# OTHERPOWER.COM

The **CUTTING EDGE** of Low Technology

### **The first of the Triplets is set free and flies!**

Over the last few weeks, Otherpower.com has been building a set of Wind Triplets -- 3 axial-flux brake disc wind turbines named Curly, Moe and Larry. The 3 brake disc alternators are identical, but Curly and Moe sport 10-foot props and Larry an 8-footer. This one is Moe, and it's up and flying at TomH's cabin. So far so good -- Moe starts spinning in 5 mph winds and has been producing good power at under 15 mph windspeeds. **We completed a detailed series of web pages about the construction of the triplets--[you can check it out HERE.](#)**

## Thank you for dropping by!

We are a group of alternative energy enthusiasts who want to spread the message that *It's EASY to make your own power FROM SCRATCH!* Otherpower.com's headquarters is located in a remote part of the Northern Colorado mountains, 15 miles past the nearest power pole or phone line. All of our houses and shops run on only solar, wind, water and generator power...not because we are trying to make some sort of political or environmental statement, but because *these are the only options available.* And we refuse to move to town.

We could never have made it to our current level of electrification up here without the help of friends, neighbors--and folks we've never met, thanks to the internet. Our goal is to share our information about experimental successes and failures alike, free of charge, with anyone who is interested. We also offer a wide selection of books and hard-to-find alternative energy parts and components on our [web Shopping Cart](#). We hope you find our pages informative, useful and enjoyable!

### The Blunt Edge of High Technology

For all questions about orders, inventory, tracking, shipping, etc. please [E-Mail our Shipping Office](#)

or call us at: 877-944-6247 (toll-free in USA) or (970) 484-7257. Our mailing address is: Forcefield  
2606 West Vine  
Fort Collins, CO 80521

Also, you can visit our Retail Store at 614 South Mason St., Fort Collins, CO

You can [send DanB and DanF an E-mail HERE](#). However, PLEASE be aware that we receive many more Email requests for free information and advice than we can possibly respond to and still run our business...they come in twice as fast as we can reply. For quicker advice and opinions alternative energy questions from experimenters worldwide, try posting your question to the [Otherpower Discussion Board](#). Please research your question by searching our discussion board and Google before posting or emailing us. If you do Email us, make sure your email has a good subject line -- if the subject is 'blank', says 'hello' or 'how are you' it will never be read - many viruses and spam contain these headers. Please keep your questions *specific* regarding topics we've written about. If you ask 'how do I build a windmill?' or 'how big a system do I need to run my house?' you probably won't get a reply...please do your homework first. If you ask us 'on your Gerbil-powered generator page, how many turns are in each coil and what direction are they wound' we will almost certainly reply promptly. If we dont, please email again and remind us. THANKS for being considerate!

## OUR NEWEST PAGE

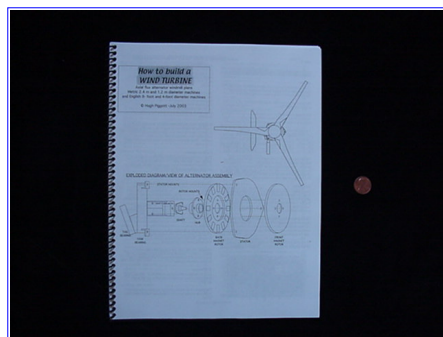

### [Hamster-Powered Alternator](#)

Skippy the Hamster is Forcefield's newest employee! We custom-built a low-rpm permanent magnet alternator onto his exercise wheel, and he lights a night light at DanF's house. We installed a data acquisition computer on his wheel too! And of course this simple alternator, buildable by kids, would work for wind or hydro power experiments and science fair projects too.

## OUR NEWEST PRODUCT

### [Axial Flux Alternator](#) [Windmill Plans by Hugh Piggott](#)

The latest of Hugh Piggott's axial-flux wind turbine plans.

Detailed CAD drawings, dimensions, photos, instructions, and theory. Build for 12, 24 or 48 vdc, both an 8-foot and a 4-foot diameter version. All the information you need to build a wind turbine from scratch!

**[Make Your Power From Scratch!](#)**

**SAFETY NOTE:** Some of the experiments described on our pages may present various hazards. Please be cautious. We are not responsible for injury resulting from neglecting safety precautions when performing experiments.

# Construction of a 10' diameter Wind Turbine

## With Furling Tail

---

PAGE 1   [PAGE 2](#)   [PAGE 3](#)

[Para Español, traducción de Julio Andrade.](#)

**These pages are HUGE with lots of photos to download, so please be patient...it may take some time. All of the diagrams drawn with DanCAD are scanned larger than they appear on these pages. Sometimes they don't show very clearly, depending on your screen size. If you have trouble reading a diagram -- first try Right Click --> View Image to enlarge it. You can also do Right Click --> Save Image or Right Click --> Print Image to get the hi-res version.**

This is a sort of diary about how we built the last 5 windturbines, all of which are pretty much identical. The windmills use axial field, dual rotor alternators, with a furling tail system and a 10 foot diameter 3 blade prop. It's very much inspired and along the lines of Hugh Piggott's latest design. [Click Here](#) to visit his site for lots of useful information.

The windturbine I'm describing here turns very freely and should start generating power at, or below 7mph. [Click here](#) to see a less detailed page about a nearly identical machine I helped a neighbor build earlier in the summer. They spin easily, they start charging in low winds, and seem to work pretty well. They are quiet, slow.. and seem safe and strong. Time will tell, this is an experiment!

Here is a fairly complete list of the materials we used, not including the tower.

80" of 1/2 - 13 allthread

10" of 1/4 - 20 allthread

44 1/2 - 13 nuts

2 1/4 - 20 nuts

1 washer 2" outer dia and 1/2" inner dia

6' of 3/4" steel pipe

6.5" of 1" steel pipe

2' of 2" X 3/16" steel bar stock

3 or 4' of 1" X 1/8" steel bar stock

A half of 1/2" plywood

about 6 square feet of 3/8" plywood

18" square piece of 3/4" plywood

A little bit of 1/4" masonite and misc lumber scraps for the coil winder

A quart of polyester resin and some fiberglass fabric

A bottle of baby (talcum) powder

thin viscosity superglue and accellerator for hardening coils

5 pounds of AWG 14 magnet wire

24 NdFeB magnets 2" diameter X 1/2" thick

strut tube/wheel spindle assembly from a volvo 240

2 11" diameter brake rotors from a volvo 740 or 850

3 boards, 5' long and at least 1.5" thick and 7.5" wide

lots of 1.5" long wood screws, at least 60

And for tools, I used common hand tools and power tools. A metal lathe is nice for this - there are a couple quick simple things that can't be done easily without it. The lathe work is easy and any machine shop could do it quickly

and cheaply for you. A bit of redesigning and one could live without it. I had a welder, a drill press, belt sander, power planer.. the usual! A draw knife is a **MUST HAVE** for carving the prop. I'd not try this project without a reasonable workspace and plenty of tools. For me, it takes about 30 hours to build one - I don't fret too much about little details or getting things just perfect.

The most expensive part of the project is the magnets, they cost around \$250. The rest of the cost depends on what gets purchased new, what gets salvaged, and resources on hand. I like to use salvaged, or recycled materials whenever possible. I'd figure the cost of the whole system not including batteries or a tower to be around \$300-\$400. In the end we get a machine which performs quite well, especially in low windspeeds. I think one would be lucky to get similar performance from a commercial machine costing less than \$1500. I think it's a great way to go so long as the resources are on hand and so long as it's fun! In the end there is a wind turbine which the builder understands, and feels comfortable maintaining, modifying, and repairing.

This page will often have pictures of different machines in progress. When we built these, I had 2 neighbors come by and we worked together on 3 machines at one time to make things a bit more efficient and fun!

Pictured above are the Volvo 240 strut assemblies we start with. Volvo made the 240 for almost 20 years! They should be easy to find. We have to remove any extra parts that come with the strut assembly.

We'll need to remove the strut inside (shock absorber), any brake parts, and the spring. One should probably either pay a shop to remove the spring, or get a spring compressor. These springs are under quite a bit of tension in this assembly. Simply loosening the large nut which holds all this together will result in the spring popping off with quite a lot of force! I've seen them fly over 20', if you are not very careful this could be quite dangerous. We'll take the wheel hub off, remove the bearings - clean and re-grease them. The Volvos are nice, they have very nice large wheel bearings which may never wear out in this application. Compared to banging your Volvo up and down the road, these bearings don't see much stress in a wind turbine application.

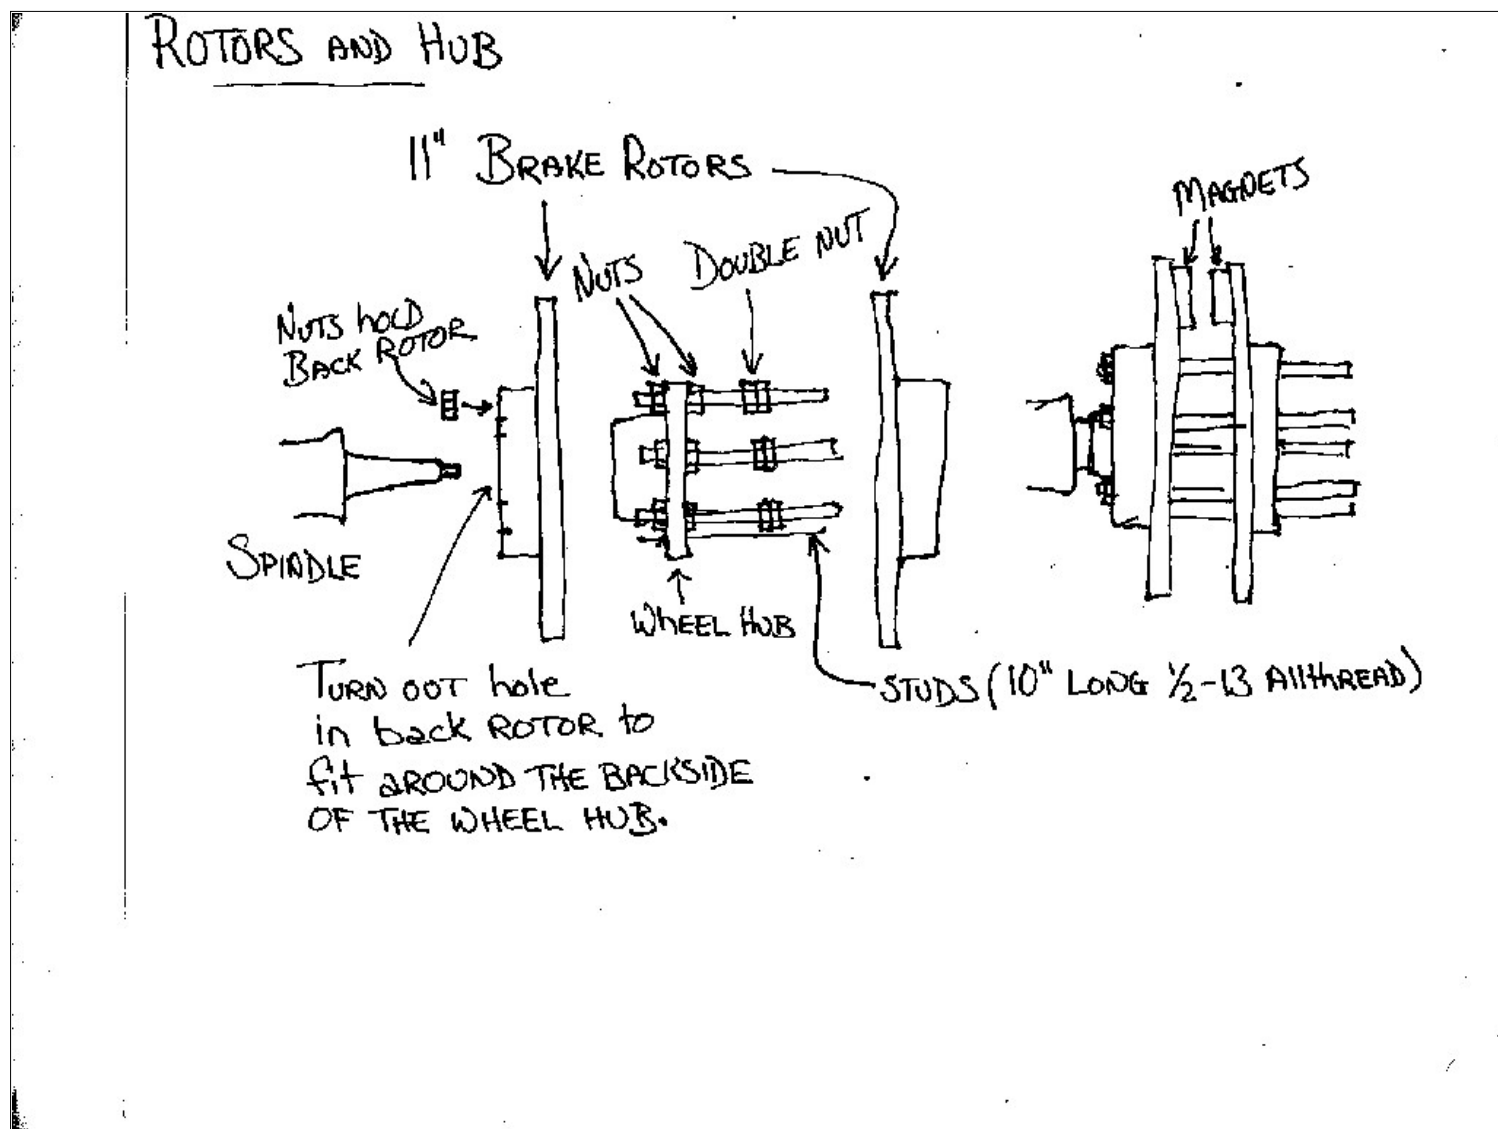

The Volvo 240 comes with 10" diameter brake rotors. I prefer a bit more diameter for a machine this large, so I found larger rotors on some of the newer Volvos - and they fit the same bolt pattern. Brake rotors on modern cars get thrown away frequently. Our local Volvo shop always has a dumpster full of them! Each machine requires 2 11" diameter brake rotors, these will be the "armature" for the alternator. Each rotor will have 12 magnets fixed to it.

I like to turn down the inside of the brake rotors just a bit. This leaves a rougher, yet flat surface for gluing the magnets down. We also leave a very thin lip on the very outer edge of the rotor to help with placing the magnets in a concentric circle - and to help hold the magnets in against the centrifugal force they'll see when the alternator is turning quickly. This is an easy operation- if I didn't have a lathe I think any automotive machine shop could do it quickly.

The other important operation with the lathe, is to bore the hole in the middle of 1 brake rotor a bit larger so that it can fit over the back side of the wheel hub. The picture below will hopefully show that.

The picture above shows how 5 long studs, made from the 1/2" - 13 allthread will hold all this together. The coils will exist between the two brake rotors, in between the magnets. These brake rotors were designed to fit over the front of the wheel hub, and the hole in the middle is not quite large enough to fit over the backside of it, so this is why we need to turn it out just a bit with the lathe. I suppose this could be done with a grinder or something...

Above is shown the brake rotors after being turned. You can see that the hole in the ones on the left is slightly larger than those on the right. After machining them, we clean them carefully with paint thinner or gasoline so that we can glue the magnets on later.

Tom is cutting pieces on the saw. It's nice to get a list of all the parts you need to cut and get it over with in one shot. Here Tom is cutting a 5' piece of 3/4" pipe, 5 pieces of 1/2"-13 allthread 10" long, 3 pieces of

1/2"-13allthread 6" long, 1 piece of 3/4" pipe about 6" long, and 1 piece of 1" pipe about 6.5" long. We also need 3 pieces of 2" barstock cut at 7" long, with a 120 deg angle on one end. These are for the bracket which will hold the stator in place. A picture of that is below. It's important to be careful and try to leave nice edges when cutting allthread, either with a bandsaw or a hacksaw! It saves time... cleaning all these ends up with a grinder so the nuts will thread on is tedious and completely unnecessary if you make careful and clean cuts.

Pictured above are some of those pieces I described above.

Above we can see the strut assembly mostly stripped of it's extra parts. The picture below will show how we need to cut this up and weld it back together to make the furling system work.

In the older and simpler wind turbines I made there was no system by which the machine could turn away from high winds. In this one there is, and part of that simple system requires that the alternator be offset to the side of the tower a bit. So we need to cut up the strut tube! I used a bandsaw, it could be done with a torch, grinder, or hacksaw. The picture above describes (hopefully) how we cut it and weld it together. The angle is not critical, and things should work fine so long as the center of the wheel spindle is about 4"-5" to the side of the main tube which fits over the tower (yaw bearing).

The picture above shows how we weld the tail pivot to the strut assembly. The 2" tall 20 degree wedge is important for this. Looking at the picture, you can see also how the tail fits over the 3/4" pipe we welded on and pivots. The tail is welded to the 1" pipe, which should allow it to pivot over the 3/4" pipe. I've noticed that some 1" pipe fits nicely over 3/4" pipe, and some does not. It's probably wise to check when buying the pipe! I wound up having to grind ours down a bit to make things fit.

At some point we'll grind (or cut) a notch in the 1" pipe to which the tail is welded. This notch will serve as the stop to determine where the tail rests in normal operation and where it stops in high winds when it's completely furled away from the wind.

Above you can see the assembly described in the last picture. Again, there are 3 because we were building 3 machines at one time.

# STATOR BRACKET

$\frac{3}{16}$ " x 2" BAR STOCK

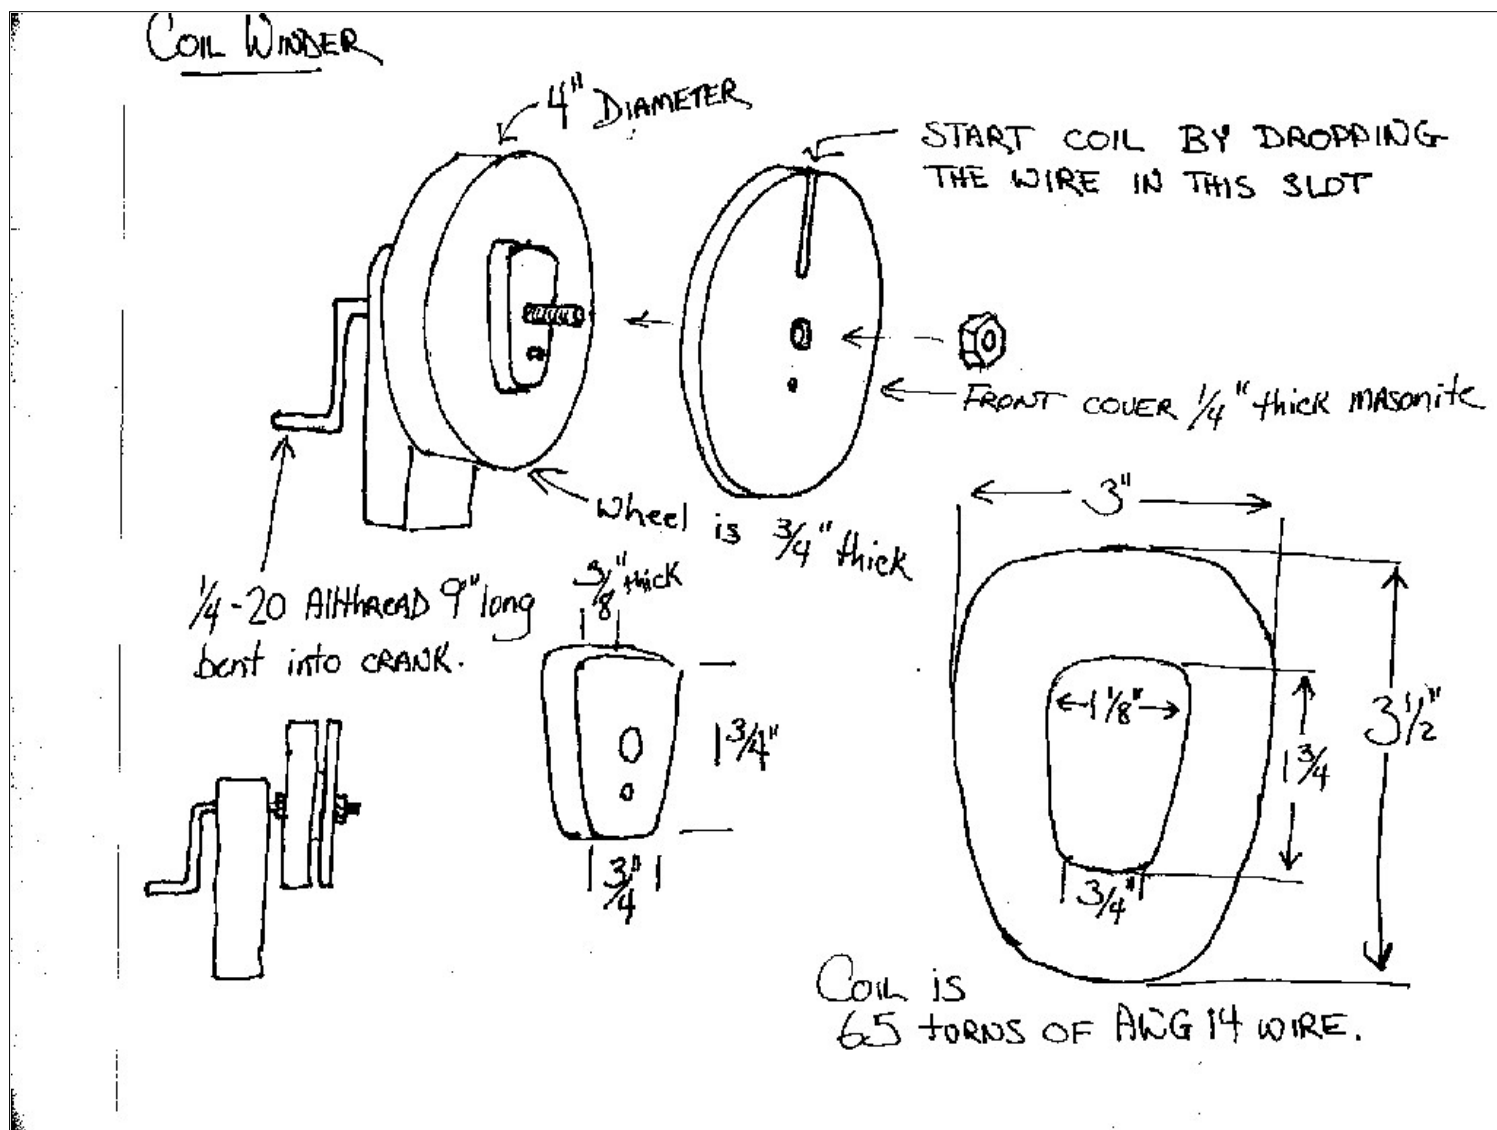

The drawing above shows the stator bracket I mentioned earlier, and how it will be welded to the assembly we've been making.

Here we see the basic frame for the windturbine with the stator brackets welded on. Now we can start really building the alternator!

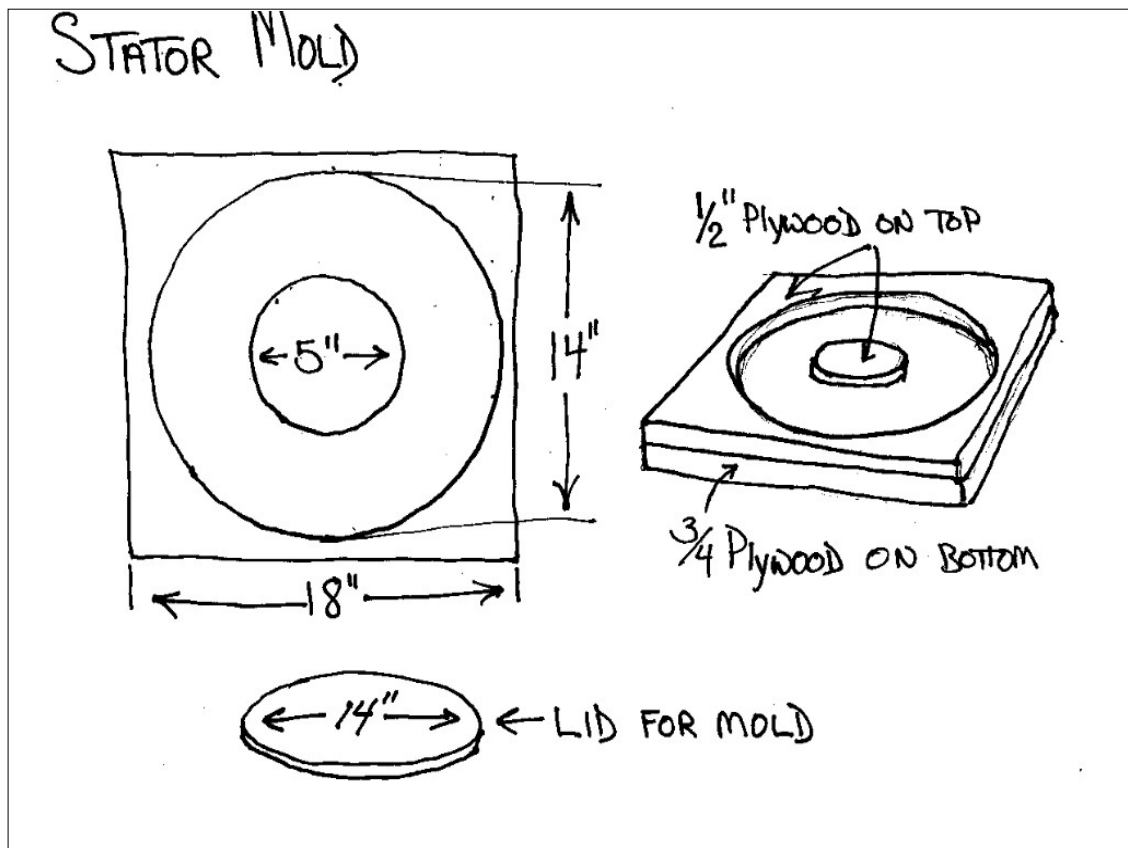

Above I've drawn some details about the coil winder I used. We need to make this because we need 9 nice tight identical coils. Each coil will be 65 windings of AWG 14 enameled magnet wire. Basically the coil winder is made up of two disks 4" diameter. I drill them 1/4" in the middle so they fit over 1/4" allthread tightly. The shaft and crank are of one piece of 1/4 - 20 allthread with a crank bent on the end. The back disk in the winder is thick wood (1/4") and it fits tightly over the allthread and it glued on there. The center part of the spool is of 3/8" material - this is the part we'll wind the wire over. I like to sand it very smooth, and give it a slight taper (so the front is slightly narrower and shorter than the back) so that the finished coils slide off easily. The front of the coil winder has a slot so we can drop the wire in there and tie it off to the shaft when we start winding a new coil. Before using it, I wax it carefully. (well be putting glue on the coils and this keeps the coil from getting glued down!) We bolt the front on it, drop the end of the wire in the slot (leaving about 10" sticking out) - and wrap the end around the shaft to secure it. I hold the wire with tension in one hand while winding with the other, taking care to keep the wire reasonably tight, and the windings pretty neat. It goes very quickly. The drawing shows about the size the coils should come out. Once the coil is done, before removing it I put a bit of thin viscosity super glue on it. It soaks into the coil tightly gluing all the windings together and making the coil quite hard and tough. I then spritz the coil with accelerator and the glue dries instantly. It's a neat sort of glue, very handy! [Click here](#) to find that on our shopping cart. Once the glue is hard the coil should be easy to remove. Sometimes they are a bit tight and gentle prying with a butter knife or something helps.

Pictured above is the glue, the coil winder with the lid off showing a coil... and a few coils I wound. Once all 9 coils are wound we're almost ready to build the stator! First we have to make a mold.

The mold we made is very simple, the picture above leaves little to be explained. It's all screwed together. It's important to sand it well, and leave the insides slightly tapered so that the casting will slip out easily. In the bottom of the mold I take a heavy black marker and draw lines at 40 deg to each other so that we have exact spaces to put

our 9 coils. The lines should be heavy so we can see them through 1 layer of fiberglass material and some resin.

Pictured above is the finished mold. The dark purple spots are caulk we used to fill gaps and cracks between wood... this just helps the casting come out more easily. Before using the mold, we need to put some kind of release agent in there. Auto polish wax works great... we didn't have any so we used axle grease! Lard, butter... I'm sure lots of things would work fine!

We need some fiberglass in the stator for strength. Pictured above DanF is cutting out 2 rings of fiberglass fabric exactly the size of the stator, 14" diameter with a 5" hole in the middle. We'll have one of these on each side of the coils for reinforcement.

Pictured above we are wiping axle grease all over the mold to assure things will come out easily in the end.

We mix up a little polyester resin and put it in the bottom of the mold. Then we lay the fiberglass fabric over that, and pour a little more resin over the top. We work it in with gloves so the fiberglass is completely soaked in resin. At that point it becomes somewhat transparent so we can see the lines we drew in the bottom of the mold and we can tell exactly where the coils should be placed. Something to note about polyester resin: It smells bad! Some folks will get headaches... it's the sort of horrible smell that can stick with you for hours! A respirator is probably wise. You don't want it in your eyes, so safety goggles would be appropriate. It's sticky - messy, so wear latex gloves or something to keep it off your skin and hands.

Pictured above we've layed the coils in the mold, as you can see they fit pretty tightly! This picture is actually from an earlier machine so it's not quite right. Since then I've shortened the coils a bit and made the hole in the center of the mold a bit smaller so that the coils have less wire in them, lower resistance - and don't come quite so close to the outer edge of the mold. It's important to push the coils in towards the center of the mold as much as possible so they are existing directly beneath the magnet rotors. The leads from the coils should stick out the sides in an organized fashion. Each coil has a "start" - the inside lead, and an "end"- the outside lead - I like to keep them organized so that wiring them up is easy later on. At this point we mix up more resin and add some talcum powder - mix it up real well. By volume, a half and half mix is reasonable though it could be thinner. The talcum powder adds some strength and lets the resin go a bit further. We pour that into the mold till the coils are covered, and then lay on top the other fiberglass fabric ring. We can then mix up a little more resin (without talc) and pour it over the top making sure the fabric is completely soaked and transparent.

Once the resin is poured we put the lid on the mold and put lots of weight on it to keep things clamped down and flat. Best is to leave it like this overnight.... I get impatient and usually wait about 2 hours!

And here we have an almost finished stator! All we have now to make a functional alternator is to bolt it on, wire it up, and add a couple of magnet rotors. Lots of pictures in this page and LOTS more to go!

[\*\*WWW.WONDERMAGNET.COM\*\*](http://www.wondermagnet.com)

In the picture above we've put the front rotor on, and basically the alternator is done. Putting the front rotor on is not necessarily easy or safe the way I do it! Perhaps better would be to weld a bracket and a nut onto the inside of the front rotor so we could safely lower it down. The force between these two magnet rotors is fantastic! What I do, is carefully hold the front rotor up, and line up the marked hole with the marked stud so I know its close to the right position. Then, quickly, I place the rotor on there so that it's resting on top of the studs! This is a bit tricky, because the magnets are attracted to the studs and unless things are fairly well centered the rotor will be pulled into the studs and I have to pull it off and try again. This could be resolved if we used stainless steel allthread studs, but I'm not sure the extra cost and difficulty cutting stainless warrants it.

Once the rotor is sitting on top of the studs slightly skewed, I can then rotate it a bit so that it lines up with the studs. **It's very important to hold the rotor in such a way that there is NO POSSIBILITY that fingers could get caught between the rotor and the stator!** I then start lowering the rotor down over the studs, and very quickly the magnetic force will yank it from my hands and it will be sucked down onto the nuts which hold it into place! Again - a jacking screw in the center of the rotor would improve this operation a good bit, I think it's well worth the time to do so and will next time! As it is, this bangs on with gobs of force and sounds a bit like a gun going off when it comes into place. Without a jacking screw or a wheel puller, it will be impossible to remove! At this point, we can rotate the alternator. The gap between the front rotor should remain the same as it rotates (none of that sort of wobble is tolerable). Again, a bit of up and down/side to side wobble could be balanced out... it means we didn't get the studs quite straight probably. But wobble that changes the distance between the stator and rotor must be fixed with the adjusting nuts.

I've really not had much problem with either though, the worst being less than 1/16". If all looks good, then we know it's well adjusted and don't have to make any changes. We'll take it apart 1 more time for painting. If all doesn't look good, we keep disassembling it/putting it back together until it does! In either case, at this point we can turn the alternator and check output. At 60 rpm (1 revolution per second) we should see about 6 volts AC between any of the two terminals on the stator.

Above is a drawing of the wheel puller as we made it. This doesn't do much to help peaceful lowering of the magnet rotor I don't think, it's not stable enough, but it does pull the rotor back nicely so that we can get it back far enough from the back rotor to safely remove it by hand. It might be better to weld the 3.5" steel part of the puller to the inside of the front rotor, this way it might be easier to use and it might serve well to lower the rotor back on easily. If I were going to do that, I think I would upgrade to thicker steel and larger allthread just to be sure nothing could bend.

In the picture above we are hand turning the alternator and testing for output.

I didn't get many good pictures of this, but above is shown the notch in the tail pivot which sets the stops for the furling system. We like to weld a bead around it to strengthen it here and hopefully prevent cracking. The drawing on page one shows this to some degree. The notch must allow the tail to pivot around so that it's almost perpendicular to the wheel spindle on which the alternator rotates during furling (in high winds) and it must stop it

As per the drawing above, the tips of the blades are only 3/8" thick, and the root is full thickness. So quite a bit of material needs to be removed. Pictured above we are cutting off this extra wood on the bandsaw. We leave a bit of extra, just in case we make a mistake with the saw, it gets tricky ripping through the thickest part of a board this way, it's best to leave some room for error.

I used to think the saw, hammer, chisel and power planer was the way to make a blade! After spending a bit of

To rough out the airfoil, First we plane (I use a power planer) the back side of the prop down so it's to the right thickness. ( $3/8$ " at the tips tapered to full board thickness at the root) Then I draw a line,  $1/3$  of the way back from the front (leading edge) of the prop, and use the draw knife (and power planer) to basically carve it into a triangle. From here it's quick to use the drawknife and the power planer to make a nice looking airfoil.

The picture above shows the airfoil almost finished up.

We pulled the tower up with a truck and a chain. It went smoothly! At the time of writing this page, the machine has been up for about a month. It turns in the lightest of winds and seems to make 10 amps in practically the lightest breeze. In higher winds it speeds up some and makes reasonable power, although again, I think the blade could be a bit larger if we wanted more power from the machine, especially in higher winds. As it is, you can never hear any noise from the blades and it's making good power when we need it most! (7-15mph winds) It seems we're getting a good 100 watts around 10mph, which is quite reasonable for a 10' prop. We probably see about 500 watts or so at 25 mph and maybe 700 at 30 when it starts furling out of the wind. 500 watts in 25 mph is a bit less than we'd hope for from the 10' prop, and I believe it's because the alternator is a bit too powerful for it.

A larger prop could still cut in nicely at 7mph and have the power to bring the alternator up to speed in higher winds. As it is, our alternator produces 12 volts DC at 110 rpm. If our 10' prop runs at a tip speed ratio of 7, we could actually be hitting that speed in about a 5.5mph wind! So it seems reasonable, that if we wanted more power from the machine, an 11 foot prop would be appropriate... although it would work the machine harder and heat up the alternator more.

So, we could run a bigger prop I think, but for safety, quiet, and peace of mind I'm quite pleased the way it is. Tom used to conserve power, he only had 200 watts worth of solar. I believe he's got well over twice the power he had, especially in winter. Since we installed this he's usually turning the machine off early in the day as he cannot seem to use enough electricity! It's been lots of fun.

I've tried to cover most of the details about building this. I'd strongly suggest that anybody considering such a project first do a bit of homework!

Check out these pages....

[Hugh Piggott's website!](#) This machine is very much along the lines of his design and his plans are the main inspiration.

[Windstuffnow](#) for lots of useful formulas, 3 phase alternator education, ideas projects and plans.

[Our Discussion board](#), because this sort of thing is mostly what we talk about!

[Windpower Workshop](#), you'd be silly to set out on such a project without reading this first!

[Hugh Piggott's Axial Field Wind turbine plans](#) are excellent! Similar to the machine described in these pages, yet lots more detail and well proven!

[The Caboose Windmill page](#) is an almost identical machine we built earlier in the year. There's less detail, but it might be useful!

# CONSTRUCCION DE UNA TURBINA DE 10 PIES DE DIÁMETRO - Con Veleta Oscilante

## Página 3

---

PAGINA  
1

PAGINA  
2

PAGINA  
3

Al final de la [página 2](#) dejamos nuestra máquina casi terminada excepto por ajustes finales, pintarla y fabricar las aspas.

Esta es la última oportunidad que tenemos de pulir nuestro trabajo eliminando esquirlas y restos de metal. Luego desarmaremos toda la máquina, la limpiaremos con gasolina y le daremos sus manos de pintura. Si quiere no pinte el estator. Las bobinas le dan un toque interesante al conjunto.

Aquí tenemos el resultado después de pintar la máquina.

**Ala sencilla.** Su grosor máximo esta a 1/3 de su anchura desde el filo de ataque  
 (Si el aspa tiene 3" de ancho, su grosor máximo está a 1" de su filo de ataque)

El dibujo anterior muestra cómo trabajamos las aspas. No hay nada de científico en ello. Es posible que con un ángulo de ataque de 5° en toda su longitud trabaje igual. El bisel puede ser recto y no curvado. La razón por la que las hicimos así fue por pura distracción. En el [sitio de Hugh Piggott](#) o en la página [Ed's page on blade design](#) seguramente habrán ideas que usted puede estudiar. La naturaleza de este alternador es tal que un aspa de 10' podría resultar pequeña en presencia de ráfagas violentas (Más de 30 KPH). Esto nos proporciona menor producción a alta velocidad pero en compensación obtenemos seguridad y silencio. Todo es cuestión del viento que se tenga.

Empezamos con tablas de 5 pies de largo, 7 ½" de ancho y 2" de espesor. Luego dibujamos el contorno de un aspa y lo cortamos. Eso nos da una plantilla del contorno de las tres aspas.

La foto de arriba muestra las tablas cortadas.

Como se ve en el dibujo anterior, la punta del aspa es de 3/8" de espesor y en el eje es de espesor completo. Hay que quitar bastante material. Una sierra es útil en el primer paso. Debemos dejar algo de espesor extra para prevenir errores.

Ni una sierra, martillo, formón ni una lijadora eléctrica sirven para fabricar un aspa. Un cepillo y en último caso una escofina es lo mejor. Hemos trazado líneas en el canto de la madera para guiarnos en la profundidad del corte. Con un buen cepillo este trabajo inicial se hace en 15 minutos. El remate se puede hacer con una lijadora eléctrica de disco o de correa.

En la foto anterior se puede ver cómo limpiamos la superficie de la madera para llegar al corte que deseamos.

Para dar forma de ala a la madera usamos una lijadora. Observe la curva que queremos en la punta.

La fotografía anterior nos muestra el aspa y su curva casi terminada.

No es bueno dejarse llevar por la perfección. Fabricar tres aspas toma un día. Pero si tratamos de hacer un trabajo perfecto podemos pasar varios días en una sola aspa. Lo importante es que parezcan lo más posible entre sí dentro de las medidas dadas.

Una vez fabricadas las unimos. Nuestra tapa consiste de dos discos de madera de  $\frac{1}{2}$ ". El disco trasero tiene 10" de diámetro. El frontal sólo 8". Las aspas deben ser colocadas equidistantes entre sí. Hecho eso, atornillamos el aspa a su sitio con bastantes tornillos. Colocadas las aspas sólo queda pintarlas con alguna pintura resistente al agua. Finalmente deben pintarse con varias manos de pintura a base de linaza.

Y aquí está todo listo. Ahora lo que tenemos que hacer es balancear las aspas, hacer el circuito eléctrico y poner funcionar la turbina. Para balancear las aspas la impulsamos a mano y determinamos qué lado pesa más al lado opuesto colocamos pequeños trozos de plomo con unos tornillos. A veces basta con arandelas.

Este alternador será instalado en la casa de un vecino (Que ayudó en su construcción. Vamos a construir una torre izable de 30' (Unos 9 metros). No es gran cosa, pero estamos trabajando con lo que encontramos por aquí. En todo caso, hay espacio libre para que el viento se desplace. En la fotografía se puede ver dónde decidimos colocar la base de la torre. Es un pedazo de granito que aflora de una roca en el suelo. Le hemos perforado varios agujeros de  $\frac{1}{2}$ " a la roca con un taladro de percusión. El trozo metálico es parte de una viga en H que servirá de base al pivote que fabricaremos de tubos. Este método de fijación es el que nos gusta por acá ya que hay bastante grandes rocas de granito aflorando no sólo para la base sino para los vientos de la torre. Al rellenar los agujeros con cabillas que pegamos con resina epóxica logramos bases muy resistentes.

El trozo de viga ha sido soldado a las cabillas. Lo normal es fabricar una base plana y nivelada. En la montaña esto no es posible. Para subir la torre no dispondremos sino de un solo cable para subir y bajar la torre. Esa base debe ser muy resistente. En un sitio plano las cosas cambiarían.

Para fabricar la torre estamos usando los restos de una escalera. Uno de sus tubos es de 2" soldado a otro tubo de 1 ½". Una de las secciones nos servirá de base de la torre y la otra nos servirá de brazo de izamiento. En la fotografía estamos cortando lo que necesitamos para soldarlo posteriormente a su forma final.

Aquí podemos ver la torre en la medida en que la armamos sobre la base.

Hemos soldado más tubo a la punta de la torre para obtener el alto de 30'. En esta foto se aprecia cómo quedará todo.

Esta es otra fotografía de cómo quedará la torre una vez izada. Ahora podemos colocar la turbina en su sitio. Para bajar la electricidad usamos cable calibre 10 conectado a los tres terminales del alternador y que baja por el centro del tubo. En la parte baja de la torre hemos colocado un tomacorriente de tres patas. Así podemos despegar el cable y desenredarlo si es que por dar vueltas el alternador eso llegara a suceder. Desde el tomacorriente nos vamos a las baterías. Esta instalación resultó muy conveniente ya que el banco de baterías de nuestro vecino está muy cerca de la torre y casi ni tenemos pérdidas de electricidad.

Tenemos tres cables con las tres fases de corriente AC que llegan a la caseta de baterías. El dibujo anterior nos muestra cómo usar diodos individuales o rectificadores para transformar esta corriente AC en DC. Ahora podemos ir a las baterías o colocar un regulador antes.

La torre la subimos usando una cadena fijada a un camión. Este generador tiene un mes funcionando. Gira a la menor brisa generando 10 amperios. En ráfagas de mayor velocidad genera mayor potencia. Pensamos que si las aspas fueran más largas tendríamos mucha más potencia, especialmente con vientos fuertes. Pero tal como está genera 100 vatios a 15 KPH. Probablemente llega a 500 vatios a 37 KPH y 700 vatios a 45 KPH. A mayor velocidad oscila fuera del viento. Nosotros diríamos que 500 vatios 37 KPH es ligeramente por debajo de lo que esperábamos, pero es que nos parece que la máquina es demasiado potente para sus aspas. Un aspa más larga seguramente haría que la generación comenzara a 10 KPH. Tal como está el generador nos produce 12 voltios DC a 110 RPM. Con un aspa de una proporción de giro de 7 esas RPM se lograrían a menos de 10 KPH. Es posible que un aspa de 11 pies sea la mejor solución a este problema. Pero esa solución traerá cola: la máquina trabajará más y recalentará el alternador.

Un aspa más larga trabajará mejor pero en obsequio a la seguridad, silencio y tranquilidad de espíritu preferimos dejar las cosas como están. Nuestro vecino apaga la máquina ahora más temprano pues parece no poder gastar la corriente de que dispone.

Le recomendamos a quienes traten de embarcarse en un proyecto parecido al nuestro que hagan su tarea. Visiten los siguientes sitios:

# Axial flux windmill plans

or "How to build a wind turbine"

[hugh@scoraigwind.co.uk](mailto:hugh@scoraigwind.co.uk)

## Introduction

The term 'axial flux' refers to a type of alternator where the magnets are mounted on **disks** and the flux between them is parallel to the axis of the shaft. This is unlike conventional alternators whose flux is radial across the air gap. The brakedrum alternator is a radial flux type.

Lately I have been developing construction techniques for axial flux alternators. In 2001, I made a construction manual available for free down load from [this site](#). Since then I have taught a lot of [courses](#) and my ideas have moved forward. I have made the process simpler and I have made the alternator much more powerful by using [neodymium magnets](#).

You can see pictures of the construction process in action during my my latest workshop course in the USA by going to the [picture pages](#) for the course. There are two slightly different versions of the design - one using inches and one using metric measurements. Both are described in full. There are also plans at the end of the document for a smaller alternator using a 4 foot diameter rotor (blades).

