Home heating, Pool Heating and Thermocouple Power, but there isn't a proper topic area for these Subjects . . .

([User Info](#))

Hi ADMIN,

first off Id like to say I'm very impressed with this board. I have learnd so much by reading it. You guys are doing a fantastic job!!! the only suggestion that I have to improve it is this// As the new postings or new post threads are added, all the posts move down the line of the list, and can quite easily move many pages back where no one can esily detect new posts to old postings/or topics. Then if someone might have thought about a suggestion for a preivious posting, that was not apperant to them at the time, that the posting remained on the "front page" of the posts. As a result most will miss late activity on a posting. unless of course your are a savvy user, and go back a couple of pages, to look for activity in a posting that you were interested in , but even doing this you are bound to miss allot, especially if you previously werent interested in all the postings back there, but then someone else might have added something, that made you interested. most of the time, like I said you just miss that oportunity.

Alot of potentially new users are finding some of these "old" postings and are actually adding to them with new posts. these people are finding these old posts thru a search engine. But most of us miss this "new" activity since the main posting stays 5 to 10 pages back on the list of postings. A fer example: some guy named Julius, cant rememer the last name, posted some very well articulated explanations to one of JCP'S perpetual motion posts, while it was in The quarentine zone. this happened acouple of months after the time of his rant. But the guy made an honset effort, and it was intersting to read.

It would be very cool if there was topic for recent additions to all preivious postings.

Keep up the exellent work guys OTHERPOWER IS #1

JW;

I have often thought a special page with everything "new" on it starting with the latest would be very useful. Kind of like how the old board did postings.

I have seen the same issues you mentioned. You can go into your display preferences for the site and get up to 50 stories per page but I find I still miss stuff and I read almost everything that goes through the site but do not go beyond the 50 that display on my "front page".

So there you go, Dan, a feature request.

Cheers.

TomW

([User Info](#))

Actually, and possible more 'do-able' in scoop would be an option to list the stories (not sure if that is the right word for it) in order of the story with the most current posting in it and going backwards in time.

Then, 'stories' that can get a quick answer drop from the first page while old favorites that never seem to die, such as laminate materials and coil turns/size/thickness will remain until they die a natural death (if they ever will).

I think most of the people that read and post most days will probably read everything new for fear of missing something valuable.

Martin.

Actually most message boards are set up so that if a new comment is added to a post it moves to the top of the list indicating that there has been new activity. That way ongoing threads don't get buried. I always thought the way this board was set up was kind of strange but it gets the job done so I was not going to howl to loud especially since there was already enough problems for the admins to worry about

ADMIN;

I did a litte looking for something, that I remember from looking at various disscusion forums, a while back. check this out <http://shouldexist.org>

most of these board software programs (meaning all, or at least execept for one) are mostly a generic program that everyone uses. Personally I think the way this one is set up is pretty dam good. Also these same programs have several customiziable features. for example the way the main page includes all new postings from all "catagorys" is working quite well. also if someone posts to one of the postings it does not change its location "ie" bring it up to the top of the list. this part of the system (board) "works fine".

heres my sugestion///

we dont really need the DIARY section. if that small portion "the diary" of the from the main page was replaced with "newest postings from all sections" the arcive capability of this

site would be greatly enhanced, this would allow new users to interact when they find an old post, these guys (potential new users) are being directed to these old posts by a search engine. unfortunately the posts these guys are finding and posting to, are so far back on the list ,or archive, nobody know's they were there, and posted a comment or question.

If someone is really that interested in your diary, then they can already "easily" link to it from your 'handle'(mine is JW) located at the bottom of your posts. so IN MY OPINION THE DIRARY SECTION IS REDUNDANT. in my mind this should be easily configured with the "existing software" that is up and running here, but I could be wrong, but creating a "whole new" page to do this is probably not practical. anyway if you change only that -repace the dirary display box, with most recent postings from all sections- for me, as a user of this board i see it as a plus. but i feel its important to "note" the board works fine, and is really good, even without this suggested minor change.

I ran a BBS system here in Huntsville, AL for over 10 years. The software was VBBS Virtual Bulletin Board System. It had a feature in the message section called new message search which would bring up any unread messages for the users. The folks using this feature could define the topics that the New Message Reader worked with. I miss this type of feature on internet boards . . .

Ed;

actually you can get to 110 using toes.

for every 10 on fingers curl one toe when all toes are curled its 100 then you still got the 10 fingers .

Cheers.