There is a lot of exciting new stuff going on at the [Otherpower discussion board](#) where Dan is extending the design and using old Volvo parts to do it based on what we did on the course in April. Dan has made a [page](#) about his latest machine.

[Other books](#)

click [here](#) for a series of snapshots of the document, or read on for full details....

---

Dear Hugh,

I just finished your latest book. Damn, it's good. Great information and written very clearly. If you are ever near Denver Colorado and want to get a beer let me know.

Sincerely,

John Steele

---

also now available from

This is a pre-publication edition, produced in small batches. A final version will be available in a few months.  
This document will probably supercede the brakedrum plans although they will still be of interest to some readers. It's easier to build and involves less hunting around for parts. The brakedrum idea has a lot going for it, but it's not the way I would do it now (ten years on).

---

The plans describe how to build **two machines**. Both have axial flux alternators and 3-bladed wind rotors.

The large one has an eight foot diameter rotor and 500 watt output.  
The smaller one (below) is half the diameter and one quarter of the output.  
We only use a single magnet disk on the smaller machine.

**"I like the plans and the info, I really feel like I understand everything in it....**

**What I really liked was the way the "Little Pancake" machine was thrown in at the end. With just a couple of pages we have a complete construction plan, once we know the principals. Reminds me of house plans, all you need is some drawings, notes, a good material list and someone to ask questions when you get stuck. "**

**Ron Dinishak**

# PMG booklet page

PMG stands for permanent magnet generator. This booklet describes how to build one. It was prepared in year 2000 by [Hugh Piggott](#), for Intermediate Technology Development Group ([ITDG](#)), as part of an [overseas aid project](#) for DfID. It is not confidential; in fact the object is to disseminate it widely.

---

The latest version of the booklet can be downloaded [in pdf format here](#)

---

Feedback is more than welcome. Please let me know what you think.

---

**Steel disks** for the pmg can be obtained in the UK from [Andy Taylor](#) phone 01305 861001 for £6 each.

--

From: taywind@supanet.com  
To: hugh.piggott@enterprise.net  
Subject: windmills  
Date: Thu, 29 Aug 2002

Dear Hugh

I have built a number of axial field pmg's (down loaded from your excellent website) and I am very pleased with them. I have recently had a batch of mild steel discs 305 dia. x 6mm with a 65mm hole at the centre as per plans lazer cut (very nice finish).

and I thought that some pmg constructors or would be constructors may have difficulty in cutting out or obtaining such discs. I would therefore be happy to supply discs at a very good price of six pounds each plus postage. I hope this could help others to enjoy constructing there own pmg/windmill as I have. I can be contacted by e-mail or phone 01305 861001 or snail mail at 18 Tillycombe Road, Portland, Dorset, Dt51lg, England. Yours sincerely Andy Taylor

--

---

The pmg is intended for small wind turbines (although it can also be used for battery charging hydro turbines). It is of the 'axial flux' type. Magnets are fitted to steel disks and spun

past coils. Here is a picture of magnets on a wheel bearing. Later I learned to embed the magnets in resin so as to prevent them from flying off at high speed. All this is covered in the booklet.

Here's a picture of the stator which is the stationary bit which holds the coils. The coils are set in resin. Here below the resin is clear so you can see the coils embedded within. A magnet rotor passes on each side of this disk and produces AC voltage in the coils.

Another magnet rotor fits on top of the stator. Next, in this early picture, I am spinning the alternator with a power drill to collect data about the output at various speeds.

Here is a set of pictures detailing the way the stator is cast in a mould

And here is the rotor casting process:-

Assembly...

and flight :-)

I am also teaching [courses](#) where you can learn how to do this.

# 1. Introduction

This manual describes how to build a 'permanent magnet generator' (PMG). We can also call it an 'alternator', because it generates alternating current (AC). It will not generate 'mains voltage' or 'utility power' AC. It generates low voltage, 'three phase' AC, and then changes it into 'direct current' (DC) for charging a 12 volt battery.

What this PMG is made of

The PMG (see diagram 1) consists of:-

- A steel spine and shaft.
- A stator containing coils of wire
- Two magnet rotors
- A rectifier

The stator contains six coils of copper wire, cast in fibreglass resin. This stator casting is mounted onto the spine; it does not move. Wires from the coils take electricity to the rectifier, which changes the AC to DC for charging the battery. The rectifier is mounted on an aluminium 'heatsink' to keep it cool.

The magnet rotors are mounted on bearings, which turn on the shaft. The rear rotor is behind the stator, and enclosed within it. The front one is on the outside, fixed to the rear one by long studs which pass through a hole in the stator. The wind turbine rotor blades will be mounted on the same studs. They will turn the magnet rotors, and move the magnets past the coils. Magnetic flux passes from one rotor to the other through the stator. This moving magnetic flux is what produces the electric power.

## Building the PMG

This manual describes how to build the PMG. Read right through it before starting.

Section 2. is a list of materials and tools for the job.

Section 3 explains how to build the special tools (called jigs) and the moulds which are needed. You can build more than one PMG with them. There are many possible ways to make these jigs and moulds, but there is only room in this manual to describe one way to do it.

Section 4 is about the stator. It describes how to wind the coils of enamelled copper wire, and cast them in resin, using the jigs and moulds.

Section 5 shows how to build the magnet rotors, using magnet blocks and steel disks, set in another resin casting.

Section 6 shows how to assemble the parts into a whole PMG. It explains how to build the mechanical parts, how to balance the rotors, and what is required to connect the wiring from the stator.

Section 7 is about testing the PMG. It contains procedures for checking that it is correctly balanced and ready to use. It describes the options for connecting up the electrical output. It also explains how to connect the PMG to the battery.

Section 8 contains additional information about the use of polyester resins, and about using the PMG for hydro power.

## What this PMG can do

This PMG is made for small wind generators (see diagram 2). To build a complete wind generator, you also need

- a tower : perhaps a steel pipe, supported with guy ropes,
- a 'yaw head' swivelling on the tower top,
- a tail, to keep it facing towards the wind,
- a set of blades, to turn it.

The spine of the PMG bolts on to the yaw head. The blade assembly fits on to the front of the PMG. The yaw head and tail need to be so constructed that the wind generator will turn from strong winds, to protect itself. (This manual does not describe the blades, tower, or yaw head.)

On test at Scoraig

## 2. WIND TURBINE

The PMG works at low rotational speed. The chart shows the power output of the PMG, charging a 12 volt battery. At 420 rpm it generates 180 watts, which is 15 amps at 12 volts ( $15A \times 12V = 180W$ ).

At higher speed, the PMG can generate more power. But high currents cause the coils to heat up, and so the efficiency gets worse as the output current gets higher. For higher speed it is better to change the stator coils, either by using different size wire, or by changing the way they are connected.

If the PMG is always used at higher speeds, it is better to use thicker wire, which can carry more current without getting so hot. Using thicker wire means there are fewer turns on the coils, which means that the PMG would not work at low speed.

To use the same PMG for both low and high speeds, it is possible to change the connections. There are two ways to connect the stator wires to the rectifier. They can be connected 'star' or 'delta'. See Section 7 for a detailed description of the star and delta connections.

See diagram 3 for the graph of power vs. speed. Star begins to work at low speed (170 rpm). Delta gives more power, but only at higher speed. Star is good in very low windspeeds, and delta is better in higher winds.

A bigger version of this PMG would be able to give higher power at lower speed.

### 3. GRAPH OF POWER VS. SPEED

#### Caution

Take care when building and assembling the PMG so that the magnets cannot come loose. This can happen under extreme circumstances. Loose magnets rubbing on the stator can then destroy the PMG.

- Follow all the instructions for casting the magnet rotors - do not simply glue the magnets to the steel disks.
- Do not hit the magnet rotors with hammers during assembly.
- Take care that there is at least 1mm gap clearance between the magnets and the stator, on both sides. (For heavy duty, or high speed, use a larger gap.)
- Do not run the PMG at speeds faster than 800 rpm on a wind turbine. (When the wind turbine yaws, large gyroscopic forces will flex the shaft, and the magnets may touch.)
- Do not mount the rotor blade assembly directly onto the front magnet rotor disk, at any point away from the studs. Mount it only onto the studs and nuts themselves, which come through the disk.
- When mounting the PMG on the wind turbine yaw mount, keep the box section 'spine' of the PMG vertically upright, and not horizontally cross-wise.

## 2. List of Materials and tools

Materials for PMGs	No. per PMG	size	Total wt. grams
<b>FIBREGLASS SUPPLIES</b>			
Polyester resin (premixed with accelerator)			2700
Catalyst (peroxide)			50
Talcum filler powder			1200
Fibreglass mat (1oz/sqfoot)		1 sq metre	300
Colouring pigment resin (if required)			50
plasticene or putty			
<b>STAINLESS STEEL</b>

Spine, shaft, hub and magnet rotor

### Materials for moulds and jigs

Composite floorboards (other ideas are possible) and wood glue

Sand paper, wax polish

(Polyurethane varnish, and PVA release agent, if available.)

Paint brushes, and thinners to clean them

13mm Plywood for jigs and formers and stator mould centre

Steel rod, or pipe, for coil winding machine

Small pieces of steel plate or thick sheet metal

<u>Bolts (with nuts and washers)</u>	<u>diameter</u>	<u>length</u>	<u>For</u>
2 with butterfly nuts	6mm	60mm	coil winder
4	10mm	25mm	balancing with jig
1	12mm	150mm	stator mould

### Tools

Safety goggles, face mask, gloves, etc. as required

Workbench with vice

Welder

Angle grinder

Hacksaw, hammer, punch, chisel

Compasses, tape measure, angle gauge.

Spanners: 8, 10, 13, 17, 19mm : two of each.

Tap wrench and M10 taps for outer holes in magnet rotors.

Brass wire to gauge the heights of magnets

Pillar Drill Press

Drill bits 6,8,10,12mm

Holesaws 25mm, 65mm

Wood lathe, or a substitute as in Section 3

Chisel for wood lathe

Jigsaw to cut wood

Scales to weigh resin. Dispenser for catalyst, plastic buckets, scissors.

Soldering iron, resin-cored solder, wire cutters, sharp knife.

### 3. Jigs and Moulds

This section describes how to make the jigs and moulds for building a PMG. Once you have made them, they can be used again, to build more PMGs.

Coil winding machine

Some coils for the stator

The PMG stator contains six coils of copper wire (see diagram 4).

The coils will be wound on a plywood coil-former. The former is mounted on the end of a crankshaft, between cheek pieces.

- Make a crankshaft, turned by a handle (see diagram 5).

- Cut a small flat steel plate 60 x 30 x 6 mm (suggested sizes) and fix it securely or weld it to the end of the crankshaft as shown in diagram 6.
- Drill 2 holes, 6mm diameter and 40mm apart, centred on the shaft.

- Cut out 3 pieces of 13mm plywood as in diagram 7.

The coil former is 50mm by 50mm by 13 thick. It has rounded corners. The two 'cheek pieces' are 125mm by 125mm. There are 20mm wide notches top and bottom in each. The notches are for putting masking tape under the coil, so that it can be taped up before removing it from the former.

- Stack the pieces with the notches in line (diagram 8), and drill holes for the mounting bolts.

The holes are 6mm diameter and 40mm apart.

Use a drill press to drill the holes exactly square to the plywood.

## 8. DRILLING THE 2 HOLES

STACK THE THREE PIECES  
LIKE THIS:-

- Pass two bolts through the holes in the flat plate, and bolt on the cheekpieces, with the coil-former between them. Use butterfly nuts if possible. (diagram 9.)

## 9. FITTING THE COIL FORMER AND CHEEK PIECES

## Jigs for the rotors

### PCD jig for drilling holes

The magnet rotors are mounted on a bearing hub (see diagram 10). The hub has a flange with holes in it. For example there may be four holes on a 102mm (4 inch) 'pitch circle diameter' (PCD). Or you may have some other arrangement. This will depend on what kind of hub it is. Here we shall say 102mm PCD.

### 10. THE BEARING HUB PCD

The PCD jig will be used to drill holes in the rotors etc.

It will also be used to balance the rotors.

The holes must be marked and drilled very precisely. (See diagram 11.)

- Cut a square piece of steel plate 125mm by 125mm.
- Draw diagonal lines between the corners and mark the exact centre with a punch.
- Set your compasses at 51mm radius (or to suit whatever PCD). Draw a circle.
- The diameter of the circle is the PCD of the holes in the hub.
- Punch both places where one line meets the circle.
- Set your compasses at 72mm. Mark two points exactly this distance from the first two, on the circle. (If you have a different PCD, this size would not be 72mm. Find the size by trial and error.)
- Drill four holes exactly 72 mm apart on the circle. Use a small drill first and then a larger one.

## 11. MARKING AND DRILLING THE PCD JIG

Magnet positioning jig (See diagram 12)

This jig is for putting the magnet blocks into the correct places on the steel disks. Only one jig is needed. Make the jig from 250x250 mm plywood or aluminium sheet (not steel).

## 12. THE MAGNET POSITIONING JIG

- Mark the centre of the workpiece.
- Draw three circles, with diameters 50mm, 102mm and 200mm, on this centre.
- Draw a pair of parallel straight lines, as tangents to the 50mm circle as shown.

- Draw 3 more pairs of straight lines at 45 and 90 degree angles to the first pair.
- Using these lines, mark the magnet positions, and cut out the jig along the bold lines as shown in the diagram.
- Draw a line connecting two opposite magnet centres.
- Place the PCD jig on top of the 102mm circle, aligned with the magnet centres, and drill four holes to match the four holes in the steel disks.

### Making the moulds

Make moulds for the stator and rotor castings. They can be turned from wood or aluminium. Another method is to make plaster or clay plugs on a wheel, like a pot. The shape of the plug would be the shape of the outside of the stator. Then make a fibreglass mould on the plug. The surface of each mould must be perfectly flat.

The moulds need to be strong and smooth. It is not easy to separate the stator casting from the moulds. Hammer blows are usually needed.

It is a good idea to wind one coil (see section 4) before making the stator mould. This coil should fit neatly in the mould.

Here is one way to make the moulds, from composite wooden floorboard sheets, using wood-turning.

### Stator Outer mould

- Cut out several disks of flooring sheet (see diagram 13), approximately 500mm diameter.

- Take all but one of the disks, and cut circular hole in each, 360mm diameter to form rings (see diagram 14).

#### 14. RINGS

- Draw a circle 360 mm diameter on the remaining disk
- Drill a 12 mm hole at the centre of this disk, to help with centring.
- Glue the rings on top of the remaining disk, to form a stack, with a hole 60mm deep (diagram 15). Use plenty of glue at the insides of the rings.
- Cut out a small disk of 15 mm plywood, 140 mm in diameter, and drill a 12 mm hole at its centre.
- Placing a 12 mm bolt through both holes, glue the small disk into the exact centre of the hollow. Use plenty of glue at the edge of the disk.

#### 15. STACK

- Mount another piece of wood or board onto a lathe, a motor or the wheel hub of a small vehicle (for example a 3-wheel taxi). This is a the faceplate (see diagram 16).
- Spin the faceplate and use a pencil to make a very small circle at the centre.
- Drill a 12mm hole precisely at this centre. Hold the drill parallel to the shaft.
- Screw the glued stack onto the faceplate, using a 12mm bolt to centre it. Use four woodscrews through the disk and into the faceplate.
- Check that the face of the mould runs true. You can do this by holding a pencil close to it while it spins. Where the pencil makes marks, the face is 'high'. Loosen the screws and insert pieces of paper between the faceplate and the stack, on the opposite side from the pencil marks. Tighten the screws and check again.

## 16. TURNING A MOULD

Now it is possible to shape the mould with a chisel. Wear a mask over your mouth to avoid inhaling the dust. Beware of loose clothing, which may become caught in the rotating mould.

Turning a stator mould on an electric motor

- Cut a smooth surface on the inner edges of the stack (diagram 17).
- The surface tapers at about seven degrees.
- The overall diameter at the outer edge is 380mm
- The diameter of the flat face is 360 mm.
- The corner inside is smooth (slight radius) not sharp.

### 17. THE SHAPE OF THE STATOR MOULD

- Turn the inner disk down to 130 mm diameter on the face (see diagram 18), with a taper. The corners are rounded as before.

## 18. CENTRE DISK

- Place a coil against the face of the mould and check that it fits comfortably - if not, then the hollow must be made a little larger, or the centre disk a little smaller. In the end, the coil's centre must be at 250 mm from the mould centre.
- Remove the mould from the lathe or motor.

## 19. HOLES IN THE MOULD

Drill four holes in the central part which are used to separate the two moulds (diagram 19). Screw some small pieces of plywood onto the underside of the mould to make 'feet'.

Stator Inner mould

- Cut disks with diameter 370mm

Sawing flat faces on the inner mould

- Drill a 12mm hole at the centre of each
- Glue them into a stack (diagram 20), using a 12mm bolt to centre them.
- The stack is at least 45 mm thick, better 50 mm.
- Turn a 20 degree taper on the rim, and round off the corner, so that the diameter reduces from 368mm to 325mm.
- Check that the outer mod fits over the inner mould, with a 6mm gap all around the edge. Then remove the inner mould from the faceplate.
- Draw 2 lines on the larger face of the mould, 340mm apart (diagram 21)
- Cut two flat faces, as shown in diagram 21

## 21. CUTTING FACES ON THE INNER MOULD

These two faces will create a thicker casting around the mounting studs.

### Magnet rotor moulds

The PMG needs two magnet rotors. Only one mould is needed, but production is easier if there are two moulds, so that two rotors can be produced at one time.

The outer mould (diagram 22) is similar to the stator outer mould, but simpler

## 22. ROTOR MOULD

Use the PCD jig to drill four holes to match the holes in the magnet disks.

Each magnet rotor also needs an inner disk mould (diagram 23), with the same pattern of four holes.

### 23 MAGNET ROTOR INNER DISK

All moulds are sanded down to a very smooth surface, and finished with polyurethane varnish and wax polish. Do not use ordinary paint on the moulds. The heat of the resin process will cause the paint to wrinkle and spoil the appearance of the casting.

Rotor mould being made and used

## Jigs for the stator

### Stator studs jig (see diagram 24)

The stator needs four 8 mm supporting studs cast into it. These studs need a jig to hold them in place, until the resin is set. This jig is made from wood 380 x 50 x 25mm. It must be made precisely, or the studs will not fit the spine later.

- Make a punch mark at the exact centre of the largest face (see diagram 24).
- Use dividers or compasses to mark arcs at a radius of 178 mm from this mark.
- Punch four marks on these arcs, 30 mm apart and 10mm from the edge.
- Drill through with an 8mm drill (using a smaller size first to be accurate). Use a drill press, to drill the holes truly square.
- Remove some of the underside of the ends of the piece of wood, so as to prevent contact with the fibreglass resin.

Paper templates (see diagram 25)

Fibreglass 'chopped strand mat' (CSM) is to be used in the stator. Make some paper templates for cutting out the pieces of CSM. Later you can lay the templates on the sheet of CSM, draw around them with a felt pen and then cut the pieces out.

## 25. PAPER TEMPLATES FOR GLASSFIBRE CSM

## 4. Stator construction

This section tells how to make a stator, using the jigs and moulds from section 3. It is a good idea to wind a coil before making the stator moulds, so that the mould can be checked for correct fit.

### Winding the coils

- Mount the reel of winding wire on an axle behind you, in line with the coil former. The wire should form an 'S' bend as it winds onto the coil (diagram 26).

- Bend the tail of the wire 90 degrees, at a point 100mm from the end. Do not handle the bend any other part of the wire; leave it straight. Bent wire does not make a compact coil.
- Place this bend in the notch, so that the tail hangs out.
- Twist the tail loosely around one of the butterfly bolts.
- Grip the wire between the reel and the winder in a piece of rag to keep it tight.
- Wind the handle of the crankshaft.

The first turn lies against the cheek piece on the side where the tail comes out. The other turns lie against each other neatly, without crossing over. Build the coil up in even layers. Count the number of turns carefully. Normally there will be 100 turns.

- When the coil is complete, pass a piece of sticky tape under the coil on both sides and bind it tightly. Do not cut off the winding wire until this is done, or the coil will spring out, and loosen. Cut the tail of wire 100mm away from the coil.
- Remove the coil from the former, and wind five more coils in exactly the same way.
- Place the coils on a table (so that they are all exactly the same way up (diagram 27) Check that the starting tail is on the upper surface, and not hidden under the coil.
- Number the coils 1-6, writing on the masking tape.

## 27. THE COILS MUST ALL BE THE SAME WAY UP

- Scrape the enamel off the last 20mm of each tail of enamelled wire, until it is all bright copper. (A hacksaw blade makes a very good scraper, when the edge has been sharpened with a grinder.)
- Solder on tails of flexible wire (diagram 28).

## 28. SOLDERING ON TAILS OF FLEX

Suggested lengths of flexible tails:

- coils 1 and 6 - 800 mm flex
- coils 2 and 5 - 600 mm flex
- coils 3 and 4 - 400 mm flex

- Cover the soldered joints with sleeving. Leave no bare copper showing.
- Label the tails with the coil number and the letter A or B. A is for the start of the coil, B is for the finish. Do not mix them up. Or use two colours: black flex for the starts and white for the finishes.
- Lay the coils out in the outer mould.
- Check that they will fit comfortably, and that the tails are long enough to remain within the mould until the exit point between coils 3 and 4. It is important to lay all the coils the same way up.

## 29. THE COILS IN THE MOULD

### Preparations for stator casting

The stator casting will contain:-

- six coils
- polyester resin and talcum powder (and perhaps pigment)
- fibreglass mat (CSM)
- four studs of 8mm x 100mm threaded rod

Also, be sure to have the moulds prepared properly. Sand them, seal them, polish them. If PVA release agent can be got, then use it.

Cut out pieces of fibreglass CSM, using the templates. There will be 2 circular disks for laying flat in the outer mould. You also need enough curved strip pieces to cover the inside wall of the outer mould in a double thickness of CSM. Overlap 25mm between pieces.

When you are sure that you have everything to hand, start the resin casting process. It is a good idea to read through the procedure first, and check that you understand it all before you start. There are notes on polyester resins in section 8.

### The stator casting procedure

Diagram 30 shows the procedure for weighing out the resin and the talcum powder. The talcum powder is only used for bulk mixes (not thin layers with CSM), to prevent overheating, and to thicken the mix. Different mixes use different weights - follow the step by step instructions below. Diagram 31 shows all the parts coming together.

### 30. MIXING POLYESTER RESIN

Mix resin with catalyst thoroughly but slowly to avoid churning in air bubbles. Add any talcum powder only after the catalyst is mixed. When the resin is mixed, use it at once. After a few minutes in the mixing bucket, it will heat up, and begin to set.

Use exactly the right amount of catalyst. Resin casting needs less catalyst than normal fibreglass work (about half the time). When the workshop is hot, put in less catalyst. Casting thick layers of resin, put in less catalyst. If in doubt, make some trial mixes of resin, to find out the correct amount of catalyst.

If there is no PVA 'release agent', then take care not to wipe the polish off the mould with brush strokes. Apply the resin with a 'prodding' action.

- Place the outer mould on some newspaper on a workbench.
- Mix 200g of resin, with 3cc of catalyst (and 15-30cc of pigment for colour, if required). Use no talcum powder in the first two mixes.
- Paint this resin all over the inside of the outer mould. Do not paint it on top of the island in the centre.
- Apply one layer of fibreglass mat (CSM), and paint more resin over it again, with a poking motion to remove bubbles. Work the resin into the CSM.
- Apply a second layer of CSM to the wall, but keep one disk for later.
- Put the coils into the mould. The wire tails all come out in one place, between coils 3 and 4.
- Mix another 100 g of resin with 2cc catalyst. Pour this over the wires of the coils so that it soaks in. Avoid making 'pools' of resin.
- Mix another 600g of resin with 9cc catalyst and 600g of talcum powder. Pour this mix into the spaces between the coils. The resin should fill the outer mould until it is level with the island at the centre.
- Shake the mould vigorously, to remove air bubbles. Rotary motion and vibration will help the resin to settle, and help any air bubbles to rise .
- Mix another 200g resin with 3cc catalyst and only 100g of talc. Put the second CSM disk over the coils and paint it with this mix. Thoroughly wash out the paint brush with thinners.
- Put the inner mould down inside the outer mould, and fit the 12 mm bolt through the centre of both. Tuck the wiring neatly into the space between the moulds. One flat spot on the inner mould sits over the part where the wires come out of the stator. The resin will rise up the sides. Some resin may spill out.
- If necessary, pour resin gently into the gap between the moulds until it rises to near the top of the female mould. You may need to mix another 100g of resin with 1.5cc of catalyst to do this. Keep notes of the amounts of resin used, for next time.
- Place the jig (for the studs - diagram 24) over the inner mould, with one end over the wire tails. Tighten the 12mm bolt with a nut. Insert the four 8mm studs into the holes, with nuts on top. The studs should be immersed in resin for about half of their length.

Six stages of the rotor casting procedure

## 31. STATOR CASTING ELEMENTS

The casting is now complete. It should become slightly warm, and harden within hours. If it does not begin to set within a few hours, then put it in a warm place to speed up the process.

When the resin is fully hard, remove the casting from the mould. Be patient and gentle if possible. Remove the jig from the studs. Tap the two moulds apart, using a bolt in each of the holes around the central hole. Knock the casting out of the outer mould by turning it over and knocking the edge of the mould gently against the floor.

## 5. Rotor construction

The magnet rotor is also a casting. There is also a procedure later for assembling the parts. First collect together the magnet plates, magnet blocks, stainless wire rope, etc. as described next.

### Magnet plates

Each magnet rotor is built on a steel disk, 6mm thick. See diagram 32. Do not use aluminium or stainless steel for this disk! The disks have to be made of magnetic material. The disk has holes to mount it to the hub - in this manual the hub has four holes, each 10mm diameter, on a circle at 4 inches (102mm) PCD. If a different hub is chosen, then all the jigs and moulds must match this hub.

At the centre of the disk is a 65mm diameter hole. There should also be four holes drilled and tapped (threaded) for M10 rod between the magnet positions, at 220mm PCD. Screw four pieces of M10 rod, 20mm long, into these holes. These will bond to the resin and help to secure the casting onto the disk.

### 32. MAGNET ROTOR DISK

The magnet plates must be flat, not warped. It is not easy to cut the outer circle without warping the plate. A guillotine can cut steel plate into an octagon (see diagram 33), without warping the plate. This is an alternative way to make the rotor disk. First cut a square, draw a circle on it, and then cut off the corners at 45 degrees. The length of each edge is 116 mm.

The magnets will be placed on the corners of the octagon.

### 33. ALTERNATIVE SHAPE : AN OCTAGON

The central hole is made with a hole-saw or it can be cut out on a lathe.

Grind the steel disks until they are bright and clean, just before putting them in the mould for resin casting. Remove any grease with spirits.

#### Magnet blocks

There are 8 magnet blocks on each rotor. Each block has a north pole and a south pole (see diagram 34).

### 34. POLES ON THE MAGNET BLOCKS

Take care when handling the magnets. Magnets can damage floppy discs, music tapes, credit cards and other magnetic media. Separate them from each other by sliding them sideways. They attract each other with strong forces. Take care not to let them fly together - they may break. Never use a hammer to assemble the PMG. You may break a magnet or break the resin holding it.

The top faces of the magnet blocks on the disk must alternate N-S-N-S-... There is a method to check that you are doing this correctly, as follows. Each time a magnet block is placed, hold it so that it repels the one before (see diagram 35). Then place it without turning it over. When they are all in, check with another magnet: it will be attracted, repelled, attracted, repelled, by each magnet in the circle.

### 35. PLACING THE MAGNET BLOCKS

The two magnet rotors must attract each other when the mounting holes are aligned. Check that the magnets next to the holes on one rotor are different from the ones next to the holes on the other rotor (see diagram 36).

### 36. THE TWO ROTORS ARE NOT THE SAME

#### Stainless Steel wire

When the PMG is turning, the magnets will try to fly off the rotors. There is a large centrifugal force pulling the magnet blocks to fly away. When we started building these PMGs, the magnet blocks were simply glued to the steel disks. When the PMGs turned fast, the magnets flew off, and the wind generators were destroyed.

Now we embed the magnets in a resin casting. Resin alone is not strong enough to hold the magnets. It should be reinforced. Wrap wire around the outside of the magnet rotors to hold the magnets in. Steel wire is strong enough, but steel would take the magnetism from the magnet blocks. We use stainless steel because it is not magnetic and it does not spoil the effect of the magnets. Stainless steel wire cable is used on fishing boats.

Before using any resin assemble the parts dry. Put the stainless steel rope around outside the magnets five times, and cut it off with a grinder or chisel. Tape it in several places so that it is in a coil, ready to drop into place later.

### Rotor casting procedure

Before starting, check that everything is ready:

- the moulds are prepared with polish or release agent,
- the magnets and the magnet disks are clean and bright (no grease),
- 16 strips of CSM are ready to fit between the magnets
- the stainless steel wire is cut to length and taped
- the magnet positioning jig is ready

The amounts of resin mentioned in this procedure are enough for two magnet rotors.

### 37. MAGNET ROTOR MOULD ASSEMBLY

- Place four bolts through the holes in the outer mould, from below (see diagram 37). Lay a steel disk in the outer mould. Place the inner mould on top. Check the taper, and place the smaller face down, so that it can be easily removed after casting.
- Mix 200g of resin with 3cc catalyst. Paint it all over the steel disk. Add 20g of pigment for colour if required. Mix 100g talcum powder with the remains of the

resin. Pour this mix around the edge of the disk until it fills the gap, level with the top of the steel disk.

- Place the magnet positioning jig onto the bolts. Place the magnet blocks on the steel disk, within the positioning jig. Take care that the poles of the magnets alternate - north, south, north, south.. Before you place a magnet on the disk, check that the underside of the magnet is repelled by the one next to it (diagram 35). When all the magnets are in, remove the positioning jig, and use it for the next magnet rotor. Remember : position the magnet blocks differently, so that the two rotors attract each other. Take care not to knock the magnets out of place, or they will slide together under the magnetic attraction.
- Fit nuts to the four bolts and tighten the central disk down onto the steel disk.
- Mix 500g of resin with 7cc of catalyst. Add 300g talcum powder. Lay small strips of CSM between the magnets and into the gap at the edge. Add resin until the CSM is soaked. Poke it, or vibrate it, to remove bubbles.
- Lay the coil of stainless steel wire loosely around the outside of the magnets, below the top of the mould. Do not let the wire fall below the magnets. Let it sit on the CSM. Take care not to move the magnets around.
- Mix 500g of resin with 7cc of catalyst. Add 300g talcum powder. Fill the spaces between the magnets until the resin mix reaches the top of the mould.

Leave the rotor castings to set hard (several hours) before you remove them from the moulds. Be patient when removing the rotors from the moulds. Do not use violent hammer blows which may damage them. Hit the mould, and not the rotor.

Four stages of the rotor casting procedure

## 6. Assembly

### Rotor balancing

Each rotor should be balanced, or the PMG will shake when it is turning. The whole PMG needs to be balanced again at the end, because the rotors may not be mounted exactly centrally. A different procedure is used for the final balancing in Section 6.

To balance a magnet rotor (see diagram 38), first attach the PCD jig (from diagram 11), using four bolts. Then balance the rotor on a spike as shown:

### 38. ASSEMBLY OF THE BALANCING JIG AND SPIKE

If the rotor will sit level, then it is balanced. If it will not sit level, then add small weights to it, or drill out some of the resin between magnets, until it will sit level. Turn the PCD jig around on the rotor, and check it again. Replace any weights with pieces of M10 threaded rod, screwed into holes in the resin between the magnets.

### PMG spine and bearing hub (see diagram 39)

Make the spine of the PMG from a 380mm length of 'box section' steel tube 50x25x4mm (sometimes called RHS). Mark the exact centre of one large face, and then mark four 8mm holes, in the same way as for the 'stator studs jig'. It could also be possible to use the stator studs jig to help drill the holes.

The hole at the centre is 25mm (or to suit the shaft used). Drill this with a hole-saw, or bore it on a lathe.

### 39. THE BOX SECTION SPINE

DRILL HOLES WITH A PILLAR DRILL FOR ACCURATE ALIGNMENT

Weld the shaft in the 25mm hole. Take care to hold the shaft as square as possible (90 degrees) to the spine, when welding it.

The bearing hub (diagram 40) fits on the shaft. It has two 50x25 mm deep-groove ballraces in it, with a spacer between them. It needs a plastic cap over the end to keep dirt out of the bearings.

Do not forget to grease the bearings. Pack them with grease around half of their circumference only. Do not fill them entirely or they will become stiff to turn.

### 40. THE BEARING HUB

Photos show the rear magnet rotor being fitted

### PMG assembly

- Cut 4 pieces of M10 threaded rod, each 200 long. They are used as studs to hold the magnet rotors to the hub. The wind turbine blades will also mount onto these studs.
- Put 6 nuts onto each stud) see diagram 41).
- Fit the studs through the holes in the bearing hub, from the front
- Put the rear magnet rotor onto the ends of the studs.
- Put a nut on the end of each stud, and tighten the other nuts down, so that the rear magnet rotor is attached to the back of the hub flange. The outer end nut should be sealed with paint or thread-sealant.
- Place the spine in a vice with the shaft upward. Place the hub onto the shaft. Do not hammer the magnet rotor while fitting. Fasten the hub to the shaft with a nut and split pin. Do not over tighten the nut. Fit a dust cover over the end of the bearing hub.

#### 41. STUDS

- Rotate the magnet rotor past a piece of brass wire. Do not use steel wire, because it is attracted to the magnets. The magnet faces should all be at the same height +/- 0.5mm. If not, use very thin shims between hub-flange and rotor-disk, to adjust the rotor.
- Using a spirit level, adjust the spine in the vice until the magnet rotor is level. Check both ways: north-south and east-west.
- Take the stator. Fit one 8 mm nut onto each support stud. Screw them right down.
- Place the stator over the rear magnet rotor

and fit its support studs into the holes in the spine. Fit more 8 mm nuts to the ends of the studs.

- Slowly lower the stator, and rotate the rear magnet rotor. Keep the stator level in both directions. You will hear a sound when the highest magnet touches the stator.
- Use the nuts to raise the stator equally 1mm on all four studs.
- Fit some washers to the 10 mm studs which hold the rotors. Always the same number of nuts and washers on each stud. A total of six nuts and two washers may be

Fitting the stator

enough. Then fit the front magnet rotor.

- If the front magnet rotor is less than 1mm from the stator at any point, then add more washers under it. If it is much more than 1mm from the stator then remove washers. To find the correct number it is necessary to remove washers until it begins to rub the stator. Then add 1mm.
- When the front rotor is 1mm from the stator, then fit more nuts on top, and tighten them securely.

Fitting the front magnet rotor

### Electrical Parts

The next section (Section 7) will describe how to connect the rectifier to the stator. I recommend using two 'single phase bridge rectifiers' (see diagram 42). They come in blocks 30 x 30 mm. The positive terminals are both connected to the battery positive terminal. (They are often at right angles to the other three. ) Both negative terminals are connect to the battery negative. The remaining four terminals are for AC connection to the stator. You will probably only need to use three of these, connected as desired to suit the speed (see Section 7).

## 42. RECTIFIERS ETC.

'Block connectors' are useful for connecting the wires from the stator. Alternatively soldering or crimping would be fine.

Use solder, or crimped 'receptacle' connectors, to connect wires to the rectifiers. Take care not to overheat the rectifiers while soldering. Bolt the rectifiers onto the heatsink, which will probably look like the one in the diagram, but can be any piece of aluminium approximately 250 grams or more in weight.

Keep all the connections under a weatherproof cover.

Two bridge rectifiers

## 7. Testing and connecting

Check that the PMG has no faults before it is put into use. It will be much easier to correct the faults now, than to return the unit to the workshop later.

### Mechanical testing

Mount the spine vertically in a vice. The magnet rotors are free to move. The shaft is horizontal, as it will be in a wind generator. Check that the wires are not touching each other, creating a short circuit which makes the PMG harder to turn.

Check that the rotor will spin freely.

Spin the rotor and listen for sounds. There should not be any scuffing or brushing of the rotor, as it turns. It should spin freely for several seconds and gradually come to a halt. If it slows down rapidly then there may be an electrical fault, or the bearings may be over-tightened.

Grasp the stator with both hands. Push one side backward while pulling the other side forward, while the rotor is spinning. It must not touch the rotor. If there is a rubbing sound, then it may be necessary to disassemble the PMG and assemble it more carefully, with more space between the rotor and the stator. Or it may be possible to correct the problem by making minor adjustments to the stator mounting studs.

Stop the rotor with one of the studs in the 3 o'clock position (diagram 43). Hang an object weighing 100 grams on this stud. The rotor should begin to turn clockwise. If it will not turn, then the bearings may be over-greased or too tight.

### 43. HANG A WEIGHT ON ONE OF THE STUDS

### Checking the balance

The rotors have already been balanced in section 6. The wind turbine blades must also be balanced in the same way. When the unit is assembled, you should check the balance again using the new procedure below. This is necessary because the rotor disk may not be perfectly central on the PMG shaft.

Repeat the starting test (diagram 43) with each of the four rotor studs in the 3 o'clock position. Try different weights, and find the lightest weight which will start the rotor turning. If one stud needs much more weight than another, then the rotor is not balanced. Fix small weights to the rotor until the balance is correct.

## Electrical testing

### Coil connection test

It would be helpful to have a multimeter when testing the PMG, but it is possible to do some basic tests with a 3 volt torch bulb. See diagram 44.

- Connect the wires 1B to 4A, 2B to 5A, and 3B to 6A. (Series connections of pairs of coils which are in the same phase.)
- Set the multimeter to '10VAC' or similar (if you have one).
- Connect the meter, or a bulb, between the wires marked 1A and 4B.

### 44. TESTING THE COILS

- Rotate the PMG slowly by hand, about one revolution per second.
- The meter should give a reading of about two volts, or the bulb should flicker.
- Repeat the test with two more pairs of wires: 2A and 5B, 3A and 6B.  
In each case the result should be the same.

If there is no reading, or a very low reading, then check that the series connections (1B-4A, 2B-5A, 3B-6A) are correct. If all these connections are good, then it is possible that one coil has been reversed (placed upside-down).

If any coils have been reversed, then it is necessary to do another test (see diagram 45), to find out which one is at fault. Connect 4B-2A and 5B-3A as shown in the diagram. Now test between 1A and 6B. There should NOT be more than a very small voltage. If there is a voltage, or the bulb lights up, then reverse the connections (swap A for B) on the coils until the voltage drops to a very low level.

When the faulty coil has been found, label the tails again, with A and B at the correct ends.

#### 45. CHECKING FOR A REVERSED COIL

There will always be a small voltage in this test, because the coils are not perfectly positioned in the mould. If the test gives more than one volt, then it should be possible in future to make a better stator by placing the coils at exactly equal distances apart in the mould.

#### DC output test

When these tests have been completed and the results are correct, then connect the rectifier, as shown in diagram 46. Connect the tails 1A, 2A and 3A together. Connect each of 4B, 5B and 6B to any three of the rectifier AC terminals (marked with 'S' symbol). This is the 'star' connection. Connect a bulb to the output. If possible, also a multimeter on 10 VDC (or similar).

## 46. DC TEST

### COILS CONNECTED STAR

Rotate the rotor by hand as before, approximately one revolution per second (60 rpm). The meter should show a steady reading around 4 volts DC (or 3 volts with the bulb present). The bulb should glow with a steady light, not flickering as before.

If there is no reading, or the bulb flickers, then there is a faulty connection or a faulty rectifier. Check the connections carefully. Try another rectifier.

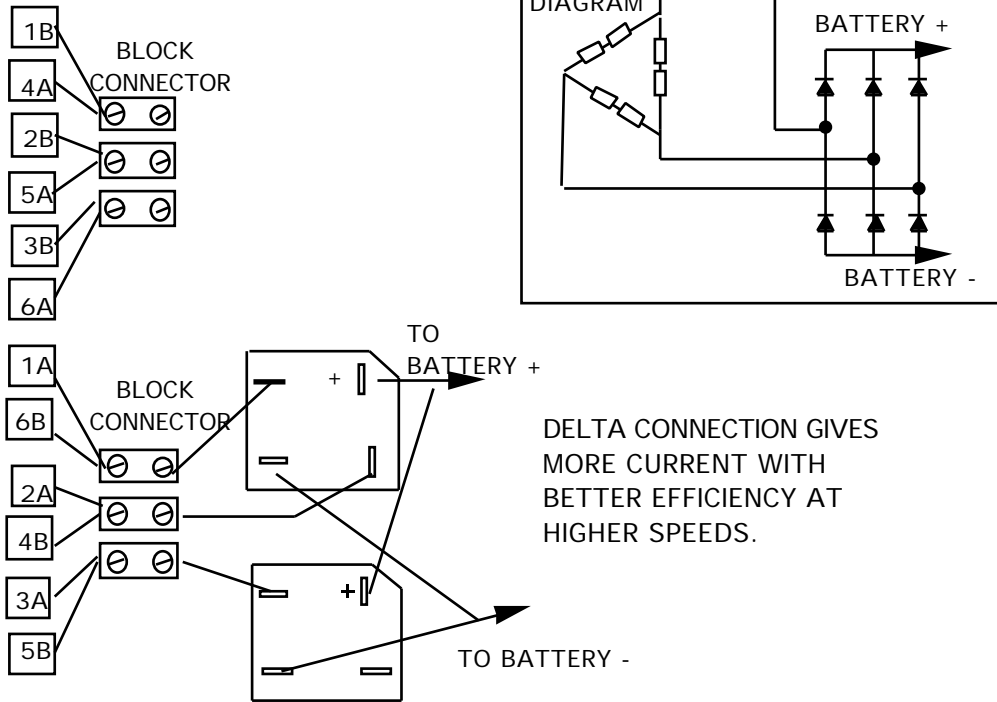

You can also test the PMG without a bulb or a meter. Simply connect the positive and negative wires from the rectifiers together (all four) in a 'short circuit'. Now try to turn the PMG. It should be stiff but smooth to turn. If it trembles as you turn it then there is a fault.

### Connecting the PMG to the 12 volt battery

#### Star and Delta connections

For low windspeeds, connect the coils 'star' as above. For high winds, and higher current output, connect the coils 'delta', as in diagram 47.

## 47. DELTA CONNECTION

It is also possible to wire a relay (see diagram 48) which will switch the connections from star to delta and back as desired.

## 48. USING A RELAY TO CHANGE BETWEEN STAR AND DELTA

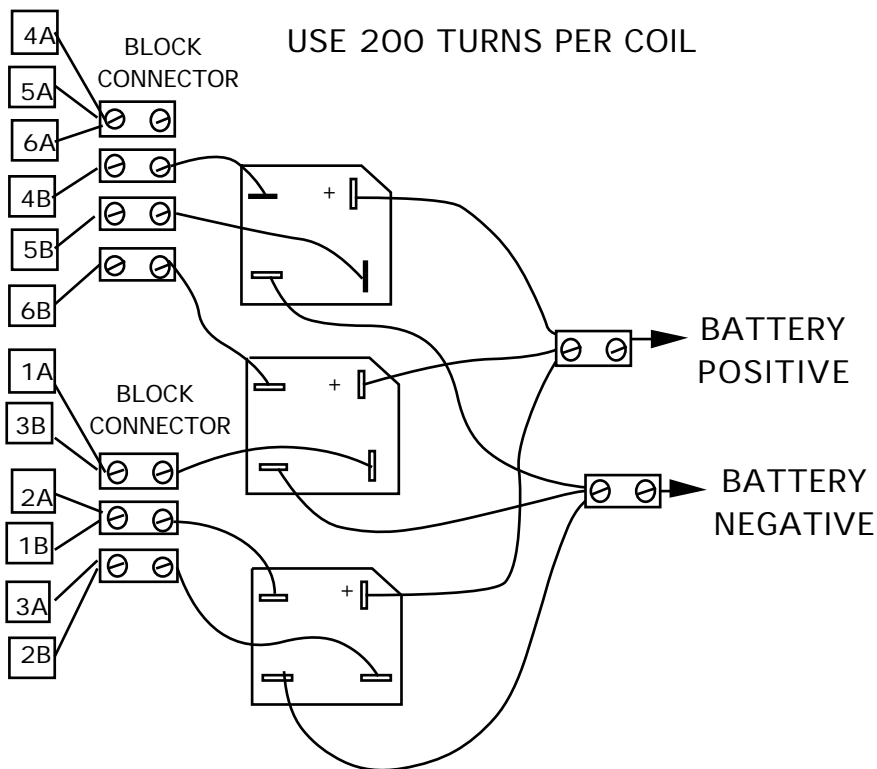

Yet another option for connecting the stator

At the time of writing this document, the above arrangement (using a relay to change the connections) is still under development. Later, an electronic control circuit will be available to automate the changeover. This is all very complex, and it so it can go wrong.

If you do not wish to have to change the connections between low and high windspeeds, then the PMG will still work. However, the efficiency will be slightly less. Three are two options:-

- If you expect mainly low windspeeds, then you can simply use the star connection shown in diagram 46.
- If you also need higher power in higher winds, you can use a 17AWG wire (1.2 mm diameter) to wind coils with 200 turns each. Then you can connect one group in delta and one group in star as shown in diagram 49. Note that you need six AC terminals on the rectifiers so you will need three rectifier blocks.

#### 49. STAR/DELTA CONNECTION

#### PMG-to-Battery Cable size

The cable from the PMG to the battery can be either three-phase-AC or DC. If the rectifier is mounted at the wind generator, then it will be DC. This is only slightly more efficient than three phase AC.

At 12 volts, the size of the cable must be large. Even if the current is only 15 amps, it is advisable to use a heavy cable. For a distance of 20 metres, the recommended size is 6 mm<sup>2</sup> (10AWG). The diameter (thickness) of each copper wire is about 3mm. A 15 amps current flowing in this cable will lose 15% of the power from the wind generator as heat in the cable. If the cable is longer, it should be heavier, in direct proportion.

## Electrical Safety

There is no danger of electric shock from a 12 volt battery. But if the wind generator is disconnected from the battery, and running fast, then the voltage will be higher than 12 volts, maybe as high as 50 volts. Do not run the PMG at high speed without a battery connected.

The battery contains stored electrical energy. When there is a short-circuit fault in the wiring from the battery, for example the positive and negative wires touching each other, this energy is released in a very high current. The cable will heat up and burn. Therefore it is necessary to use a fuse or a circuit breaker on every wire which attaches to the battery positive terminal. Use one fuse for the wind generator and a separate one for the cable to the load (the lights, or whatever uses the power). See diagram 50.

### 50. CONNECTING THE BATTERY

Battery acid is bad for the clothes and the skin. Do not splash it. Be especially careful of the eyes. If there is an accident, the best cure is to flush with plenty of water.

Batteries produce hydrogen gas, which is very explosive. Do not make sparks near a battery or it may explode, and throw acid in the eyes!

### Battery Charging

Lead acid batteries should be kept in a charged condition. In the case of a wind powered system, you may have to wait for a wind to charge the battery. But be careful not to discharge the battery too deeply, or to keep it too long in a discharged state, or it will be damaged (sulphated) and become useless. Stop using a battery before it is fully discharged. If there is a problem with the wind generator, then charge the battery from another source within two weeks.

Charging the battery too hard will also damage it. At first, when the battery is discharged, it is safe to use a high current, but later the current must be reduced or the battery will overheat and the plates will be damaged. The best way to fully charge a battery is to use a small current for a long time.

Watch the battery voltage. If the battery voltage is below 11.5 volts, then it is being discharged too much. If the voltage is high (over 14 volts) then the battery charging current is too high. Use less current or more current in the loads to correct these problems. If there is no voltmeter available, then the user should watch the brightness of the lights and follow these rules:-

- Dim lights, mean low battery. Use less electricity!
- Very bright lights mean too much windpower. Use more electricity!

A good way to use more electricity is to charge more batteries in windy weather, perhaps charging batteries from neighbours' houses.

There are simple electronic circuits which can regulate the battery voltage automatically. They are called 'low voltage disconnects' and 'shunt regulators'. If the user is not willing to watch the battery voltage, then it is necessary to fit a disconnect and a regulator.

## 8. Additional information

### Using polyester resin

Polyester is the plastic substance used in fibreglass work for building boats, car body parts, etc. Various things are added to it to make it work better for various jobs. Talk to your supplier and explain what the resin is to be used for. Your supplier should be able to help you.

### Hardeners

There are two systems used to harden polyester resin, and each system uses two chemicals. For resin casting and most fibreglass work we use peroxide and cobalt. ('Body filler pastes' use the other system.)

Cobalt is a purple fluid. Ask the supplier to mix the right amount of cobalt into the resin. After it is mixed, the resin must be stored in the dark, or it will harden.

Peroxide is a hazardous chemical. Avoid contact with skin. Store in a PVC container, in the dark, below 25 degrees C. Never mix it with cobalt (except for the cobalt already in the resin), or it will explode. Mix very small quantities (about 1-2%) of peroxide with resin or it will overheat.

### Wax-free 'Air inhibited' resin 'B'

This type of resin is used for 'gel-coats' on boat moulds, where the resin is going to be built up in stages. We do not recommend using this resin for the PMG. Any exposed surface will remain tacky indefinitely. Ask for resin 'A', or better still 'casting resin'.

### Thixotropic additive

A special powder of very light silica is often added to resin to make it thicker, so that it is easier to spread it with a paint brush. This powder is not needed for casting resin. If it is already added, it does no harm.

### Styrene monomer

Approximately 35% of the resin as supplied is styrene monomer. This is used for thinning the resin. It causes the smell. It is possible to add a little more styrene monomer (10%) to make it more liquid.

### Pigment

Pigment is used to colour the casting, if a coloured finish is desired. Add pigment to the first mix, which will be on the outside of the casting. Add no more than 10% pigment to the mix. It is not necessary to add pigment to the resin. Without pigment, the casting is transparent and the coils are visible.

## Fibreglass

The resin has almost no strength without fibreglass. It is available in sheets of 'chopped strand mat' (CSM). It is also possible to buy just chopped strands, and to mix them with the resin. This is useful for the magnet rotor castings. Add a little resin to the fibreglass, and press out all the air bubbles, before adding more resin.

## Talcum powder

Talcum powder is a cheap filler which can be mixed with the resin after the peroxide has been added. It makes the resin mixture much cheaper, and a little thicker. Resin can be mixed with up to twice its own weight of talcum powder. The powder also helps to reduce the heat build-up in large resin castings.

Using painted moulds in Peru

## Mould preparation

### Polyurethane varnish

Ordinary paint should not be used on moulds. Better to use nothing. If possible, use polyurethane varnish. This will prevent moisture coming out of a mould made from wood, plaster or clay. Smooth the varnish off with sandpaper before polishing it.

### Polish

Polish the mould several times before using it first time. Rub all the polish off with a rag and then leave it some hours and do it again. Silicone polish is not compatible with PVA release agent. Use wax polish.

### PVA Release agent

Paint this over the mould and let it dry. It forms a sheet of PVA, which greatly helps to separate the casting from the mould.

## Using the PMG for hydro power

The PMG can also be used for charging batteries from small hydro turbines. It will be ideal for low head, low power sites, because it is efficient even when producing only a few watts. It can also be used for higher head higher power sites, because it is capable of high power outputs at high rpm.

There is a danger of rust damage to the magnet rotors in a very humid or wet environment such as in a hydro application. It is advisable to galvanise or plate the steel components with zinc.

### Low head sites

Here are some examples of conditions where the PMG could work without modification (connected delta). It would need a simple 'impulse' runner mounted on the front magnet rotor.

Head (metres)	10	10	5
Flow (litres/second)	1	5	5
Net Power(watts)	40	200	100
pcd runner (cm)	37	27	23
speed (rpm)	325	440	360

### High head, high power

At higher rpm, higher power is available from the PMG. Doubling the speed can also double the output voltage and the current, offering four times as much power with the same efficiency as before. The PMG may overheat under these conditions, so it may be better to keep the current the same, and have better efficiency. Much will depend on whether the water is used for cooling.

In any case, increasing the speed improves the PMG's power handling abilities considerably. It would be risky to run a wind turbine at high speeds, because of the problem of gyroscopic forces on the rotors, but this problem does not arise with hydro power, because the shaft axis is fixed.

If higher voltage is not required, then the stator winding can be changed to give 12 volts (as before) at the higher speed, but deliver higher current without overheating. This is done by connecting the coils of each phase in parallel instead of in series. Or the coils can be wound with fewer turns of thicker wire. This is better still, because parallel and delta connections can suffer from parasitic internal currents.

Do not use the star/delta connection (diagram 49) for hydro power where the speed is constant. There is no advantage.

# Homemade Easter Egg Anemometer

**UPDATE 12/05/2003 -- We've been building and flying [Bicycle Speedometer Anemometers](#) recently. The project is more expensive than this one, but it's simpler and easier to build. We used our [Anemometer Cup and Hub Assembly](#) to save time, and an inexpensive digital bicycle speedometer to calculate speed and acquire data. Another cool project, check it out! And you can use the pre-built cup assembly on this Easter egg anemometer project, too, to save time.**

In any wind generator installation, it's critical to be able to measure wind speed. That gives you a baseline against which to measure your machine's performance, and anemometers respond much more quickly to changes in windspeed than do wind generators. Commercial anemometers are very expensive and the operational concept is pretty simple, so we decided it would be cheaper (and MUCH more fun) to build our own! Plastic Easter Egg halves made ideal (and very colorful) cups.

**Our homemade anemometer...a fun project!**

We chose a really neat little brushless DC permanent magnet motor as the basis for our DIY anemometer. The reason for this choice was simple...these motors contain a superb little ball bearing that would cost far more new than the entire motor cost surplus! In addition, the internal windings of the motor provide enough circuitry to calibrate the anemometer by both frequency and voltage output.

**Brushless DC motor--note the really nice ball bearing!**

In the past, we've built anemometers based on small DC hobby motors. While these units did work, there were problems to overcome. Most hobby motors use cheap bushings instead of bearings. The bushings tend to fail rather quickly, since they are not designed to withstand the forces put on them in an anemometer. Their voltage output is not linear with the windspeed, but instead tapers off as speeds get higher. And there is quite a bit of physical resistance in the motors, resulting in high startup speeds.

The internal circuitry of our brushless DC motor consists of 12 coils, and a permanent magnet ring that spins around them. These motors are NOT like a normal DC motor...they require a special driver circuit to make them spin. If you apply plain DC current to the motor, it will simply seek a point aligned with the coils, stop, and burn out. The motors have 3 leads...a common in the center and 2 outputs (well, actually inputs!). For connection to measuring equipment, you need only connect to the center common lead and one of the side ones. The output of the motor when spun as an anemometer can be measured with a multimeter set for AC volts, or by counting pulses with a frequency meter or BASIC stamp. We had the best results using a Fluke 87 multimeter set for measuring Hz (cycles per second). There are 12 internal coils in the motor, but we only measured the output of half the coils (since we connected to only one power lead). Therefore, a meter reading of 6 Hz equals one revolution per second (60 rpm). Both frequency and voltage readings from the motor are quite linear, making for easy calibration. The other advantage of counting frequency over measuring voltage is that the length of the data cable would affect voltage readings; when counting frequency it can be any length and the calibration will stay the same.

**Internal coil layout of the brushless DC PM motor**

### **Materials and Tools Needed:**

- brushless DC PM Motor (check our products page, we do have these available surplus from time to time)
  - 4 plastic Easter eggs, 2.2" dia. (use the hemispherical half)
  - 3 short pieces of steel rod (we cut them from an old oven rack)
    - 3 nuts to fit the steel rod
    - 3 small self-tapping screws to mount the motor
  - 1 piece of solid plastic for the hub, 1/4" thick, about 3" dia. (ours was Lexan®)
    - 1 PVC 1 1/2" to 2" reducer
    - 1 length of 1 1/2" PVC for the mast (2 ft or longer)
  - 2-conductor wire for the data cable...telephone wire works great
    - epoxy

### **Construction**

To build the mount, first solder and insulate the data cable wires to the center and one of the outside terminals of the motor. Using a hacksaw, cut the wide 2" end of the PVC reducer off to leave a flat plate (about 0.4" wider than the 1 1/2" side of the reducer). Thread the wires through the reducer, and screw the DC motor mounting lugs onto this flat plate, pressing the motor into the 1 1/2" hole. It's a tight fit...we also used epoxy in addition to screws in mounting the motor, and had to bend the leads out straight to fit them in.

To construct the hub, first cut the 1/4" plastic sheet into a 3" dia. circle. We used a lathe. A hole saw would be the next best choice. If you don't have a lathe or hole saw available, remember that plastic is pretty easy to cut! You can cut it out roughly with a hand saw, chuck it to a mandrel, and spin it with a hand drill against a piece of sandpaper to make it circular. This piece does need to be perfectly circular so the anemometer will be balanced, but the exact diameter is not critical. The center hole in the hub should press fit tightly on the motor--the diameter needed is about 0.83". Since we didn't have a hole saw or bit in this size, we again used the lathe. With no lathe, it would be easiest to drill a centered hole slightly under this diameter and ream it out to a tight fit using a

file or a small sanding drum on an electric hand drill. Again, the hole must be perfectly centered so the machine will be balanced. Lastly, lay out the 3 holes for the cup spokes at exactly 120 degree angles. Drill into the outside diameter of the hub with a bit sized for the steel rod you have chosen--it should again be a very tight fit. Be sure to drill all 3 holes to the same depth so hub balance is maintained.

To build the cups and spider, first carefully drill 2 holes into the rim of each Easter egg half, about 1/4" to 3/8" in from the edge. Be sure the holes are aligned so the egg will hang straight on the rod. Cut the 3 rods to exactly the same length, so the weight will be equal. Weld or solder a nut to the end of each rod. Slide an egg half onto each rod, align them to vertical carefully, and glue them down with epoxy on both sides. After the epoxy cures, weigh the rods on a sensitive scales and file off the solder or weld material until the weights match exactly. Rough up rod ends with sandpaper, cover with epoxy, and insert the rod/cup assemblies into the hub. Be sure they are all inserted to the same depth to maintain hub balance. I also glued the edges of the cups to the hub directly with epoxy for added strength; with longer spider arms this would not be possible.

Cover the inside hole of the hub with epoxy, and press fit it tightly onto the motor. Epoxy the 4th egg half onto the top of the hub to cover the bearing as a weather shield. We turned a groove into the hub top to accept the egg, but it should hold with just epoxy. Thread the data cable down through the piece of pipe you've cut for the mounting mast. That's it for construction! There are many variations to this design that could work equally well, if not better...in particular, the hub could be designed in many different ways depending on the materials and machine tools you have available.

I chose the anemometer diameter of 7.4" completely arbitrarily. As is, it starts spinning at about 8 mph, which is slightly below where our wind generators start spinning. It would be nice to have it respond in lower wind speeds; for the next one I'll probably extend the spider arms an inch or so to solve this. Lighter cups and hub would also help, but I wanted this unit to be very sturdy...we get winds in excess of 100 mph up here!

### **Calibration**

This is the fun part! You may wish to build a vehicle mount for the anemometer, though it can be

calibrated just fine by someone other than the driver holding it out the car window, away from the car's slipstream. If you choose to calibrate it without a mount, the holder should wear thick welding gloves and eye protection in case it comes apart. DanF's anemometer calibration rig is shown below...the unit rides a good 6 ft above the truck cab, out of the truck's slipstream and turbulence. **SAFETY NOTE: THERE ARE NO POWER LINES UP HERE WHERE THE CALIBRATION WAS DONE!!!! IF THERE ARE POWER LINES IN YOUR AREA, DO YOUR CALIBRATION SOMEWHERE ELSE, or use a lower mast!!!**

It's essential to pick an absolutely calm day for calibrating the anemometer. Any wind will throw off your readings significantly. First, we checked my truck speedometer using a GPS receiver. It turned out to be right on, so it wasn't necessary to use the GPS any further. We connected the data cable leads to a Fluke 87 multimeter set to measure Hertz. Radio Shack and Harbor Freight also sell some inexpensive multimeters that count frequency, you shouldn't need to spend too much money on one. Then it's simply a matter of the driver trying to maintain constant speeds and calling out the vehicle speed to the passenger, who writes down the speed and frequency readings. We later repeated the procedure while measuring AC volts and made a chart for them too. Since there was the occasional breeze during our calibration, we took readings travelling both up and down the road, and averaged them.

### Reading Wind Speed Directly

The simple solution for reading wind speed directly as mph was a quick paper template overlaid on the meter's "bar graph" display. While the numerals on the meter must be translated to get actual windspeed, the bar graph can be read directly against the calibrated paper template.

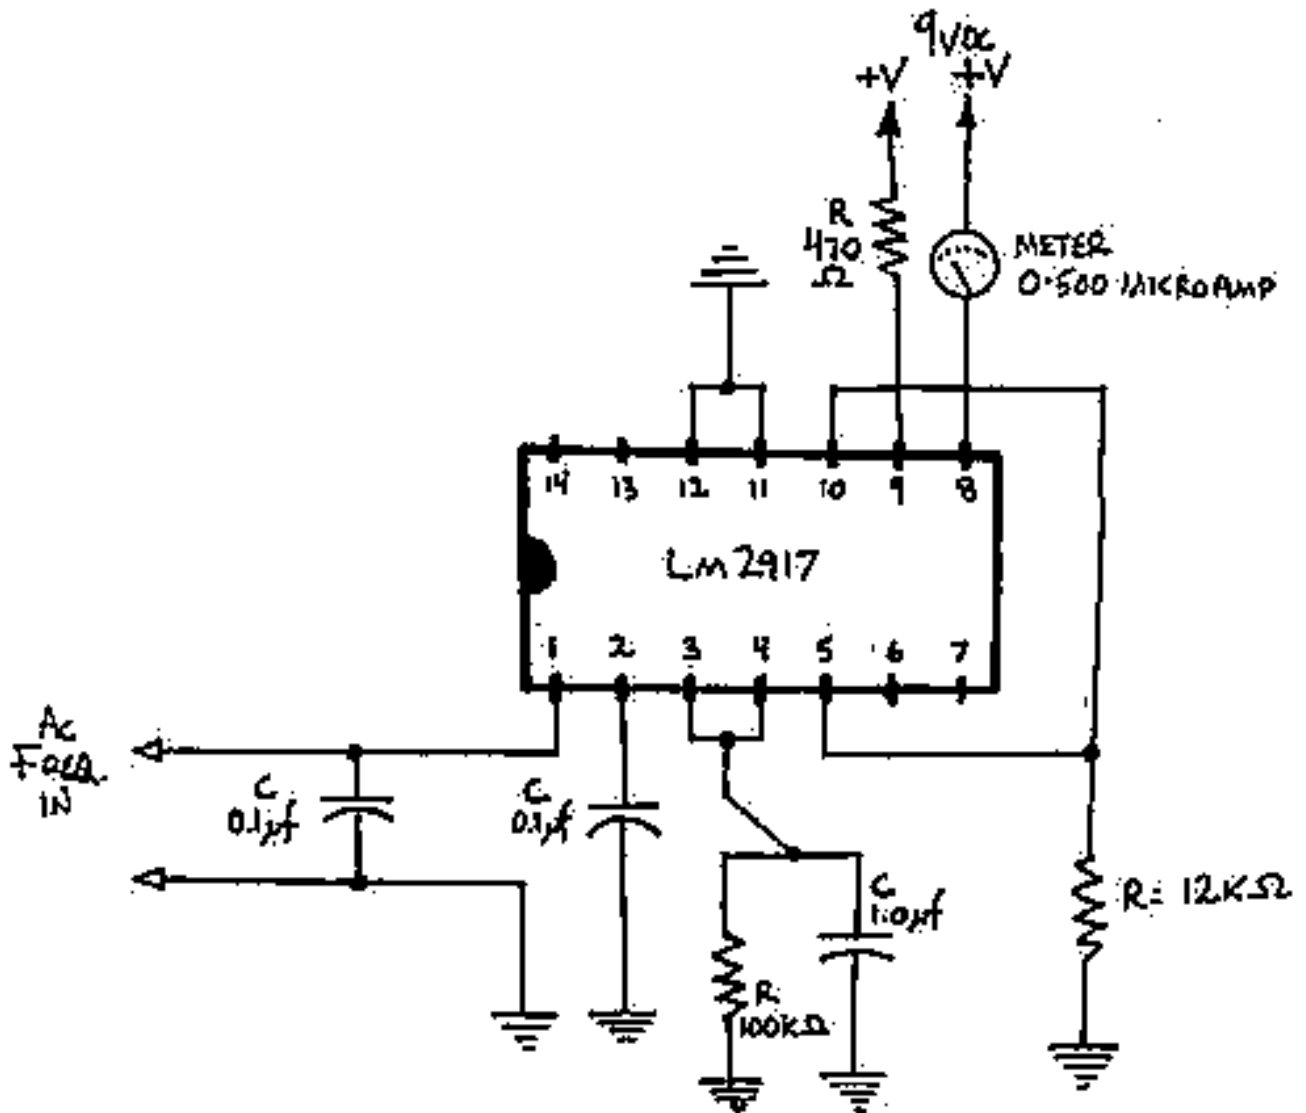

However, DanF has quite a silly fondness for large old analog meters--he wanted to watch windspeed on an excellent old 8"x10" analog microammeter (salvaged from a pH meter). The meter reads 0-500 microamps on a scale of 0-14 pH. The LM2917 frequency to voltage converter chip proved to be a perfect choice for this application...it can even drive much more powerful analog meters with no problems and minimal external circuitry. The chip costs under \$3 at most electronics stores, and only 3 capacitors and 3 resistors are needed to get it working.

The LM2917 provides an output voltage proportional to the input frequency. It differs from the LM2907 in that it has an internal Zener diode voltage reference--the supply voltage can change without affecting the output. It can be used in many applications and configurations...in this case, it provides a 0-500 microamp current proportional to a frequency of about 0-90 Hz. With the anemometer design above, that means full scale (500 microamps) equals about 60 mph.

**DISCLAIMER:** DanF is NOT an electronics expert. He still believes in 'magic smoke' inside electronics components...if you mess up and let the smoke out, it's very hard to put it back in the

right places. He used extensive trial and error (plus some help from a member of the Otherpower.com message board) to get the resistor and capacitor values right...so there's no guarantee we will be able to help you if you want to use this circuit in a different configuration! END DISCLAIMER. The manufacturer's data sheets for building circuits with this chip are located [HERE](#), and have many useful charts, calculations, and schematics for possible circuits. The circuit was taken right from the 'application notes' pages. There is also an 8-pin version of the LM2917 available; the two are very similar, and the datasheet will tell you how to connect between them. All parts were purchased at Radio Shack, with the exception of the LM2917 chip--I had to go to an electronics store for it.

The 470 ohm resistor from pin 9 simply drops the supply voltage a bit. The circuit will work as-is from a 12-14v supply also. The meter can be any 0-500 microamp meter. The resistor from pins 10 and 5 sets the full-scale amperage for the meter...12K ohm gives you approximately full scale at 500 microamps; a trimmer pot could be added here if you want high precision. The 0.1 microfarad capacitor across the frequency input terminals is simply to filter out spurious signals...the chip is very sensitive, and will read frequencies seemly from nothing if not filtered. The other 2 capacitors and 100K ohm resistor were calculated right from the chip's datasheet....there's a chart and a formula for selecting them. All resistors are 1/4 watt.

I first built the circuit on a solderless breadboard. I highly recommend this...unless you build the exact same circuit shown here and use the exact same motor for the anemometer, you'll need to adjust some or all of the component values. The breadboard makes this easy to do. Once everything is calibrated and working properly, switch the circuit over to a soldered version; PC boards are available at Radio Shack that match the connections inside the solderless breadboard. Buy a 50 cent IC socket for the chip, and solder that into the board instead of the chip itself! It could save you much grief...

From your calibration procedure with the anemometer, you should have a listing of what frequency equals how many miles per hour. If your calibration was done on a windless day, it will be easy to figure out how many Hz equals how many miles per hour. In my case, it ended up that a 6 Hz frequency increase equalled a 4 mph windspeed increase. I did a final calibration check by spinning the anemometer at a constant speed, noting how many Hz were produced, and marking where on the meter this speed fell. In my case, 34 Hz = 25 mph = 4.6 pH (this WAS a pH meter to start with!). I drew a new scale on white paper, matching the meter's, but with new tick marks for every 5 mph. I carefully glued this new scale on the meter face (being careful not to damage the needle), with the 34 Hz/25 mph/4.6 pH mark lined up as a calibration reference.

Since I wanted the unit to be portable, it is designed to run from a 9V battery. It's been running for over a week now (in fairly windy conditions) on this battery--power use is very low! Thanks to the chip's internal voltage reference, accuracy will not degrade as the battery is discharged...it will run until power is too low, and then stop completely. Meter deflection is very crisp and defined...when a gust hits the unit, the needle jumps up quickly. The scale is completely linear, unlike DC hobby motor anemometers in which the upper part of the scale is compressed. I am VERY pleased with how this project turned out! And so far, I have not let any of the magic smoke out of any components. ;~)

# An Easier Homemade Anemometer

## Built using a digital bicycle speedometer

**The completed anemometer cup and sensor assembly.**

Sigma Sport Targa digital bicycle speedometer -- about US\$25 at any bike shop.

DanF's [Easter Egg Anemometer](#) has been up and flying beautifully for 2 years now. This new design is much easier and quicker to build, but costs a little bit more initially. We learned how to build it during our trip to Guemes Island, WA for [Hugh Piggott's](#) homebuilt wind power seminar for [SEI](#). It uses a digital bicycle speedometer to count pulses from a magnet and reed switch on the anemometer cup assembly, and the speedometer translates this automatically to mph or kph. It also keeps track of your maximum gust, average windspeed, and total wind miles -- so it works as a wind odometer too! Very useful for doing wind power site evaluations.

## Parts List

- **Digital Bicycle Speedometer** -- We used a Sigma Sport Targa because of the peak speed, average, and odometer features. It's available at almost any bicycle shop for about US\$25.
- **Anemometer Cup and Hub Assembly** -- We used a pre-built Polycarbonate (Lexan®) cup and hub assembly. It's available on our web [Shopping Cart](#). You could use any commercial or homebuilt cup assembly for this. Check out our [Easter Egg Anemometer](#) page for details on how to build your own.
- **NdFeB Magnet** -- The magnet that comes with the speedometer is a rod shape, and we found it easier to fit a 3/8 inch diameter by 1/16 inch thick disc magnet to the cup assembly rather than the rod. It's Item #75 on our Shopping Cart, and costs only US\$0.20.
- **Bearing Assembly** -- Many different designs of bearing assembly will work. You want it to spin as freely as possible, so you can get better response and also measure very low wind speeds. For this project, we used the same ball bearing DC brushless PM motor as in our [Easter Egg Anemometer](#), and we removed the coils to make it spin more freely....we just need

the bearing for this project. The motor costs only US\$2.50. It's Item#2105 on our shopping cart. You could use any sort of bearing assembly you can devise from scratch, just make sure it spins VERY freely.

- **PVC reducer fitting** -- 2 inch to 1.5 inch white PVC reducer coupling.
  - **3 Machine screws** -- #4-40 , 1/4 inch long.
  - **Glue** -- epoxy, PVC cement, and thread lock compound are needed.
  - **Tap** -- a #4-40 tap, available at hardware stores.
- **Mounting supplies** -- 1.5 inch diameter PVC pipe for mast; telephone or other thin wire to extend sensor wire.

## Assembly

Cut the PVC pipe reducer off with a hacksaw right at the flange, on the big 2 inch side. This gives a wide, tapered rim surface to mount the bearing assembly to. See photos below. Using a file, cut a notch in the flange just big enough to fit the sensor from your bike speedometer. Cut it deep enough so that the sensor can ride flush with the pipe.

Place the bearing assembly upside down in a vise so it's suspended by the flange. DON'T tighten the vise. Gently tap the center bearing loose from the back using a Phillips screwdriver and small hammer. Or press it out on your drill press. Gently pry the coils out using a flathead screwdriver. Gently press the motor back together -- if you go all the way back in now, the motor will bind and not spin freely!

*Optionally, you can skip that entire step. However, there will be a bit more resistance in the bearings from cogging, and it will take a couple more mph of wind to set your anemometer spinning. By prying the motor open, you also risk bending and ruining it. So you might want to have an extra*

*available if you try this. The performance difference is very small with the coils left in. Our success has been mixed with removing the coils from these motors -- it's hard to get them back together so they are tight but still spin freely.*

**Disassembled Motor**

**Coils removed from Motor**

Drill out the center of the hub with a 1/4 inch hole. The exact center is already drilled with a tiny hole, so it's easy to get it perfect.

To mark the anemometer hub for drilling the mounting holes, we cut off 3 small nails with wirecutters, and dropped them point-up into 3 of the small holes in the motor. We then centered the hub around the motor shaft (si it does not touch the shaft) and pressed down to mark the holes. See photo below. Then drill your 3 holes.

**Nails in motor for marking hub holes.**

**Completed anemometer hub assembly**

Now, tap your 3 mounting holes in the motor. Don't push any deeper than the holes already are, or you will distort the metal and sieze up the bearing -- it'll be ruined. Assemble the anemometer cups onto the hub -- they press in, but you have to press hard! Put thread lock compound on the #4-40 machine screws, and attach the cup and hub assembly to the motor. Try it, and it should spin freely by just blowing on the cups. This is essential -- it should spin in the slightest breeze. And it should be nearly perfectly centered on the bearing. To seal the top (acutally the bottom, after mounting the thing upside down) we just epoxied a poker chip on there to cover it -- perfect size!

**Completed anemometer hub assembly, mounted in PVC reducer, with sensor attached.**

Next you'll need to install the trigger magnet and rpm sensor switch, then mount the cup, hub, and bearing assembly into the sawed-off reducer. Mount a small NdFeB magnet to the inner shoulder of the cup assembly with epoxy. Use a file to notch the PVC reducer mount to accept the sensor that came with the bike speedometer. We simply used epoxy to glue the sensor tightly in the notch. Be sure to test the sensor before glueing it into place! The range at which it will trigger depends on the location and strength of the magnet. Ours triggered best at about 1/8" clearance between the magnet and sensor. We found the sensor triggered best by pointing the small end of it right at the magnet (see picture above). The sensor wire with the speedometer is only a couple feet long, so we snipped it and used telephone wire to extend it to 20 feet long, so it could run right into the house for mounting the speedometer display inside. We used small machine screws and epoxy for mounting the bearing assembly.

**Finished unit, ready for pole mounting.**

Because of how our bearing assembly is built, there's a big chance that water could get down inside the bearing assembly and ruin it. So we opted for mounting these anemometers upside down, with the mounting pipe pointed down. The mount can be any design you come up with with 1.5 inch PVC pipe, using Tees, 90 deg bends, anything that fits your mounting area.

## **Testing and Calibration**

For testing the new anemometer, I once again used my truck testing rig. It's simply a pipe mounted in the bed of my pickup that sticks up 6 feet over the top of the cab. Just be careful about overhead power lines and branches while you are testing! The only problem with truck testing anemometers -- is that even the slightest breeze will completely destroy your test results. You'll need to find an absolutely breezeless day for calibration. If you already have another anemometer that's calibrated (or rent one from the local renewable energy store for a day), you can just mount your new one near the old one and compare the readings.

The bike speedometer uses the measured circumference of a bicycle tire to calculate the bike's speed, using the number of tire revolutions per minute as tallied by the sensor mounted at the bike and the magnet mounted to the wheel. But with anemometer cups, there's a bunch of 'slip' involved -- the cups to not catch all the wind that goes by. So you can't just enter the anemometer's circumference into the speedometer. That's why calibration by some method is required. With our 2

anemometers, the offset number entered into the speedometer was 1320 (mm). If your unit is showing a higher speed than the truck or test anemometer, you increase the diameter that you enter into the computer. If your anemometer reads low, you decrease the diameter. A change of 5-10 mm makes a big difference! But after fiddling with it for a while, you should be able to get very close. If you get widely varying readings -- there is probably too much breeze for testing.

## Fun Features of the Bike Speedometer

The speedometer computer has some fairly sophisticated data acquisition features, available by pushing buttons. You can have it track the maximum speed recorded, at reset it at your leisure. Using the odometer on the Targa unit, you can also track total wind miles -- a feature found only on expensive commercial scientific anemometers! It will also track your average windspeed -- but keep in mind this is a different figure than 'average windspeed' as rated for a potential wind power site. The bike speedometer **ONLY** averages the wind *when the wind is blowing*. True 'average site wind speed' readings take into account all the hours that the wind is not blowing at all. But the information can still be useful when designing or selecting a wind turbine.

**We hope you enjoy building this project as much as we did. It's a very quick and simple way to build a very accurate anemometer. Thanks to Ed Kennel of the University of Washington for showing us this system out on Guemes Island!**

Miscellaneous pictures.....

Why does the sun never come out for the group photo?

This is the bigger of the two machines we finished during the course. Rotor diameter is 8 feet (2.4 metres).

Guemes Island Resort, where we stayed. Chris Freitas of Ouback stops by with his wireless winch.

Robert Preus came to talk to us. [Robert](#) is the distributor for [African Windpower](#) in the USA. There was one AWP machine in the classroom, and another on a 150 foot tall tower across the road. The one on the tower looks pretty small.

Later, Robert gave us a talk about how wind turbines fail. In the picture below he has a hub from a Jacobs machine.

Andy Gladish was in charge of metalworking but he can also do **stick** welding.

Here are Dan Fink and Dan Bartmann. They supplied the [magnets](#), the wire and some music.

They also worked hard on the smaller of the two machines. Here Dan Bartmann applies some subtle persuasion.

An evening session on 'magnets at work and play'

Course staff from top left : Ian Woofenden (SEI and Home Power), Brain Faley (Shoreline Power), Andy Gladish and BJ Daniels of Guemes

Hugh Piggott, and Win Anderson and Michael McGuinnes of Guemes

We were using Win's shop for the week. BJ and Win helped with the [woodworking](#).

---

Dan Whitney came back and brought the machine he built [last time](#) using a Ford truck brakedrum.

---

Putting the larger machine onto the tower for erection. The tail is a map of the island.

The big machine is on the tall tower (twenty feet up but still not nearly tall enough) and the little 4' diameter machine is on a short stand in the foreground.

Of course we had no wind to speak of and the best I saw was a 7 watt output.

Later we did truck testing of the small machine. I recorded 30 amps output at 16 volts. But to get that output I had to hold down the furling tail and we had to hit about 45 mph. Not very scientific, but lots of fun!

At 30 mph we got about 10 amps at 15 volts and the tail was starting to furl.

---

**In October 2003, the SEI workshop lead by Mick Sagrillo erected Win's machine at the Guemes Island store for grid intertie with some pv.**

Here is the power room with the SW inverter that manages the inertia.

**"What a warm, sweet feeling on a dark, ugly day to look  
up and see that mill makin' watts!"**

# Hamster-Powered Night Light With Custom Low-RPM Alternator

---

**Though Skippy the Hamster powers this night light by running on his exercise wheel, the same concepts and low-rpm alternator design could be applied to a school science project using different energy sources! A small wind or hydro turbine could easily power this alternator.**

The Otherpower.com staff thought of building a hamster-powered nightlight a couple years ago at a rather, uh, soused company Christmas party. Then recently Analise, an 8th grader from Albuquerque, NM, contacted DanF through the [AllExperts.com](http://AllExperts.com) Science For Kids forum, asking 'Can a rodent generate enough electricity to power a light by running on it's wheel?' That was enough inspiration for us to start the project, and we soon added Skippy the Hamster to the Otherpower.com payroll. He's a Syrian Hamster, and we chose that breed since they are nocturnal and like to run on the exercise wheel. Analise will be using a mouse named Ghost for her science fair project.

**Skippy the Hamster**

The first criteria we needed to design the alternator was an estimate of the Revolutions Per Minute (RPM) a rodent can generate on the wheel. The lower the RPMs, the more difficult it is to design a good alternator for it. Analise took a stopwatch to the local pet store and recorded how many times the wheel went around in 10-second intervals, then multiplied these figures by 6 to get RPMs. She found that most rodents can make between 40 and 60 rpm on the exercise wheel. That gave us a starting point for the alternator design.

Our first thought was to use a DC hobby motor to generate the electricity, so we could charge up some NiCad batteries to run a light. However, we immediately ran into the same problems as when we built toy wind turbines using hobby motors -- at the required low RPMs, most hobby motors cannot get the voltage high enough to start

charging batteries. And you often can't tell what a hobby motor is rated at, there is not usually a specs plate on it. So you might have a 500 RPM motor, or a 10,000 RPM motor! The rated RPMs of the motor determine at what RPM it can make a certain voltage. None of the DC hobby motors we had available could make even 1.2 volts (the voltage of a single AA NiCad) at 40-60 rpm. So we scrapped the idea of using a DC motor as a generator. Plus, the required diode (to keep the battery from just spinning the motor) would drop the voltage by at least another 0.7 volts. It would be possible, but complicated (and bad practice) to use gearing or a belt and pulley system to raise the RPMs -- the friction losses in the gearing system would be major, and design would be complicated. Rodents like to chew, and a rubber belt would be fair game. Plus it's much more fun to build your own alternator than to use a pre-made hobby motor!

### Frame and Bearing Construction

So, we chose to scratch-build a tiny low-RPM alternator for the hamster wheel. The first issue we noticed is that the wheel that came with the cage was noisy when Skippy ran on it. VERY noisy! That meant that some of Skippy's energy was being converted to sound by mechanical vibration--and we want all of his energy to go into power production! So the first thing we did was modify the wheel with a new ball bearing. We simply used one of our inexpensive, [surplus DC brushless motors](#). Although the design of the motor itself is exactly like a permanent magnet (PM) alternator, these motors can't produce enough power to even light an LED at low RPMs. We used it simply because it was a cheap source for a really nice little ball bearing, and was easy to mount the wheel to. You could use any free-spinning bearing that's available--off an old skateboard, rollerskate, anything that spins freely and you can mount the wheel to.

### Surplus brushless DC motor used for the ball bearing inside and easy mounting

To mount the wheel to the motor, we simply centered it on the wheel and marked 3 holes from the top of the hub for drilling. The motor hub has 6 holes--3 are tapped to a weird little SAE 2/56 thread, the other 3 are blank. We used a simple 4/40 tap to thread these smooth holes to fit 4/40 machine screws, and mounted the wheel to the motor hub with these. The motor was then mounted to a thin piece of wood. The entire wheel is free-standing on this wooden bracket -- it does not have to mount to the side of the rodent cage.

**Wooden frame showing motor mounting, from back side**

### **Permanent Magnet Alternator Construction**

The next step was building an alternator onto the wheel. A big advantage of using a Permanent Magnet (PM) alternator for any kind of power generation is that no brushes are required for electrical contact to the spinning part (the armature, also called a rotor)--the magnets spin, and are not connected to the coils in any way. So we simply fitted a steel ring with magnets evenly spaced on it to the flat side (the axis) of the wheel. This makes it an 'axial-flux' alternator....if you fitted the magnets to the curved surface of the wheel around the circumference it would be called a radial-flux alternator.

**alternator mounted to back side of wheel**

We cut out a ring of approx. 16 gauge steel to fit the wheel. You could easily use 2 coffee can lids stacked and cut out for this-- you could use a drill and tin snips for this. We used a hole saw for the inner circle and a bandsaw for the outer. Be careful, when the steel is first cut the edges will be very sharp! Grind them down with a wheel or file so they are safe for both you and your rodent. This steel ring behind the magnets forms a more complete magnetic circuit so there's more flux passing through the stator coils. It also makes it much easier to mount and evenly space the magnets, since they stick to it.

**Magnets mounted on steel ring**

We chose the magnet size with the limited amount of power a hamster can produce in mind. They are our [Item #30](#), 3/4 inch diameter by 1/8 inch thick Grade N-35 Neodymium-Iron-Boron magnets. Very powerful, but not

too heavy. You can make up for lots of design and mechanical tolerance problems by using very strong magnets in a homemade alternator! If you use weaker magnets, your power output will be significantly reduced. We used 14 magnets because it was the largest EVEN number of magnets we could space around the ring, so this may vary depending on the size of your rodent's wheel. You must use an even number of magnets. We spaced them evenly using playing cards...by trial and error we found the right number of cards to use as a shim between each magnet.

It's important to get them spaced evenly. *The magnets also must be placed with the North and South poles alternating on each magnet.* And the edges of the magnets should be aligned in a perfect circle, too. Read on for magnet mounting details.

Compared to the giant, finger-breaking magnets we used in our [10 foot wind turbines](#), these little magnets are pretty safe and easy to work with. They are, however, powerful enough to pinch skin and give you a blood blister, so handle them carefully and keep out of reach of young children. Parental guidance is needed for older kids too.

**Please read our [Magnet Safety Warnings](#) before starting the project!**

First, place one magnet on the steel ring and center it between the inner and outer edges of the ring. Tack it down with a drop of cyanoacrylate glue (Superglue®) applied around the edges--be sure to use [thin viscosity glue](#), so it will wick underneath the magnets and set up. It also helps to have [glue accelerator](#) around--one spritz of this and the glue sets up instantly (keep your fingers out of the way!). Now each magnet must be placed with the opposite polarity of it's neighbors facing out. To get this right, carefully take each new magnet off of the stack, and carefully hold it up to the next magnet mounted on the ring. If it repels, hold the magnet exactly as it is oriented and gently snap it to the ring. Use this test for placing each magnet, and check it when you are done...the magnets should alternately repel and attract the magnet in your hand as you go around the ring testing. Remember, you must always use an even number of magnets. After they are all placed, use playing cards to space them so they are aligned evenly around the circle. And make sure they are aligned in a perfect circle radially too -- check the inner and outer diameters of the circle of magnets and slide them around to get perfect alignment both ways. When everything is good and you've checked to be sure the magnets alternate in polarity, tack all of them down with drops of thin superglue applied around the edges of the magnets.

To make things simple, we simply centered the magnet disc on the back of the plastic hamster wheel, and held it in place with 4 more strong magnets stuck to the inside of the wheel! This makes it easy to remove, but still holds it tightly on there. You could also use glue if needed. Remember also in designing your mount -- the magnetic field from the magnet disc should be away from metal cage bars or other metal parts.....it will be attracted to these metal parts and will be slowed down significantly.....you'll be wasting lots of hamster power. And use caution handling the disc -- it will be powerfully attracted to ferrous metal or other magnets.

The next step is winding the coils. We wound one, tested it, and found we needed more voltage, so we ended up using 2 coils. Each coil is 400 turns of [#30AWG enameled magnet wire](#). We used a simple hand-held coil winder, and made up a new center insert to get the coils the right size. The inner hole of the coil should be about the same size as each magnet you are using. You could also wind the coils around a tube that's the right size, but the elliptical coil shape we got by using a winder performs a little better, and the tapered form in the middle makes it easier to get the finished coil off of the winder. The important thing is to pack the wire in there as evenly and tightly as possible.....the finished coils should be about 1/4 inch thick, with each leg of the coil about 1/4 inch wide and the center hole matching the magnet size. Here's a detail of how we built the winder:

Here's DanB winding a coil. Notice how the spool of magnet wire is on a pin in the vise to permit easy feeding. We also wax the winder form with crayons so superglue won't stick to it...makes it easier to remove the finished coil. Leave a big tail on both ends of the magnet wire.

Once you get 400 turns on the coil, twist the leads together so the coil won't unwind, and drip superglue into the coils. We then hit it with accelerator to speed the drying time. Then disassemble the winder and carefully remove the coil. Hit it with more superglue if it wants to come apart on you. At this point you can even spin the wheel and hold the coil up near it by hand. In our first test we showed about 1.2 volts AC when doing this. That told us we needed another coil, which will double the voltage when hooked in series and in phase with the first coil. You'll need to strip the wire ends with sandpaper, razor blade, or knife before connecting.

At this point you can mount the first coil. We simple glued it to a small block of wood and glued this to the frame. Get the coil as close to the rotating magnet ring as possible without it touching. We ended up with a big airgap here due to the wobbly motion of the wheel....about 1/8 inch. But the big magnets make up for this tolerance flaw. You should get an AC voltage reading now from the mounted coil when you spin the wheel. We could get more power out of the coil by mounting laminates or another magnet rotor behind them, like we do when building [wind turbine alternators](#). But we decided that Skippy probably wouldn't care either way, and one side of the magnetic circuit open made for much easier construction.

**Closeup of mounted coil.**

Next we wound the second coil, identical to the first one. Here, however, it's very important to orient and mount the second coil correctly! It should be placed exactly the same way as the first. The easiest way to figure this is to use a voltmeter. Connect one lead of the first coil to one lead of the second coil and set your meter for AC volts (remember to strip the insulation off first). Hold the second coil away from the alternator and spin the wheel.

You'll see the voltage from the first coil. Hold the second coil up to the alternator and spin it again. If you see approximately double the voltage, it is placed right. If you see no voltage, it's backwards. Flip it 180 degrees, so the other face points towards the magnets. When you know you have the coil oriented right, glue it to your mount (like with the first coil, we used a small block of wood that can then be glued right to the wooden alternator frame).

You also must place the second coil in phase with the first. The easiest way to do this: Have a helper hold the wheel so that the coil is exactly centered on one magnet. While your helper keeps the wheel from moving, place the second coil so that it is also exactly centered on a magnet and glue in place. We placed ours opposite each other, but you could place the second coil anywhere -- right next to the first, or whatever you want, as long both coils are centered on a magnet when you place them.

Now you can test the alternator. You should again see about twice the voltage you saw with one coil. If not -- first make sure all the wires are thoroughly stripped! It's trickier than you'd think. It's also possible you got a coil reversed. Try flipping one coil over and see if that works. And also check to see that a magnet is aligned exactly over both coils at once, so it's in phase.