Wow , Too Cool

My immediate reaction, is to disassemble the calculator and solder a coupla wires onto the "Equals" button, and mount the calculator where you can easy see the readout.

Very clever! The pushrod on the coil winder would be an ADC (Analog to Digital Converter)!

Re: The 88 cent counter ([none / 0](#)) (#11)  
by witapple on Mon Dec 22nd, 2003 at 02:22:24 PM  
MST  
([User Info](#))

I have used an old calculator in the past for similar purposes but instead of using a cam to push the button I put a magnet on the shaft and set a reed relay close to the shaft so it would be triggered once for every revolution, and then ran wires from the reed relay to the button contacts on the calculator.  
You do have to reset the calculator after a while cuz they only count so far but works fine for short periods of time.

Re: The 88 cent counter ([none / 0](#)) (#12)  
by Norm on Mon Dec 22nd, 2003 at 07:11:32 PM  
MST  
([User Info](#))

Like I said when I first posted this it was mainly for those that didn't know this could be done, I figured a large percentage of us probably already knew that you could use it for a counter, but it was just recently that I accidentally discovered that you could reset it. This feature makes it twice as nifty. Plus they're so inexpensive anymore. Norm.

Seems like somebody did this on the other board. He wired the switch with a jack coming out. He made two plugs for it. One went to his device to "count" revolutions. He made another that was shorted out. That meant the shorted one could be placed in the calculator so it would work like normal. The other was used when he wanted to use it as a counter. Of course for \$.88 a pop, you could probably forego the extra plug.

Or did I dream that?

Bach On

"remote living" here IS an appropriate place for this kind of question. And  
home grain production is still done by the very most remote and/or  
hardcore homesteaders.

I think I've seen info on home-built threshing machines in older issues of  
The Mother Earth News, and possibly an issue of Back Home. The latest  
issue of TMEN has a photo of a homesteader threshing by hand, and she  
is not looking particularly pleased about the whole process. I can see why  
you want to build a machine!

ADMIN

Guerreiro;

We got to discussing this over on IRC and since the threshing machine was first invented in the early 1800's we can't figure out where you got the idea there was such a thing as an ancient machine?

Prior to that it was all done by hand near as we can tell. If you have other information please share it with us.

Cheers.

by cevonk ([cevonk\(at\)signhere\(aol.com\)](mailto:cevonk(at)signhere(aol.com))) on Wed Dec 3rd, 2003 at 02:06:35 PM MST  
([User Info](#))

I hope no one will be upset if I quote scripture in the historical context of ancient threshing machines:

Deuteronomy 25:4 Thou dost not muzzle an ox in its threshing.

Until the early industrial revolution, AFAIK, all threshing was done by hand, or by having oxen (or other draft animals) tread on the straw (wheat, rice, whatever) while attached to a large, spoked wheel mounted on the threshing floor.

Winnowing was done by tossing the grain into a breeze. Placer miners (gold mining) in the desert use winnowing machines consisting of a big fan, in front of which they toss dirt from which they want to separate gold dust and nuggets.

Hi, new here.

Having worked on a LOT of old combines and thrashing machines, I would say that the chain flail would workk great for grain, and would be a snap to build. Suggestion: don't weld the chain flails to the shaft, bolt them. They WILL eventually wear out. Wheat and other grains are surprisingly abrasive.

The article mentions a sieve to separate the wheat from the chaff. I would suggest building it with two layers of screen. Even better would be two layers of sheet metal perforated with 1/2" holes. To adjust the size, you just slide one screen so the hole size is larger or smaller. If you are getting too much chaff through the sieve, close the holes a LITTLE bit (like a 1/16"). Also, it's not going to work too well without a fan blowing air up underneath it. Think of building a large box, with a blower pushing air up through the sieve set over the top. You can shake the sieve yourself or you can rig up some sort of shaking device with a motor and linkage. The air blows the lighter chaff up and into your face :( while the heavier grain falls down into the box. When it's getting full, stop and empty it.

The bad news: I would be very surprised if this home-brew device was capable of cleaning grain well enough for human consumption. Unless you like chaff in your bread, you will have to get it cleaned anyway. Try buying a "fanning mill" from a farm auction. It is what farmers used to use to clean and treat seed wheat and would clean wheat as fine as you want it.