### **Data Acquisition**

**Bicycle computer for data acquisition.**

Next, we want to install the data acquisition computer for the system. We used an inexpensive bicycle computer, available at any bike store. The trigger is simply a cylindrical NdFeB magnet, and comes included with the bike computer. We disassembled the sensor and trigger to show how they are constructed. You don't have to do this unless you want to. The sensor is simply a reed switch connected to the computer -- I had already used the sensor from this computer for another project, so I just got another reed switch and made a new sensor, shown below.

Again, you don't need to do this unless you want to.

**magnet trigger glued to outside radius of wheel**

### Reed switch trigger

We simply taped the reed switch sensor to a small piece of wood and glued it to the frame. The magnet must pass within 1/8 to 1/4 inch of the sensor to trigger it. Now you need to tell the computer the circumference of your rodent's wheel, in millimeters. There will be a special button for setting the wheel size, consult the owner's manual of the bike computer. Skippy's wheel turned out to be 540 millimeters in circumference. After the computer is set, spinning the wheel should show you a miles per hour reading! Skippy does from 2-3 mph at normal speed, and slightly faster when DanF's cats are leering at him through the cage walls. The computer will also keep track of maximum speed, average speed, time spent on the wheel, and total miles run for you. We just got Skippy's system up and running, so we don't have any data yet for average hamster-miles per night yet.

### Lights

As we mentioned before, we were not able to get enough voltage with this simple 2-coil design and low rpms to charge a battery. The losses from rectifying the AC output of this alternator into DC would be very large...over half the voltage made. We could double the number of coils or number of turns of wire -- but then the resistance in the coils is getting very high, and the machine runs inefficiently with more than half it's output going to make heat instead of light. These are the exact same sort of trade-offs we must make when designing alternators for home wind turbines too! However, the opportunity for experimentation is excellent. Adding more coils would be one way to do this. With enough voltage to overcome the drop from rectifiers, a self-contained system could be built. An LED nightlight that turns on automatically when it gets dark, run off a rechargeable battery, charged by

the hamster alternator. Please drop us an email if you experiment more with this project!

So, we decided to run 2 super-bright red LEDs off the alternator directly. We chose red because they need the least voltage of any color to light up.....about 2 volts to get real bright. Other colors will work too, but they need higher voltage and therefore won't be as bright at any given speed. LEDs only pass current in one direction, so we connected the 2 backwards from each other....when one is lit, the other is off. The frequency of the flicker changes as the hamster changes speed. The light is bright enough in DanF's living room to find the bathroom at night when Skippy is running. Run Skippy, run!

### **Experimentation and Rodent Psychology**

Another interesting fact -- though it's hard for the hamster to make higher voltages with his low-rpm wheel, he has torque to spare. 2 LEDs are barely taxing him.....we are drawing only about 30 milliamps into the LEDs at Skippy's top speed. If we add more electrical load to the circuit, he could make more power, with a resulting increase in physical resistance on the wheel---like running uphill. We have yet to try small incandescent flashlight bulbs in the circuit--something that draws more power and makes more physical resistance against the wheel spinning. We did try more LEDs -- he had no trouble lighting up 6 of them. Next we plan to try an array of low-voltage incandescent flashlight bulbs to get optimum power output without tiring Skippy out too much. DanF is guessing that Skippy is good for 200 milliamps without tiring, and we'll post our data as it comes in.

You can observe this alternator loading effect by disconnecting the alternator's leads from the LEDs. Spin it by hand -- it should spin freely for quite a long time before stopping. Now spin it, and short the alternator leads together -- it stops very quickly. Now try it with the LEDs hooked in -- it stops more quickly than having nothing at all connected, but spins longer than when shorted out. Skippy can run against the shorted wheel fairly well, but gets tired and doesn't run as many hours per night. So the goal is to find out, by experimental data, just how many lights (how much current) Skippy can push.

This illustrates another principle of designing alternators for wind turbines -- the relationship between the power available from the source (the wind or the hamster), the RPMs possible, the electrical load that's connected, and how much energy the alternator can take out of the system and turn to electricity. All of these factors involve design trade-offs. Again, the opportunities for experimentation here are endless! How much power can the rodent make without getting irritated with how much load is on the wheel and refusing to run? Does using high-performance food for working hamsters help? How about weighing the hamster's food and figuring how efficient he is at converting kibbles to electricity? Tracking watt-hours per hamster-mile (wH / hM)?

The bicycle computer gives you an incredible amount of data for your project! It always shows you the speed of the hamster in miles or kilometers per hour. It remembers maximum speed, and keeps track of the total miles run by your rodent, with a resettable trip odometer too. The resettable timer shows you how many Hamster-Miles (hM) were run each night, and it will also compute the average speed maintained when the wheel is turning.

We bet that Analise will be working on some of these challenges for her project, and keeping careful records. We just helped her with the alternator design -- I don't think they teach it in school these days. And we hope others will try this experiment, and refine it for their own needs too! As for us -- the silliness level here at work has reached an all time high--even more so by finding out that the project actually works! Skippy is happily employed by Forcefield and keeps DanF from stumbling during those late-night trips to the bathroom. We'll keep feeding him hamster chow (Skippy, that is) and see how many watt hours he makes yearly!

**A WORKIN' Hamster!**

Rodent exercise wheels vary in size, and there are many ways to make mounts and bearings. So we are not including a complete parts list --hopefully your experiment will vary! If it does, please send us a photo of it. You may not have some of the tools we used available. Hopefully we've provided enough information so you can design a custom alternator for your own Chinchilla Challenge, Rat Race, or Hamster Hill Climb. One absolutely essential tool for this project is a multimeter--mandatory for any kind of electricity experiment. You can get one at Radioshack or Home Depot for only \$10-15, and a student will have uses for it until graduation and beyond.

And while we probably could have built this project without Superglue, it sure made it go together fast.

# Wind Power

---

Wind power can be an excellent complement to a solar power system. Here in Colorado, when the sun isn't shining, the wind is usually blowing. Wind power is especially helpful here in the winter to capture both the ferocious and gentle mountain winds during the times of least sunlight and highest power use. In most locations (including here) wind is not suitable as the **ONLY** source of power--it simply fills in the gaps left by solar power quite nicely.

## OPTIONS FOR GETTING STARTED IN WIND POWER

### Build your own!

Building a wind generator from scratch is not THAT difficult of a project. You will need a shop with basic power and hand tools, and some degree of dedication. Large wind generators of 800 watts and up are a major project needing very strong construction, but small ones can be built mostly of wood, and be up and flying in a weekend! In fact, we highly recommend that you tackle a small wind turbine before even thinking about building a large one. A machine shop in which you can turn metal parts on a lathe is very helpful, but any automotive shop that is equipped to turn brake rotors could make these parts for you at low cost.

*In most locations, GENTLE winds (5-15 mph) are the most common, and strong winds are much more rare. As you'll see by examining our latest machines, our philosophy about designing wind turbines is to make large, sturdy machines that produce good power in low wind speeds, and are able to survive high wind events while still producing maximum power.*

**Here's a roundup of all of Otherpower.com's homebrew wind turbines. The individual web pages give construction and performance details. We've changed many things in our designs**

**over the past few years, so if you are reading an older page, be sure to check out what we've been doing recently before you start the project. Enjoy!**

**10/10/2003 -- The Triplets -- 3 new 10-foot diameter dual-rotor brake disc wind turbines!**

These 3 nearly identical machines are built with the same design as the mill at the Caboose (5/20/03, below) but we streamlined the construction process significantly and built 3 machines at the same time -- Curly, Moe and Larry. These are the latest of our designs, and they perform great in low winds. Detailed DanCAD drawings and dimensions on this page.

**5/10/2003 -- New Brake Disc Mill**

9-foot dia prop, furling tail, 3-phase, separate laminate assembly with excellent specs. Many improvements over our previous designs! Spins up and makes power freely in low winds, and governs itself in high winds.

**5/20/2003 -- Dual Rotor Brake Disc Mill**

Up and flying at the Caboose. Excellent low wind performance with 10 foot prop, great furling system.

**The Wood 103**

A 100-watt windmill built entirely from wood! More of a demonstration than anything, but a quick weekend project that will teach you about windmill construction.

**The Wood A-X**

A quick-and-easy 200 watt windmill, built mostly from wood! Perfect for a remote cabin or RV, this one is quick and easy, and we are working on an updated version too.

### DanF's Wood A-X

DanF's version of the Wood A-X is very similar to the original, but with slightly sturdier construction. The props are interchangeable between the two. Some problems to be fixed here, but in progress. .

### Ward's Prop Gallery

Ward and his collection of broken props, tails and stators. This is what happens when you let DanB and DanF use you for a wind guinea pig! But Ward's tower has the best height and wind exposure in the area, so it's where we try and make windmills blow up to further our research. And he's a good sport!

### 400-watt Volvo Windmill

One of our older designs with no furling system. But it has been up and flying for a year and half now.....with no furling system.

### 400-watt Volvo Windmill

Again based on a Volvo brake disc, this one has a 3-bladed prop that is slightly smaller than Ward's mill. It's an ongoing experiment too...a new stator is in the works. One of our older designs with no furling system.

### Building Towers for Wind Turbines

Details, diagrams and photos of many different ways to construct tilt-up towers -- ranging from the extremely solid and sturdy to the quick and dirty, field-expedient versions!

### Designing, Building and Flying a Wind Turbine

Just our collection of information on all phases of the process! If you are new at wind power, it might help explain some confusing aspects of this 'black art.'

### [Induction Motor Conversion Mill](#)

Built using an AC induction motor converted to a permanent-magnet alternator. We've since found that from-scratch PMAs are more efficient than conversions.

### [Small Science Fair Windmill](#)

With a small computer fan blade as a rotor, this little mill makes a great science fair project. The frame is made of PVC pipe, and nothing is too big or fast to be very dangerous. It will light a small bulb using a box fan for power.

## [Glossary of Wind Power Terms](#)

**A high-tech test rig for our high-tech wind generators! Otherpower.com's trusty Model A Ford windmill tester.**

*Click on the image to see a 15-second MPEG video of the Model A wind test experiment*

### **Find an antique**

If you find an old windmill for sale, first make sure it's intended for generating electricity instead of just pumping water. One common old windmill that's often found for sale used is the **Wincharger**.

The other popular wind generator of the era was the **Jacobs**. These were of higher quality than Winchargers--but many of both are still flying today. Several people around the U.S. restore, service and stock parts for old windmills. And the Jacobs is still being made today! The current production models are very large and expensive, with over 10 kW output--they are magnificently designed and built. Check out the [Manufacturer's Website](#) for more information and cool pictures.

Electricity producing wind generators were very popular in the 1920s and 1930s all over rural America. They were available in many different sizes and voltages, and can often be found for sale in rural farm communities. Most models are quite suitable for a modern remote power system no matter what voltage they are. If you are able to locate an old wind generator, some basic maintenance (rust removal, lubrication, and testing) could put it back in working order quickly. They were built to last--before Rural Electricifation, they were the ONLY source of power for many rural farms and ranches. [Backwoods Home Magazine](#) published an excellent article in 2001 about finding and restoring old wind generators.

[Otherpower.com](#) is always interested in purchasing used wind generators, including these!

### Buy a commercial wind generator

Suitable only if you have more money available than time. Prices range from \$500 to \$5000 for small-scale wind turbines up to 5 Kw. Your wind generator retailer should provide you with LOTS of information regarding many issues if you choose to purchase a wind generator! Since you will be spending lots of money, it might be wise to survey your site with a logging anemometer before making a commitment. The [AWEA Discussion board](#) is a good place to ask questions about commercial wind generators, and [Mike Klemen's Wind Generator Page](#) has lots of performance data on a variety of commercial wind turbines that he has flying. Check out our [LINKS](#) page for retail suppliers. Or contact the wind turbine manufacturer directly and have them point you toward a retailer nearby.

# 9' Diameter Brake Disk Windmill

With Furling Tail

This page is a diary about my latest wind turbine experiment from May of 2003. Although a bit more complex, it features some significant improvements over the brake disk turbines I've made in the past.

[Para Español, traducción de Julio Andrade.](#)

This is what I started with. It's the front strut, brake and wheel assembly from a Volvo 240. The Volvo parts are good, and since they are rear wheel drive this front assembly is simple and inexpensive from junk yards. They also built these cars for about 20 years, so the parts are easy to come by. Volvos are somewhat heavy cars, so the bearings are large and the brake disks are larger in diameter than most.

Above are pictured the important parts. The spindle and strut tube will make up the main frame of the wind turbine. The blade will bolt down to the front of the brake disk, where the rim used to fit on the car. That stator shown below will replace the backing plate that used to cover the back of the brake rotor. Of course the machine will use the wheel hub, and the strong wheel bearings from the car. I take some care to inspect the used bearing, clean it and grease it again. Normally in the past I've used the same brake disk that came with the assembly. In this case, I noticed that the front brake rotors from the Volvo 740 (a heavier car) were a whole inch larger in diameter (11 inches), and they fit over the same wheel hub, so I aquired the larger brake disk off the 740 for this project. It's important to consider when disassembling these struts that the spring is under some tension! One should compress and clamp the spring.

This wind turbine has a furling system so that in high winds the alternator and blades will turn sideways out of the wind and protect itself from overspeeding. To do so, the tail must raise. The weight of the tail ultimately determines when the machine can furl. This seems to be the most popular furling system on small home brew machines, and the idea has been perfected by Hugh Piggott from [Scoraig Wind Electric](http://www.windstuffnow.com). Go to his site, or [www.windstuffnow.com](http://www.windstuffnow.com) for details about how this system works. In this case, the center of the alternator sits about 4 inches off to the side from the center of the mast. I did this by cutting the strut tube off at about 4 inches from the wheel spindle and welding it onto the side of the remaining tube at somewhat of an angle. The tail will pivot over a 1 inch diameter pipe which is welded to the assembly at an angle of about 20 deg from the mast.

Above is another picture of the same assembly.

The tail is shown above. Actually - when I got 'round to testing this the tail came up too small and too light weight. I wound up making it slightly larger in the end. The end which attaches to the wind turbine is a short segment of pipe slightly larger than the 1 inch diameter pivot, which is welded to the main frame of the windmill.

Above is pictured the main frame, with the tail mounted. I painted the metal frame with green epoxy enamel to prevent rust and keep things looking as nice as possible.

Although probably not necessary, I like to cut a bit off the back of the brake disk from the inner diameter, almost all the way out to the outer edge, but not quite. This leaves an edge, about 1/16 inch high, which catches the magnets to help hold them in. It also leaves a nice clean flat surface. Since the magnets will also be glued and held in with some polyester resin, it's important after cutting this to clean it and make sure it's oil and iron filing free so the resin sticks well.

Pictured above are the magnets I used. This machine has 12 magnets, each one is 1.8 inch diameter and 1 inch thick. They are available on our web [Shopping Cart](#).

The magnets lay down on the brake disk such that each one has the opposite pole facing up as the one next to it. Alternating North and South poles all around the disk. I push the magnets all the way out to the lip I cut and space them approximately by eye. Then I use shims (playing cards) and go 'round the circle so they are perfectly spaced. The space between the magnets here is about 1/2 inch (or exactly the thickness of 49 playing cards).

I think the leakage (magnetic field which is going from magnet to magnet before it has a chance to go through the coils) between these 1 inch thick magnets is significant. More space between them would reduce that, it is also possible that thinner magnets (like 1/2 inch) might even work as well, or better. Once the magnets are spaced evenly, I wrapped some tape (duct tape) around both the inside and outside of the brake rotor so the edge stuck up about half an inch, creating a dam, or cavity in which I could pour polyester resin to glue the magnets down and keep the space between them. I wish I'd caught a picture of that.

I made a simple hand cranked coil winder.

I tested lots of coil shapes and sizes. Lots of things worked, but through lots of testing and some good advice I wound up deciding on this wedge shaped coil. The coils are wound from AWG 14 wire, and each coil has 60 turns. They are 3/8 inch thick, and the width (I never measured it) is such that exactly 3 coils fit over 4 magnets. Unlike the past machines I made which were single phase, this one is 3 phase. This setup seems to squeeze a bit more power from the same magnet rotor and also offers some benefits in reducing line loss. The alternator will also run more smoothly as 3 phase, meaning basically less vibration. Since there are 12 magnets, I need 9 of these coils and 3 coils will be wired in series to make up each phase.

The inside of the coil winder is waxed (I used crayons) so that glue wont stick to it. After the coil is wound, and the top removed from the coil winder, I put thin viscosity cyanoacrylate 'super glue' in the coil and spritz it with accelerator which hardens the glue instantly. This makes for very hard, strong coils that don't come apart easily.

Pictured above are the coils, and the magnet rotor (the magnets are not glued down yet, actually I never did that till the very end and never got a picture of it finished).

I made a mold out of partical board. The circle is 14 inches in diameter and I divided it into nine parts and drew lines so that I know where to place the coils. The top of the mold is the cutout from the bottom. The mold is 1/2 inch thick. I waxed the mold so that the resin would not stick to it. Once I place the coils and pour the resin, the top will get clamped in, and the wires from each coil will poke out the edge so all the wiring will be done later.

I cut two disks of fiberglass fabric about 14 inches in diameter. I put one down in the bottom of the mold before placing the coils. Then I put down a thin layer of polyester resin. I then put each coil in its place. I took care to make sure each coil is placed the same way. In other words... when the coil comes out of the winder, it has a top, and bottom side. I made sure they are all the same way so that the inside wire of the coil (the start) and the outside wire (the end) come out the same for each coil. Although not absolutely necessary it makes for much easier wiring later on. Once all the coils were placed, I filled up the mold with polyester resin mixed with talcum (baby) powder. The powder makes the resin go further and makes things a bit stronger. Once the mold was filled I put another fiberglass fabric disk over the top, and poured over some straight (no talcom powder) resin. I thin clamped the top on the mold with the wires poking out.

The reason for the red, and green coils is simply that I ran out of magnet wire! The green stuff is extra high temperature wire rated for about 400 deg F, and the red is less - but it will work fine.

After a couple hours I opened the mold and the stator is pictured above.

You can see in the picture above how the center of the stator is drilled out the same as the backing plate. The center hole has to be a bit larger (2.5 inches) so that the bottom of the wheel hub will fit inside it. The mold could have been modified to leave this hole in the stator and it would've saved some resin, but it was easy to use a hole saw and resin is cheap. On past machines I've made, the back of the stator was plywood, and steel laminates (which help to conduct the magnetic field through the coils) were glued into the plywood. The coils were glued over the top of the laminates, and the plywood bolted to the windturbine frame. A problem I had was that the laminates were getting yanked out of the plywood by the very strong magnets. In this machine, the laminates will be a separate part which simply lay (stuck there by the force of magnets alone) behind the stator. Or, with a smaller and faster prop it would probably run just fine without laminates at all.

Pictured above is the stator bolted onto the machine. I've also got the wheel hub on here. You can see how the studs (where the lugnuts used to go) have been replaced by longer (7 inch long) pieces of 1/2 inch allthread. The studs were pressed in, and are easily knocked out with a hammer. The allthread is held on with nuts on each side, and then another nut is used on each one to hold the magnet rotor out the proper distance so that the magnets run very near (about 1/8 inch) the stator.

Above the whole machine starts coming together so that I can wire, and test the alternator. I used 6 brass bolts for binding posts to hook up the 3 phases. My intention with this alternator was to wire it in Delta.

Here you can see how the laminates simply "stick" to the stator when the magnetic rotor is on. This is convenient, because it is easy to remove the laminates before removing the magnet rotor! It can otherwise be difficult to pull the magnet rotor loose when the laminates are built into the stator. Of course, this design with the fairly thick coils and removable laminates means I have a pretty thick airgap (distance from magnets to laminates). Past machines I've made could have much thinner coils and probably make slightly better use of the magnets.

The laminates I used here are actually a coil of very nice Silicon steel which I got from Ed at [Windstuffnow.com](http://Windstuffnow.com). Also go there for lots of good information on all aspects of building and designing small wind turbines.

Probably not necessary, but I glued the steel laminates into a plywood ring to make them easier to handle and prevent corrosion.

Here the machine is pretty finished up except for the prop. At this point I've got about 20 hours into the project if I don't count the mess I have to clean up later.

I made the blades from wood about 8 inches wide and 1.5 inches thick. Each blade started out 5 feet long, for a 10 foot prop. Here you can see I cut out the shape for one prop. Then I used it as a template and cut the others to match.

These are simple blades (as usual with me...). The tips are pitched about 4 deg, and the middle of the blade about 6 deg. From there it pitches steeper and steeper until the angle takes up the board thickness near the root of the prop. The airfoil is designed to do little more than 'look like an airfoil' and the thickest part of the airfoil is about 1/3 of the way back from the leading edge towards the trailing edge.

It'd probably work better if I designed it 'properly'. Hugh Piggot has some good information on this on his website [here](#) and Ed from [windstuffnow.com](http://windstuffnow.com) offers some nifty software which figures it all out for you!

I've seen several commercial machines which have very simple non-tapered, non twisted (straight pitch) blades which work fine, so it inspires to me to keep things simple.

Before doing any carving, I cut one slot with a cross cut saw at the point where the angle of the blade is steepest. This is insurance that I won't ruin the hub area of the blade with the drawknife should I make a mistake or have the wood split.

After attending Hugh's seminar this spring... the drawknife has moved to the top of my list as the favorite tool to use. Very fast, and very accurate. No need for a chisel and the only power tools were used for finishing. I roughed out the whole prop with this quickly and then finished it up with a power planer and a belt sander.

Pictured above the top of one blade is finished.

Here you can see the airfoil, and the back of the prop.

I rounded the tips to look nice, although later in testing I wound up cutting them off as the prop was too large and a bit slow.

The blades are sandwiched between two plywood disks and held together with a ton of screws. In the past I've used glue here, but I opted not to this time thinking that the screws, along with the tight squeezing that happens when the prop is bolted on would be good enough. This way if I ever need to replace one blade it will be easy.

Pictured above she's pretty much finished up on the nose of my truck for testing. When I do this I have a battery in the truck on the floor, some rectifiers, and meters so I can get a rough idea of how much it charges at certain speeds. This also allowed me to test the furling setup. In the first test it was clear the tail wasn't quite big enough or heavy, as it wouldn't run square with the wind and started furling at about 15 mph. The next morning I increased the tail size some and made it from thicker wood. As it is now - the tail is back about 36 inches from the machine, and it's about 4 square feet in area. It works reasonably well, although a bit larger might be better. I'm keeping it as it is because my tower is not so strong and I want it to furl early.

This is a big improvement from past machines, mainly in that it turns in practically no wind at all and the slightest breeze spins it up to charging speed quickly and quietly. Past machines I've made wouldn't start till they saw a 10mph wind, and then it took them some time to spin up--so they were not nearly as responsive. The reasons for this improvement: the good laminate material I got from Ed, the 3 bladed prop, and the poor (wide) airgap (these laminates are not seeing near the magnetic field intensity as others I've made). It's always spinning even on a still day - and it seems to be making an amp or two at 7mph. At 10 mph it charges 12 volts at 8-10 amps. 15 mph I see about 15, and at 20 mph it's doing 30 amps and just starting to furl. At 25 mph it's furling out of the wind almost half way and doing about 35 amps and at 30 mph it's more than half way turned out of the wind and charging about 45 amps. I believe the power I'll get from this in very light winds will add up significantly and prove it to be a much better producer than others I've made, some of which actually had more powerful alternators.

In one test I added some weight to the tail. Although it was still somewhat turned out of the wind, it was producing about 60 amps at 30mph. So, if I add weight to the tail it will produce much more, but as it is it's less stress on my tower. I also think that the majority of the power I see from it will be in winds below 20mph so this is the area I'm concerned about.

Above is a good picture of how we test them on the truck. [Click Here](#) to see a brief movie of the truck test!

In this picture I'm tying it up so we can more easily navigate the trees on our driveway for the ride home. This picture does give a good idea of how the furling system works, as the wind puts force back on the blades it makes the machine want to fold up like this - but in order to do so the tail must be raised! So the furling system is a balancing act between the force back on the blades, and the weight of the tail.

This is how it looks now up on my tower with the blades cut down to 9 foot diameter and the larger tail. It's been doing well now for a few days, starting to turn below 5mph and definitely making power. It's definitely an improvement over past machines. I notice significantly less line loss due to the 3 phase power, and it generates in much lower windspeed because it turns much easier. To do it over again, changes I'd make would be a still larger tail, and/or... cut down the prop size maybe a bit more. I'm pleased with it though and will probably leave it as is. Can't wait to make the next one!

As a dedicated "do it yourselfer" I put this site up for all those who share similar DIYS skills and convictions.

I hope what I have here helps you in your endeavors in some way, big or small.

This site is maintained using windpower only. My entire office is powered by the wind.

[Email me](#) Please send me feed back about this site or any questions you may have.

***[A semi-new Vawt... the "Lenz turbine"](#)***

**[New addition ...](#)**

An educational 3 phase turbine kit. Comes with everything you need to create a 3phase wind turbine. Great for science projects, learning about 3phase PMG alternators, and alternative energy. The kit includes 6 very powerful neodymium magnets. Check it out!

**Budget builders....**

More Neodymium magnets for those on a budget. They make nice alternators as shown in the section "[Alt from scratch](#)"

These are the new magnets I've been working with. They have proved to be quite impressive for building the axial flux type alternators and for building motors for electric vehicles. I have a few extras for those interested in them. Click on the picture to go to the builders corner page.

The

original 6 ft turbine with a car alternator and chain drive. It was changed to the axial Flux type alternator and ended up being much more efficient and powerful. The chain drive was quite noisy because of the cogging in the modified alternator. It was in service for about 2 years and is now down for maintenance. Actually it will be refitted with a new alternator using the new magnets and the blades refurbished.

The downwind turbine, a very small but quite efficient little unit. This one was a bit more complicated to build but it features the star/delta controller ( check the link on downwind turbine for more detail)

One of the original alternator modifications. This one had a rewind stator and the modified rotor using Neo' magnets.

# 3 Phase Basics

## Understanding 3 phase alternators....

Three phase is nothing more than single phase with 2 extra coils slightly out of phase with first. Basically "Phase" relates to the timing of the magnets passing over the coils at different times. With single phase the magnets and coils all line up with each other and are said to be in "phase". The diagram below shows single phase wiring....

In a single phase unit the coils are wound opposite of the first. That is to say one is wound clockwise and the next is counter clockwise. If your unit has 8 magnets then it would also have 8 coils. With 3 phase you would have 3 coils for each pair of magnets. A pair meaning one north and one south magnet. There are many combinations for any one set up. For instance you could use 8 magnets and only have 6 coils without overlapping them... or 3 set of 4 coils in series. For now we won't worry about the combinations and stick with the basics. Below shows a diagram of 4 magnets with the placement of each of the coil sets...

As you can see the first phase covers only the north pole magnets and are wound all in the same direction. The other of the two are identical to the first with the exception they are offset equally. The next diagram shows all the sets in place for a 4 pole alternator. You end up with 3 start wires labeled A,B,C and 3 end wires labeled D,E,F. The output wires to this arrangement would be A, C and E. The reason E is an output or ends up being a "start" wire is because when the magnet passes over the 2nd phase its out of phase between the 1 and 3 so the ends are reversed instead of winding them in the opposite order.

Now to connect the ends and change the AC to DC for battery charging... Below shows the star and delta symbols and 2 different types of rectifiers. Either rectifier can be used for star or delta. You can use diodes and make your own rectifier set up or you can purchase the standard rectifiers. Notice on the standard rectifiers one AC lead isn't used. Similar to the diodes, a rectifier that is already made up for such use and my personal preference is a unit from a GM alternator. They seem to give the best rectified output out of all of them. I'm not sure why but they do. They are expensive to buy new but usually you can get them from the junk yard fairly cheap. Sometimes get the whole alternator for around 15 bucks. They also make a nice clean set-up.

There are basically two ways to wire a 3 phase alternator, star ( or Wye) and Delta. With Delta you get lower voltage but more amps. In star you get higher voltage but less amps. You can calculate these by using the square root of 3 ( or 1.732 ). Each coil set is a "phase" of the alternator so when you measure voltage, ohms or current to test one phase of the alternator you would measure the "phase". Once you know what the output will be from one phase you can calculate the "line" output of either delta or star. The line voltage would be measured from any 2 of the 3 outputs. If one phase measured 22 volts in your test and 10 amps then the star configuration would produce 38 volts and 10 amps (  $22 \times 1.732$  ). The amps remain the same as the phase measurement because the star is basically series'd to another phase. In Delta you would get 22 volts at 17.32 amps (  $10 \text{ amps} \times 1.73$  ). If you calculate this out  $22 \text{ volts} \times 17.32 = 381 \text{ watts}$  and  $38 \times 10 = 380 \text{ watts}$ ... so what is the advantage? Typically the resistance in Delta is 1/3 the resistance of star. If the resistance of star was 1.5 ohms we could calculate the output ( see formula section ). Lets assume the

test was at 600 rpm, we achieved 38 volts in star ( about 16 rpm per volt ) so at 1000 rpm we would get 62.5 volts less battery voltage of 12.6 = 49.9 volts / 1.5 ohms = 33.26 amps \* 12.6 = 419 watts... not to bad. Now in delta we had 22 volts at the same rpm ( about 27 rpm per volt ). So at the same 1000 rpm we get 37 volts - 12.6 battery = 24.4 volts / .5 ohms = 48.8 amps \* 12.6 = 614 watts. Almost a 200 watt gain !!! The advantage of star is the higher voltage at lower rpm which means our unit would have to make 201 rpm to start charging at 12.6V where the Delta would require 340 rpm to start charging.

Some Basic factoids about 3 phase.... Most of the electric power in the world is 3 phase. The concept was originally conceived by Nikola Tesla and was proven that 3 phase was far superior to single phase power. 3 phase power is typically 150% more efficient than single phase in the same power range. In a single phase unit the power falls to zero three times during each cycle, in 3 phase it never drops to zero. The power delivered to the load is the same at any instant. Also, in 3 phase the conductors need only be 75% the size of conductors for single phase for the same power output.

And there you have it ! Not really much more difficult than single phase but much

more efficient !!!

I will be adding things as time goes on so keep checking back from time to time. If you would like to see other items that are not listed send me an email and let me know what your looking for...

## Large Steel Discs

### Steel Discs

I have 3 sizes available right now, 8 inch, 10 inch and 12 inch. All made from 1/4" steel plate. Great for prop mounting hubs, magnetic discs for use with an axial flux machine or a combination of both.

**8 inch disc \$11.95**

**10 inch disc \$14.95**

**12 inch disc \$19.95 Out of stock... sorry,check back**

There is no center hole in these but I will mark and center punch them so it will be easy to find and drill the center to any size you desire. If you know what size hole you need I can drill them for you but there will be a \$5.00 set up fee.

### Very Large Ceramic magnets

These are the magnets I've been using for the downwind turbines. They are very large Ceramic 5 type magnets. They are easily cut with a tile saw. The dimensions are 8.35" diameter with a 4.66" hole in the center by .75" Thick. There are 3 mounting holes in the magnets. If cut into 12 sections will cut through the holes. This doesn't cause any problems with the alternators. Shown here marked off for 12 equal sections. It could be cut in any other configuration also.

The magnet uncut is only **14.95** plus shipping. The magnet weighs 5 lbs. Depending on how its cut this comes out to about 1.25 per magnet cut in 12 sections. 1.50 ea cut in 10 sections or 1.86 cut in 8 sections. One tested with 12 sections on an 8" disc with 36 slots for a 3 phase unit made over 700 watts. They make very nice units.

### Very Large Neodymium Ring magnet sections

If your looking at making lots of power... and I do mean LOTS you may want to investigate the neodymium magnets I've been using for testing. One unit has achieved over 3500 watts using an 8 inch disc with 16 magnets. These are custom made and 16 magnets make an 8 inch OD ring with a 4 inch ID.

The above shows the magnets mounted on an 8 inch disc using 12 or 16 poles. They also fit nice on a 10 inch or the 12 inch discs I sell above.

**NOTE: Under no circumstances should you attempt to assemble the rings without a steel backing. They are near impossible to get apart without destroying the magnets or your body!!!!**

I have a limited supply of these so you may want to get them as long as their available.

These are rather expensive and are priced as follows...

**\$6.50 each (normally 8.00 each)**

or

**\$96.00** set of 16 (normally 120.00)

**( while they last !!!)**

If your interested in any of these send send an email to [elenz@windstuffnow.com](mailto:elenz@windstuffnow.com) .

**Smaller Magnets for the budget builders**

These are the ones I used in my smaller alternators. Also, built a 400 watt unit for the 6ft prop with these shown in the Alt from Scratch section. They make nice inexpensive alternators for wind power.

They measure 1 inch x 1/2 inch x 1/8 inch thick

These are being sold for only **.99 cents each** so a batch of them won't break you. Buy them by the 100's

**Ask about discounts for quantities over 100**

If your interested [email me!](#)

3Phase turbine kit

## Educational Three phase turbine Kit

This kit comes with everything you need to assemble a 3 phase wind turbine. Including easy step by step instructions to build and wire it. The kit also includes 6 powerful neodymium magnets.

**All for only \$29.50 plus 4.95 shipping**

The turbine stands approximately 8 inches tall and is 6 inches in diameter. Although not a real powerhouse, it will charge ni-cad batteries and run LED's without a problem. Only basic tools are needed for assembling the kit such as a drill, various

drill bits, 7/16" wrenches, #1 phillips screwdriver. You will also need some tape and super glue.

Winding the coils has been made easy, using a slightly different approach that anyone can do. The slotted stator makes it very easy to hold the wires in place

The base is up to you and can be a simple board with feet or a PVC plug to mount it on a pole.

Very simple and fun to build!!! Order one today. If your an educator ask about quantity discounts so all your students can learn.

You can download the instructions to see if its something you would like to build. The instructions are now in PDF format which makes it simple to print and use

[Click here for the download \(50k\)](#)

## *Assembling your 3phase turbine Kit*

### Turbine Kit Parts List

- |    |                                      |
|----|--------------------------------------|
| 1  | 1 Stator ( slotted thingy)           |
| 2  | 2 Blade mounts ( triangular plastic) |
| 3  | 1 8 inch x ¼ inch threaded rod       |
| 4  | 2 ¼ inch standard nuts               |
| 5  | 1 ¼ inch nyloc nut                   |
| 6  | 2 ¼ inch washers                     |
| 7  | 3 Aluminum Blades                    |
| 8  | 6 Neodymium magnets 1" x .5" x 1/8"  |
| 9  | 3 50 turn coils of magnet wire       |
| 10 | 15 #4 x ¼ phillips head screws       |
| 11 | 6 N4001 diodes                       |
| 12 | 1 3 ½ " steel disc                   |

### Tools you will need to assemble this kit

#### **Drill**

**5/32 drill bit**

**1/8 drill bit**

**¼ drill bit**

**#1 Phillips screwdriver**

#### **Pliers**

**7/16" wrench**

**Tape**

**Super glue**

**Mild grease or oil**

Start by finding the steel disc and cut out the template above. A flashlight is handy to line up the center hole. Lay the steel disc on the flashlight and lay the template over the disc. Line up the center hole with the light shining through the hole. This will center the template. Tape the template in place and use a center punch to mark the 3 holes. Use a marker to mark the lines on the disc where the magnets will be placed. Remove the template and drill the marked 3 hole locations using a 1/8 inch drill bit. When this is done take a ruler and connect all the lines on the disc. This will be the placement of the magnets. The two triangles have small divits in the sides and top. Use a 5/32" drill bit to drill into these divits.

Continue by locating the steel disc, triangles, 2 washers and threaded rod as well as the 2 standard nuts as shown below.

Take one of the nuts and screw it on the threaded rod about 2 inches down. Place one of the washers on the rod and one of the triangles with the washer groove toward the washer. Place the second triangle on the other one with the washer groove up as well as another washer. Install the steel disc with the lines showing and install a nut. Line up the 3 holes in the steel disc with the 3 holes in the triangle. Install the 3 screws to hold the disc in place. This assembly is to assure the disc is centered on the triangle. Below shows the assembly jig assembled.

Remove the disc and triangles from the rod and find the 3 turbine blades. Install one turbine blade on the triangle attached to the disc. Attach the other triangle to the top of the blade. Make sure you have the washer groove upward and the triangle lines up with the blade. Below shows the first blade assembled and the turbine assembled.

Flip the unit over showing the steel disc and find the magnets. The magnets have to be placed on the disc with alternating poles. Such as North, South, North, South etc. It really doesn't matter which is north or south as long as they alternate. The simplest way

to do this is to place the first magnet down on the disc centering in on one of the lines. These can be superglued in place if necessary.

Take the next magnet and hold it a distance away from the magnet already on the disc, If it attracts then flip it over... it should repel. This is the way it should go down on the next line same as the first. Remember the magnet should repel the one before it. The rest of the magnets can be installed at this point. When you get to the fifth one it's a good idea to double check your work using the last one to test the poles. Circling the poles one should attract the next repel and so on. The last magnet will repel both the ones beside it.

This portion of the turbine is completed for now. Set this aside and find the 3 coils of wire and the stator ( slotted plastic thingy). As shown below...

Untwist the coils and take one from the three. Notice there are two wires coming out from the coil. One wire is short and one is longer. When installing the coils the short wire should be on the right hand side. The short wire represents the “Start” of the coil and the long one is the “End” of the coil. Using some tape and a marker label the ends of the coil 1S and 1E. A fine point sharpie works nice for this. Below shows the coil with the ends labeled...

At this point you should get some tape ready to help hold the wires in the slots as we go along. Cut 6 pieces about 1 inch long and stick them to the table edge or somewhere easily accessible. Bend the wire to a 90 degree angle just left of the edge of where the two wires come out of the taped connection. You can place this in any slot to start with and place a piece of tape over the slot to hold the wire in place as shown below...

Bring the bottom of the wire, leaving a small loop while skipping two slots back up through the slot as shown below....

The top wire will come down through the same slot forming one of the six coils to be completed. A piece of tape covering the slot will hold the wires in place once again. The picture below shows the completed first coil...

The next coil will be similar to the first, skipping 2 slots, the bottom wire goes up through the slot and the top coming down through the same slot. A piece of tape to hold the wires in the slot. Below shows the next coil in place...

Continue on until all the coils are in place. The last coil will share the same slot as the starting coil. You'll have to pull the tape up, install the wire and replace the tape. When completed should look like the one below...

Now you have completed all the coils of one phase. You've just created a single phase alternator. The next two phases will go in the same as the first. The next phase will start in the slot directly to the right of the start of the first phase. Start by finding the long and short wire as with the first coil and label the start and end as you did with the first only this one will be labeled 2S and 2E for the second phase. Shown below is the beginning of the second phase...

Follow the same pattern as you did with the first phase and using tape to hold the wires in place. Below shows the second phase in place...

Proceed with the third phase the same as the first two filling the remaining slots. Shown below is the first coil start and the completed stator...

That completes the stator at this point. Assembling the stator to the turbine is a simple step. But, before we continue you should decide on the base. The base can be a board with feet which I will show in the following assembly or you can use a PVC pipe plug that will fit a pole to mount it on. Simply drill a hole in the plug and bolt the stator to the plug. Makes a nice pole mounted unit for experimenting. For simplicity I've chosen to make this one on a wooden base. A simple square of wood and 4 feet has been made for the instructional version. Below shows the base ...

A  $\frac{1}{4}$  inch hole has been drilled through the center for mounting the stator and 4 wood feet glued to the base. Mount the stator using the threaded rod and two nuts provided in the kit. Below shows the stator mounted to the base...

Slide the magnet end of the turbine unit over the rod, install a washer on top making sure it drops into the washer groove of the triangle and install the nyloc nut provided in the kit. When tightening this nut make sure its not tight against the washer but not loose enough to allow the washer to jump out of the slot. The turbine should rotate freely. Make sure the magnets are not hitting the stator or wires and rotates without much friction. If the lower hole is difficult to install on the rod you can run a ¼ inch drill through the hole to make sure its free of burrs. Also a little grease or oil can be applied at the top and bottom pivot points to further reduce any friction created at these points. Below shows the completed turbine on base...

To make the stator a bit more permanent you can coat the wires with a clear enamel. This will help stiffen the looseness of the wires and hold them in place much better. Polyester resin works well also if you have some on hand .

From here we need to wire it up so it can actually do some useful work. There are basically two ways to wire a 3 phase alternator, star and delta. The “star” configuration gives you more volts but less amps and the “delta” gives you less volts but higher amps. I will show you how to wire it both ways but for the instructional model I will wire it in star.

The connections of the wires for star configuration are:

1S – 2E – 3S are output wires  
1E – 2S – 3E are all connected together

The connections of the wires for delta configuration are:

1S to 3E

2E to 1E  
3S to 2S  
each of the three pairs are output leads.

Below is a diagram of star and delta configurations...

We will be using diodes to rectify the AC voltage coming from the alternator to DC voltage. Shown above in the delta configuration. You can use standard rectifiers shown above in the star configuration but with the power this unit makes the diodes are sufficient.

Since the output of the alternator is in the form of AC (alternating current) its not storable. To make it storable we convert it to DC (direct current). In order to do this we will use standard diodes to make a rectifier. Notice the band around the diode, it is on the end in which the direction the voltage/current will flow. You can connect the diodes together by soldering the ends or simply twisting them together. I have twisted the sets together for simplicity but soldering them makes a nicer looking end product. Below shows the pairs of diodes twisted together...

The picture isn't very clear but if you look closely each of the pairs are going in the same direction. That is to say the band shows the flow from left to right. The twisted portions shown here will be the AC inputs.

The next picture shows the ends of the 3 pairs twisted together forming the pos (+) and the neg (-) sides of the diodes. These are the ends that will connect to a battery for charging or become the outputs for powering an LED light or other. You can purchase a battery holder and NiCad batteries from Radio shack and wire it to the rectifier. Below shows the diode rectifier twisted together to form the rectifier (left) and input and output of the assembly ( right)...

To complete your system you can install a Zenier diode of 3 volts and an led to make a simple shunt regulator. When the batteries reach 3 volts the light comes on telling you the batteries are charged and burns off the extra voltage. If the wind stops and the

batteries are not being charged anymore the light will burn off any excess in the batteries. When the voltage drops to just below 3 volts the light will go out leaving the batteries at a full charge. The simple shunt diagram is shown below...

Below is the alternator wiring diagrams for both “star” and “delta” configurations ...

Now you have a completed RE (Renewable energy) system. Experiment and have some fun !!!

# Gm Alt mod

This originally started out as a 37amp alternator from the late 60's to early 70's. I machined the rotor to accept the magnets, then glued them in place one on each "finger" of the old rotor. 14 of them total. Below is a picture of the first rotor. The epoxy I used didn't hold when I spun it up to around 2500rpm. I changed to the Aircraft structural epoxy ( the kind used to hold wing ribs in place ) and this worked very well. In the case you can see the brush assembly was completely removed. There was no need to power the field coil any longer. This unit will now produce 750 watts of power at just under 2000rpm

I had some problems cutting the rotor because of the hardness of the material used for the rotor. I went through 3 cutting bits during the process. I decided to try a different approach on the next one. I pressed the shaft off the old rotor unit completely and made another rotor out of a piece of 6061-T6 aircraft aluminum I had laying around. Although it seems like a bit more work ( starting from scratch ) it actually didn't take as long and I can use the same cutter on other projects also. Below is a picture of the shaft removed from the rotor and the aluminum rotor pressed on the shaft...

Most of the machining was done after the shaft was pressed into the new rotor. The next one shows the soft iron strip cut to fit the slot. The slot was cut deep enough to recess the magnets and the metal strip. The next picture shows the metal strip with a magnet laying in the groove

I roughed up the metal strip with a 20grit sanding disc ( paper with a rock glued to it - its pretty rough ). Then proceeded to glue the strip into place. I used a hose clamp to pull it in place and hold it until the epoxy set up. Actually put it in the oven at 150 degrees for an hour to help cure it a bit quicker.... worked well. The picture on the right shows the magnets in place and the spacing....

Below shows the magnets all glued in place and the rotor is ready to go back into the case....

After the new rotor was installed, the first tests came out quite good. Initially turning the rotor I noticed less cogging with the larger magnets. On the machine it showed 36.1 volts at 1500 rpm. It came up almost another volt from the first one. Amps were similar to the first. This one produced 50 amps at 1850 rpm. I rewound a stator with one size wire smaller and installed it in a case using this rotor and it now produces 50 volts at 1500 rpm but the output amps dropped ( give and take unfortunately ).

Above... all the parts to the completed unit and the unit completed

Below is a comparison chart of the three units I've tested....