How to safely weld electrical conduit

---

Hello All,

Remember in high school shop class how we were warned not to weld galvanized electrical conduit because the Zinc fumes are poisonous? Well, I've spent the last 20 years carefully grinding the galvanized away before I weld or braze. (The grinding probably produced as much Zinc fumes as welding would have.) So yesterday I was reading about electro-polishing and I occured to me that I should be able to electro-etch the zinc away from the steel. An hour later I had a fast and clean method for removing the Zinc. I took a plastic bucket and put a ring of lead around the bottom. The lead came from a stained glass supply store. They call it lead cane. The end of the lead bent up the side of the bucket and hooked over the rim. I put about 4" of water in the bucket and mixed in a 1/4 cup of lye. Next, I attached the negative clip of my battery charger to the lead cane and the positive clip went on the conduit. With the conduit in the water / lye mix, bubbles formed and the water turned black as the Zinc was eroded away in about 30 minutes. If you want it to go faster, add more lye. If your battery charger overheats, add more water. I intend to let the Zinc settle in the bucket and re-use the mix. Do this outside because the bubbles are at least Hydrogen and Oxygen and wear safety glasses and gloves. Lye in a open cut hurts terribly.

Have a good day

John

I don't know what's best for zinc, but you can probably use something else than lye for the electrolyte. I have some friends who use electrolysis to remove rust and corrosion from Civil War artifacts. They use salt (table salt-sodium chloride) for the electrolyte & about 6v. They adjust the amount of salt to keep the amps low enough for the battery charger.

Talk to someone who really knows their chemistry. Note that usually an acid is used to make the electrolyte, you are using a base. If a basic electrolyte is required, you may still be able to use something milder than lye. But I don't see what difference it makes as long as the solution will conduct electricity - just keep the conduit more positive than where you want the zinc to be drawn to. Different electrolytes will work at different rates, probably all slower than the lye solution unless you try some strong acids.....

### [Testing a Wind Generator](#)

By [KnightOfEpsilon](#), Section [Homebrewed Electricity](#) [Science Fair](#)

Posted on Mon Nov 10th, 2003 at 06:03:52 PM MST

I need help with testing this wind generator I'm planning on building.

I'm doing a science project involving different types of wire for a small wind generator similar to this one I found on otherpower.com:

<http://www.otherpower.com/woodmill.html>

I was wondering how I could test this generator. The web site said that it was attached to a car and tested at 25 mph, but they didn't say how they kept it attached to the vehicle. Could anyone tell me how I could do that, or suggest any other methods of testing the generator? Thanks.

[Testing a Wind Generator](#) | 2 comments (2 topical, 0 editorial)

Re: [Testing a Wind Generator](#) ([none / 0](#)) ([#1](#))  
by [DanB](#) on Mon Nov 10th, 2003 at 06:15:36 PM MST  
([User Info](#))

It was a small wind turbine... I made a bracket that tied it down to the front bumper and then had a brace that went over the back of the car and I tied the back brace down to the roof, and the spare tire which mounted on the back of the car.

(that was a model A ford with a bad paint job... and they are tall, some cars might be harder!)

You can certainly test a small alternator like that with a drill... it will give you some idea of alternator performance anyhow! When I used the car, we pretty much had a battery on the floor, and a volt meter and an ammeter so we could record output vs a rough approximation of windspeed. I would not say that sort of testing is either accurate, safe, or legal though... so - do so at your own risk!

The wooden windmill was a fun experiment, I'd seriously consider building an axial field alternator though... it's easier, and you'll most likely get better results with fewer magnets.

This one: <http://www.otherpower.com/woodax.html> works better and is overall a bit easier to build I think. The alternator is simpler...

To do it over again there are a few things I'd change however. Like.. next time Id use smaller shaft and bearings, that one was a bit hard starting due to stiffness in the ball bearings. And.. if you were serious about using the machine and having it last, I'd probably avoid using wood. But that page should offer

Thanks, I appreciate the help. By the way, where would you suggest I look for parts to build the AX? I've never really built anything before, so this is a little overwhelming. What I want to do is experiment with the same alternator using 18, 20, 22, and 24 gauge wire.

What kind of magnets should I use? Would ferric magnets do the trick, or should I go with the neodymium boron kind?

Also, for the rotor blades on the AX, how much do you think the diameter of the swept area can be decreased without sacrificing too much power?

Sorry if these questions seem a bit novice, but I'd appreciate any help I can get.

[My Tiny Savonius NiCad Battery Charger\(Pics\)](#)

Hi Guys.

At LONG last, a couple of friendly shutter bugs came to visit with their digital cameras, so I am including the pictures of my teeny tiny Nickel Cadmium "C" cell charger.