	<u>Original modification</u>	<u>New Rotor</u>	<u>New windings</u>			
<u>RPM</u>	<u>Open Volts</u>	<u>Amps</u>	<u>Open Volts</u>	<u>Amps</u>	<u>Open Volts</u>	<u>Amps</u>
300					9.9	
400					13.2	
500			12		16.6	1.7
600	13.9	1.4	14.5		20	4.5
700	16.2	2.8	16.8	3.7	23	7
800	18.6	6.6	19.2	7.7	26	9.5
900	20.9	10.5	21.6	11.8	30	12.8
1000	23.2	14.4	24	15.8	33	15.3
1500	34.8	33.8	36	35	50	29.5

# Darrieus Type

This was a fun wind project and I learned a lot about these from researching and building this. This is a Darrieus type wind turbine. Probably more in the cycloturbine class. Most of the Darrieus type turbines don't start themselves and need an external source to start the spin. Actually it should be stated that they don't start themselves reliably because in certain circumstances they will start and run by themselves. This project incorporates a tail driven cam that angles the blades in and out of the wind and probably more of a drag type than lift type and **will** start by itself - reliably. As soon as the tail is pointed to the wind... its running! The pictures below show the small unit I built as an experiment into the wonders of these fascinating machines...

This unit was approximately 2 ft tall ( blades ) and 2 ft in diameter and would spin around 450 rpm's in a 20 mph wind. I've had several different small pm motors attached to it for testing and the best one was an electric "weed eater" motor which would produce about 50 watts in a 25mph wind. I was quite impressed for its size and materials it was made from. It was up for about a year and had survived a 70 mph storm. I really wish I had a tach on it that day, the only visual on it was the tail and center. It did however suffer a main bushing seizure the very next day.... A little grease and it was back up and running.

The next one soon to come is a 3 ft by 3ft unit with the same tail driven cam design but incorporates lift on the upwind blade.....

Below are some pictures of the new unit.... First two show the mounting and hinges as well as the push/pull rod for the tail driven cam... I made provisions for 2 setting for the wing control rods. The farther out the less movement and the closer in the more movement. Close in there is alot of torque but less rpm and farther out the rpm goes up and the torque goes down.... interesting although I believe the power output is about the same. It runs just a bit faster than the wind and calculated a TSR of about 1.5 to around 3 with the movement lessened.

The next one shows the completed unit on a 6 ft ladder.... and it had a 6 mph breeze at the time so it was difficult timing the shot....

I've taken this unit out in a 12mph wind and as soon as the tail points into the wind its off and running. Doing a performance test using the old "finger dyno" on the shaft I could not stop it from turning... as hard as I was squeezing it simply would not stop... I was impressed... and the dyno was measuring some extreme heat!! I decided not to go any further with this one and a new project springs to life.... A 4 ft dia x 6 ft tall blades... possibly a 3 bladed unit with the cam design...

We'll see.....

# Microwave wind generator

This is a lesson on recycling. Everything here was built from scrap microwave ovens with the exception of the bearings and pivot mount also the plywood. Microwave ovens have an abundant source for the materials used in making an alternator and the rest of the components of an actual working wind generator. They contain large 2 1/4" round magnets ( 2 in each unit - in the magnetron ) plenty of sheet metal ( cases ) and even useful wire in the transformer. You could actually use the transformer metal as the stator laminates.

This will probably dry up my source for microwaves but you can call any appliance repair and find many microwaves free for the asking. I called one shop just to inquire about the possibility of getting a couple, they told me they had a few. I went over there and he directed me to the warehouse where there was about 40 of them. He looked at me, smiled and said if you take one you have to take them all.... I really think he was kidding but 3 trips later they were all in my shop. I tore them down and started saving all the little parts that could prove to be useful for other projects... screws, rubber feet, micro switches, fans, transformers, etc... ( I don't throw nothing away ) and about 80 magnets.

I started out by cutting an 10" disc out of plywood, cut strips of steel out of the case to make the laminates. Coiled the strips to form the stator and epoxied them to the board. I used strapping tape on all the metal strips which served two purposes, One to help hold the whole thing together and Two to isolate them from each other thus reducing eddy currents. I machined 24 slots to hold the wire and started the winding process.

Below are the beginning shots of the process...

There is 60 feet of 3/4" steel in this stator. The stator is 8" in diameter and 2" wide. Below show the winding in process...

The white inserts are made out of old milk cartons to isolate the wires from the steel. Each picture shows each of the 3 phases being placed into the slots. This was wound on the stator itself and each phase is wound as if it were a single phase unit. There are 36 wires in each slot making up 18 turns per coil. And yes I know I blew my rule number one... Keep it simple. The slots really are unnecessary but do help to bring the power and efficiency up and since this is a small turbine ( 28" diameter) I needed all the efficiency I could get.

Initial testing of the alternator came out quite promising. At 600 rpm the open voltage was 29.6 volts. My goal here is to make a very small turbine that will produce 150 watts in a 30

mph wind. After many doodles and calculations, 3 or 4 pads of paper later this is what I've come up with. I'm not going to show the turbine in great detail and all the alternator functions will be left out as there is a patent pending on this unit, although won't be manufactured out of microwave ovens in the end.

Below is the preliminary installation of the stator on the pivot head of the turbine. You can see the coils are shrouded and sealed...

This next picture shows the microwave magnets taken from the "magnetron" and setting on an 8" steel disc. Also shows the octagon plywood rotor ( 14" ) and the blades mounted on the rotor assembly. Using steel blades makes the rotor quite heavy and would be extremely susceptible to high winds and over speeding. This is simply a test unit and will not be installed permanently...

I've calculated the stress point to be somewhere around 1100 to 1200 rpm before the wood structure would come apart, this being winds at around 50mph. This could be changed by adding longer mounting tabs on the blades and installing 3/16" bolts instead of the sheet screws. The blades are 7" tall and 8 of them are installed on the plywood. Each blade is set at an angle of 10 degrees. The metal came from a large microwave case and was bead blasted and is now ready for paint. The plywood will be coated in poly resin ( fiberglass resin ) to seal and waterproof the assembly, the magnets will be resin'd in also.

After all was assembled, unfinished and semi balanced, testing went fairly well. The performance of the "microwave" turbine was below my projected output but not bad for its size. The maximum output achieved was 90 watts in a 30mph wind. It performed well in lower winds giving 22 watts in a 14mph wind. No powerhouse by any means but for its size ( 28" - not much bigger than a basic box fan) it did quite well.

All in all a good lesson in scavenging and making due with what is available. The entire project cost about 8 bucks not including any labor. Comes out to about 8 cents a watt....

I've dismantled this unit since and have added a different rotor with 6 blades. Initial tests on the new one are providing much better results but still about 20watts under my goal here. Initial testing showed an overall efficiency of 23%. The eight bladed ( steel blade) was giving me about 11% ( not impressive by any means). I'll post some images of the new rotor shortly.....

The blades are carved from standard 2x4 board scraps and the center was brought down from the 14" octagon to a 10" circle allowing for more blade area....

Still only 30" in diameter, testing was done in a 14 mph wind and the results are coming out good. Unloaded the blades run around 720 rpm and with a load 570 rpm. Using a slightly dead battery with a 50 watt load its making 11.75 volts at 1.7 amps ( total of 19.9 watts ). The total available watts for that area of blade is 77.78 so that makes the overall efficiency of around 25%. It will make about 170 watts in a 30mph wind and the efficiency drops to around 22%. Still just over 13 amps at 12.7 volts... not bad for a tiny turbine...

Still testing various configurations and shields.....

# Poured Stator

This is the beginning test of a full size poured stator. I've done some small ones in the past for stirling engine projects but never really followed up on them. Bob Gayle inspired me to follow up on it to see if would really perform equally as well as a steel slotted stator. Initial tests are showing some losses over the steel core but with the ease of fabricating it may well be worth the efficiency loss over labor involved with the steel slotted cores. Here is a picture of the poured core stator ....

To keep it simple I used fiberglass resin as the binder and mixed in the iron powder.

It was basically a paste when mixed. There is about 5 pounds of iron powder in this stator. Actually, very little resin was needed to saturate all the particles, guessing at around 6 oz. The slots are .46 deep and .3 wide for 14 turns of #15 wire through 36 slots. There will be 12 magnets used on this one. I plan to test the unit with both ceramic 5 magnets and neodymium type. Ceramics are nice in the sense there is little to no cogging effect but I don't expect the cogging of the neo's will be bad enough to hurt performance much.

Below is a picture of the stator completed with all its windings...

The next one shows the stator just as it was being finished with the 3rd phase. Notice the special clamp for getting the last phase in place. Typically the last phase goes in sort of free hand, but, because of the wire size used in this one this is near impossible. The clamp holds snug to the stator core and allows you to wind the wire without having to use all 12 fingers on each hand

The initial tests proved that this unit would work but at less efficiency than the steel strips. I suppose the efficiency loss is a fair trade off for labor. The unit has 12 poles using the 1.5" round neo's. 12 turns per coil and 12 coils per phase ( 36 coils total ), Each phase came in at .3 ohms. #15 wire was used for some fair power. Because of the low turns of wire the rpm per volt came in fairly high which would require a fairly good size prop to drive it. An 8 ft prop designed to run at around a TSR of 8 would work quite nicely making around 650 watts of power in a 28mph wind. Not to bad for a small 8 inch unit.

I plan to do some brief testing with some ceramic magnets cut from the large rings I sell in the "builders corner" of this site under products. I'm sure it won't be a potent as the neo's but something I have to give a shot. This will increase the magnet area considerably so the loss shouldn't be drastic.....

Stay tuned

# OTHERPOWER.COM

The **CUTTING EDGE** of Low Technology

### **The first of the Triplets is set free and flies!**

Over the last few weeks, Otherpower.com has been building a set of Wind Triplets -- 3 axial-flux brake disc wind turbines named Curly, Moe and Larry. The 3 brake disc alternators are identical, but Curly and Moe sport 10-foot props and Larry an 8-footer. This one is Moe, and it's up and flying at TomH's cabin. So far so good -- Moe starts spinning in 5 mph winds and has been producing good power at under 15 mph windspeeds. **We completed a detailed series of web pages about the construction of the triplets--[you can check it out HERE.](#)**

## Thank you for dropping by!

We are a group of alternative energy enthusiasts who want to spread the message that *It's EASY to make your own power FROM SCRATCH!* Otherpower.com's headquarters is located in a remote part of the Northern Colorado mountains, 15 miles past the nearest power pole or phone line. All of our houses and shops run on only solar, wind, water and generator power...not because we are trying to make some sort of political or environmental statement, but because *these are the only options available.* And we refuse to move to town.

We could never have made it to our current level of electrification up here without the help of friends, neighbors--and folks we've never met, thanks to the internet. Our goal is to share our information about experimental successes and failures alike, free of charge, with anyone who is interested. We also offer a wide selection of books and hard-to-find alternative energy parts and components on our [web Shopping Cart](#). We hope you find our pages informative, useful and enjoyable!

### The Blunt Edge of High Technology

For all questions about orders, inventory, tracking, shipping, etc. please [E-Mail our Shipping Office](#)

or call us at: 877-944-6247 (toll-free in USA) or (970) 484-7257. Our mailing address is: Forcefield  
2606 West Vine  
Fort Collins, CO 80521

Also, you can visit our Retail Store at 614 South Mason St., Fort Collins, CO

You can [send DanB and DanF an E-mail HERE](#). However, PLEASE be aware that we receive many more Email requests for free information and advice than we can possibly respond to and still run our business...they come in twice as fast as we can reply. For quicker advice and opinions alternative energy questions from experimenters worldwide, try posting your question to the [Otherpower Discussion Board](#). Please research your question by searching our discussion board and Google before posting or emailing us. If you do Email us, make sure your email has a good subject line -- if the subject is 'blank', says 'hello' or 'how are you' it will never be read - many viruses and spam contain these headers. Please keep your questions *specific* regarding topics we've written about. If you ask 'how do I build a windmill?' or 'how big a system do I need to run my house?' you probably won't get a reply...please do your homework first. If you ask us 'on your Gerbil-powered generator page, how many turns are in each coil and what direction are they wound' we will almost certainly reply promptly. If we dont, please email again and remind us. THANKS for being considerate!

---

## OUR NEWEST PAGE

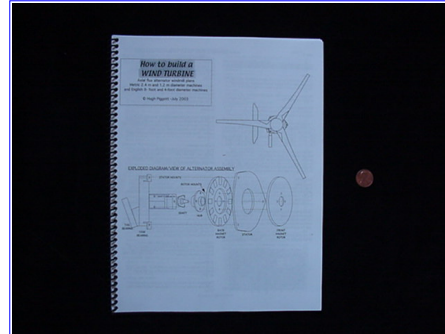

### [Hamster-Powered Alternator](#)

Skippy the Hamster is Forcefield's newest employee! We custom-built a low-rpm permanent magnet alternator onto his exercise wheel, and he lights a night light at DanF's house. We installed a data acquisition computer on his wheel too! And of course this simple alternator, buildable by kids, would work for wind or hydro power experiments and science fair projects too.

## OUR NEWEST PRODUCT

### [Axial Flux Alternator](#) [Windmill Plans by Hugh Piggott](#)

The latest of Hugh Piggott's axial-flux wind turbine plans.

Detailed CAD drawings, dimensions, photos, instructions, and theory. Build for 12, 24 or 48 vdc, both an 8-foot and a 4-foot diameter version. All the information you need to build a wind turbine from scratch!

**[Make Your Power From Scratch!](#)**

**SAFETY NOTE:** Some of the experiments described on our pages may present various hazards. Please be cautious. We are not responsible for injury resulting from neglecting safety precautions when performing experiments.

# About Us

---

Otherpower.com is owned by ForceField--a small business, run completely out of our homes. Our inventory and shipping office is in Fort Collins, Colorado, USA. It is usually staffed Monday thru Friday, 9-4 Mountain Time, and is a very busy place! Some of our staff live and work in a very remote area west of town, high up in the mountains. They are connected to the office thru the miracle of [Starband](#) 2-way satellite internet service. Since there are no telephone or power lines up there, please be aware that when you call our toll-free number, the person you wish to talk to may not be in the office--though we can certainly relay a message! However, everyone in our company is available via [Email](#).

## Forcefield's Websites:

### [Otherpower.com](#)

A huge FREE resource for alternative energy enthusiasts and experimentors. Build your own low-rpm permanent-magnet alternators, battery chargers, anemometers, windmills, hydro turbines and more. Free information on building remote power systems for cheap. Very active discussion board...get your solar/wind/hydro power questions answered fast! Many DIY projects and experiments. Unusual and hard-to-find components and books!

### [Wondermagnet.com](#)

The world's most powerful magnets in dozens of shapes and sizes. Magnet and magnetism FAQs, safety information, science experiments with magnets, amazing demonstration images, very active magnet science discussion board! Diamagnetic levitation, superconductors, magnetic water treatment, unusual uses for strong magnets. Links to other magnet science resources. Great selection of unusual experimental science and magnet books!

### [Matchrockets.com](#)

Experimental Science for Everyone! This site is still under construction, but there's lots of neat stuff there already. You'll find all of our science experiments from Otherpower and Wondermagnet collected here in one place, and lots of other new experiments too!

---

We sell our products exclusively on the Internet. We do have a mail-order catalog available. If you would like a copy, please call, write or email us! Customers may place orders on the order form and pay via check, money order, paypal, or through our secure credit card processing form. After

payment is received, we ship products on the same or next business day via UPS or Priority Mail.

We also sell certain products on Ebay, including magnets and one-of-a-kind experimental science and alternative energy components. Our Ebay user ID is [pie](#), and we have many thousands of positive feedbacks.

FORCEFIELD was created in 1998. One day DanB purchased a computer and browsed the web for the first time. Mark suggested that Dan give eBay a try. Dan immediately became hooked as he experimented selling a variety of odd products, and quickly discovered that surplus magnets had tremendous appeal.

The next step was the creation of the web site. Initially it was a scanned image of a hand-written sign, declaring "FORCE-FIELD" with a phone number.

Since then, we have been gradually growing, selling larger numbers of a greater variety of products. Otherpower.com was our next big project, a natural thanks to the remote rural environment where much of our staff lives. Our web sites are continually growing as new products, experiments, information, and functionality are integrated into the pages. The project has grown considerably and has developed into full-time work for many of us. We're not on the NASDAQ yet, but we plan to be, someday.

Our goal is to share our information free of charge with anyone who is interested. Information is a very powerful tool, and we hope our experiments with magnets, alternative energy and experimental science are helpful to you. However, if you need magnets, books or science supplies please consider ordering them from us! We hope you find our pages informative, useful and enjoyable.

## THE PEOPLE

**We all take up slack when it's necessary. We try our hardest to be friendly, honest, and *FAST!* It is our goal to provide complete satisfaction for each and every one of our customers--please let us know if you are having a problem, and we'll try our best to help. We currently have 5 full-time and 2 part-time employees, some of whom work at the office, some at home.**

---

**DanB** is the founder and CEO of ForceField. He is President of Mad Scientist Activities and Vintage Electrical Equipment, which means he is involved in every aspect of the company! He lives high up in the mountains west of town with wife Michelle and daughter Maya. Like his brother Matt, he has unusual tastes in [cars](#). DanB plays nearly every stringed musical instrument ever made (guitar, mandolin, fiddle, banjo, and (his favorite) washtub bass) and builds his own instruments too.

---

**Maya** is our President of Research, Development and Theoretical Physics. She facilitates progress in

our cutting-edge quantum electromagnetism, wind power design, and perpetual motion research laboratory. (Maya, at age 4, has a PhD in Theoretical Physics from Cambridge University.)

---

**Michelle** is our President of Support Services. She helps all Forcefield employees in keeping their sanity, and she also provides technical and maternal assistance to Dr. Maya.

---

**Mark** is our President of IT Services, Linux Operations, and Computer Wizardry. He keeps our in-house servers running, repels evil Crackers and ScriptKiddies, writes the CGI scripts that let you order our products, and generally waves his magic wand to make everyone's computers perform as they were instructed. If things start to go wrong, he waves his magic axe at the computers and they start to behave. He is what is known as a "Linux God." Mark has a post-graduate degree in physics and is thus responsible for pseudo-scientific issues. He firmly believes that perpetual motion and faster-than-light travel are impossibilities. If you want to know why you should NEVER trust your website, business, and customers to Micro\$oft products, he can tell you. Our company computers are CERTIFIED Micro\$oft-Free, except for the United Parcel Service system. He is an accomplished jazz, classical and bluegrass guitar player.

---

**Matt** is our President of Business Operations, Extreme Golf and Old Dodge Powerwagons. He is often found at our shipping office in town answering the phone, taking orders, solving shipping and inventory problems, and answering Email until the wee hours of the morning. He also has a cabin way up on the mountain, and spends the rest of his time up there playing Extreme Golf, working on his vintage 1948 Jaguar, and [pulling his 1951 Dodge Powerwagon out of the crick.](#)

---

**Kristy** is our President of Shipping and Customer Relations, and Supreme Ruler of the Office. She keeps everything running smoothly, makes our customers happy, and generally makes order out of chaos at our office. Everyone down there does exactly what Kristy tells them to do! She plays a mean fiddle and will someday surpass [Alison Krauss](#) in legend.

---

**Paul** is our President of Packing and Magnetic Flux Analysis. He is an expert in cancelling magnetic fields so we can safely ship your magnet orders, and tests each package before it goes out using a scientifically-designed electron-beam-deflection system. He plays a mean banjo when we get together and jam up on the mountain.

---

**Hank** is our President of Morale, Cuteness, Sweetness and Light. He spends all day at the office with Mommy Kristy and Daddy Paul, and is an expert at being good while entertaining the Forcefield staff. He loves bluegrass music (he's listened to it since before he was born!), and will probably surpass both Brad (below) and Hank Williams in musical prowess by the time he turns 12....that's only 11 years away!

---

**DanF** is our President of Vices, Web Pages and Firefighting. He produces most of our magnet, experimental science and alternative power web pages, administers the message boards, and writes

articles and copy for us. He also lives way up on the mountain, and is on call 24/7 to respond next door to DanB's house when giant balls of flame, huge sparks, and loud noises emit from the Wondermagnet/Otherpower Research Laboratory Facilities Trailer. He is a State-Certified firefighter for the local Volunteer Fire Dept., and has decided that the only safe way to live next door to DanB is to have a Fire Truck parked in your yard. So he does -- it's a 1967 Jeep 5/4, type 6x wildland engine. DanF plays the banjo and trumpet (not at the same time), and built his own banjo.

---

**Brad** is our President of Custodial Engineering, Disassembly Services and Organizational Services. He is our newest employee, takes apart magnet assemblies so we can ship you your surplus magnets, and keeps the office clean and organized so Kristy doesn't quit. This is his secret life...in his *real* life, he's the lead singer, guitarist and songwriter for the [Open Road Bluegrass Band](#). They just recorded their second album, and are an absolutely *top-notch* traditional bluegrass band! Their live shows are incredible, try to catch them if you visit Northern Colorado. Just don't tell Brad's fans that he walks around the Forcefield office with a pink feather duster in his back pocket!

Thank you for visiting! Please [Email](#) us if you have any questions or comments.

Sincerely,

***FORCEFIELD***

[WWW.WONDERMAGNET.COM](http://WWW.WONDERMAGNET.COM)

# Otherpower.com Live IRC Chat

**Chat live with alternative energy enthusiasts worldwide, using IRC! No matter what time of day or what day of the week it is, you are virtually guaranteed to find someone else online that shares your interests.**

If you are unfamiliar with IRC and how to get it working on your machine, please check out our [IRC Help](#) area.

## #otherpower Live Alternative Energy IRC Chat

**Server:** otherpower.serveirc.com

**Channel:** #otherpower

**Port:** 6667

**OR use the [Web Browser IRC Client](#).**

The #otherpower IRC channel was formed by wind power enthusiasts who frequent the [Otherpower.com Discussion Board](#). There is almost always somebody here, 24/7 on any day of the week, willing to talk about alternative energy, homemade wind generators, low-rpm alternators, remote homesteading, good beer and more.

Since quittin' time in one world time zone is breakfast time in another, this channel is always active. *JimU is running this IRC server on a Laptop running Linux, powered by it's own renewable energy system (solar and wind). We believe this is the only RE-powered IRC server on the internet!*

**If you do not have IRC running on your computer, you can still connect without installing any software by using a [Web Browser IRC Client](#). The client used is CGIIRC. It works great, and is a simple way to connect.**

When you log into IRC, this is the server that's running it! It's completely RE powered, and runs Linux.

While you're at it, you can also check out the [IRC users Photo Gallery](#) -- cool pics from IRC users!

## IRC (Internet Relay Chat) Help

If your IRC software has a command line interface, you would type:

`/attach otherpower.serveirc.com`

`/join #otherpower`

to connect.

A great resource for information about IRC: [IRChelp.org](http://IRChelp.org)

- **Windows**--If you do not have IRC software running on your Windows machine, your best bet is to find a shareware IRC client program and install it. Some common IRC programs for Windows are [mIRC](#), [PIRCH](#), and [ViRC](#). Or, even better, switch to [Mozilla](#) for all your web browsing and email in place of Microsoft Internet Explorer and Outlook Express. Mozilla has an easy-to-use IRC client (Chatzilla) built in--and as an added bonus your computer will be nearly immune to all the common web and email viruses. If you don't want to deal with installing software, you can still use the [Web Browser Java IRC Client](#) if your web browser

is Java-enabled. If you see a blank box when you open the page, either you don't have Java installed for your browser, or your version of Java is old. You can download the latest version of Java [here](#).

- **Linux**--If you are running Linux, you almost certainly already know how to use IRC! Your install of Linux came with a built-in IRC client. X-Chat is popular one, but there are many choices.
- **MacIntosh**--Since we use Linux instead of Macs up here, we can't provide much help here. But check out [IRChelp.org's Mac IRC page](#) for advice and Mac IRC shareware.

[More Info \(Links\)](#)

### **New collection of IRC servers.** (December 13<sup>th</sup> 2003)

A list with a fresh collection of IRC servers for mIRC is available in the [servers.ini](#) file on our website. Save the file to the mIRC directory on your harddisk (c:\mirc\ or similar), replacing the old file, and enjoy this refresh! The server list will immediately be available to you from within mIRC. Have fun exploring some new IRC networks!

### **Charity appeal: child vaccinations across Africa**

(November 20<sup>th</sup> 2003 - updated December 20<sup>th</sup> 2003)

Thanks to all of the mIRC users who registered their copies of mIRC between November 20th and December 20th to support our appeal, 100% of your registration has been donated to the [International Federation of Red Cross and Red Crescent Societies](#) for use in their [measles campaign](#) in Africa. **2826** mIRC

users registered, raising a total of **\$55,230.00**. Many thanks to everyone who helped out! **The appeal is over, however if you still have any questions about it please email [Khaled](#) or the [Red Cross](#).**

### **mIRC 6.12 has been released!** (October 13<sup>th</sup> 2003)

mIRC v6.12 has been released to address a remote vulnerability found yesterday, capable of crashing your mIRC. The vulnerability affects versions of mIRC from v6.0 onwards, so it is highly recommended that you upgrade to mIRC v6.12. You can do so by downloading the new mIRC from the [download page](#)!

### **mIRC 6.11 has been released!** (October 10<sup>th</sup> 2003)

A fresh new version of mIRC! With this new release we hope to address most the comments, requests and remarks we received after the release of version 6.1. Of course this new version fixes lots of

the small but nevertheless annoying buggies found in the previous version. Details of all changes are available on the [news page](#). Discussions about the changes and features in this new version are very welcome on the [message board](#). Have fun and [download and try mIRC 6.11!](#)

### **mIRC 6.1 has been released!** (August 29<sup>th</sup> 2003)

With this release we hope to address most of the comments, requests and remarks we received after the release of version 6.03. Several new features and functions have been implemented. Details of all changes are available on the [news page](#).

#### **What is IRC?**

IRC (**I**nternet **R**elay **C**hat) is a virtual meeting place where people from all over the world can meet and talk; you'll find the whole diversity of human interests, ideas, and issues here, and you'll be able to participate in group discussions on one of the many thousands of IRC channels, on hundreds of IRC networks, or just talk in private to family or friends, wherever they are in the world.

#### **What is mIRC?**

To use IRC you need a small program like mIRC, an IRC client for Windows, written by [Khaled Mardam-Bey](#). mIRC is a friendly IRC client that is well equipped with options and tools. mIRC is shareware, which means that you can [download mIRC](#) and try it out freely for 30 days to evaluate it. If during, or at the end of, the evaluation period you decide that you would like to continue using mIRC, you must [register your copy](#).

#### **Message board**

The mIRC website has a useful and friendly [message board](#) where you can post questions if you need help, or just discuss mIRC and IRC-related issues. The message board can be used by anyone, so feel free to dive right in. If you're new to the message board and wish to post questions, make sure that you log in as a New User first.

#### **mIRC Release announcement list.**

We can send you an announcement by E-mail as soon as a new mIRC version has released! Subscribing to this list is very easy; just fill in your E-mail address below and we will make sure you will be among the first to know about every new mIRC version. We will update you on the new functions and features in mIRC and you will get a list of fast download addresses. We guarantee your E-mail address will only be used for release announcements. Read more on the [mailing lists](#) page.

# Energy Conservation

## Electricity Wasters

**Remote Controlled appliances**--TVs, VCRs, stereos and such that turn on when you push a button on the remote. We've measured some TVs that use 6 watts (half an amp out of a 12-volt battery) just sitting there waiting for you to push "ON" on the remote!

**Refrigerators**--normal, mass-market refrigerators waste huge amounts of power with both inefficient compressor motors and lack of insulation. A frost-free cycle adds a huge electric heating element every couple days to waste even more power.

**Wall Warts**--Those ubiquitous black cubes that plug into your sockets. These force you to make 12 volt DC power to charge your batteries, convert it to 110 volt AC with an inverter (and with

## Conservation Solutions

Plug these appliances into **switched power strips** and turn them on only when needed. Yes, this means you must get off your butt to turn the TV on and off, and your VCR will never show the correct time. But you'll save lots of power.

Use either a **propane refrigerator** or a special **energy-efficient refrigerator** designed for remote power systems, such as the SunFrost or VestFrost. Chest freezers are also available in both propane and efficient electric. The initial cost increase will pay for itself quickly if you use batteries for energy storage.

If possible, **buy or make 12 volt DC converters** for these items (try Radio Shack's multi-voltage universal cigarette lighter adaptor)--then you'll be converting 12 volt DC directly into whatever DC voltage you need with very little loss. Also, you can at least **plug all these warts into a power strip** so you don't use power when your item is turned off.

**Example of the perfect energy-efficient, multi-use appliance--Kodiak the Dog**

**Kodiak is a truly multipurpose appliance--she saves hot water by prewashing dishes, firewood by helping warm the bed, and electricity by vacuuming food scraps off the floor.**

power loss), then they convert it back down to around 12 volts DC (again at a loss). Plus they use power when your printer, charger, laptop computer, etc. is not even on!

### **Incandescent Light**

**Bulbs**--These dinosaurs produce 90% heat and only 10% light. Halogen lights are only slightly better, but last much longer.

### **Electric heat in**

**general**--Despite what the power company says in their advertisements, electricity is a very poor, inefficient way to make heat if your home is not on the grid. This goes for electric stoves, heaters, coffee makers, air conditioners, water heaters, crock pots, deep fryers, etc. None of these should be included in an alternatively-powered home. It does -not- apply to microwave ovens, since they only operate for a few minutes per day, though at high power draw.

Use **LED, fluorescent and compact fluorescent bulbs** in most of your lights, AC and DC. 120 volt AC versions are available at any hardware store. Use 12 volt DC halogen bulbs instead of 12 VDC

incandescents. Fluorescent and compact fluorescent bulbs are available in 12 volt DC versions for a higher cost, since they are not common items at the local hardware store. **Try the new LED bulbs.** [Click here to check out our efficient lighting page.](#) See our [products page to order do it yourself kits for LED lights](#)--they use far less power and last 10 times as long as even compact fluorescents!

[\(click here for home built LED lamp information\)](#)

[Click here to see a solar-powered outhouse way up in the mountains!](#)

Wall Wart

## **Early to Bed, Early to Rise**

**makes a man healthy, wealthy and wise**

**(and saves lots of power in the winter)**

We're not kidding! Around 40 degrees latitude where we are, you can expect only half as many full-sun hours in December as in June. Add to this increased use of lights during long winter nights, and you'll find that Ben Franklin's adage will also save lots of electricity.

**Phantom Loads--**Any appliance that draws power even when turned off. Includes the TVs and VCRs with remotes mentioned above, anything that has a clock (microwave, clock radio), and anything where you touch a button to turn on the power instead of just flipping an old-fashioned switch, even such innocuous items as washing machines.

**City Slicker Habits--** We're not joking here either. People who move to a remote area and expect to run their solar-powered house the same way they did in town are in for a rude surprise (ruined batteries). Those of you who have spent a year or more reading by kerosene lamp or candle, hauling water in 5-gallon buckets, and using a stereo powered by AA batteries will marvel at how wonderful even a single solar panel and battery are--and will conserve power to keep the system working for as long as possible!

Again, **use a power strip or wire a switch to the outlet** where such things are plugged in. Phantom loads also wreak havoc on inverters. If the inverter is designed to shut down at night to save power, they will keep it on. Buy a clock that runs on AA batteries instead of AC power.

**Be aware of your power use** at all times. **Turn off the light** every time you leave the room. **Early to bed, early to rise** for the whole family, at least in winter. In the bathroom, **if it's yellow, let it mellow; if it's brown flush it down.** Do all your power-intensive chores (vacuuming, washing machine, power tools, water pumping) when the generator is running. Make your spouse and kids pay attention too, even to the point that they call you "**the Power Ogre.**" Make your family generate their own power on a treadmill or bicycle generator to watch TV or movies...at least until divorce is threatened!

**The Lawrence Berkeley National Laboratory calculated that phantom loads waste the equivalent of the output of 5 power plants each year!**

Liz generating electricity to power the TV and VCR. The kids complain and call me the Power Ogre; we compromised and made their mother exempt from this requirement for watching movies. [Click here for plans on making this bicycle.](#)

Regular electric grid customers in our area can voluntarily pay more for their electricity in order to subsidize wind power plants in Northern Colorado. The concept has caught on quickly.

# Efficient Lighting

---

**Incandescent lights are basically electric space heaters that give off light as a byproduct. They are VERY inefficient, wasting most of the power they consume as heat.**

**Since lights are one of the biggest power uses in a remote home, pay close attention to what kind you use. If you replace all of your lights with efficient versions, you may be able to get by with fewer expensive batteries and solar panels!**

You may have noticed that we've made major changes to this page. This is because of new information given to us by some lighting experts regarding lighting efficiency. Our thanks to Don Klipstein and Victor Roberts for the engineering lessons...

**Otherpower.com's lighting recommendations in a nutshell:** For best efficiency, use fluorescents of any type. Install standard fluorescents in workspaces where you can stand the blue-tinged light, hum and flicker. Use compact fluorescents in living spaces for a more 'friendly' ambiance. Use halogen lighting for outdoor applications where temperature causes problems with fluorescents. Use white LED lighting for applications that normally use dismally-efficient small incandescents...task lights, nightlights, pathway lighting, exit signs, and flashlights. Don't use incandescent lighting at all if you can afford to avoid it.

## Lighting Efficiency Ratings

A standard way of rating lighting efficiency is in lumens per watt--this figure accounts for all of the light produced by a bulb. This rating does not necessarily reflect how much usable light is thrown on your work area. The reflector and fixture will have a large effect on this. So be sure to read our guidelines for each type of lighting discussed below--lights that show a lower efficiency may still save you energy depending on the application.

- **32 watt T8 fluorescent**--85 to 95 lumens/watt
- **standard F40T12 cool white fluorescent**--60-65 lumens/watt
- **compact fluorescents**--low 30's to low 60's lumens per watt, usually 48-60
- **T3 tubular halogen**--20 lumens/watt
- **white LED**--15-19 lumens/watt
- **standard 100 watt incandescent**--17 lumens/watt
- **incandescent night light bulb (7w)**--6 lumens/watt
- **incandescent flashlight bulbs**--dismal, less than 6 lumens/watt

**But wait! What about all the white LED high-efficiency claims that are all over...including the claims that used to be on this site?** Unfortunately, much of this information is incorrect.

Comparing the efficiency of a white LED light with a compact fluorescent by measuring the intensity of a tiny spot within the beam does NOT give proper efficiency results. We got much of our data for efficiency claims from an article in Home Power Magazine ([click here to see this testing article](#)) and in literature from LED distributors. The problem? All of the light from our LEDs is concentrated in a 20 degree beam, while the incandescent and compact fluorescent lights were tested without fixtures...and most of the light they produced was never measured in the test, since it sensed only light falling on the sensor. It's OK to compare different lights by how brightly they illuminate a certain size area...but put a reflector behind the compact fluorescent and incandescent bulbs in the test rig and the data would change significantly. Therefore, while the LED lights in this test may illuminate a small area as brightly as other lights, they are NOT significantly more efficient. **LEDs can still be a good choice for illuminating your workbench, for example, as long as the light cast onto your small work area is as bright as you need--in this case your LED light could be a good investment for saving power, especially if your old incandescent fixture is also lighting the rest of the room where you don't need the light (like in the Home Power experiment link above).** If you try and light an entire living room with an LED fixture, though, you are not saving much--in that case you want a wide dispersal of light, and a fluorescent fixture would be the hands-down winner for efficiency, cost and practicality.

**Another thing to keep in mind--notice that with current commercial lighting products, the smaller the incandescent bulb, the less efficient it is. For small-sized and lower-light-intensity applications such as task and reading lights, pathway lighting, exit signs, and flashlights, LED lights will be much more efficient than the equivalent small incandescent.** This is because fluorescent light products in these small sizes are not available commercially. We are currently researching remote power applications for small cold-cathode fluorescents, which are commonly used to backlight LCD screens. We hope to have more information about these lights soon, though they are still significantly larger than LED products...too big to use in anything smaller than a very large flashlight.

## LED lighting

Despite our new information regarding white LED efficiency claims, they are still VERY useful in certain applications. They are an excellent, efficient replacement for the terribly inefficient SMALL incandescent bulbs found in task lights, nightlights, pathway lighting, exit signs, and ESPECIALLY flashlights. As the amount of light needed gets larger (lighting an entire room, for instance) LEDs are only marginally more efficient than a 100 watt incandescent--but a nightlight made with white LEDs is almost three times as efficient as the incandescent it replaces. Also, if run at recommended current levels, LED lights should last tens of thousands of hours, a huge improvement over other lighting technologies. They are also very shock and cold resistant, perfect for portable and outdoor applications.

Groups of 3-9 white LEDs are effective as reading lamps. 3 of our white LEDs running together use only 0.22 watts! Single white

LEDs make great pathway lights, and can be left on all the time. Flashlights can be easily converted to use LED bulbs...this is probably the best application for them. Converted LED flashlights have become my favorite lights for fire/rescue and wildland firefighting, since the batteries last 6 times longer, I've never replaced an LED bulb, and light output is more even, though slightly dimmer than the original.

[Click Here for information about home built LED room lighting](#)

[Click here for information on converting flashlights to LED bulbs](#)

**otherpower.com offers state of the art white LEDs in bulk for experimentors to make their own LED reading and path lights, and flashlight conversions.** Visit our [products](#) page for ordering information.

## Compact Fluorescent

These lights were a huge advance in energy efficient lighting--very efficient, with 10 times longer life than an incandescent bulb. Plus, the light quality (color temperature) is much warmer than normal fluorescents, they fit in most normal light fixtures, and flicker is hardly noticeable. Models are available for any application, including spotlights with reflectors.

We highly recommend these lights in both 120 volts AC and 12 volts DC models. The AC versions are available at any hardware store and are very inexpensive for efficient lights (\$8 to \$15 each). DC compact fluorescents are more expensive because of limited demand for 12 volt ballasts, but only the ballast is different for AC and DC compact fluorescents--the bulbs are the same! We may soon offer interchangeable compact fluorescent bulbs and ballasts for both 12 volt DC and 120 volt AC systems. Currently, interchangeable parts are available from Jade Mountain.

The only drawbacks to keep in mind for compact fluorescents are 1) they are not very bright at cold temperatures, and 2) the quality of light is still not as good as halogen or incandescent bulbs. I personally use 12 volt DC halogen bulbs for reading lights, while lighting whole rooms with compact fluorescents.

# Standard AC Fluorescent Lights

These really are a very good, energy efficient method of area lighting, and are widely available. They are the most efficient room light available. Problem is, the quality of light is very irritating to some people. It's too blue, and the flicker is extremely annoying to me. Perhaps this is a reaction to my lifelong aversion to large office buildings with windows that don't open! But fluorescents make great energy efficient lights for shops, garages, etc. where you don't have to spend too much time in the winter. I also use them for under-cabinet countertop lights in the kitchen.

## Quartz-Halogen Lights

These bulbs are only about 15% more efficient than standard incandescents, but are available in 12 volt DC versions. They were a lifesaver for our house--the inverter doesn't have to run to use them, they are more efficient, and the quality of light is excellent for reading or any other use. They fit in ALL standard light sockets, so the monetary investment is low. AC versions are available anywhere, and are still more efficient than standard bulbs. They give out lots of light even in an outdoor situation where its 25 degrees below zero, and last almost 3 times longer than incandescents. We hope to offer 12 volt DC Halogen bulbs for sale on our products page soon, as they are difficult to find--even most RV shops don't carry them, only the innefficient 12 volt incandescents.

# Standard Incandescent Bulbs

They give out more heat than light. Only 40 cents each, or lots more in 12 volt versions. Popular electricity wasters, seen in almost every grid-connected house. Edison's invention changed the world, but much more efficient lights are available now. Besides, **EDISON HAD GRID POWER!**

## Gas Lights

A real technological innovation a hundred years ago, these lights are still effective today if you have no electricity and some propane or gasline to burn. Humphrey has been making these lamps for 92 years, they are available from Jade Mountain, Lehmans, and certain Amish catalogs. They make some noise, but not too much.

Coleman lanterns are another familiar gas light--they use white gas that is vaporized in a heated generator tube. These are VERY noisy! Also, the mantles in these lights (and in kerosene mantle lamps) are treated with radioactive thorium--it doesn't pose much of a hazard, but don't carry mantles in your pocket! The thorium from lantern mantles can be used to construct a home built lightning detector for fun or experiments--see our plans on this website.

[Click here to read about making a home built lightning detector!](#)

## Kerosene Lamps

The Aladdin mantle version of these (with the tall glass chimney) produces lots of light and heat, more than enough to read by. Regular kerosene lamps produce enough to read by, barely, but are much brighter than a candle. But most of us up here spent at least a year with ONLY kerosene for lighting, and it sure beats a candle or nothing! Be careful of the fire hazard--don't burn these lights unattended.

Amory Lovins of the Rocky Mountain Institute calculated that replacing a 75 watt incandescent lightbulb with an 18 watt compact flourescent (that gives the same amount of light) would, over the lifespan of the new bulb, prevent the emission of about 1 ton of carbon dioxide and 8 kilograms of sulphur dioxide into the atmosphere, plus a huge savings on electricity cost. And, the compact flourescent will last over 10 times as long.

# Home Built LED Lighting

Light Emitting Diodes (LEDs) have been around for years in red, yellow and green. New technological advances have given us incredibly bright blue and white versions--the white LEDs on our products page are state-of-the-art in brightness. The rated brightness varies by how wide the beam angle is. LEDs with a super-high brightness rating also have a very narrow beam angle. Wider-angle LEDs have a lower brightness rating, but may put out just as much light. It's important to choose the beam angle to suit your needs.

- **LEDs can last tens of thousands of hours if used at rated current**
  - **No annoying flicker like from fluorescents**
  - **LEDs are impervious to heat, cold, shock and vibration**
- **No breakable glass is used, and LED lights can be waterproofed for marine use**

White LEDs are perfect for replacing small, inefficient incandescent bulbs in night lights, flashlights, path lights, task lights and exit signs. Try 6-9 white LEDs for reading and task lights, and 1-3 LEDs for flashlights and path lights.

# Designing LED lighting

LED ratings are specified by current, not voltage. For longest life, we recommend you run them at 20-25 milliamps (ma). HOWEVER, in our LED flashlight conversions (and many commercial LED flashlights), the LEDs are run at 50-60ma, twice the rated current. One of our test LEDs ran at 98ma for over 200 hours without damage or appreciable light loss. So go ahead and experiment with running them at over rated current if you are willing to take the risk of a shorter life. In my opinion, a flashlight bulb that lasts 100 hours is a huge improvement and cost saver over the incandescent alternative which gives only 15-20 hours before it dies.

You must use some method of limiting current to your strings of LEDs. The easiest is simply using the right number of LEDs for your supply voltage. Each white LED gives a voltage drop of 3.6 volts. So, for a 115 volt DC light, you could use 32 white LEDs in series ( $115 / 3.6 = 32 \pm$ ) with NO current limiting (they will limit themselves by their inherent voltage drop). Reverse polarity will not damage an LED unless the voltage is very high--it simply will not work, and will not pass current through. The diagram below shows how the LED package is marked for polarity.

The next easiest is a simple resistor. The resistor does consume power, though, but is usually needed since an 'ideal' 3.6 volt source is rarely available. Use Ohms law (Resistance(R)=Voltage(E)/Current(I)) to calculate the value and wattage needed:  $(R=E/I)$

Each white LED gives a voltage drop of 3.6 volts. As an example, for a 12 volt light, you can run a maximum of 3 white LEDs in series at full power ( $3.6 \times 3 = 10.8$  volts drop). Subtract this from your supply voltage of 12 volts to get the additional voltage that must be dropped (in this case,  $12 - 10.8 = 1.2$  volts of additional drop needed). In this case,  $1.2 \text{ volts of additional drop} / .025 \text{ amps (25 ma)} = 48 \text{ ohms}$ . Use the next highest value of resistor available, 50 ohms. You must also be sure the resistor can handle enough current. Volts x Amps = Watts; resistors are rated in watts. So in this case,  $12 \text{ volts} \times .025 \text{ amps} = 0.3 \text{ watts}$ . A 1/4 watt resistor would work fine, but if you run a second string of 3 LEDs in parallel, each string would need its own 50 ohm, 1/4 watt resistor. It's important that each string has its own resistor....putting them in parallel with a single resistor is bad practice. We didn't know this when this article was first written....thanks to all the folks that pointed this out!

## 12 VOLT LIGHT DIAGRAMMS

This method is cheap and works great, but there's one problem--voltages in a remote power system (or car, for that matter) tend to vary. In our home system, voltages range from about 12 volts when the batteries are low up to 14 volts when equalizing the battery bank. An LED lamp string designed to run at 25 milliamps at 12 volts would be pushing 64 ma at 14 volts, which would be very bright and PROBABLY last at least a few hundred hours...but then then when your batteries are low, the LEDs will pull only 10ma or so, making them very dim. If you are looking for maximum lifespan (which could be over 10 years of run time) and brightness that doesn't vary with your battery condition, try a voltage regulator circuit (below).