This first one is a simple head on shot showing the general assembly. I just used a simple 2X4 frame, and held it up with sections of "borrowed" clothesline from an extra kit my wife had...

This one shows the alternator close up. You can see the little black ceramic magnets that are hot glued into place. Little note here: Don't use hot glue on ceramic magnets. It seems to weaken them.

Here's a blur while it spins. You can also see the thin metal ring that I put in behind the coils to pull a little more magnetic field through. I'm not too worried about eddy currents or heat build up with the tiny amount of power this mill creates (about 4V and 800mA in a good stiff wind).

And here's the oversized eye screws I used to secure the clothesline "guy wires" to the frame...

Thanks to Lucie and Steve for the pics. Very nice.

Now... On to the next one... BIGGER...MORE POWER!!  
(Insert appropriate gorilla grunting noises here.)

Regards,

Xeroid.

How about some more construction details - particularly the windings. And did you use any kind of regulation for charging the ni-cads? I've still got a 250w Picoturbine kit to build one of these days so I'm particularly interested in how you constructed the rotor. TIA,  
Russ

Whoa! Hang on there! This is just one of the tiny little rechargeable flashlight battery chargers. I only used 16 1.25"X 0.5" X 0.25" ceramic magnets on a round 12" or so diameter of light gauge steel.

I modified the version from picoturbine (I believe called the "beta" plans) that charges 2 "AA" cells to try and get more juice in order to charge 3 to 6 size "C" nicad cells. The plans call for 60 wraps of 20 guage wire, I used 80, since I needed higher voltage.

I used a zener diode to act as a "safety valve". The zener will only be by-passed once the battery pack reaches 3.6V (3 cells in series) and then the excess power can flow past the blocking zener into an LED and a couple of 10ohm resistors in series (so 20ohms). I paralleled in some capacitors after the rectifier diode bridge I built in order to get a smoother DC flow. The only thing is, I should have used varying sizes, as it seems to spike the voltage when all three of the same kind hit their capacity and unload all at once (or seem to).

Regards, XEROID.

Excellent job. Free electricity is good electricity. I wouldn't worry about the hot melt glue damaging the ceramic mags, they're just naturally weak. Seriously, once you experience the power of neodymium magnets, you'll never go back to ceramic. They're just not even in the same league. The ceramics are fine for a small project because they're inexpensive, but for major volts/amps/watts, there is no substitute for neos.

Best regards,

troy

Re: My Tiny Savonius NiCad Battery Charger (Pics) ([none / 0](#)) (#5)  
by xeroid ([centurion27@lycos.com](mailto:centurion27@lycos.com)) on Wed Sep 10th, 2003 at 02:51:53 PM MST  
([User Info](#))

Thanks Troy.

I actually started this little project so long ago, I don't think I had as yet discovered the sheer power of neos yet. The instructions said to use ceramics, so I bought them, and I just built it with what I had.

Actually, I am thinking of gluing some 1 1/4" X 1/2" X 1/8" neos ON TOP of the ceramics just for fun to see what kind of crazy efficiency boost I can get.

That and it's bound to start charging in much lower winds...

Regards, XEROID.

### [Nuked my Zener Diode - Oops!](#)

By [xeroid](#), Section [Homebrewed Electricity](#)  
Posted on Fri Aug 29th, 2003 at 12:20:48 PM MST [Science Fair](#)  
[Nuked my Zener Diode - Oops!](#)

Hi Folks.

I built a little Picoturbine.com based savonius for charging nicads. I built the little overcharge protection circuit which uses a zener diode to shunt excess power through a resistor to burn it off.

The only problem was that the original design was intended to charge 2 size "AA" nicads, and I wanted to charge 3 size "C" nicads. I think I "NUKED" my single little 3.6V zener diode with the higher amp output of the 3 "C" cells.

Okay, I have essentially NO electronics training or knowledge, so could someone with greater wisdom than me please help me build a reasonable overcharge protection for these cells? I have a couple of 10W 10ohm resistors to burn the excess power off.

The output of the alternator is about 4.1 - 4.5V at top speed (sorry, no tachometer yet, but this is as fast as I've ever seen it go in a fairly strong wind) and about 0.8 - 1 amp.

I'll try and get pictures soon. A friend of mine who owns a digital camera is coming over for dinner in a little over a week, so we'll see.

Thanx in advance.

Been burning up zeners myself ([none / 0](#)) ([#1](#))  
by TomW on Fri Aug 29th, 2003 at 12:34:46 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Xeroid;

Thats kinda funny since I have been killing zeners and regulators myself just lately.

I gotta ask just how is this circuit wired? is the zener in series with the batts or what?

Usually, but not always, a zener is used across a voltage source to clamp it to a specific level. If that is the case it seems like the batteries you charge with it should not really affect current through the zener. I could be wrong it has been awhile since I did much electronics at the circuit level.

Anyway add some info and I am sure one of the real experts on circuits will chime in with solid information.

Cheers.

Zeners huh,

These are a strange breed of diodes I think. they will act like a regular run of the mill rectifier diode. then at their "turn on" voltage they will internally short, and conduct in both directions. Until the voltage drops and then they go back to regular "check valve"(rectifier) type operation.

Basically in my mind what I see happening here is that you have the Zdiode in series with your resitors, and all that in parallel with the batt's and charger leads. If so then you may just have to increase the load capacity of your Zdiode. And you may be correct, that your new batteries are popping the Zdiode. Something you could also try is using the Zdiode to activate a small relay to open the charging circuit, instead of a dump load. Hopefully this wont cause any over speed problems for you. And since the impedance in the relay coil is quite high, you could use the same Zdiode(after replaced). basically while the zdiode is conducting, it is in a series circuit with the relay coil and batteries. while the relay is energized, it uses battery voltage and disconnects the positive lead of the charger circuit. Allowing the "relay to remain on" until the battery voltage decreases to a point that the Zdiode stops conducting. then the cycle repeats endlessly if necessary.

If over speed was a factor you could use the relay to route the dummy load, if it is double position double throw. I'm pretty sure you will be okay if the charging circuit is open for such a small set up. I just recently bought some Zdiodes that could carry 40amps while conducting both ways. And of coarse there are many different breakdown voltages avilable. The charts for selecting Zdiode's usually include many "turn on" or "break down" voltages. I happened to be lucky that there was a really good electronics store nearby and they helped me find the right chart to select mine. But the mail order companies usually are willing to help if you basically know what you are looking for.

-JW

by laskey on Fri Aug 29th, 2003 at 05:00:51 PM MST  
([User Info](#))

As far as I see it you really don't have a problem. You're just not using the right zener diode. You need one that can handle the current you're feeding through it. 4.5Volts X 1Amp = 4.5 Watts. You need a 5 Watt zener to handle what you put through it. Which I'm pretty sure are available.

Cya,

Chris

Re: Nuked my Zener Diode - Oops! ([none / 0](#)) (#4)  
by RobD on Fri Aug 29th, 2003 at 05:40:00 PM MST  
([User Info](#))

Zener diodes are, in most cases, not designed for high current applications. They work wonderfully well in circuits where bias or reference is required and noise is not a problem (Zener's are inherently noisy buggers). You might want to look into three terminal regulators. Easy to hook up and can take a lot more current than zeners. In fact I think Radio Shack has a little blurb on the back of some of there regulators telling how to hook them up.  
RobD

Re: Nuked my Zener Diode - Oops! ([none / 0](#)) (#5)  
by charged on Sat Oct 4th, 2003 at 02:36:12 PM MST  
([User Info](#))

Use your zener to control the base lead of a power transistor that's been properly heat-sinked.

Use a 2N3055 with the collector connected to your positive "overshoot" power point, the same place you had the positive going into the zener previously. The emmitter goes to your overshoot load.

The zener is connected between the collector (+) and the base lead through a variable resistor. When the zener senses the overcharge, it turns on the base lead through the current control resistor and allows the excess charge to bleed off.

The transistor can handle MUCH more power than the zener, which is only intended to be a circuit voltage control mechanism. A zener is NOT intended to be a high power charge control device by itself.

## Size Relationships

By [wooferhound](#), Section [Magnets & Magnetism](#)  
 Posted on Thu Aug 28th, 2003 at 06:48:27 AM MST [Science Fair](#)  
 Coil and Magnet Size Relationships

I asked this question last week and nobody touched it, so I'm asking again and rephrasing the question. What size should the coils be in relationship to the magnets?

If I have a 2 inch square magnet, How big should the coil be?

If I have a 1/4 inch diameter magnet. How big should the coil be?

.

[Size Relationships](#) | 4 comments (4 topical, 0 editorial)

Re: Size Relationships ([none / 0](#)) ([#1](#))  
 by [DanB](#) on Thu Aug 28th, 2003 at 10:38:52 AM MST  
[\(User Info\)](#)

it depends a bit on the spacing between the magnets, and somewhat on how many phases the machine will be.