Therefore, we highly recommend a simple voltage regulator chip for the safety of your LEDs. White LEDs are expensive, and it would be a shame to blow them out. Parts for a current-limiting circuit are very cheap--less than \$2. Regulator chips are available for various voltages. Use the Ohm's law calculations above to select the resistor for the voltage you choose. Or, use the regulator in a current-limiting configuration to run the LEDs. You can also use an LM317 adjustable voltage regulator set to the exact voltage needed by your strings of LEDs. See the circuit diagrams below.

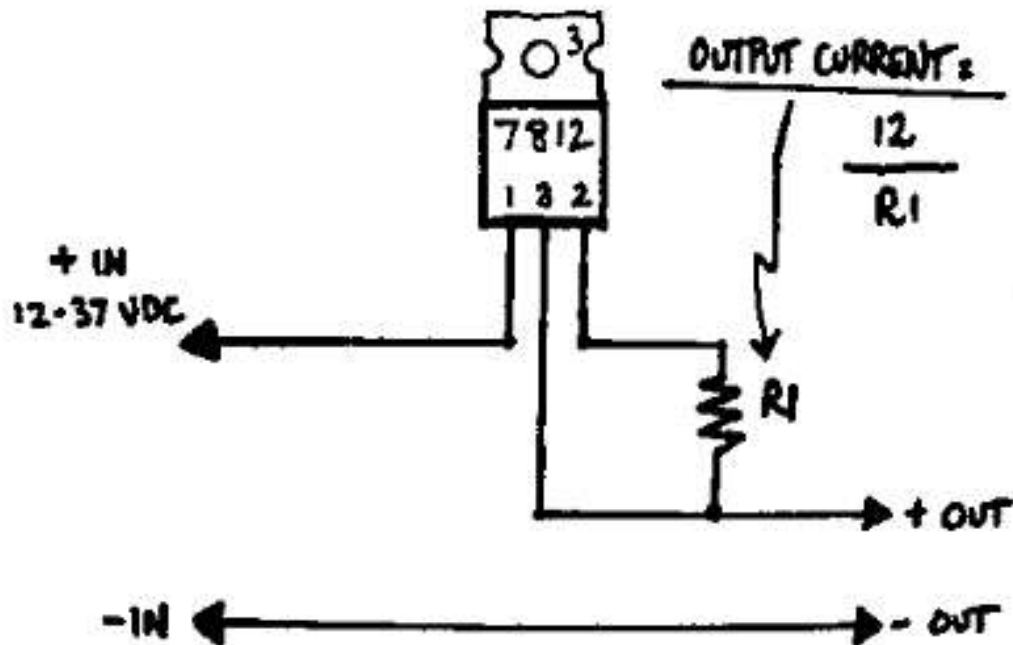

## 2 possible regulator circuits using the 7812 regulator chip

## 12 VOLT VOLTAGE REGULATOR

With this voltage regulator circuit, choose your current-limiting resistors as described above. Output will be 12 volts DC no matter how high your input voltage goes...up to 37 VDC. This protects your LEDs from fluctuating system voltages.

## CURRENT REGULATOR

If you use the 7812 in this current-limiting configuration, make sure resistor R1 has a big enough wattage rating to handle ALL the current. Just choose R1 for 25 ma if you are running one string of LEDs, 50 ma for 2 parallel strings, etc.

# Large AC LED lights

**You may have noticed that we deleted the circuit diagram for a 'monster' 32 LED room light. The simple circuit presented here earlier had some serious design problems in terms of peak voltage and efficiency. Thanks to the many people who pointed out the problems to us! We were also concerned about safety considerations; 120 VAC current is not to be trifled with by people not experienced with it. If you have little or no electrical knowledge and want to try a 120 VAC LED room light, purchase a commercial version. If you DO have 120 VAC electrical experience, keep reading...**

First, note that 120 VAC house current varies in different parts of the country. You will probably have to adjust the component values in your circuit to match the exact voltage at your location. The most efficient way to run LEDs from 120 VAC is to use no series resistor at all, but instead a non-polarized series capacitor before the rectifier. We also highly recommend a fuse in the circuit before the capacitor and rectifier. The capacitor must be rated at least 200 volts. A good foil capacitor is expensive (\$5 or so) but also gives very low losses and will not get warm. Such capacitors may be found in certain older fluorescent lamp ballasts. The true beauty of the capacitor-rectifier-LED light is the flexibility in the number of LEDs. If you use fewer LEDs, your series capacitor for 25 mA would get smaller and cheaper, while a series resistor would waste more power and would have to get bigger and more expensive.

Here's some examples of 120vac LED circuits -- from someone who knows more about electronics than we do.

[http://ourworld.compuserve.com/homepages/Bill\\_Bowden/page10.htm#lineled.gif](http://ourworld.compuserve.com/homepages/Bill_Bowden/page10.htm#lineled.gif)

We also highly recommend using a multimeter (\$10) and solderless breadboard (\$5) for designing your home built LED fixtures. Both are available at Radio Shack. With the multimeter, you can check your polarity, voltages, resistors, and current draw before assembling the final version of your light by soldering. The breadboard allows you to make changes to the circuit without soldering, and makes it easy to transfer the working circuit to a soldered version--solder-in PC boards are available that exactly match the connections of your solderless breadboard. (see photo below).

## Other LED design and handling concerns

- If your LED mounting does not allow any air circulation, we recommend running them at 18-20ma instead of 25ma to avoid any heat buildup, which will shorten their life.
- LED lights generally do not need reflectors, as the angles at which they emit light are set internally. Our white LEDs emit in a 20 degree arc. Very little light is wasted from shining in the wrong direction.
- Although our LEDs are not powerful enough to require eye protection labelling, DO NOT look directly into the beam from a close distance, just like with a halogen lamp.
- Solder your connections quickly and efficiently, using a small (less than 30 watt) soldering iron. LEDs can be ruined if the internal temperature gets too high from soldering.
- Do not place too much strain on the LED leads when bending them. Bend the leads ONLY below the square tab on each lead.
- LEDs are sensitive to static. The manufacturer recommends a grounding wrist strap, but we have had no problems without one during our research. Just be careful not to drag your feet across the carpet and grab a handful of LEDs...or simply touch a grounded metal chassis before handling LEDs.

# STORAGE BATTERIES

**"FEW  
BATTERIES DIE  
A NATURAL  
DEATH...MOST  
ARE  
MURDERED"**

---Unknown Industry  
Representative (please  
take credit for this quote if  
you originated it!) Source:  
Sunelco Planning Guide

**BATTERIES ARE  
YOUR MOST  
IMPORTANT COMPONENT**

Your battery bank is *THE MOST* important part of your remote power system. If you have to cut corners to afford the system you need, skimp somewhere else. The rest of your system is only as good as the battery bank!

**BATTERIES ARE ANTIQUE TECHNOLOGY**

Well, OK, not quite! But the most common and cost-effective banks of large batteries for remote power storage are the flooded lead-acid type, and a battery reference book from 1910 will give you all the information you need about charging and maintenance. And like the antiques, modern batteries for remote power use are still heavy and cumbersome to move.

**"DEEP-CYCLE" BATTERIES ARE NOT**

Unfortunately, there's not a battery out there that thrives on abuse. "Deep-cycle" batteries are designed to resist damage from repeated deep discharges (50% to 80% of capacity used up)...but will still last significantly longer if discharged by only 20%.

## CHECK OUT THIS CHEAP AND INFORMATIVE BATTERY BOOK!

*Secrets of Lead-Acid Batteries* by Thomas Lindsay is one of the best reference books on the subject that we've ever seen. Plus, it's cheap, since he doesn't waste any paper talking about irrelevancies. Available on our [Products Page](#) for only \$4.95!

## BATTERY MYTH:

**"Never leave batteries on the ground or a concrete floor...all the power will leak out."**

This one is a "rural legend"--batteries don't care what they sit on. It probably originated from when batteries came in porous wooden cases. There are some truths behind this myth, though! All batteries do self-discharge over time when they are not being charged. If dust and dirt build up on the battery tops, sulfuric acid will carbonize the grime into an electrical conductor, acting like a short circuit across the terminals and quickly draining the power. Cold temperatures also reduce available power from a battery. And thermal gradients can reduce the life of large battery...this can occur when the air temperature around a battery is much warmer than the surface it is sitting on.

# Remote Power Systems

---

**CHECK OUT THIS GREAT, INEXPENSIVE BATTERY REFERENCE BOOK!**

*Secrets of Lead-Acid Batteries* by Thomas Lindsay is one of the best reference books on the subject that we've ever seen. Plus, it's cheap, since he doesn't waste any paper talking about irrelevancies. Available on our products page for only \$4.95!

## Lead-Acid Batteries

listed in order of suitability to remote power use, in our humble opinion

- **Industrial forklift batteries.** These are truly top-of-the-line for a remote home, if you can afford them. Highly recommended for their longevity and resistance to abuse. Available in single 2-volt cells or trays of 3 cells (6 volts). 15-25+ year life expectancy. **Advantages:** longest life, most resistant to deep-discharge abuse, durable metal case, interconnect wires built-in, available in many capacities. Best value for the dollar when factored over service life. **Disadvantages:** Very high initial cost, extremely heavy.
- **Deep-cycle solar batteries (L-16s).** The most common choice for remote power systems. Originally designed for industrial floor sweepers, but very well-suited to remote power use. 6-volt batteries. 5-6 year life expectancy. **Advantages:** good service life, fairly resistant to occasional abuse, reasonable cost. **Disadvantages:** not as resistant to abuse as industrial cells.
- **Golf cart batteries.** Often used in small systems or as "training batteries" for flatlanders who move to the mountains. But don't expect more than 2 or 3 years from them if your system gets frequent or heavy use. 6-volt batteries. 2-3 year life expectancy. **Advantages:** very low cost, available at many discount stores, lightweight. **Disadvantages:** short service life, vulnerable to deep-discharge abuse.
- **Solar gel cells.** Expensive, but good for certain specialized applications such as on boats, RVs, and computer backup power supplies. 6-volt batteries. 2-3 year life expectancy. **Advantages:** maintenance-free, no hydrogen emissions, low self-discharge rate, shock-resistant, spill-proof, cold and heat resistant. **Disadvantages:** expensive, requires special charger and regulator, vulnerable to abuse, life expectancy very short for the price.

- **Telephone cells.** Manufactured with lead-calcium instead of the lead-antimony compound of normal batteries. Not really designed for remote power use, but often available at surplus/salvage for very low cost. Can give extremely long service if pampered and not abused. Keep careful track of your battery bank's state of charge with an amp-hour meter and only shallow-cycle the batteries or they will expire quickly. 2-volt cells. **Advantages:** extremely low cost (sometimes even free), very low maintenance, can take very heavy use if not deep cycled. **Disadvantages:** cannot be deep-cycled without damage, very heavy, usually only available used, so condition is unknown, lower voltage than lead-antimony cells for charging, equalization, and metering, battery bank must have more capacity to avoid deep-cycling.
- **RV/marine batteries.** Very low cost with a very short life, but better than a car battery. 12-volt battery. 6 month to 1 year life expectancy. **Advantages:** very low cost, lightweight, available at any hardware store. **Disadvantages:** short life, will not tolerate abuse.
- **Car batteries.** Better than reading by kerosene or candle light, but will last a few months at best.

---

## Nickel-Cadmium Batteries

[\(if you are looking for information about small NiCad batteries \(AA, C, D, etc.\) click HERE\)](#)

These batteries are super-expensive and hard to find unless you come across a surplus deal. They are very sensitive to damage from deep discharging, though a myth has circulated for years that NiCads should be deep-cycled. It's not true, even for AA-size batteries! They do, however, have some unique properties that are worth mentioning, since surplus NiCads do become available on occasion.

Industrial NiCad cells do not exhibit a "memory effect" like their smaller AA, C and D brethren. Both appear to "die quickly," but this is really just a function of their power curve--NiCads release power at a constant voltage until they are almost empty, then quickly taper off into nothing. Therefore, voltage readings are useless in determining state of charge. They can freeze without damage, and require different regulator and charger settings than lead-acid batteries. NiCad batteries of different ages and capacities can be mixed, which does not work with lead-acid cells. **Advantages:** very long life if not deep-cycled, can freeze without damage, different sizes and ages of battery can be mixed.

**Disadvantages:** Expensive, voltmeter cannot be used for measuring state of charge, cannot mix with lead-acid batteries, special charger and regulator required.

## Surplus Submarine Batteries

If anyone has used these puppies or knows where to get them, please let us know!

# Surplus Klingon D7 Heavy Cruiser Starship Batteries

Thanks to a warp in the space-time continuum and improved Klingon-Federation of Planets relations, these batteries may soon be available. Dilithium-Deuterium construction. Each cell is approximately the size of a Volkswagon beetle and weighs 12,000 kilograms (convert this unit to normal peoples units at [metricsucks.com](http://metricsucks.com)). 872,000 Amp/Hour capacity, 2 volt cells. Check our products page for availability.

# Small Rechargeable Batteries

## (AA, C, D, etc.)

Buying rechargeable AA, C and D cells for your Walkman (TM), flashlight, GPS, toys, etc. can be a very good investment. If you factor the cost of disposable alkaline batteries over the service life of rechargeables, the cost for disposables is almost 1000 times higher! Add to this the factor of pollution in landfills from disposables, and the choice of using rechargeables is a very good one. However, rechargeable NiCad and NiMH cells are not suited for every application. Hopefully, our advice will be helpful for your choices.

- **Disposable Alkaline Cells**--These are very powerful batteries and will work for all applications. However, they are incredibly expensive to just use and throw away. Don't even bother with chargers that say they will recharge disposable cells...the batteries are not designed for this, and you will be wasting your money if you have to **depend** on the batteries like we do up in the mountains. **Advantages**--long storage life without use, very powerful, available everywhere, just use and throw away. **Disadvantages**--Very expensive since they can only be used once, heavy, pollution concerns in landfills, poor power output in cold temperatures.
  - Use disposable alkalines when your electronic equipment must sit for months without use. An example would be the flashlight in your drawer or truck that hardly ever gets used. Our radios in the local volunteer fire department have all been converted over to use disposable alkaline cells for this reason (at a cost of \$50 per radio--they were designed for NiCads). Rechargeables self discharge very fast compared to disposables, and our radios must be ultra-reliable, since hazards to life and limb are involved. A few incidents where NiCad powered radios were dead after sitting for 3 months in the fire truck was all that it took to convince us. The alkaline cells perform admirably in these conditions, and we haven't had a problem since the conversion. Of course, the cost of these disposable cells comes out of the fire department budget and not our pockets.
- **NiCad (Nickel Cadmium) Rechargeable Cells**--These can be found almost everywhere, from laptop computers to cordless phones to electric shavers. However, they are being quickly phased out in favor of NiMH (Nickel Metal Hydride) cells because Cadmium is a **VERY** toxic metal that lasts forever in landfills and pollutes groundwater...even rechargeables eventually end up in landfills. Don't be guilty of this! Most battery dealers will accept dead NiCad cells for recycling! Though the initial cost is high for the batteries and charger, they save a substantial amount of money in the long run. These cells self-discharge quickly, and should not be used in applications where the device they power has to sit unused for months at a time. **Advantages**--can be recharged many times, good power compared to weight, constant voltage output until cell is discharged (flashlights don't gradually get dimmer and dimmer...they stay at the same brightness until they suddenly go out). **Disadvantages**--Toxic waste in landfills, fast self-discharge when sitting unused, regular chargers may actually damage batteries and reduce life, lower voltage (1.2 volts instead of 1.5 with disposables)

means special adaptors are required in some equipment (though equipment designed for rechargeables may need an adaptor to use disposable batteries), very sensitive to overcharging or deep discharging.

- The so-called "memory effect" in NiCads gets lots of press, and lots of special chargers designed to "fix" it. This is mostly a myth! NiCad cells **can** exhibit this effect in appliances like a "dustbuster" vacuum cleaner, where the appliance is used for only a couple minutes at a time and then put back on the charger. After a few months of this, the batteries will only charge up to the level they were discharged to over and over. In most applications, the memory effect is not even an issue, though special equipment is available that fully discharges ("conditions") the batteries before recharging. This is another myth! These batteries are ruined by being run down until they are empty, too, just like expensive remote power batteries. To avoid the dreaded "memory effect," every couple of months simply run your dustbuster or cordless drill longer than you need, until the motor -just- starts to slow down. Recharge it. Problem solved.
  - For best NiCad life, use your video camera or laptop until the batteries are ALMOST dead, but not completely. Avoid any product that claims to "condition" your batteries.
  - Recharge the batteries until they are full (use the time estimate that came with the equipment manual), then immediately remove them from the charger. NiCads are VERY sensitive to overcharging, and will be ruined in a few months if you let them sit in the charger.
  - If you are really anal-retentive about your batteries (a good thing--you'll save lots of money in replacements!), find a charger that charges first at a high rate (1 amp or so) with PWM (pulse-width modulation), then switches to a trickle charge to finish, then completely shuts off. We don't know of one that does this so far, please let us know if you have one. Plans are available in a back issue of Home Power magazine--we are currently experimenting with them.
- **NiMH (Nickel Metal Hydride) cells**--These are the new high-tech replacement for NiCads. Most new laptop computers and cordless phones come equipped with these cells now. The biggest advantage is that dead batteries don't contain nearly as much toxic waste as NiCads, a good reason for switching in itself. Otherwise, their performance is similar to NiCads with a few real advantages besides. **Advantages**--Higher power density than NiCads (more power by size and weight), no toxic waste in the landfill, can be recharged many more times than NiCads, no "memory effect" (see above). **Disadvantages**--Even more sensitive to overcharging and complete discharging than NiCads, self discharge rate very high, so don't leave them sitting for even a couple weeks.
  - Within a few years, these cells will completely replace NiCads just by virtue of the toxic waste issue. Just keep in mind that if you leave NiMH cells sitting in the charger cradle for too long, you WILL ruin them.
- **Lithium Ion Cells**--While not rechargeable, these batteries have some special properties that make them very useful in certain applications. They have an incredible storage life--years and years without self-discharging. They pack more power than a standard alkaline cell, but weigh very little, and function perfectly in cold weather where alkalines would give up quickly. Use these very expensive, non-rechargeable for special applications. I use them for my firefighting equipment--flashlights, GPS, emergency strobes--where the equipment may

sit for 2-3 months between uses.

# Battery Bank Wiring

## 12 volts versus 24 volts

---

Most remote power systems are wired for 12 volts. Some larger systems are wired for 24 volts. It's a delicate call to make this decision in most cases. Even larger voltages are used in some huge systems. The main advantage of 24 volt systems over 12 volts is that wire size is cut in half throughout the system. Besides affecting battery bank wires, this includes solar panel, wind generator and hydro plant wiring, too--if you have hundreds of feet of wire, this cost can add up quickly. The disadvantages of using 24 volts are that 1) you'll need an expensive, power-wasting transformer to run 12 volt lights and appliances, and 2) if you want to buy a cheap, Chinese inverter, they are only available in 12 volt versions. More expensive inverters are available in different voltages.

### Series and Parallel Battery Wiring

Lead-acid batteries always have 2 volt cells wired in series to give the desired voltage. Some batteries have 3 2 volt cells in the case, already wired together for 6 volts. Most battery banks use a combination of series and parallel wiring.

Series wiring increases voltage but **NOT** amp/hour capacity.

Parallel wiring increases capacity but **NOT** voltage.

### Series Wiring Example

Parallel Wiring Example

Typical remote power battery bank using 2 volt batteries  
(series + parallel)

## Typical remote power battery bank using 6 volt batteries

(series+parallel)

= 12 VOLTS, 600 AMP/HOURS

### Battery Bank Wire Sizing

Batteries can put out a huge amount of power in a short time. It is important to use big enough wire for your series and parallel connections between the battery terminals (the interconnect wires) and to the inverter.

**Note: We do not guarantee the accuracy of any of our information regarding whether it meets NEC code or not!**

**For BATTERY INTERCONNECT wires, use #4 gauge if you have a 500 watt or smaller inverter. Use #2 gauge for an 800 watt inverter, and go with #2/0 for larger inverters. If you can afford using #2/0 welding cable or can find a surplus deal on it (we did), we highly recommend it for battery interconnects no matter what size inverter you have since it is so flexible. Keep in mind that welding cable may not meet NEC code, even though it is clearly the best and safest choice (because of welding cables' flexibility, it puts little strain on the connection points) for battery and inverter wiring. Go figure!**

### Buss Bars

It often saves a lot of trouble later to install + and - buss bars directly off of your battery bank, connected with wire thicker than what you need for your inverter ([click here to jump to the inverters page for the inverter wire sizing chart](#)). These buss bars give you extra room to hook up new windmills, solar panels, meters, loads, etc. Use rectangles of at least 1/4" thick copper, drilled with extra holes. It's easy to tap threads into copper, too--this will speed your hookup time (no nuts

necessary on the back side of the buss bar). If you have an amp/hour meter, it's shunt should go between the - (negative) buss bar and the battery bank so that all power collected and used is measured.

# Solar Power

---

Solar power is the basis for all life on earth! Solar heating has been used for thousands of years to warm dwellings. But solar electricity (photovoltaics) is a very new industry. We will be expanding this website to cover solar space and water heating soon--please email us with suggestions and your own experiences. For now, we are concentrating on solar electricity.

## A ZERO-MAINTENANCE GENERATOR

Solar panels have **no moving parts**. You just sit them out in the sun, hook up the wires, and collect power, without adding fuel or replacing worn-out parts. It's amazing that nobody knows for sure how long a solar panel will last. That's because many of the very first photovoltaic panels are still producing power today.

## USED SOLAR PANELS

**If you are going to buy solar panels, compare them by Dollars per Watt. Used solar panels are a bargain in every way. The old ARCO panel shown here has been in the sun for around 20 years, and produces only 10% less power than when it was new!**

[otherpower.com buys and sells used solar panels in any quantity! Click here for more information.](#)

Northern Colorado, where we are located, has LOTS of people living in remote mountainous areas with no grid power. Over the last 2 years, we have tried to obtain used solar panels from various sources, and have had NO LUCK at all. In many cases, used panels are selling here for the same price as brand new ones. We'll keep trying, but we most likely will not be able to sell used solar panels.

## DOLLARS PER WATT versus SPACE

Used solar panels produce less power per square foot (or square meter...convert these units at [metricsucks.com](#)) than do new panels. A modern solar panel might produce twice as much power as an old one of the same size--but will cost **more** than twice as much. That's why you should compare dollars per watt! The best current deal on new 50 watt solar panels is about \$4.25 a watt--\$212 for a 50 watt panel, in quantity. Other new panels of about the same size can produce 120 watts, but cost \$700--\$5.83 per watt. The only difference is size--unless you have limited mounting space (rarely a problem), panels that cost the least dollars per watt are the best deal. **You just put up more of them!**

# Water Power

Large scale hydroelectric power has been used worldwide for a long time to generate huge amounts of power from water stored behind massive dams. Small scale hydropower has been used for hundreds of years for manufacturing, including milling grain, sawing logs and manufacturing cloth. However, it can also be used **without a dam** to generate electricity for home scale remote power systems. These so-called micro-hydro installations can be a very good complement to a solar power system, as they produce electricity 24 hours a day.

**Waterwheels**--It's important to differentiate between water wheels and water turbines. A water wheel is the antique version we are all familiar with--a massive wooden wheel that slowly turns as the creek pours down over it. Water wheels spin slowly, but with lots of torque. This presents problems for generating electricity, as complex gearing is required to reach a rotation

speed high enough to produce power with an alternator or generator. By the time this torque is sent through the gears, a huge amount of power has been lost to friction. However, one of our neighbors did construct a water wheel generator that produces a steady 2 amps of power, 24 hours a day. He used a natural dam (a log that fell across the creek years ago) to get the fall and to mount the generator on. Some of the locals were positive it wouldn't work, but that was 6 years ago, and the device is still producing power now! [Click here for more information on this clever water wheel.](#)

**Turbines**--All of the commercial micro hydro generators available today use a small turbine connected to an electrical generator or alternator. Water is collected in an intake pipe upstream, travels down to the turbine in plastic pipe, and is forced through one or more nozzles by its own gravity pressure. No dam is needed; systems without a dam are called "run of river" systems. By this time, the water is moving VERY fast, and it spins the turbine wheel very fast. Power is generated by a generator or alternator directly connected to the turbine wheel (no gears or pulleys

needed). All of the factors below must be calculated correctly for your micro-hydro equipment to make power most efficiently. All commercial micro-hydro setups are custom-made by the manufacturer for your specific application. For proper operation, you must supply the manufacturer with specific data about your site, most importantly the vertical drop in feet (called "head"), the amount of water flow available during different seasons in gallons per minute, and the length of pipeline required to get a sufficient head.

Look for more information on home built water turbines here soon!

- In general, for a water turbine you need at least 3 feet of fall and at least 20 gallons per minute of flow. If you have more fall (head), less water is required. You can calculate potential head with a water level, a contractor's level and stadia rod, or with just a string level attached to a measuring stick. The more fall and flow that you have, the more potential power you can generate. You can measure flow by building a weir in the creek and measuring how fast it will fill up a 5 gallon bucket.
- Your pipeline must be of a big enough diameter to minimize friction loss in the pipe. Your micro-hydro supplier can give you specific information regarding this.
- Nozzle size and turbine wheel type are all interrelated to your total head and flow. Again, your hydro supplier will customize these for your specific application. Often, different size nozzles are designed to be switched in and out as stream conditions change throughout the year.
- There are two main types of turbines, impulse and reaction. With impulse turbines, a jet of water is created by the nozzle and squirted onto the wheel. Reaction turbines are more akin to propellor that spins **INSIDE** the pipe, generating power.
- The 3 primary impulse turbine wheel types are Pelton, Turgo, and Cross-flow. Pelton wheels are used in low flow, high head conditions, and Cross-flow wheels are for high flow, low head installations. Turgo wheels are somewhere in the middle. Francis and propellor turbines are the most common reaction type; the Francis design is very similar to the innards of a centrifugal pump.
- Home built reaction turbines have been built using centrifugal pumps running in reverse (generating power with moving water instead of using power to move the water). We hope to have more information about experimenting with this soon.

# Simple Home Built Waterwheel

This machine was built by a neighbor of ours in about 2 hours, 6 years ago. It's been in constant operation since, except when the creek is frozen. He chose a natural dam, which was created when a tree blew across the creek. The tree is approx. 20" diameter. A slot was cut in the tree to channel the water into the turbine. The turbine was made from a junk squirrel cage fan. The fan housing was bolted to the tree, so that the water poured into the "output" of the fan, and came out a hole which was cut in the bottom of the fan housing, making for an "undershot" waterwheel. He used the pulley which was already on the fan, and belted it to a surplus computer tape drive motor (the kind they used to use in large computer tape drives, check our Products page for availability). The gear ratio is 1:3-- the generator turning 3 times faster than the water wheel. They make excellent low rpm generators. This system charges 2 amps into a 12 volt battery, 24 hours per day! His only power needs were 2 lights, and a small car stereo, the water wheel provided more than enough. It doesn't work after the creek freezes(4-5 months of the year), and he simply lets it freeze over each year, without any apparent damage.

It's easy power, cost next to nothing to build, and is low maintenance. The front bearing has failed twice (once every 3 years), but no effort was made to keep water out of the bearing--doing so might fix this problem. 2 amps may not seem like much, but consider the cost of solar panels required to produce 576 watt hours per day! Simple improvements could certainly be made to make a machine like this much more efficient. It uses a normal V belt, which introduces a lot of friction and loss. I don't know for sure, by my guess is the V belt may suck more than half the available power here. Gears, or a smaller belt would be interesting. I don't believe he ever took the time to try different pulley combinations either, it's possible there is room for improvement. Since we have been experimenting with them, it seems like a homebuilt wooden alternator or induction motor converted to an alternator (see our experiments page for more information) would work more efficiently by charging at lower rpm. Considering all the room for improvements, it's reasonable to think a unit like this could provide twice or three times the power. 50 watts, 24 hours per day would be an incredible amount of power considering the cost, low maintenance, and only about 20" of head on a small creek.

Other simple undershot waterwheels have been made using 55 gallon metal or plastic drums with attached vanes, suspended above a river. Please let us know about **your** experiences with home built hydro power!

# INTERNAL COMBUSTION

---

Alternative energy can be expensive. The system that meets your needs 90% of the year could cost a fraction as much as the system that will always provide more energy than you need. Even with an excellent solar array and wind power supplement, there will be times when the sun doesn't shine for weeks, and the wind won't blow. In order to keep your batteries from cycling too much, a gasoline backup is usually wise. On this page we'll show some systems at work.

A good gas backup should be quiet, reliable, and efficient. Unfortunately...this sort of machine is very difficult to find these days. Only in the last couple of years has anyone put effort into building a commercial generator designed specifically for charging batteries. This is surprising considering how much research and development has gone into solar panels, windmills, etc. Most generators today are designed to run 120VAC appliances; most of them are loud, and all the affordable ones are lightweight, cheap, and not designed for the long haul. Using a normal 120VAC generator to charge batteries is terribly expensive, requires frequent maintenance, is generally loud, and not very efficient.

There are a couple of alternatives....

## Find an antique!

[Click here to check out our antique Maytag battery charger!](#)

My favorite option, and it should not be difficult for most folks with some mechanical inclination to find an old lightplant, restore it to usable condition, and make good use of it for many years. Keep in mind, most of these antique lightplants were built for daily use. Properly maintained, they could run a lifetime with very little trouble. Check out my 1930's Delco below...

[<Save this link for an MPEG movie of this charger running>](#)

Delco made lots of these in the 20's and 30's. When I got mine, it was seized. The cylinder and valves looked like they came from the bottom of a lake! I spent one afternoon beating the piston loose, lapping the valves, and making other small modifications. It runs well now - although it could certainly use a good valve job. Although this machine was designed for 32 volts, it starts and runs well on 12 or 24

volts. Mine runs well on gasoline, but seems to prefer kerosene, or diesel. Its good for about 25 amps at 12 volts, and consumes a little over 1 pint of fuel per hour( a little less with kerosene, a little more with gasoline). Surprisingly, it seems to run best of all on citronella tiki lamp oil, which is probably mostly kerosene. And we've had

no mosquitos around for months now! Electric start makes it convenient. It runs slow, under 1000 rpm, so with a good tailpipe and muffler, it's very peaceful to have running. It weighs in somewhere around 300-400 pounds, and the size of the castings/bearings/brushes etc. almost guarantee that it should run, and stay put, forever.

## Build your own!

Something as simple as a small lawnmower engine belted to a car alternator can do a wonderful job of charging batteries very efficiently. Most lawnmower engines have crummy mufflers...this is real important, noise pollution is intolerable. It is best to use an oversized engine...run it slow and gear up the alternator. It will run quieter, and last longer. 5-10 horsepower is a good match for a 30-50 amp alternator. Watch for more information about this here soon. Home Power Magazine has had some excellent articles about building one of these.

## Buy a New Dedicated Gas Battery Charger

These chargers are a commercial version of the home built model we discussed above. We have not tested any of these chargers, but are VERY relieved that other people are as frustrated as us with the maintenance, noise and inefficiency of charging 12 volt DC battery banks with a 120 VAC generator.

We know of 3 companies that manufacture dedicated gas battery chargers. Check out [wildernessenergy.com](http://wildernessenergy.com), and [epowerchargerboosters.com](http://epowerchargerboosters.com). We congratulate these companies for their foresight, and urge you to check out their products! We will be testing them out soon.

## Buy a normal generator

The least desirable option in our opinion, but may be your only choice if you have a 220 volt AC well pump or do not have time to work on an antique or build your own. Click below for more information about regular 120/220 volt AC generators.

# Maytag battery charger

This page features a small battery charger we built from an old "antique" Maytag gas engine, and a computer tape drive motor. We only spent about an afternoon on this one, so lots of room for improvement probably exists.

These motors were popular back in the 1930's, and were built by Maytag, mostly for use in washing machines, although other accessories were available to be used with them, including a small battery charger, similar to this. I found this motor at a local "flea market", and they can be easily found. If interested, a good one can usually be had from Ebay for less than \$200! These are 2 stroke motors, with an interesting governor. When the engine comes up to speed, a centrifugal governor breaks a contact in the ignition, preventing the engine from firing. When idling, the engine will hit about once per second, about once per every 6-8 strokes. When under load, the engine will fire however often is required to maintain speed. Neat looking, and sounding engines, they are also very reliable and easy to start. All these Maytag engines have kick starters.

The base is made from treated posts and 2X4's held together with lag bolts. The generator is one of those old computer tape drive motors which make excellent low rpm generators. We try to always offer these on our products page, but if none are available, they can usually be found on Ebay. Although not yet tried, good chance this whole charger would work better with an alternator or an old car generator for reasons which I will explain later. The generator has a 5" pulley on it, the gas engine has a 4" pulley, stock for the Maytag engine. This setup works reasonably well for charging 24 volts, but when hooked to 12 it bogs down the engine too much and it dies. To fix this, a higher rpm generator could be used, or a larger pulley would do, probably 6-8" diameter on the generator.

In conclusion, with a well tuned engine and the right pulley combination this unit should do a fine job of charging at about 150 watts. There are certain drawbacks to both this type of engine, and the generator we are using. The engine is a two stroke, they tend to be noisy and inefficient, but..they sure are cute, and fun to watch. Maytag engines are an excellent value where antique engines are concerned. They are still easy to get parts and support for. The tape drive motor we are using makes a fairly good generator, with the right sized pulley. The drawback, they don't cool very well, and if run for extended periods at full output (about 15 amps) they will get hot! An improvement might be to use an old car generator or an unregulated alternator and use an appropriate field resistor to properly match the load to the engine. Although not "ideal" a charger like this could easily be used to recharge small systems or car batteries. A more efficient design would probably be a modern 4 stroke engine (like a briggs from a lawnmower) and an alternator. That sort of setup could easily provide 500 watts or more, and might even use less fuel! Let us know if you have any comments or questions about this project! We are always experimenting with odd ways of making electricity and love to hear input on that matter!

What in the world could all those magnets be doing stuck to that big flywheel? This could be our next inefficient gas charger!

# EXPERIMENTS

We at Otherpower.com have always been in a quandary...we have more time on our hands than money, and remote power equipment is *expensive!* That's why we started making our power from scratch! The experiments presented here are not to be interpreted as "plans" or "kits"--they simply show what we did, and how it worked. Some of these experiments worked well, some were partially successful, and others were complete failures! But we hope that our experiences will provide a good starting point for your own experimentation. **If you have any experiments that you would like to share, please contact us by [Email](#) or post on our [Discussion Board](#).**

**WARNING!! These experiments are things we and other people have done. We are serving only to share free information and take no liability for the dangers imposed should somebody attempt these experiments at home. Most of these could be dangerous! If you are unsure of the dangers involved, DO NOT try any of these experiments! Always wear eye protection and gloves. FAILURE TO INITIATE AND FOLLOW YOUR OWN SAFETY PROCEDURES MAY RESULT IN BODILY INJURY OR DEATH! Possible hazards include high and low voltage electrocution, large items spinning very fast that could remove your head, high towers, power lines, battery acid, explosion danger from hydrogen or propane gas, and faulty wiring causing fires. IF YOU ARE NOT SURE, DON'T EVEN START!!!!!!**

## [10/10/2003 -- The Triplets -- 3 new 10-foot diameter dual-rotor brake disc wind turbines!](#)

These 3 nearly identical machines are built with the same design as the mill at the Caboose (5/20/03, below) but we streamlined the construction process significantly and built 3 machines at the same time -- Curly, Moe and Larry. These are the latest of our designs, and they perform great in low winds. Detailed DanCAD drawings and dimensions on this page.

## [Hamster-Powered Alternator](#)

Skippy the Hamster is Forcefield's newest employee! We custom-built a low-rpm permanent magnet alternator onto his exercise wheel, and he lights a night light at DanF's house. We installed a data acquisition computer on his wheel too! And of course this simple alternator, buildable by kids, would work for wind or hydro power experiments and science fair projects too.

### [5/10/2003 -- New Brake Disc Mill](#)

9-foot dia prop, furling tail, 3-phase, separate laminate assembly with excellent specs. Many improvements over our previous designs! Spins up and makes power freely in low winds, and governs itself in high winds.

### [5/20/2003 -- Dual Rotor Brake Disc Mill](#)

Up and flying at the Caboose. Excellent low wind performance with 10 foot prop, great furling system.

### [DanB's Homebrew Volvo 240 400-watt Windmill](#)

One of our older designs, but still functional. No furling system.

### [Choosing Alternators and Generators for Wind Power](#)

A guide to help you figure out where to start for your application...

### [Ward's Homebrew Volvo 400-watt Windmill](#)

One of our older designs. 7-foot prop, no furling system.

### [Volvo 140 Disc Brake Alternator](#)

One of our earlier designs.

### [The Wood 103](#)

The infamous "Wood 103," a 100-watt windmill made entirely from wood--and from scratch! You can also download our entire Home Power Magazine article [here](#).

### [Regulator for PM Alternators](#)

Uses the Lenz effect to change alternator wiring from series to parallel and back. Not a very practical design, but a great demonstration.

[Windmill Testing with Model A](#) Our windmill testing rig--a 1930 Model A Ford! Cool video.

[Converting Motors Into Alternators](#) How we have converted AC induction motors into permanent-magnet alternators

### [The Wood A-X](#)

Sequel to our infamous Wood 103, this all-wooden 200-watt wind genny uses sturdy ball bearings. One of our older designs, but we are working on a new version.

### [Surplus Tape Drive Motors](#)

How to use surplus tape drive motors for wind and hydro power

### [Homebrew Easter Egg Anemometer](#)

A very quick and easy project for accurately measuring wind speed. Good science project for kids, too!

### [OOPS! Always Tighten Your Cable Clamps](#)

How a very small oversight caused a major disaster while raising a windmill on a 40 foot mast! No humans, dogs or pickup trucks were hurt.

### [Homebrew Wind Generator](#)

Uses an AC induction motor converted to a permanent magnet alternator

### [Homebrew Wooden Alternator](#)

A very powerful permanent magnet alternator built from wood, and from scratch! We use it as a demonstration unit at our retail magnet store!

### [Science Fair Wind Generator](#)

A bunch of ideas for building tiny wind generators for science projects.

### [Anemometer made from Bicycle Speedometer](#)

Very simple and easy to build! Uses a standard, inexpensive bike computer to calculate wind speed and acquire data, including maximum gust, wind miles, average speed, and hours of wind. Built using our pre-made anemometer cup assemblies so it goes together fast.

### [Homemade Waterwheel](#)

Built from a surplus squirrel-cage blower and a surplus tape drive motor

### [Maytag Engine Battery Charger](#)

A slick little homebrew battery charger using a car alternator and old Maytag engine

### [Automatic Solar Water Pumping](#)

Cheap! DanF's solar pumping system with one solar panel and a small Shurflo pump

### [Antique Witte Engine Charger](#)

A beautiful old engine hooked to a modern car alternator for battery charging

### [Homebrew Float Switch](#)

When DanF's commercial float switches failed, he built this reliable homebrew magnetic version

### [Charger Built From Dead Inverter](#)

This dead 1000 watt Heart inverter found a second life as a powerful homebrew AC battery charger

### [Bicycle Powered Generator](#)

Make your spouse and children pedal if they want to watch TV! Or use it to charge batteries, pump water, etc. in remote areas.

### [Homebrew Lightning Detector](#)

Watch the charge potential rise as a thunderstorm moves in...predict if it'll hit you or not!

### [Simple Homebrew Ammeter](#)

Build a big, beautiful, accurate ammeter from cheap surplus materials. Digital is cool, but analog can be a work of art!

### [Convert Gas Generators to Propane](#)

Propane generators are easy to start and reliable...and they are perfect for cold climates. But DON'T TRY this...you could blow yourself up!

### [Convert Flashlights to Use LEDs](#)

Get longer battery and bulb life with these easy white LED conversions. DanF uses them extensively for the local Fire Department

### [Disk Drive Magnet Alternators](#)

Our earliest alternator projects using dirt-cheap, readily-available hard disk drive magnets. Be sure to follow through the update pages too!

## SYSTEMS

### [Ward's Cheap Solar Power System Page](#)

How Ward put together a complete cabin power system for under \$700!

## [Solar Powered Captive Caboose](#)

How Dave put together an inexpensive solar power system for his new captive caboose.

# 10' Diameter Brake Disk Windmill

With Furling Tail

This page is a diary about my latest wind turbine experiment from June of 2003. Although a bit more complex, it features some significant improvements over the brake disk turbines I've made in the past. All the machines I've made in the last two years featured a single magnet rotor with steel laminates, and coils in between. This one is using two magnet rotors turning together with the coils in between. It has some advantages in that there is no loading on the bearings, and no losses in the laminates so it turns very freely. Be patient, there are a LOT of pictures detailing the construction [here](#).

Yesterday my freind and neighbor Dave came up to start building a wind turbine for his small power system. Currently he's got 2 105 watt solar panels setup which do OK, but his site is not excellent for sun. He does have a pretty good wind site up the hill from his caboose. His system is 12 volts, so were building the machine for that.

As usual, we started with some Volvo parts (just have too many around....). We're using the front strut assembly off a Volvo 240, and two 11" diameter brake disks which fit the wheel hub. This machine will be very much like the last one I made. [Click here](#) for more details about that. The main change we're making here, is that this will be a dual rotor machine. The tail will also be slightly larger and longer. It should be slightly more powerful at lower rpm than mine was, we're using slightly more magnet and exactly the same 3 phase stator design as I did last time.

To make the furling tail assembly, I cut the strut about 6" from the wheel spindle. We want the spindle (and therefor the alternator and the prop) to be offset from the tower about 5" to the side.

I ground it out so its a good fit for welding. It will be welded on at an angle to provide more contact between the two pieces making the joint stronger. I also like to weld it on so that the spindle (and therefor the alternator and the prop) is pointed up about 2 deg to help keep the tips of the blade away from the tower.

Pictured above you can see what I described a bit better. You can also see the wedge I was setting up on the back side to hold the tail pivot out at about 20 deg.

I like to cut the brake rotors down so that there is a slight lip (about 1/16 inch) to hold the magnets in. This helps a bunch too in spacing the magnets out evenly later. Pictured above Dave is doing this on the lathe.

Here Dave is learning to run the lathe and his friend Fred is cutting up various metal pieces which we'll need.

This is how the brake rotors look after cutting them down to make a lip on the outside which holds things together. I don't think this step is necessary - but it's easy and provides some insurance against magnets flying loose. It also makes a nice clean flat surface to put the magnets down onto.

You'll notice that the rotor on the right side has a larger hole in the middle than the one on the left. We turned it out a bit so that this rotor could actually fit on the back side of the wheel hub! (where I put the stator on past machines...). This way the back rotor sits behind the wheel hub with its magnets pointing forward towards the stator.

Here Dave is struggling with strong magnets trying to lay them down with about a quarter inch between each one. They kept sliding together - he was getting a bit frustrated! These magnets are 2" diameter X 1/2" thick. They go down with alternating poles up. Were using 12 of these on each rotor. Once they get placed down and approximately evenly spaced, we used playing cards as shims to make sure the space between each magnet was exactly the same. Its kind of trial and error, but it goes very quickly. Once they are right - a few spots of super glue on each magnet holds them in place untill we pour polyester resin around them.

Since this is a dual rotor machine, the stator will not be able to bolt on in place of the backing plate like I've done in the past. The stator will have to be in between two rotors, and held on by a bracket which ties into the outside of the stator. These are the pieces I made up for this bracket. The bracket will actually bolt on in place of the backing plate (to the strut assy behind the wheel spindle). These 3 pieces are cut from 3/16" thick X 3" wide steel, and they are 7" long.

Above you can see how those go together. After this we drilled holes in the center to bolt it down, and a large 1.75" dia hole in the center for the wheel spindle to pass through. We also need to drill holes out at the ends to accept allthread so we can mount the stator to it.

Pictured above Dave is winding up some coils. Just like my last one, each coil occupies the space of about 1 and 1/3 magnets (so 3 coils take up space occupied by 4 magnets, so there are 9 coils in the stator). Its 3 phase, so each phase consists of 3 coils in series.

The coils are made up of 65 windings of AWG 14 wire.

Here Dave is putting duct tape around the inner and outer diameters of the magnet rotor. This simply serves as a "quck and dirty" sort of mold, so that we can pour the resin around the magnets and it hopefully wont run out the sides!

Pictured above is the mold we made for the stator, and we're putting some fiberglass fabric in the bottom to strengthen it.

We first poured a bit of resin in the bottom of the mold (got the fabric saturated) and then placed the 9 coils in. Then we cover the coils with more fabric, and pour resin over those and put the lid on the mold.

Here we are pouring resin (mixed with talcom powder) into the magnet rotor. Well have to make 2 magnet rotors, but for now we're just doing one. It is possible the alternator will work OK with only one magnet rotor and the other rotor simply serving to conduct the field of these magnets (like laminates except itll be rotating) - so were not doing the 2nd rotor untill we test the alternator. We may even decide to use different magnets on the 2nd one.

Pictured above the main chassis of the wind turbine is pretty much together. You can see now how the stator bracket bolts on. The tail boom is 5' long.

Here you can see the magnet rotor, and the stator mold while the resin sets up. The battery serves as a weight to hold the top of the mold down tightly.

After about 2 hours we opened the mold and took the stator out.

Above you can see how we replaced the studs in the wheel hub with long (10 inches) pieces of allthread. The allthread will serve to hold the magnet rotors, and the prop securely to the wheel hub.

That's where we were at after 1 day (About 8 hours of work). You can see things starting to come together! It should be said, this machine is very similar to the one we built at the [SEI Wind turbine workshop on Guemes Island](#) in April. It's very much along the lines of Hugh's [Axial Flux Windmill Plans](#). If I really wanted a guaranteed good machine, I'd probably follow them to the letter, but I like to play with junk I have on hand and experiment a bit. I should also say - again, we have about 8 hours into this so far, and I believe we'll have it completely finished in about 20 hours. But it might come out a bit cleaner, prettier - and possibly a lot better if we took a little more time on certain steps. Time will tell! It's fun though, and since I have limited time to put towards this sort of thing, and Dave only has a few free days available, we're trying to move things along quickly.

Here we were putting allthread and nuts into the stator bracket to hold the stator on. The allthread is 1/2" diameter with 13 threads per inch.

Pictured above you can see the notch in the tail hinge which determines the angle of the blade during normal operation and when it's furling in higher winds. We reinforced the pipe around the notch to make things stronger, my guess is it might crack eventually if we didn't.

Here Dave is putting the stator on over the first magnet rotor. It's interesting to note here... with one magnet rotor on the machine, and the 3 long pieces of steel allthread which hold the stator on, that the magnets are somewhat attracted to the allthread and at this point the machine cogs a bit. When we attended [Hugh Piggot's seminar in Guemes Island](#) in April, we used stainless bolts for this, so the magnets would not be attracted to it. I kind of wondered if this cogging would get worse with the 2nd magnet rotor on (since there'd be twice the magnets and the top rotor might be getting attracted to the nuts on the front of the stator)... or better, since the magnetic circuit would be completed and the lines of flux would be concentrated between the magnets. As it turned out, when we did put the 2nd magnet rotor on the front of the stator this cogging disappeared completely. I was planning to replace this steel allthread with stainless, but as it turns out I think it is not necessary.

Here we're gluing magnets on the 2nd rotor. It is very important that the 2nd rotor line up perfectly with the 1st one. In other words, wherever we have a North pole facing out on the 1st rotor, we must have a South pole facing it on the 2nd rotor. Keeping in mind that there are 5 studs which hold the 2nd rotor on, we have to take care to position the magnets exactly. What we did, is put the 2nd rotor on without any magnets, and made some marks around it noting the position and polarity of the magnets on the 1st rotor. We then positioned the magnets on the 2nd rotor accordingly. This worked out well.

Here we basically have the whole alternator together. At this point we could spin the alternator by hand. We're getting about twice the voltage at any given rpm now with two rotors than we were with only one before. We didn't have a tach, or even a clock with a second hand.... so no real numbers yet. But it seems to be hitting cut in voltage (12 Volts) perhaps a bit below 100 rpm.

We soldered all the connections on the stator and made 6 lugs (2 for each phase) from brass screws and brass nuts. It can get tedious stripping all the ends of the magnet wire, a good way is to burn the insulation off with a propane torch, and then sand it lightly.

Here the alternator is pretty much done, and the tail is finished! The tail occupies between 5 and 6 feet of area. (If you look real close at the ammeter on the wall, you can see that my [last wind turbine](#) is putting out about 40 amps. It was a breezy day!)

I drew up and cut out the profile for one blade, and Dave is tracing it onto blank boards in preparation for making the other two. The wood here is 6/4 (an inch and a half thick) Eastern White pine, and it's 7.5 inches wide. It's pretty lightweight, but fairly dense and strong. We have a couple knots to work around here, but not too bad.

Here Dave is cutting out the blades on the bandsaw.

Since the blades get very thin (in this case about 3/8") at the tips, it saves time to remove some of the thickness of the board with the bandsaw.

Pictured above we are roughing out the front of the blades with the draw knife.

At the end of the 2nd day we had the front side of the blades roughed out. Each blade is 5 feet long, for a total diameter of 10'. The pitch at the tips is 5 deg, and it gets steeper to about 6 deg in the middle of the blade, at which point it gets steeper quickly towards the root (near the hub) until we pretty much take up the whole thickness of the board. No real scientific blade design here, just going with what feels good and what's worked fairly well in the past! I've since been advised, and will do this next time - to reduce the pitch at the tips of the blades to something like 2 deg. This would make it a bit faster and a bit quieter.

Here we are finishing up the front of the blades with a power planer. We did most of the work with the draw knife, but the power planer does nicely to finish things up quickly.

While Dave was planing on the blades I made up a cable with lugs on it and wired the alternator in Delta. For more details on Star, or Delta wiring and 3 phase alternators, checkout Ed's 3 phase basics [here](#).

Here we are roughing out the back side of the blade (making an airfoil) with the draw knife.

Same as above, working over the back side of the blades with a draw knife, but here you can really see things coming together! This blade is nearly done.

Once the blades were carved and sanded fairly smooth, we put them together - measuring from tip to tip to make sure the distance between tips is equal. Then we used 10 inch diameter plywood disks, one half inch thick, and screwed one on each side of the blades with a ton of wood screws to hold them together.

This is a simple tool I made to go with the machine. Notice my beautiful welds... (I have one of those cheap 120 AC mig welders which barely work on good power. Up here I have to run it off my generator which stalls quickly when I start welding. Welding here is very frustrating...)

Once you get two magnet rotors like these made up, and close to each other, it become impossible to pull one off without a tool. This makes the job easy. It should also be said... one of these rotors is a very powerful and dangerous thing! Two is twice as bad... anything that gets between them gets smashed. This tool does a nice job of removing the front rotor, but it's not so useful for putting it on gracefully! On this machine we've simply been lining it up and letting it snap into place which works fine as long as you keep your fingers clear! (I did get my thumb in there and my thumbnail was the only casualty. I think I got lucky...) Better would be for me to weld a nut right in the center of the front rotor and then we could use this same setup for smoothly lowering the front magnet rotor onto the alternator.

Here is a picture of the wheel puller in action. It doesn't pull it quite straight, but it does a good enough job to make it very easy to pull the rotor off by hand once it's a few inches back.

We pulled the whole thing apart in preparation for painting. Here you can see all the alternator parts on my workbench.

Here Dave is putting primer on the machine. First we ground off some of the uglier welds and then cleaned it carefully with gasoline to remove any oil.

That's pretty much where we wound up at the end of day 3! We used wood stain on the hub and tips of the prop, and on the tail. The rest is good old Avacado green epoxy appliance enamel just like on my last machine. At this point we need to make adjustments in the airgap, get some wobble out of the magnet rotor on the front, balance the blades and test it!

Here Dave is soldering up 6 bridge rectifiers we'll need in order to convert the 3 phase AC current into DC current useful for charging batteries.

We made a short tower that fits the front of my truck. In the end, this short tower will go on top of Daves (probably wooden) tower down at the caboose. The machine weighs too much to lift it up this high, so we had to disassemble it, and reassemble it on the truck for testing.

It was a pretty good calm day for this sort of testing today, although the more I do it the more I'm starting to take this sort of data with a "grain of salt". We get pretty consistent readings at higher speeds, but lower speeds (like 10mph) come in all over the place. When testing like this, I have a 12 volt battery on the floor of the truck, a volt meter, a frequency meter, and a DC ammeter. The frequency meter always gives numbers that bounce around and I don't trust it fully, but the numbers did seem to make some sense this time, so I'll write down the rpm as we got it and it may.... or may not be right! This battery was about half charged - and we ran the power to it with about 20' of AWG 14 extension cord (I figured this kind of simulates a longer line from the windmill to the battery made of better wire, plus... it was handy). When we do this, we always run one way down the road at a certain speed, turn around and go the other way at the same speed - so that we can kind of average the numbers out. Even the lightest breeze will cause it to do much better one way than the other.

So here's what we come up with roughly in the truck test...

Our neighbor Tom is in the Volvo pacing us (his speedometer works... mine doesn't) with his flashers on to warn oncoming traffic.

It starts charging at around 110-120 rpm and the frequency meter in the truck was in agreement with the tachometer I used on my workbench.

At 10mph we were getting readings ranging between 5 - 20 amps, 10 amps seemed a pretty good average, so a little over 100 watts. At 10 mph the frequency meter didn't

seem to be working so we got no rpm readings. (we later found it a wire had come loose)

At 15 mph it was producing about 15 - 20 amps consistantly both directions. At 20 mph 25-30 amps, and it was just starting to furl. At 20 amps output it seems to be running right around 400 rpm. At 30 amps output it's running right at 500 rpm.

At 25 mph we seemed to be getting around 30 - 35 amps and it was furled out some all the time.

At 30 mph we got consistant readings of 37-40 amps and it was quite furled out by this time (I'd say it was at about 45 deg to the wind). At 37 amps output we recorded around 550 rpm.

I've certainly seen higher numbers from past machines which did not furl before - but I don't think I've ever done so well at very low windspeeds, which is what's important. Output could be increased I think by adding weight to the tail (so it furls a bit later) and making a better stator. I think it's fine as is though. It runs square with the wind - the tail seems of fairly reasonable size and overall it runs pretty well. I like the double rotor design, it's a bit more work than others I've made, but it has 0 load on the bearings, and 0 losses in the laminates. I can give this alternator a good spin by hand, and then walk across my shop and give one of my old laminate alternators a good spin. The old ones will rotate once or twice and then stop... this one will keep turning for 10 or 20 seconds. Time will tell how it holds up! Sure was fun though. We've got 4 days into it now since we started with the front strut assembly off a Volvo and all that's left to do is get it into the air down at the caboose.

# 9' Diameter Brake Disk Windmill

With Furling Tail

This page is a diary about my latest wind turbine experiment from May of 2003. Although a bit more complex, it features some significant improvements over the brake disk turbines I've made in the past.

[Para Español, traducción de Julio Andrade.](#)

This is what I started with. It's the front strut, brake and wheel assembly from a Volvo 240. The Volvo parts are good, and since they are rear wheel drive this front assembly is simple and inexpensive from junk yards. They also built these cars for about 20 years, so the parts are easy to come by. Volvos are somewhat heavy cars, so the bearings are large and the brake disks are larger in diameter than most.

Above are pictured the important parts. The spindle and strut tube will make up the main frame of the wind turbine. The blade will bolt down to the front of the brake disk, where the rim used to fit on the car. That stator shown below will replace the backing plate that used to cover the back of the brake rotor. Of course the machine will use the wheel hub, and the strong wheel bearings from the car. I take some care to inspect the used bearing, clean it and grease it again. Normally in the past I've used the same brake disk that came with the assembly. In this case, I noticed that the front brake rotors from the Volvo 740 (a heavier car) were a whole inch larger in diameter (11 inches), and they fit over the same wheel hub, so I aquired the larger brake disk off the 740 for this project. It's important to consider when disassembling these struts that the spring is under some tension! One should compress and clamp the spring.

This wind turbine has a furling system so that in high winds the alternator and blades will turn sideways out of the wind and protect itself from overspeeding. To do so, the tail must raise. The weight of the tail ultimately determines when the machine can furl. This seems to be the most popular furling system on small home brew machines, and the idea has been perfected by Hugh Piggott from [Scoraig Wind Electric](http://www.windstuffnow.com). Go to his site, or [www.windstuffnow.com](http://www.windstuffnow.com) for details about how this system works. In this case, the center of the alternator sits about 4 inches off to the side from the center of the mast. I did this by cutting the strut tube off at about 4 inches from the wheel spindle and welding it onto the side of the remaining tube at somewhat of an angle. The tail will pivot over a 1 inch diameter pipe which is welded to the assembly at an angle of about 20 deg from the mast.

Above is another picture of the same assembly.

The tail is shown above. Actually - when I got 'round to testing this the tail came up too small and too light weight. I wound up making it slightly larger in the end. The end which attaches to the wind turbine is a short segment of pipe slightly larger than the 1 inch diameter pivot, which is welded to the main frame of the windmill.

Above is pictured the main frame, with the tail mounted. I painted the metal frame with green epoxy enamel to prevent rust and keep things looking as nice as possible.

Although probably not necessary, I like to cut a bit off the back of the brake disk from the inner diameter, almost all the way out to the outer edge, but not quite. This leaves an edge, about 1/16 inch high, which catches the magnets to help hold them in. It also leaves a nice clean flat surface. Since the magnets will also be glued and held in with some polyester resin, it's important after cutting this to clean it and make sure it's oil and iron filing free so the resin sticks well.

Pictured above are the magnets I used. This machine has 12 magnets, each one is 1.8 inch diameter and 1 inch thick. They are available on our web [Shopping Cart](#).

The magnets lay down on the brake disk such that each one has the opposite pole facing up as the one next to it. Alternating North and South poles all around the disk. I push the magnets all the way out to the lip I cut and space them approximately by eye. Then I use shims (playing cards) and go 'round the circle so they are perfectly spaced. The space between the magnets here is about 1/2 inch (or exactly the thickness of 49 playing cards).

I think the leakage (magnetic field which is going from magnet to magnet before it has a chance to go through the coils) between these 1 inch thick magnets is significant. More space between them would reduce that, it is also possible that thinner magnets (like 1/2 inch) might even work as well, or better. Once the magnets are spaced evenly, I wrapped some tape (duct tape) around both the inside and outside of the brake rotor so the edge stuck up about half an inch, creating a dam, or cavity in which I could pour polyester resin to glue the magnets down and keep the space between them. I wish I'd caught a picture of that.

I made a simple hand cranked coil winder.

I tested lots of coil shapes and sizes. Lots of things worked, but through lots of testing and some good advice I wound up deciding on this wedge shaped coil. The coils are wound from AWG 14 wire, and each coil has 60 turns. They are 3/8 inch thick, and the width (I never measured it) is such that exactly 3 coils fit over 4 magnets. Unlike the past machines I made which were single phase, this one is 3 phase. This setup seems to squeeze a bit more power from the same magnet rotor and also offers some benefits in reducing line loss. The alternator will also run more smoothly as 3 phase, meaning basically less vibration. Since there are 12 magnets, I need 9 of these coils and 3 coils will be wired in series to make up each phase.

The inside of the coil winder is waxed (I used crayons) so that glue wont stick to it. After the coil is wound, and the top removed from the coil winder, I put thin viscosity cyanoacrylate 'super glue' in the coil and spritz it with accelerator which hardens the glue instantly. This makes for very hard, strong coils that don't come apart easily.

Pictured above are the coils, and the magnet rotor (the magnets are not glued down yet, actually I never did that till the very end and never got a picture of it finished).

I made a mold out of partical board. The circle is 14 inches in diameter and I divided it into nine parts and drew lines so that I know where to place the coils. The top of the mold is the cutout from the bottom. The mold is 1/2 inch thick. I waxed the mold so that the resin would not stick to it. Once I place the coils and pour the resin, the top will get clamped in, and the wires from each coil will poke out the edge so all the wiring will be done later.

I cut two disks of fiberglass fabric about 14 inches in diameter. I put one down in the bottom of the mold before placing the coils. Then I put down a thin layer of polyester resin. I then put each coil in its place. I took care to make sure each coil is placed the same way. In other words... when the coil comes out of the winder, it has a top, and bottom side. I made sure they are all the same way so that the inside wire of the coil (the start) and the outside wire (the end) come out the same for each coil. Although not absolutely necessary it makes for much easier wiring later on. Once all the coils were placed, I filled up the mold with polyester resin mixed with talcum (baby) powder. The powder makes the resin go further and makes things a bit stronger. Once the mold was filled I put another fiberglass fabric disk over the top, and poured over some straight (no talcom powder) resin. I thin clamped the top on the mold with the wires poking out.

The reason for the red, and green coils is simply that I ran out of magnet wire! The green stuff is extra high temperature wire rated for about 400 deg F, and the red is less - but it will work fine.

After a couple hours I opened the mold and the stator is pictured above.

You can see in the picture above how the center of the stator is drilled out the same as the backing plate. The center hole has to be a bit larger (2.5 inches) so that the bottom of the wheel hub will fit inside it. The mold could have been modified to leave this hole in the stator and it would've saved some resin, but it was easy to use a hole saw and resin is cheap. On past machines I've made, the back of the stator was plywood, and steel laminates (which help to conduct the magnetic field through the coils) were glued into the plywood. The coils were glued over the top of the laminates, and the plywood bolted to the windturbine frame. A problem I had was that the laminates were getting yanked out of the plywood by the very strong magnets. In this machine, the laminates will be a separate part which simply lay (stuck there by the force of magnets alone) behind the stator. Or, with a smaller and faster prop it would probably run just fine without laminates at all.

Pictured above is the stator bolted onto the machine. I've also got the wheel hub on here. You can see how the studs (where the lugnuts used to go) have been replaced by longer (7 inch long) pieces of 1/2 inch allthread. The studs were pressed in, and are easily knocked out with a hammer. The allthread is held on with nuts on each side, and then another nut is used on each one to hold the magnet rotor out the proper distance so that the magnets run very near (about 1/8 inch) the stator.

Above the whole machine starts coming together so that I can wire, and test the alternator. I used 6 brass bolts for binding posts to hook up the 3 phases. My intention with this alternator was to wire it in Delta.

Here you can see how the laminates simply "stick" to the stator when the magnetic rotor is on. This is convenient, because it is easy to remove the laminates before removing the magnet rotor! It can otherwise be difficult to pull the magnet rotor loose when the laminates are built into the stator. Of course, this design with the fairly thick coils and removable laminates means I have a pretty thick airgap (distance from magnets to laminates). Past machines I've made could have much thinner coils and probably make slightly better use of the magnets.

The laminates I used here are actually a coil of very nice Silicon steel which I got from Ed at [Windstuffnow.com](http://Windstuffnow.com). Also go there for lots of good information on all aspects of building and designing small wind turbines.

Probably not necessary, but I glued the steel laminates into a plywood ring to make them easier to handle and prevent corrosion.

Here the machine is pretty finished up except for the prop. At this point I've got about 20 hours into the project if I don't count the mess I have to clean up later.

I made the blades from wood about 8 inches wide and 1.5 inches thick. Each blade started out 5 feet long, for a 10 foot prop. Here you can see I cut out the shape for one prop. Then I used it as a template and cut the others to match.

These are simple blades (as usual with me...). The tips are pitched about 4 deg, and the middle of the blade about 6 deg. From there it pitches steeper and steeper until the angle takes up the board thickness near the root of the prop. The airfoil is designed to do little more than 'look like an airfoil' and the thickest part of the airfoil is about 1/3 of the way back from the leading edge towards the trailing edge.

It'd probably work better if I designed it 'properly'. Hugh Piggot has some good information on this on his website [here](#) and Ed from [windstuffnow.com](http://windstuffnow.com) offers some nifty software which figures it all out for you!

I've seen several commercial machines which have very simple non-tapered, non twisted (straight pitch) blades which work fine, so it inspires to me to keep things simple.

Before doing any carving, I cut one slot with a cross cut saw at the point where the angle of the blade is steepest. This is insurance that I won't ruin the hub area of the blade with the drawknife should I make a mistake or have the wood split.

After attending Hugh's seminar this spring... the drawknife has moved to the top of my list as the favorite tool to use. Very fast, and very accurate. No need for a chisel and the only power tools were used for finishing. I roughed out the whole prop with this quickly and then finished it up with a power planer and a belt sander.

Pictured above the top of one blade is finished.

Here you can see the airfoil, and the back of the prop.

I rounded the tips to look nice, although later in testing I wound up cutting them off as the prop was too large and a bit slow.

The blades are sandwiched between two plywood disks and held together with a ton of screws. In the past I've used glue here, but I opted not to this time thinking that the screws, along with the tight squeezing that happens when the prop is bolted on would be good enough. This way if I ever need to replace one blade it will be easy.

Pictured above she's pretty much finished up on the nose of my truck for testing. When I do this I have a battery in the truck on the floor, some rectifiers, and meters so I can get a rough idea of how much it charges at certain speeds. This also allowed me to test the furling setup. In the first test it was clear the tail wasn't quite big enough or heavy, as it wouldn't run square with the wind and started furling at about 15 mph. The next morning I increased the tail size some and made it from thicker wood. As it is now - the tail is back about 36 inches from the machine, and it's about 4 square feet in area. It works reasonably well, although a bit larger might be better. I'm keeping it as it is because my tower is not so strong and I want it to furl early.

This is a big improvement from past machines, mainly in that it turns in practically no wind at all and the slightest breeze spins it up to charging speed quickly and quietly.

Past machines I've made wouldn't start till they saw a 10mph wind, and then it took them some time to spin up--so they were not nearly as responsive. The reasons for this improvement: the good laminate material I got from Ed, the 3 bladed prop, and the poor (wide) airgap (these laminates are not seeing near the magnetic field intensity as others I've made). It's always spinning even on a still day - and it seems to be making an amp or two at 7mph. At 10 mph it charges 12 volts at 8-10 amps. 15 mph I see about 15, and at 20 mph it's doing 30 amps and just starting to furl. At 25 mph it's furling out of the wind almost half way and doing about 35 amps and at 30 mph it's more than half way turned out of the wind and charging about 45 amps. I believe the power I'll get from this in very light winds will add up significantly and prove it to be a much better producer than others I've made, some of which actually had more powerful alternators.

In one test I added some weight to the tail. Although it was still somewhat turned out of the wind, it was producing about 60 amps at 30mph. So, if I add weight to the tail it will produce much more, but as it is it's less stress on my tower. I also think that the majority of the power I see from it will be in winds below 20mph so this is the area I'm concerned about.

Above is a good picture of how we test them on the truck. [Click Here](#) to see a brief movie of the truck test!

In this picture I'm tying it up so we can more easily navigate the trees on our driveway for the ride home. This picture does give a good idea of how the furling system works, as the wind puts force back on the blades it makes the machine want to fold up like this - but in order to do so the tail must be raised! So the furling system is a balancing act between the force back on the blades, and the weight of the tail.

This is how it looks now up on my tower with the blades cut down to 9 foot diameter and the larger tail. It's been doing well now for a few days, starting to turn below 5mph and definitely making power. It's definitely an improvement over past machines. I notice significantly less line loss due to the 3 phase power, and it generates in much lower windspeed because it turns much easier. To do it over again, changes I'd make would be a still larger tail, and/or... cut down the prop size maybe a bit more. I'm pleased with it though and will probably leave it as is. Can't wait to make the next one!

# Water Pumping

Water pumping is a wonderful use for alternative power technology. Even if your ranch house is powered by conventional power from the grid, what about getting water to your cattle on the back 40? Windmills have been used for over 100 years for this purpose, but other alternative power methods are effective too. Really, ANYTHING is better than pumping water by hand, but gas powered generators are the worst of the bunch.

First, a word about **your well pump**. The standard well pump your well drilling company will install is usually a 220 volt AC model. If they tell you, "don't worry, your solar system will run this just fine if you add a 220 volt transformer," DON'T believe them! This has been a big problem with a certain well pump company in our area. Standard 220 well pumps are very inefficient, and the required 220 transformer wastes lots of power. A huge Trace 2500 watt inverter can only sometimes power one of these behemoths--even if the pump IS able to start, all your lights may dim every time the well pump kicks on, resulting in premature inverter failure. We recommend you avoid this sort of system if at all possible. The only solution if you have this sort of well pump is to run a generator to fill your cistern, or replace the pump with a variety suited to remote power. And if you have a remote power system, why be dependent on a gas powered generator for all your water? It will eventually leave you stranded without water, and usually at midnight when its 20 below zero outside. **Spend an extra 1000 bucks on a 12 volt deep well pump or a super efficient 120 volt AC model.** You can pump with your regular remote power system, your generator will last longer, and if it won't start when its 20 below zero, you still have water.

**The single 75 watt solar panel shown here pumps water to my house from a shallow spring.** It moves the water at 75 gallons per hour in full sun. The total lift to the house from the spring is 35 feet, the total horizontal distance is 480 feet. The pump is an inexpensive Shurflo pressure pump, controlled by a Photocomm controller and Linear Current Booster (LCB). There are float switches at the spring and at the cistern underneath the house. **No batteries are used**, but I installed jumper cable lugs at the pump so that I can hook up my truck battery to the pump for times of no sun (our cistern is only 150 gallons). This system has run for over a year now without any maintenance.

**In any remote water pumping situation, avoid using batteries if AT ALL possible!** Your water storage tank should be your battery--that is, your

system should pump water fast enough and your cistern should be big enough that you can last through as many days of no sun or wind as necessary. Batteries are a waste of money and resources in a remote water pumping system, unless you are planning some sort of specialized application.

**Home water pressure pumps**--For pressurizing your tap water, the best choice is a 12 volt DC pressure pump. These are inexpensive, efficient and reliable, and the pressure settings for turning on and off are built-in. They cost from \$40 to \$200. 120 volt AC versions are very inefficient, using far more power than necessary.

[Click here for information on our solar water system.](#) It uses one solar panel to pump spring water 480 feet horizontally and 45 feet vertically to our cistern under the house.

### Power for Water Pumping

- **Solar**--Solar technology is very well suited to pumping water, even more so than the traditional windmill. A typical system includes one or more solar panels, an efficient 12 volt DC pump, a controller (with float switches), and a "linear current booster" (more about this later). As long as it's daytime and the float switches show that the water source is not empty and the cistern in the house is not overflowing, the pump will run. The linear current booster allows the pump to run even if it's cloudy out.
- **Wind**--The traditional windmill is still useful technology. The pump is directly coupled to the wind generator. The only problem comes if there is no wind for a few days at a time, and with maintenance. The leather seals on this sort of pump wear out and require replacement. The Bowjon windmill system uses pressurized air to pump water, and requires very little maintenance. It can also be used to generate power. Other systems have been built using an electric wind generator, linear current booster, and pump, as described in the Solar section above.
- **Water**--Yes, water can be used to pump water. The device involved is called a "water ram." It uses your local stream's water pressure to move a fraction of the total stream flow uphill--as much as 30 times the total fall. Water rams can be purchased, or built at home with PVC pipe and valves. Look for more information on this here in the future.
- **Gasoline**-- A waste of resources. Avoid it if possible.
- **Hand Pumps**--Better than not having water, if you have no resources available. Or if you can get your kids to do it. Different hand pumps are available commercially (my grandma had one), or pumps can be constructed than run on foot power instead of hand.

**Linear Current Booster (LCB)**--This device trades voltage for extra current to start a pump. Electric pumps take more power to start up than they take to run, and the LCB takes care of this problem. It will allow your pump to start and run even on cloudy days.

# Dan F's Solar Water Pumping System

[Para Español, traducción de Julio Andrade.](#)

**This solar water pumping system has been in service for over a year with zero maintenance. It supplies water from a shallow spring to our house, and is sufficient for a family of 4, plus dogs, cats and plants. Many principles of good system design were incorporated--the system has been a real time saver for our family. Previously, we filled our cistern with garden hose and a gasoline-powered pump!**

## **System Specifications:**

- Total Vertical Lift: 45 feet
- Total Horizontal Distance: 480 feet
  - **No batteries used!**
- Power Source: one 75 watt solar panel
- Pump: 12 volt DC Shurflo pressure pump
- Controller: Photowatt with limit switches and LCB

- Float switches were installed at both the spring and the house cistern. This way, if the spring runs dry or the cistern is full, the controller will shut off the pump.
- The controller's built-in Linear Current Booster (LCB) allows the pump to start up even on cloudy days. Without an LCB (solar panel hooked directly to pump) it would take full sun to start.
- All pipe is buried 4 feet deep. We added 2 extra runs of pipe so we can switch over if one run freezes.
- The pump is always under forward pressure, since it is in a valley below the spring. If the pump ever runs dry (due to feed pipe rupture or float switch failure at the spring), an air bleed valve was installed at the output side of the pump. Otherwise, air bubbles will make the pump cavitate and not work. This process was required upon initial pump installation, too.
- We added + and - lugs at the top of the "manhole" where the pump and controller are located. This way, if we are without sun for a few days, I can drive my truck down there and hook up jumper cables from the truck battery to fill the cistern.

**UPDATE! Both float switches failed during February 2001. That's only 1 1/2 years of life, and the switches cost \$40 each! This caused me considerable consternation--the root cellar was flooded when the cistern switch failed. The other switch up at the spring works only part of the time.**

**NEW UPDATE 12/03/2003 -- The manufacturer of the float switches, SJE Rhombus, found these pages on the internet, and contacted us out of the blue recently. They informed us that we are using the wrong model of float switch--the controller only switches a tiny amount of current in the float switches, but the model we got is made only for high-power loads that arc across the contacts. The retailer who recommended this model to us and who we purchased them from has been bought out by another company. *SJE Rhombus is sending us 2 new float switches of the proper kind, free of charge. We thank them for GREAT customer service!***

**[CLICK HERE](#) to see the details of why they failed, the reason the manufacturer does not recommend this model for this application, our cheap, home-built replacements, why THEY failed, and information and specs on the new switches that SJE Rhombus sent us that ARE made for this application!**

# Sistema Solar de Bombeo de Agua de Dan F

---

Este sistema ha estado en uso por más de un año sin requerir mantenimiento alguno. Lleva el agua desde un manantial de poca profundidad a nuestra casa y atiende una familia de 4 personas además de algunos perros, gatos y jardín. Se han respetado buenos principios de diseño que le ahorran mucho tiempo a la familia. En el pasado nuestra cisterna era llenada via una manguera con una con una bomba de gasolina.

## **Especificaciones del Sistema:**

- Elevación a la vertical: 15 metros
- Distancia horizontal: 150 metros
- **No se emplean baterías**
- Fuente de poder: Un panel solar de 75 vatios
- Bomba Shurflo de presión de 12 VDC

- Controlador Photowatt con interruptores de límite y LCB (Amplificador Lineal de Corriente)
- Interruptores flotantes fueron instalados en el manantial y en la cisterna. Si el manantial se seca o la cisterna se llena el sistema se apagará.
- El LCB hace que la bomba arranque aún en día nublados. Sin él el arranque sólo sería posible en día soleado.
- Toda la tubería está enterrada a 1 metro de profundidad. Se han tendido dos circuitos de tubos para el caso de que una se congele.
- La presión sobre la bomba es positiva, ya que está en un valle debajo del nivel del manantial. Si la bomba se secase (Por rotura de la tubería o fallas de los interruptores flotantes) se instaló una válvula de purga de aire a un costado de la salida de la bomba. Así evitamos cavitación de la bomba.
- Añadimos terminales + y – en el sitio de ubicación de la bomba y el controlador. Si no llegara a haber sol por varios días podemos alimentar el circuito de la bomba con la batería de mi camioneta.

**¡ACTUALIZACION!. Ambos interruptores fallaron en Febrero de 2001. Han transcurrido sólo 1 ½ años y los interruptores cuestan \$40 cada uno. Esto nos causa mucha consternación. El piso del sótano está inundado. El interruptor del manantial sólo trabaja de vez en cuando.**

**NUEVA ACTUALIZACION 3-12-2003. El fabricante de los interruptores, SJE Rhombus encontró estas páginas en Internet y se puso en contacto con nosotros. No informaron que estamos empleando el interruptor inadecuado – el que usamos sólo está manejando cantidades mínimas de corriente y el nuestro está diseñado para cargas completas. Nuestro distribuidor fue adquirido por otra empresa. *SJE Rhombus nos enviará dos interruptores nuevos gratis. Les agradecemos su excelente servicio post venta***

MAGNETS

# Failed Float Switches and Home-Built Replacements

[Para Español, traducción de Julio Andrade.](#)

**These things cost \$40 each and failed after only 1 1/2 years! The reason why? The retailer sold us the wrong switch for our application....read on! The manufacturer, SJE Rhombus, has sent us 2 replacement float switches of the right kind, free of charge. Thanks for the great customer service, SJE Rhombus!**

I was quite distressed in February 2001 when these expensive commercial float switches failed. They are the standard variety found at farm supply stores; They were recommended and sold to us by a retailer who obviously did not know what they were talking about, and have now been bought out by another company.

The one on my cistern failed completely, letting the solar pump overflow the tank and flood my root cellar. The one at the spring continued to correctly and turn off the pump when the water level got low (whew...otherwise, if the pump sucked air from the spring instead of water, I'd have to remove all the fiberglass insulation layers, climb down in, and bleed the air from the line). But the switch also started failing to reset itself...so I'd have to hike up the hill to the spring through 3 feet of snow, open the spring house and manually shake the switch to make it reset. What a drag.

We cut open a switch to see why it failed

### **Why they failed (we think)**

Everything appears fine with the inner mechanism of the switch. No corrosion was noticed on the contacts. These switches were originally designed to be used for the direct switching of 120 volt AC pump loads. In my application, they are only switching a miniscule amount of power from the pump controller box instead of the whole load. We are guessing that the switch design depends on a tiny 120VAC arc to jump between the contacts every time the switch triggers.

**UPDATE 12/03/2003 --why they failed, from the manufacturer--**  
the float switch manufacturer, SJE Rhombus, has sent us 2 new replacement float switches, free of charge. They found this page on the internet and contacted us out of the blue. Our guess was correct -- the model of float switch we used (the PumpMaster) **REQUIRES** a 120vac load to arc across the contacts -- that's what keeps the contacts clean.

With the controller system I am using, only a tiny amount of DC current is used for the float switches to control the controller/LCB box. This tiny amount of current does not arc, and that caused the switches to malfunction. The replacement switches they are sending us free of charge are called the MicroMaster, and are rated for this application.

Thanks again to SJE Rhombus for great customer service.

### **Our Do-It-Yourself Float Switch**

We decided to try a simple, homebrew version. My home-built version uses a well made of 1 1/2 inch PVC pipe with a cap on one end. Holes

are drilled in the end to allow water in, but not let the float drop. The float is just a pill bottle super glued shut with a strong magnet glued to the top. The switch is a glass-encased magnetic reed switch that triggers when it is about 1 inch from the magnet. It is sealed inside a plastic soda straw and inserted through holes drilled in the PVC above the top of the tank (so the switch never touches water). I drilled a series of holes to allow easy calibration of where the switch turns on and back off by moving the reed switch up and down.

The finished float switch

## Magnetic reed switch

Float with magnet glued on top

So far the new switch has been very reliable. It took a bit of adjustment to get the magnet to trigger the reed switch without sticking to it and holding the float up when the water level dropped. All in all this was about a 2 hour project, including epoxy drying time. Total cost was ZERO for me, since all the parts were from my junk bin. New, the reed switch would cost less than a dollar, same for the magnet.

**Update 12/03/2003 --- well, after 2.5 years of service the home-built float switch finally failed. We actually received a couple emails from experts predicting that they would fail, and why. They were right! The reason -- after all those cycles, the big neo magnet in the float magnetized the tines of the reed switch. Eventually, after many cycles, the magnet now has to be much closer to the switch to make it trigger at all and shut off the pump. *The fix was easy -- I just replaced the reed switch at a cost of about 30 cents!* These homemade switches are still a good, cheap way to go -- just be sure to monitor your system and make sure everything is working right so you don't flood your water cistern room!**

# Power Systems

---

## How Cheaply Can You Get Started in Alternative Power?

We get asked that question a bunch. The cheapest, most basic system possible consists of simply an old solar panel and a truck battery, plus some Romex! That's how everyone up here at Otherpower got started in solar power, too. But for a higher comfort and convenience level, check out [Ward's Cheap Solar Page](#)-- We wanted to see how cheaply it could be done, and his *really nice* little AC/DC system came in at under \$800.

---

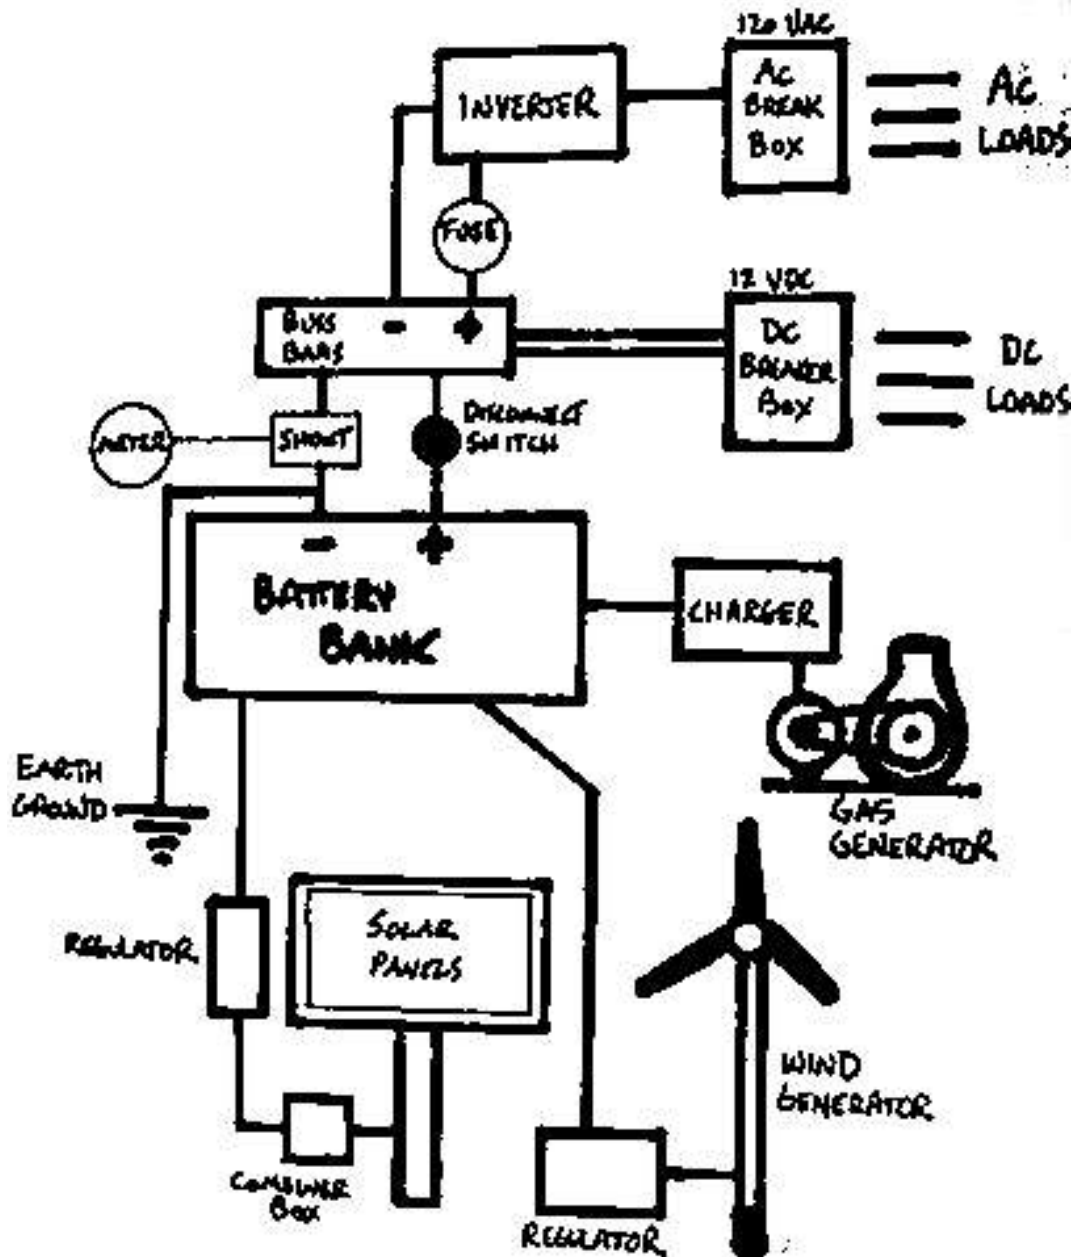

Here's a basic rundown on how a remote power system functions, and a diagram of a typical system. Click on any highlighted keyword to jump to a page about that subject.

First, your electricity is produced by [solar panels](#), [wind generators](#), [hydro generators](#), and/or a [gasoline generator](#). This electricity is usually in the form of 12 volt direct current (12 VDC). Some gasoline generators produce 120 volt alternating current (120 VAC), and require a [battery charger](#) to convert this to 12 VDC.

Your electricity then flows to your [batteries](#) through a charge controller, with a [meter](#) in the line to tell you what's happening with the system. The charge controller shuts off the charging current when your batteries are full.

When you run 12 VDC lights or appliances, the current flows from your batteries, through a meter and fuse box to your appliance. Devices that run off of 120 VAC take their power from an inverter, which converts the 12 VDC to 120 VAC. Inverters are available that can power your whole house through regular AC wall outlets, or in small versions that can run only one device at time.

Below is a diagram of a sample power system:

*This page is still in progress...we have LOTS of information to add!*

# Ward's Cheap Solar Power System

We've been asked the same question over and over, ever since Otherpower.com was created: 'How cheaply can I build a solar power system?' The answer, of course, is 'it depends on what you want to run!' If you want to run a normal house in town off of solar, you're in for a investment of tens of thousands of dollars, thanks to a house that's almost certainly full of power-wasting, inefficient lights and appliances. But if you can start from scratch...that's a different story! The awesome little 7-sided log cabin Ward bought has *never* had an electrical system...in fact it was built back the 1960s using NO POWER TOOLS of any kind. The builder didn't believe in power tools...It's located only a mile from Otherpower.com headquarters.

**Total cost of Ward's cabin solar power system :  
Less than 700 Bucks!**

Ward thought carefully about what electrical appliances he needs to run at his new home. It's important to do this before planning and purchasing your power system! He's a bachelor, but still

wanted enough 'stuff' for a comfortable lifestyle. Here's what he came up with for essential items:

- **Lighting**--all lights to be high-efficiency. 120 VAC compact fluorescent (CF) lighting was chosen because bulb cost is so cheap compared to 12VDC CFs (\$50/ea for 12VDC, \$9/ea for 120VAC)
  - 120 VAC CF room light, 9 watt
  - 120 VAC CF light over kitchen counter area, 6 watt
  - 12 VDC halogen light in bedroom, 20 watt (this way he can turn off the inverter before bed to save power, and still have light to get back to the bedroom). Plus, halogen lights are better for reading
  - 120 VAC Halogen outdoor spotlight, 50 watt....there's bears, cougars, and rogue moose up here all the time. Better to see them first when you have to visit the outhouse at 3 AM!
- **TV/VCR**--We have about zero TV reception up here...so it's hard to waste much power on television. So Ward bought a little 13 inch color TV, rated 54 watts (though in normal use it draws only about 25 watts), and brought up his VCR from town. Winter nights up here are long and dark, and movies can save you from serious depression!
- **Boom Box**--Get the CHEAPEST one available. Why? Because *Fancy stereo/TV equipment that lets you turn it on and off with the remote will draw power even when it's turned off!!!* The inexpensive model he bought has a hard-wired on/off switch, and wastes no power (called a 'phantom load') when off.
- **Future Needs**--always remember to factor these in when designing a system! Eventually he might put in pressurized water (with a 12VDC pressure pump), more lights, etc.
- **Non-Electric Appliances**--these can save you lots of money on solar panels and batteries. The 'downtown' versions suck up electricity fast, but these simple alternatives are far more efficient.
  - **Refrigerator**--Propane, RV size. Less than \$200 used from an RV dealer, uses very little propane so it can be run off of 40 lb. portable tanks. Ward's road is too rough for propane trucks.
  - **Heating**--Woodstove, from Harbor Freight.
  - **Cooking**--Propane cooktop, used from an RV dealer.
  - **Water Heating**--A big pot of water on the woodstove!
  - **Plumbing**--Maybe a pressurized water system in the future, but just a sink with an outside drain and 5-gallon buckets for now.
  - **Outhouse**--The outhouse works just fine, is not subject to mechanical breakdown, and uses no electricity. TIP: During winter when it's 20 below zero outside, keep the toilet seat in your house near the stove, and bring it with you when you have to visit the outhouse!

**South Side of Cabin Showing Solar Panel.** Shading is from trees...Ward's planning on some chainsaw work, both for solar exposure and wildfire protection! That's DanF's dogs, Kodiak and Tarmac, in the picture.

## System Components

- **Battery Bank**--4 golf cart batteries. 6 VDC, 220 amp/hours, only \$45.99 each from Sam's Club. Wired in series and parallel, these give 440 amp/hours of storage. That's more than enough for the minimal loads in the cabin, especially when you consider that the owner is away from home at work during the day, giving the system time to charge back up.
- **Solar Panel**--BP 75 watt, from an internet distributor. \$310 new, plus \$20 for shipping. Wired to controller and battery bank with #10 Romex.
- **Solar Panel Mount**--Home built from 1 inch aluminum angle, adjustable for summer and winter positions. About \$20 total for aluminum stock, nuts, and bolts.
- **Charge Controller**--An industrial model from Jade Mountain, rated for 16 amps (to provide room for adding more solar panels later), and cost only \$62. Ward had to buy 2 fuse holders and 20 amp fuses, mount this controller on a home-made aluminum heat sink and build a cover himself....but for the price he'll be able to add 2 or 3 more solar panels without a new controller.
- **Inverter**--A 350-watt Wagan from Harbor Freight, only \$40. Includes fuse on main power

cable and overload shutdown. DanB has used one of these for a year, heaping abuse and neglect on it, and it's performed like a champ. The only drawback of this model is that the fan is on all the time, and produces a little noise. Ward plans to turn the inverter off at night, and during the day while he's at work.