For single phase... its a hard call in my opinion. Ideally, the coil should occupy the space of 2 magnets so that one leg (by leg we mean one "half" or "side" of the coil) is always seeing the opposite pole of the other. If both legs of the coil see the same pole, no power is generated during that moment. But in my own tests, it seems like I get a little bit more power in the single phase setup having the same number of coils as magnets, even though in theory that's not ideal.

In theory the hole in the coil should be about the size of the magnet. In practice I think a bit of a compromise might be ideal, so that the inner diameter of the coil is a bit smaller than the magnet.

For multiple phases, the coils will probably be larger than 1 magnet, unless you stack coils.

Best is to build your magnet rotor - and Id space the magnets evenly or put them maybe a bit closer together, but dont put more space between the magnets than the magnets are wide. Once the rotor is built.... figure a way to spin it and test some different coil shapes/configurations etc... then you'll know!

A search on this board for magnets, coils... possibly "coil shape" will definitely yield some results!

Re: Size Relationships ([none / 0](#)) (#2)  
 by J Steele ([Jvsinthal@yahoo.com](mailto:Jvsinthal@yahoo.com)) on Thu Aug 28th, 2003  
 at 01:23:11 PM MST  
[\(User Info\)](#)

Here is a drawing that shows a permanent magnet alternator. The coil windings stay still and the magnets and steel backers move. The drawing attempts to show how the flux lines move thru the magnets, across GAP2, into the next magnet, thru the steel backer, to the next magnet, and so on. You can see from the drawing why you want GAP2 to be as small as practical, so that the field is strongest. As Dan described, to design a coil you need to know the size of the magnets and the size of GAP1. GAP1 can be made very small but it will allow the flux to "short circuit" the intended path for the flux. I show this short circuit in the area labeled "weak flux." For my guess, I would make GAP1 at least as large as GAP2 but smaller than the width of the magnet. Also notice from the drawings that the width of the coil windings should be less than the magnet width. I would guess that the windings should be about 90% of the magnet width. If you make the winding wider than the magnet you'll get a flattened sine wave. I would also attempt to make the windings wider than thicker so that GAP2 can be reduced. (My drawing did not convert to jpg well, the circles labeled "coil windings" are intended to show individual wires passing through the plane of the screen.)

I hope this makes sense.

John

If you make the winding wider than the magnet you'll get a flattened sine wave. I would also attempt to make the windings wider than thicker so that GAP2 can be reduced."

These are among the fundamental questions.

When strong magnets like neodymium ones are now widely available I think that the knowledge will grow how to design permanent magnet alternators very effective.

It is clear that if you widen the gap between the magnets you will loose power (because in the empty area there is no flux at all), even if you as well gain something by getting them far apart from each other, because then there is less 'leakage' from a magnet to the next one in the line. Somewhere between the extremes there is the optimum, how to get the best power at suitable RPM.

So these factors influence each other.

The magnetic power of the magnets as well influences the best design probably...

There are several different theories concerning the best design.

Some people say that the dual disk design is the best, some deny that proposition.

One quite good method is to copy a quite successful design, you can find several of them by studying 'Otherpower' website, Hugh Piggott's web-site, Ed's website (<http://www.windstuffnow.com>) and others.

I would tend to agree (intuitively) with your guess about gap sizes there...  
except I think that it depends very much also on the magnet shape. Rectangular, or wedge shaped magnets have their edges overall running parallel, so leakage will be more if the magnets are close. Disk magnets would only be touching at one point if they were in direct contact - so leakage is bad only at that one point. I think you can safely pack disk magnets a bit closer to each other than rectangular,, or wedge shaped magnets... even if you have a big airgap. In cases like with some of Eds machines, with slotted Laminates and very very small airgaps, perhaps leakage between the magnets is probably not such an issue at all.

will it work?

[Science Fair](#)

when I was 15 and doing time in reform school, one of my teachers told me about an idea he had to make energy. He then drew me a picture and explained how he would make a miniature ferris wheel and hang 8 freon bottles on it. Four full and four empty and run hoses from the full one to the empty one on the opposite side. then stick the whole thing in a water trough. as long as the water was hotter than air temp, he said as the full bottle dipped into it, it would turn to gas and go thru the tube to the top bottle and turn back to liquid, thus constantly turning the wheel perpetually. Would this work? and if not, why not? and has anyone built one of these?