- **Metering**--Cheap digital multimeter, only \$10. Not real accurate, but enough to determine general battery state of charge. Plus, the controller has an LED to indicate full charged condition.

## TOTAL SYSTEM COST: Less than 700 bucks!

Battery Bank -- 4 Golf Cart Batteries

Power Panel with Inverter and Charge Controller

BP 75 Watt Panel

---

**It would be impossible to power a home down in town with a system of this size...but this design goes to show that if you are conservative with your power use, realistic with your expectations, and thrifty with your equipment purchases, you can power up a home for under a grand. Just don't try to plug in that damn air conditioner!**

# Building a wind generator from scratch

Mostly...

Chuck Morrison ©2001,2002,2003

## Disclaimer

This publication is **not** a manual for constructing your own wind turbine. If you do so, you are on your own and incur all the risks yourself. Information included here is incomplete and may be misleading. You owe it to yourself to do your own research and understand these subjects thoroughly before undertaking such a project. I would suggest that you look into purchasing a prebuilt wind generator and save yourself a lot of time and money. It will still be a great adventure and our wind enthusiasts and entrepreneurs need your support. Please note that these documents are being created as I go along. Thus there will be information that is based on conjecture and inexperience. This means that some of it will be pigheadedly wrong, just plain not true or only partially true.

## Web Sites of the pros

For great information and a look at the old country see [Hugh Piggott's web site](#). My ancestors came from very near where Hugh lives now (is the wind the real reason the Morrisons left Scotland ?) .

## Why do this crazy thing ?

I undertook building a wind generator simply because I wanted to. I'd been fascinated by them since the mid 1970s when I became aware of them through my reading about alternative energy sources. The romance of it struck a chord that has never stopped ringing. It was because of the challenge of learning new things and it seemed like fun, so I started. It has turned out to be very educational and very time consuming. It is an ongoing project that has yet to be completed. I include this narrative and photos because I didn't find much like it on the web and thought others might like to share the experience vicariously.

U.S. Patent Number 6,616,402 and other patents pending including international (PCT) <http://www.uspto.gov>

Six rotors give many times the power of a single rotor turbine of the same diameter...

We are currently funded by The California Energy Commission:

[http://www.energy.ca.gov/contracts/smallgrant/2003-02-21\\_awards\\_02-02.html](http://www.energy.ca.gov/contracts/smallgrant/2003-02-21_awards_02-02.html)

Doug Selsam with 3 kW prototype, utilizing seven 7-foot diameter rotors, nearing completion at ground level.

View from region of generator - 3 kW prototype Selsam Multi-rotor wind turbine partially assembled on stand at ground level

Parts is parts...hub, diodes, disk brake assembly, monoshock, alternators, and associated components

Experimental Prototype Selsam Wind Turbine with four 4-foot diameter rotors (left).

Selsam Turbine with four 4 foot diameter rotors furling to a horizontal configuration at about 30 mph, still producing full power. Downwind rotors are protected by the slipstream of the upwind rotor, limiting power production and thereby protecting from a runaway situation which would burn out the generator. This stops what would otherwise be a geometrically climbing power curve and begins to level it out above the rated wind speed. Conventional "1000 watt" turbine can be seen furling sideways in background, "cringing" at the force of this strong wind, and consequently producing very little electrical power when the wind speed is above the rated speed, where the best opportunity for producing power actually exists.

Power curves for a Selsam Multi-Rotor Wind Turbine with four 5 foot diameter rotors show a solid 1000 watts average power output at 28 - 29 mph. This is at 5000 feet elevation in Tehachapi, CA, where the air is about 14% thinner than at sea level. Most "1000 watt" turbines will actually average only about 600 watts at this windspeed, even if the data is corrected for altitude. Notice that at 35 mph, where most small wind turbines are producing very little power due to sideways furling, we are producing 1600 average watts - 2000 average peak watts.

This "1 kilowatt" model produces 1200 watts at 33 mph  
We see peaks of up to 1400 watts at 33 - 34 mph  
New highest peak 1686 watts at ~34 - 35 mph!

We're calling this one the "**Quadrunner**" - We're pleased to see this prototype running very smoothly during the first few months of preliminary testing. Utilizing four 45" diameter sets of *Air-X* blades from *Southwest Wind Power*, placed approximately 7 feet apart, it's up and producing power during the first few weeks of operation. Preliminary readings show 800 watts at 27 mph, 1000 watts at 30 mph, and 1200 watts at 33 mph. We've seen **peak** output of **1400 watts** at ~34 mph, and **1686 watts** at wind speeds of ~35 mph. The generator is a dual-shaft 1 hp PM DC motor specially fabricated for us by *Leeson Electric*. In high winds, we are pushing this motor/generator over its designed power rating, as we had hoped we would, but it is well-cooled by the flow of wind, so it can handle the extra amps. The filament-wound carbon fiber driveshaft for the compound rotor is from *Advanced Composites Products and Technology* in Huntington Beach, CA. The frame is welded steel, as per the "heavy metal" design philosophy. Note that we are now utilizing a tail for quicker response to changes in wind direction. It is tracking perfectly. (Note: U.S. and International Patents issued and pending)

Here's the "Quadranner" beside a Whisper H-40 from SWWP, which is a bit further from the camera, at the testing facilities of Windtesting.com. According to Brent Scheibel, founder and Chief of Operations at

Windtesting.com, the two turbines are generating comparable amounts of power. The new "Quadrunner" has a much faster rotational speed (RPM), and so far makes a pleasant sound - not too loud either.

Above is a rendering of an 8-rotor model having an offset angle in the horizontal plane, Rendering by Michael Sanchez of Dreamworks, the movie animation company.

To The left, a 3-rotor experimental Selsam Multi-Rotor Turbine unit is seen being tested at the facilities of Windtesting.com in Tehachapi, CA. It produces an average of 1200 watts at 30 mph at 5000 feet elevation.

Below is an early prototype that was able to produce 400 watts using modified 18" diameter wooden model airplane propellers as rotors.

U.S. Patent Number 6,616,402 and other patents pending including international (PCT) <http://www.uspto.gov>

Rendering of a Selsam Multi-Rotor Wind Turbine by Michael Sanchez of Dreamworks Animation (above).

**Ready to Rock** - a "condensed" version shown for the photo, with a 3/4 hp generator, held by the inventor, Doug Selsam.

**Parts that will were used to assemble an early version of an offset axial flow multi-rotor semi-horizontal**

Here are the blades of a 20 inch diameter turbine, that produces about half a kilowatt. They will be mounted on a shaft that projects for a long distance forward, and backward, at an angle from horizontal, so that the wind encounters the rotors like a stairway. Each additional rotor brings more power. The combined output from all these small rotors really adds up.

This Turbine Utilizes Massive Parallel Wind Processing (MPWP) to maximize the wattage generated for a turbine of a given diameter.

## **April 2002 Pictures of the Selsam Wind Turbine... The Sky Serpent Flies in Tehachapi, Calif.**

---

The New Turbine is flown in Tehachapi, mounted to a Tower by Brent Scheibel, of General Electric Wind and owner of WindTesting.com

Well, it's up and running, with data being logged. Not doing too badly on the first day. The winds are averaging in the teens, sometimes high teens, gusts in the low 20's. The faster it turns, the smoother it runs. With 18" diameter rotors, we're putting out a varying current running between 100 and 200 watts. At 30 mph we get about 400 watts.

Brent Scheibel, WindTesting.com, His wife, Teri, with their dog Ezra, and Doug Selsam, windmill is seen in background

This is the test team, Brent Scheibel, who handles Anemometry over at Zond / Enron Wind - now General Electric Wind Energy, and runs Windtesting.com, His wife Teri, their dog Ezra, who barks at windmills, and Doug Selsam, the inventor. Brent really knows his windmills, from the biggest to the smallest, and handles large towers with ease.

## **Balanced, High-Output, Rapid-Rotation Wind Turbine**

U.S. and International Patents Pending  
Douglas Spriggs Selsam

*Fig. 1*

An illustration from pending U.S. Patent application 09/9\*\*\*\*\*:  
"Balanced, High Output, Rapid Rotation Wind Turbine"

Doug Selsam

**Currently Used Technology:**

Current wind turbines are a refined version of a 1000 year old design, originated when cast iron was a high tech material. These wind turbines suffer from the following problems, challenges, and drawbacks:

1. **Inordinately heavy rotor weight** since larger rotors become disproportionately heavy.
2. **Inordinately slow blade rotation** since larger rotors turn more slowly.
3. **Inordinately robust drivetrain** required due to high rotor mass & high torque of slow rotation
4. **Gearbox required** due to slow rotor rotation, since a generator needs to turn faster.
5. **Not self-aiming** – special apparatus required to maintain a heading into the wind.

6. **Inordinately complex mechanisms** required to **prevent damage** in gale force winds.
7. **Excessively robust support structure** required to hold up all that excessive weight.
8. **Excessive maintenance costs** are required to service this inordinately complex machinery.

**NEW** Our Multi-Rotor technology neatly solves **all** of these classic problems in wind turbine design. Our new design, now proven in small models, combines the power of **multiple smaller rotors** mounted to a **single elongate driveshaft**, to give the **same power** as a single larger rotor, with **less cost, weight, and complexity**. Smaller rotors **weigh less** for the swept area, and **turn faster**, thereby **dispensing of the need for a gearbox**. Our new design is naturally **self-aiming**, requiring no dedicated apparatus to achieve this, and is **generally simpler**, having **fewer moving parts**, requiring less maintenance. We expect to validate this revolutionary **California design, using multiple rotors coupled to a single elongate shaft** as being able to harvest **more wind energy at less cost** than current models which use only a single rotor.

**The car headlight at Doug's feet is 50 watts** The rotor size is only **fourteen inches!** Wind speed in the 20's mph (more rotors produce more power)

**Proprietary position - Our Unique Design:**

**This entirely new class of wind turbines was developed in California.**

Currently funded by The California Energy Commission

[http://www.energy.ca.gov/contracts/smallgrant/2003-02-21\\_awards\\_02-02.html](http://www.energy.ca.gov/contracts/smallgrant/2003-02-21_awards_02-02.html)

U.S. Patent Number 6,616,402 and other patents pending including international (PCT) <http://www.uspto.gov>

**NEW**

Our new proprietary **California** design utilizes a **multiplicity of rotors** mounted at spaced intervals along a single elongate driveshaft. This **lightweight yet strong carbon fiber shaft** is aimed into the wind, with the **nose pointing slightly downward, so that each rotor encounters fresh, undisturbed wind**. The shaft is **balanced** fore and aft about a centrally located generator, which it **directly drives**. This assembly is mounted so that the center of aerodynamic drag is slightly downwind of an azimuthal pivot point, making it **conveniently self-aiming** while using no extraneous device to achieve this self-aiming behavior.

The result is a **lighter, faster-turning, self-aiming, simpler, more reliable wind turbine**, having **fewer moving parts**, using **substantially off the shelf components**.

The inventor, Doug Selsam, testing a small prototype of an entirely new class of wind turbines

---

## What Makes Our New California Class of Wind Turbine Better? A Detailed Explanation of the Advantages:

First, let's look at some of the problems with wind turbines today – then see how our design solves these problems.

Existing Wind Turbines, using the modern "Danish Design", based on the "Old Dutch" design, have made great advances, and are indeed awesome machines, yet suffer from certain classical challenges. We will address our solutions to these problems one at a time:

### 1. Problem # 1 – Inordinately Heavy Rotor Weight - Larger Rotors (propellers) are heavier for the amount of wind captured:

The volume, and hence the **mass**, of a rotor is proportional to the diameter **cubed**, while the swept **area** is only proportional to the diameter **squared**. (typical volume/area relationship for any solid, 3-D object) This means that the amount of wind a rotor can capture, in relation to its mass, is **inversely** proportional to rotor diameter. In other words, if a rotor's **diameter is increased by 10 times**, the **area** (and hence the amount of wind captured) is **increased by 100 times** (good), however, the **mass has increased by 1000 times!** (bad) The **larger** turbine can only capture **a tenth** as much energy compared to its mass! This simple mathematical fact tends to limit the size of current single-rotor wind turbines. (Note that this same effect of scale is the reason why **an ostrich can't fly**, while a small **flock of geese**, weighing the same amount in total, can easily undergo **transcontinental migrations**, and a **hummingbird**, whose name we borrow for our smallest model, **can easily hover**.) The largest turbines have rotor diameters of well over 100 feet. These monstrous structures must be made to perform for many years, and have many problems with stress and fatigue. The giant blades are notoriously difficult to manufacture **and ship**.

**Currently used Solution: Keep making larger** and larger single-rotor turbines anyway, regardless of the inherent problems of scale, because nobody has thought of a better solution.

**OUR SOLUTION: Smaller Rotors weigh less per unit of swept area.**

We mount **multiple, smaller rotors**, at spaced intervals along a **very elongate, carbon fiber composite driveshaft**. (The shaft is at a slight angle from the wind direction so each rotor gets its own fresh wind.) Multiple small rotors **weigh much less** than a single larger rotor sweeping an equivalent total area, can be much **lighter in construction**, and are far **easier to produce**. They **consume less material, cost less**, and are **much less subject to material fatigue**.

### 2. Problem # 2 - Slow Rotation – Larger rotors turn too slowly:

For a given wind speed, the rate of rotation (RPM) of a rotor is inversely proportional to rotor diameter, meaning that larger rotors turn more slowly. The largest turbines rotate at less than one revolution per second. Generators, on the other hand, require a faster rate of rotation (typically 1800 - 3600 rpm). There are two classic solutions to this problem, both of which add cost, weight, and complexity to a wind turbine:

**Currently used Solution #1 to remedy slow rotation – Add a gearbox:** A gearbox can be used to convert the slow rotation provided by a large rotor to the faster rotation required by a generator. This solution is **heavy, expensive, noisy** and introduces a source of **friction, wear, and unreliability** to a wind turbine. Reliability is of paramount importance in a wind energy installation. Gearboxes consume **about 20% of the cost** of current wind turbines.

**Currently used Solution #2 to remedy slow rotation – Use a specially-built, low speed generator or alternator, having many more poles than usual:** Small to medium-sized wind turbines often feature specially-built alternators having many extra poles, to generate useful power at a slower rate of rotation. This strategy allows the alternator to be directly driven by the rotor, saving the wear, expense, and power loss introduced by a gearbox. Unfortunately, this strategy has its own drawbacks, being:

- only useful up to a certain size;

- heavy, adding weight to the installation and therefore requiring a more robust support structure;
- wasteful of materials, since the alternator must be much larger;
- expensive, since the specially made, slow speed alternators are not only larger and heavier than they would otherwise need to be, but must be specially fabricated, rather than taking advantage of existing, standard, off-the-shelf types of generators and alternators. Such special generators are considered as more expensive initially than using a gearbox, but with less maintenance costs in the long term.

**OUR SOLUTION: Small rotors rotate faster than larger ones**, so for small to midsize turbines of our new design, a **conventional generator or alternator** can be **directly driven** within a proper rpm range. Multiple rotors give more power for the same diameter than a single rotor. Our design needs no gearbox. (Very large turbines of our new design may utilize some gearing, but, due to faster rotation, it need be **much** less robust for the power generated than current models require.)

---

**More Rotors = More Power: Multiple Rotors deliver more power, at a faster speed, for less weight**

---

### **3. Problem # 3 - Drivetrain must be inordinately robust - The aforementioned high rotor mass and slow rotation require the supporting drivetrain to be much stronger than the generator's actual driveshaft:**

The **robustness** required of a driveshaft transmitting a given amount of power is **inversely proportional to rpm**. A typical wind turbine drivetrain has a very heavy shaft to support the single, ponderous, slowly-turning rotor, and to transmit its power to the gearbox. The slowly turning portion of the gearbox must be similarly robust. Not only is it transmitting a large amount of power at an excruciatingly slow rate of rotation, but this low speed driveshaft and its bearings are supporting the huge rotor in a non-balanced, projecting, cantilevered manner.

As the rotational speed increases within the gearbox of a conventional wind turbine, the gears and driveshafts become less robust. The output shaft of the gearbox - the quicker-turning shaft that **actually drives the generator** - is **much thinner** and less massive than the input shaft driven by the single giant rotor.

**Currently used solution: Designers have no choice** but to make the rotor end of the drivetrain much more robust than the generating end.

**OUR SOLUTION: A Faster-Turning Driveshaft can be less robust for the same power:** Our higher speed drivetrain need not be more robust than what is required to drive the generator, and to support the multiple, lightweight rotors.

**Also, Our New Design is Better Balanced: Our Generator is located approximately at the center of our driveshaft.** Our elongate carbon fiber composite driveshaft with its multiple small rotors, weighing much less than a single large rotor sweeping an equivalent area, is supported near its midpoint **by the bearings of the generator**, and so is also approximately **balanced about these bearings**, fore and aft, rather than being cantilevered in one direction, and needs no other bearings.

Fig. 118

An easy 200 watts in about a 20 mph wind or so, lighting the four 50 watt car headlight bulbs you see at Doug's feet. We get much more power than this in higher winds. This kind of power output is unheard of for an 18" diameter horizontal axis windmill! – the secret? Multi-Rotor technology, made possible by the strength of modern carbon fiber materials.

This rotor is really thirteen rotors harnessed as one, giving an order of magnitude (~10 times) more power than a single rotor design of the same diameter.

In stronger winds this prototype blows out these lights like flashbulbs - poof!

---

4. **Problem #4 - Special, dedicated apparatus required for directional aim, adding mass and complexity:** Current wind turbines are **not self-aiming**.

**Currently used Solutions:**

1. A **tail** consisting of a vertical fin projects downwind from a central pivot point, forcing the single rotor to aim into the wind. Used for smaller to midsize turbines.
2. An **active mechanism**, comprising a wind direction sensor, a microprocessor, and powered, heavy-duty, gear-driven aiming machinery constantly adjusts the aim of the huge rotor to keep it pointed into the wind.

Either of these **currently used solutions** to the aiming problem adds **mass, complexity, and cost** to the installation.

**OUR SOLUTION: Self-Aiming Behavior: Our machine simply locates the center of aerodynamic drag downwind of an azimuthal pivot point.** This may be accomplished by either having the driveshaft slightly offset to the aft direction, or by having the entire assembly offset slightly downwind from a master pivot point. 6 rotors upwind and 7 rotors downwind has been working well so far. **The machine eagerly seeks the wind, and stays headed windward.**

---

5. **Problem #5 – Inordinately complex mechanisms required to prevent damage in gale force winds – any wind turbine that is efficient at gathering wind will be in danger of damage should that wind reach excessive velocities. Some means must be provided to prevent such damage.**

**Currently used Solution:** Current wind turbines require either a special mechanism to "furl" the single rotor (turn its aim sideways to the wind) or a means to adjust the pitch of the blades, to prevent damage

in storms. This adds further to the cost and complexity of the installation.

**OUR SOLUTION: Simple protection from damage in excessively high winds -**

Our new design is **resiliently mounted** at a slight angle from horizontal. In high winds, the resilient carbon fiber composite driveshaft is pushed to a more horizontal position, placing the rotors directly in line with the wind and with each other, so that upwind rotors act to shield downwind rotors (wind shadow effect). This protects from overspeed conditions.

**6. Problem # 6 Excessively Robust Support Structure Required:** All of this inordinately heavy equipment, including the disproportionately massive blades, must be installed and supported at a sufficient height to encounter strong winds. The **heavier** this equipment is, the **more robust** must be the support structure. The single super-massive rotor carries a huge amount of angular momentum, and so is not very tolerant of flexibility in the tower, instead requiring a "hard mount".

**Currently used Solution:** use more steel in the tower to make it stronger. Today's towers account for about 20% of the cost of a turbine installation.

**OUR SOLUTION: Less robust supporting structure required: - Lighter weight and less angular momentum,** as well as the

Fig. 5

**balanced mounting**, and the **resilience** of the **elongate driveshaft** of our new design, allow a **lighter tower** to be used, even one that has some "give".

**7. Problem #7 - Maintenance: Complex machinery** requires **more attention** and **maintenance** for continuous operation. Such maintenance is made more complicated by the fact that the equipment is at a **dangerous height** above the ground, and often, by its very nature, in a **remote location**.

**Currently used Solution: Hire more personnel**, and buy more equipment, vehicles, tools, lubricants and replacement parts, to constantly attend to the complex mechanisms.

**OUR SOLUTION: Less Maintenance required - Fewer moving parts** and a simpler method of operation translate to less labor, equipment, vehicles, tools, and spare parts required to keep it all running smoothly.

**NEW!**

This **vast improvement** over the state of the art utilizes the lightweight strength offered by **recent advances in composite materials** to place multiple rotors along a single shaft. Multiple small rotors are **lighter**, and rotate **more rapidly** compared to a single rotor of equivalent area. More rapid rotation **reduces or eliminates the need for a gearbox**. Extreme reliability demands such simplicity. This entirely new class of wind turbines is balanced, and self-aiming, with an offset from horizontal to allow each rotor to encounter fresh wind.

Because our **rotors cost less**, having far **less total mass**, and our **generator costs less**, and the **gearbox is eliminated**, and our drivetrain, **rotating at a faster rate**, can be less substantial and still deliver the **same power**, and because it is **self-aiming**, requiring no azimuthal guidance system, our new windmill can be made for less than **half the price** of the competition. Because it is **lighter** and **better balanced**, with **less angular momentum**, and a **resilient driveshaft**, a **lighter gauge tower** can be used. For these same reasons it's **safer**. And because it's **simpler**, it requires **less maintenance**, and has **less downtime** than current designs.

14 inch rotors lighting a 50 watt car headlight. More rotors = more power! So balanced it's comfortable to hold right in your hand - and very easy on the bearings!

#### Products and Projects Planned:

We plan to **continue building larger and larger prototypes** of our **California** design, developing at **least one for commercial production**. We will also continue to develop related designs, and continue to secure intellectual property protection for the entire family of designs.

#### Unique Capabilities:

Our **patent pending California design** is **lighter, faster, simpler, quieter, and self-aiming, more reliable**, with **fewer moving parts**, delivering **more energy for the money**.

#### Competition:

Virtually all other companies in the wind energy business are now using the "Danish Design" based on the ancient "Standard Dutch" single rotor design at this time. We predict that, rather than being competition, other wind energy companies will become partners and/or licensees utilizing our superior technology.

#### Market Penetration Strategy:

We plan to continue development of our new class of wind turbines, to prove that the technology will work in a small to medium sized installation, and to produce at least one production model for commercial sale. We project that the resulting test data, as well as the attention garnered from the superior performance of our production models, based on cost per kilowatt hour, will create a demand for licensing by others. We will also continue to develop some of the **more advanced** versions of the **California** design, incorporating a **rotating tower/driveshaft** and/or **atmospherically buoyant versions**. These even more advanced technologies may become production models or licensed to others.

#### Strategy and Objectives:

The immediate **objective** is to prove the technology for a new and improved class of wind turbines, by building and testing a reliable prototype of a size suitable for household use. This entirely new class of wind turbine is expected to further reduce the cost of wind power. We expect to eventually to derive a revenue stream from our overall, long term effort. The more far-reaching **objective** is to reduce dependence on oil and other fossil fuels, from whatever source, making the world a cleaner and safer place.

#### The overall strategy is:

1. To secure **international patent coverage** for the **Revolutionary New wind turbine designs, conceived in California, and** revealed in U.S. Patent Application Numbers 09/8\*\*\*\*\*, and 09/9\*\*\*\*\*, by Douglas Spriggs Selsam.
2. To continue to **build larger and improved prototypes** of wind turbines based on these **California** designs, and to further refine the designs. Each prototype is tested and studied, defects corrected, and a larger

prototype built.

3. To secure further intellectual property protection on any improvements made.
4. To arrange for **production of at least one commercial model**, using the **California** design called "Balanced, High Output, Rapid Rotation Wind Turbine" from U.S. patent application number 09/9\*\*\*\*\*.
5. To further develop more **advanced California designs**.
6. To **further benefit humankind** and to **profit** from the intellectual property generated by **licensing the technology** to others.

#### Accomplishments:

Currently funded by The California Energy Commission

[http://www.energy.ca.gov/contracts/smallgrant/2003-02-21\\_awards\\_02-02.html](http://www.energy.ca.gov/contracts/smallgrant/2003-02-21_awards_02-02.html)

U.S. Patent Number 6,616,402 and other patents pending including international (PCT) <http://www.uspto.gov>

- An **entirely new class of wind turbines** has been invented (which doesn't happen every day), which is **lighter, faster, simpler, quieter, and less expensive**.
- Several small **working prototypes** have been constructed by the inventor, **proving that the concept is viable on a very small scale**.
- **Two U.S. Patents** as well as an **International (PCT) Patent** have been filed for this new class of wind turbine.
- **One U.S. Patent has issued**, the other **has been allowed and will issue soon**.
- **Government assistance and grants**, as well as **funding from private sources**, are now being sought to assist in further development of this new class of wind turbines.
- We have filed for **PCT (Patent Cooperation Treaty)** coverage based on priority established from these U.S. Patents. For a certain period of time we will then have the option of obtaining international patent protection in whatever specific countries we deem advantageous. This means that we could enjoy a **positive revenue stream into the U.S. and to California** from around the world from this revolutionary new type of wind turbine technology **for the next 20 years**.

---

#### F.A.Q. - Frequently Asked Questions:

Q1. Doesn't the wind shadow from one rotor inhibit the next rotor from getting wind?

A: That's definitely a factor to consider. Our driveshaft is at an angle from horizontal, with the nose pointing slightly downward so that, with proper spacing, each rotor gets its own wind. In addition, the forward tilt of the rotors tends to direct the wind downward, pulling more fresh wind through the machine from above...

Any slight losses of power from wind shadow effects are more than made up for by the overwhelming combined power of a multiplicity of rotors.

15/18

Fig. 16

Q2. Can two or more of the Selsam Multi-Rotor Wind Turbines be combined on a rotating frame to form a single self-aiming wind-power-production structure?

A: Yes. Multiple turbines mounted to a single rotating armature are self-aiming as a combined unit. Multiple levels are also possible.

Q3. Is the Selsam Multi-rotor wind turbine well suited for rooftop mounting?

A: Yes! The low profile design makes good use of the flow of air over a roof. The multiple rotors combine for smooth, quiet, relatively vibration-free operation.

Q4. What about the fact that the horizontal axis rotors aren't aimed exactly into the wind, but instead are aimed slightly downward from horizontal? Don't they lose a lot of power?

A: Another good point. Luckily, a slight deviation from the wind direction has almost no effect on a rotor's performance. The offset angle can also be in another plane, such as horizontal, useful in larger installations where rotor size is a significant fraction of tower height.

Q5. What about the bearings? Isn't there a lot of radial loading from the weight and wind loading amplified by the leverage of the length of the shaft?

A: The upwind section of the shaft approximately balances the downwind section. This minimizes radial loading on the bearings. That allows long bearing life.

Q6. Why doesn't it need a tail, or a dedicated azimuthal orientation means of any kind?

A: We feel that since a tail doesn't contribute any power, get rid of it and put on something that does produce power, like more rotors. A conventional tail is like a partner on a tandem bike who refuses to pedal! We simply place the center of aerodynamic drag of the entire driveshaft with its attached rotors slightly downwind of an azimuthal pivot point, and the machine will faithfully stay headed windward.

Q7. What about protection in high winds?

A: Several factors act to protect the machine in high winds: First, at the higher Reynolds numbers that come with increasing wind speeds, the length of wind shadows effectively increases, so that upwind rotors will begin to protect downwind rotors. More importantly, the downwind section of the shaft will tend to bend to a more horizontal direction, placing downwind rotors more into the wind shadows of the upwind ones. Finally, the generator and shaft can be resiliently mounted, so that they are blown into a more horizontal orientation by very strong winds, so that overall rotor exposure is reduced, while power output and rpm are maintained. The key to proper behavior at all wind speeds is that progressively more rotor surface is exposed in low winds, and less in high winds. No furling cycle is involved, so there is never a time when no power is generated because of excessively strong winds. The action is also not as radical as furling, and is less prone to "finicky" behavior.

Q8. What designs do you have in mind for the future? Are they also covered by your patents pending?

A: Yes, and the future is wide open. This design is an important advance, yet is still just the tip of the iceberg. Future patent pending designs include atmospherically buoyant versions that incorporate helium-filled or hydrogen-filled kite-like aerodynamic lifting bodies instead of a tower. Others utilize buoyant, inflated rotors. We have much more advanced designs still. We have had preliminary discussions with some NASA personnel

indicating that such turbines might find use as easily deployable power sources on Mars.

Q9: Despite all the logical reasons why this new design seems to be a step forward, I'm having trouble accepting it. It seems too simple or something - I can't quite put my finger on it, but it bothers me. Is there any help for someone like me?

A: Innovative designs are often surprisingly simple. Advances in materials science make such progressive designs more practical. Progress inevitably involves change. Just close your eyes and relax, and keep repeating this mantra: "More rotors mean more power".

Q10: Utility-sized Turbines are being made larger all the time. Will yours scale up to Megawatt sizes?

A: So far they are scaling up beautifully. They are surprisingly stable even in very strong winds. We don't see any upper limit yet - further experiments will tell us how big they can get. For a given power rating, say 1 megawatt, our rotors are much smaller, about 1/3 of the diameter or less, and weighing a total of only about a third as much, collectively, with 2/3 less angular momentum. Blade stress considerations would thus be reduced, for a given power rating, using our design. This would suggest that the upper size limit for this design could also be in the megawatt range, and for atmospherically buoyant versions, possibly higher.

Q11: The trend has been going toward low speed, high torque alternators and generators.

A: Only because there hasn't been any other choice, except using a power-robbing, maintenance and wear-prone, heavy, expensive gearbox. By comparison a specially-built, multipole generator designed for low speed, high-torque generator has indeed been an attractive, albeit initially expensive alternative, but a generator made for normal speeds is still preferable, if there is a choice. There's a reason generators have traditionally been made for a faster RPM, given a choice. They can be smaller, and lighter, and simpler, by just turning faster. Also, at a faster RPM, the same power is transmitted at less torque, so the drivetrain can be less robust. The result is a lighter, simpler, more economical installation. When this new design is scaled up, we, too will preferentially take advantage of specially built, multipole generators with many poles for slow, high-torque operation. Our design, however, can be more powerful before it reaches a size where such a specially-built low speed generator is needed.

Questions to ask yourself:  
 How many wheels does your car have?  
 Not just one? What about trucks?  
 How many cylinders in your engine?  
 More cylinders run smoother - and have more surface area per unit mass.  
 How many cars in a train? Not just one? Why?

It's much easier on the track. Economy of scale - repeating units...

How many sails on a clipper ship? Not just one? Why not?

How many tiles around your bathtub? Not just one huge thick tile? Better surface to volume ratio with multiple small tiles? Just checking...

How many tiles on your roof? Not just one big, thick tile? Better surface area to mass ratio with multiple smaller, thinner tiles? I see.

Why do we look up and see a flock of geese, rather than just one giant goose? (run!) Why do ostriches and all other birds over a certain size have to walk everywhere?

How many engines on a large airplane? How many props? Why not just one big prop?

How many loops of wire in a generator? Not just one? Why not? More power?

How many fingers do you have? How many Toes? How many teeth?

How many leaves on a plant?

Now how many rotors should a wind turbine have?

[Specifications](#)

[Using your own Alternator or Generator \(Power Chart\)](#)

[Field Switch](#)

[Maintenance](#)

[Parts list](#)

[Troubleshooting Guide](#) [Testimonials](#)

[Prices & shipping](#)

---

**Note:** This design is developed from plans published by the USDA in 1939. Typical use supplies 12 v. fluorescent light, radio, and laptop for a cabin. Please let me know what you think!

## Dragonfly Theory

Designed for people who operate and maintain their own system. Dragonfly philosophy recognizes that nothing manmade lasts forever, but planned obsolescence is like being patronized by vampires. To avoid this, the Dragonfly is designed to last as long as the user has interest, with locally available spare parts, few critical tolerances, and the maintenance technology somewhere between a paper airplane and a bicycle. Components are adaptable to the supply: off the shelf hardware, lumber, and any variety of alternators or generators.

Included with plans are directions for construction, wiring, trouble-shooting, towers, battery maintenance, site selection (wind appraisal without an anemometer), some sources of inexpensive materials, and instructions for blade making and balancing (though I also sell blades and kit blades). Blades are twist taper cut from 2x4 lumber.

Watts per dollar, Dragonflies are one of the most "efficient" wind generators on the market, though one could expect that initial low cost might be offset by higher maintenance, this is not necessarily true, and depends on the local environment. I personally know of one that was 4+ years old, near the coast, and still working fine after 2 years without an inspection.

## Self-Feathering

The feathering mechanism consists of a horizontal hinge which allows the blade, axle, and alternator to tip back as a unit to spill high winds over the top. It is held in operating position by its own weight and a coil pull-spring. Units that I sometimes make are guaranteed to survive winds to 80 mph, when the blade is properly balanced, and the field is loaded. Manual shutdown for stronger wind can be accomplished from the ground.

The blade, bearings and drive pulley rotate as one unit about a fixed axle. The v-belt drive pulley is available in several sizes from heating and air-conditioning stores, and may be easily interchanged to obtain the best power ratio.

## Specifications

Frame Material: wood, metal brackets.

Net Weight: 50 lbs.

Blade Diameter: 9 feet.

Blade Material: wood, stainless steel.

Blade Weight: 10 lbs.

Minimum windspeed: 10 mph.

Maximum output: 700 watts at 45 mph with Chrysler alternator and a 10 inch drive pulley.

# Using your own Alternator or Generator

Any alternator will work, but those with higher rated output means more wind is necessary to overcome the draw of it's large field, so big alternators won't produce in milder winds. Generators and lower rated alternators loose the power advantage of storms, (which occur to a greater or lesser extent about every 2 weeks worldwide), but take better advantage of wind below 10 MPH. Some desirable characteristics are:  
 Rated Power Output: 400 to 800 watts.  
 RPM Output Range: between 200 and 1,000.  
 Alternators starting around 450 rpm.

The alternators exposure to the elements is not a problem unless the unit is used in a marine environment. Otherwise there is nothing at the top of the tower that won't be found under the hood of a car, except sunlight which may affect the wiring insulation.

If the unit IS in a marine or other harsh environment, marine alternators are available with enclosed brushes, bearings and a corrosion resistant finish. Electrical terminals can be coated with protective caulking or shellac.

## Field Switch

There are two kinds of automatic field switches shown in the Dragonfly plans, either will do: one is a momentary switch that requires occasional cleaning, this switch is normally on and is turned off by the weight of the feathering mechanism at rest in still air. The other is an enclosed mercury switch (good to 32 degrees below zero) which is clamped to the side of the feathering mechanism. The blade is designed to have a high RPM which will create a vacuum behind it to instigate feathering. When the RPMs are sufficient to produce electricity, the blade has already begun to feather slightly. As it tips back, the mercury switch tilts, or the momentary switch closes, to turn the field on.

## Maintenance plan A:

Check list in order of probability, depending on climate, 2 to 4 times a year:  
 1): loose nuts, or fatigue at wire terminals. Too much loose stuff means the blade's out of balance. See manual for balancing.

- 2): belt tension.
- 3): check for wear or dirty turntable brushes.
- 4): loose or dry blade bearings (grit in bearings or unbalanced blade). Zerks require grease gun, should be greased regularly.
- 5): tight feathering hinge (need oil?)
- 6): check wood parts for rot, warp, or splitting.

Maintenance plan B: Wait till it stops working, then fix it. This actually is practical, but risks complications like: parts falling off, drained battery, or working in the rain.

---

## Testimonials

The following customer responses testify to the simplicity of design and construction of the Dragonfly wind generator as well as its durability and the ease with which it can be modified to local materials and conditions.

... I really like your design and feathering mechanism. Around Thanksgiving the mill went through an 8 hour storm with winds 50 to 60 mph with one recorded gust of 78 mph and held together.

N.S., Ferndale, WA

...also the other (Dragonfly) worked very well with a permanent magnet generator which I borrowed from a friend...

P.A.W., Kingman, AZ

..We would like to try another machine at a second location...

B.B., Glendora, N.J.

...instead of the mercury switch, I have a centrifugal switch from a Coleman furnace that turns it (a Chrysler alternator) on at about the time it is going fast enough to charge...

J.C., Kingman AZ

We presently (1982) have 20 wind students on-site on our Energy Education Center working with a Dragonfly wind generator that is on campus...

P.E., Red Wing, MN

... the prop blades were very nice and the plans were good... the Dragonfly has proven to be very practical and has been through the worst weather here in more than 100 years. I just had to write you to tell you I am very satisfied with the whole project. Thru rain snow, sleet, hail, sub-zero and winds to 60 MPH plus. It turned 2 days and nights thru a snowstorm and in the morning

the prop hub looked like a giant sunflower made of ice and snow...

R. H., Hampton Bays, NY

## Prices

Plans: \$15.00

Available by download only, approximately 27 pages (depending on the printers resolution). Please provide current email address.

Blade Balance Kit: 1lb \$15.00

A piece of copper pipe, 2 washers, and string. weights not included. Works only for Dragonfly design, easy to make, get plans & make your own.

Kit blade set: 14 lbs. \$100.00

pitch and foil are rough cut, centers not located. holes not drilled. Needs sanding, painting, and sometimes light planeing. Does not include bearings, pulley, or hub.

Finished Blade Set: 14 lbs \$200.00

centers not located. holes not drilled. Does not include paint, bearings, pulley, or hub.

Individual blades: 5 lbs cost = 1/3 set, kit or finished

All blades sold unbalanced and unpainted. A stainless foil strip comes attached to the leading edge in finished blades, and included unattached with kits. Does not include bearings, pulley, or hub.

Shipping: Blades delivered within 3 weeks. Inside US & Canada: by United Parcel Service. COD accepted for postage. Outside US & Canada: please specify carrier and include correct postage. Sorry, no foreign COD.

Payment: in advance by PayPal, Credit Card, Check or Money Order. I'm sometimes away from my site for a week at a time, so please be patient Send Check, Money Order or by [Western Union](#) to: WS Cornelius Enterprises, POB 57, Albion CA 95410-0057

# REALTIME CONTROL

## DIY Rotorvane Anemometer

- \* LED dials display wind speed, wind direction and maximum gust
- \* Serial port allows direct connection to a computer or modem
- \* Integrated data logger stores wind speed and direction distributions
- \* Windows™ software supports realtime display and logged data retrieval
- \* [Rotorvane™](#) sensor provides accurate data from simple, reliable hardware
- \* [Low cost Kit](#) contains the critical electronic and mechanical parts

These pages describe how to build an elegantly simple vector anemometer. It is an accurate and reliable standalone instrument for general use and has features which simplify its use in more complex applications.

The LED dials display wind speed to within a knot or so and wind direction within a few degrees. Pressing the pushbutton displays maximum gust speed and direction. Holding the pushbutton down resets these.

Web-based weather servers and other computers can read the wind data directly from its serial port. Its serial port can be connected to a modem, allowing remote wind monitoring via a dialup line.

The built-in data logger records speed and direction distributions and so stand alone it collects and stores the data for wind power site assessment.

One sensor measures both speed and direction and the download is general purpose twinlead. This reduces cost and improves reliability.

We supply a Kit containing two bare printed circuit boards, the less common electronic parts and the specialised mechanical parts. You provide the other items required, and build and calibrate the instrument. Total cost is typically around US\$95.

Electronic construction is fairly straightforward, and likely to be uneventful for those who have previously successfully built electronic kits. Mechanical construction requires only a drill and a few other hand tools.

Our Rotorvane for Windows package allows you to read and save current and logged data from a DIY Rotorvane Anemometer, and to plot wind speed and direction in real time. The anemometer can be either directly connected to the computer serial port or connected via modem. This package (and the VB source code) can be downloaded free of charge from our site.

Rotorvane™ technology is the intellectual property of Realtime Control. The design is copyright. Permission is granted to copy the hardware design provided it is used with a microcontroller supplied by REALTIME CONTROL.

# Micro Hydro Power Plants

	<p><b>Micro Hydro Power Plant Overview &amp; Power Calculations.</b> Knowing how to calculate the generating capacity of a Micro-Hydroelectric Power Plant is of prime concern. The following pages are a compilation of data I've collected over the past 20 years or so on power production &amp; control as related to Micro-hydroelectric power plants.</p>
	<p>Induction motors have been used as generators for decades. This is called Induction Generation. Induction Generating is the simplest method of generating electricity. Your local power company furnishes most of the things you'll need in except for hardware. The Power Company furnishes the Voltage Control, Frequency Control and excitation you'll need to run your induction motor as an Induction Generator.</p>
	<p>Anyone contemplating building a Micro Hydro Power Plant must know how much water is available. Weirs and several other methods for measuring water flow from small streams to rivers have been around for centuries. The pages following include basic weir construction as well as Weir Charts.</p>
	<p>Several Tables detailing various mechanical properties of various pipe types (PVC, Steel &amp; Others)</p>
	<p>A basic outline of why a Governor / Load Control is needed for Synchronous (Real) Generators, as well as some AC theory within the context of line frequency &amp; high &amp; low voltage conditions.</p>

	<p>Most of the basic Turbine types are on this page with photos and their theory of operation. Several "Older" turbine types will also be found here</p>
	<p>"The Banki Water Turbine", Oregon State University, Civil Engineering ,Department Engineering Bulletin Number 25 By C. A. Mockmore and Fred Merryfield. Originally published in 1949. Details the theory of operation of the crossflow turbine. Very math intensive. Original document scanned in PDF format. You will need Adobe Acrobat (available on my Links &amp; Sources page) to read this.</p>
	<p>Various "home-brew" method for machine work need for the Banki Crossflow Turbine. It's not really as easy as you've been lead to believe! You still need a small machine shop in your backyard.</p>
	<p>Waterhammer basics. What it is, how to control / prevent it as well the math to find peak excess pressure.</p>
	<p>A look into the past. A variety of waterwheel types with photos. Nothing technical here, I just like old Waterwheels.</p>
	<p>Various "Hardcopy" publications I used as research for this web sits as well as internet links relative to hydro power.</p>

# Uncle Joe's Funny Stuff About Electricity

## The Layman's Guide to Electricity

## The History of the Water Transformer

# Unusual Electrical Terms

## How Vacuum Tubes Work

# Portable Lightplants and Generators

**W**elcome! For some ethereal reason, I have a genuine interest and fascination with generators and electricity. I'm sure it all started 39 years ago when I was 4 years old and was playing in the basement of our house. Little did I know, I was about to get my first electric shock. I reached over to move a large electric fan, that had a short in it and was hot with 120 volts of good 'ol Alternating Current. Well, it took me quite a while to let go of that fan and after I did I went screaming to Mom. I had to be thinking, "What in the world happened and why did that hurt? What mysterious force did that?" After that experience, I was hooked on electricity.

My Uncle Norm (Mom's brother) did nothing to dispel that fascination! He would bring me boxes of electronic/electrical/mechanical "treasures", books and other things that furthered my interest. A lot of fascinating stuff for a curious kid like me. Geesh, I learned a lot of things from him! He is a superb machinist and craftsman of the first order.

Because of all the above reasons, I've built, designed and played with various forms of "Rotating Electrical Machinery" throughout my lifetime.

I'm not sure if it has reached the obsession level yet... I still have a job so maybe I'm OK...?

(In building the more critical components of these generators, I have to give credit to Dewey King, NJ8V, a master machinist. He helped me with the machining and design of many of the parts, adaptors, couplings and other things too numerous to mention. If he ever decides to call in my debts to him, I'll be out at least an arm, a leg and my firstborn...)

---

One of the neatest ones that I built was this Delco Automobile Alternator (3 phase) that I converted to a single phase alternator. Voltage is regulated by a [homebrewed regulator](#). The generator/engine combination is mounted on a small welded steel frame and powered by a typical lawnmower-type Briggs and Stratton Classic 3.5 hp engine.

It is capable of 700 watts at 120 Volts AC or DC output. The AC frequency is about 250 to 400 hz, depending of engine speed. You may ask, "What can you power at that frequency?" Plenty! Lightbulbs don't care what frequency they operate at. Devices that are power-transformer operated, such as a radio, TV, VCR, etc. work very well on this frequency.

I included a full wave diode bridge to also provide 120 Volts DC. This makes it possible to operate any universal-motor operated device. Power saws, drills, angle grinders, etc.

This generator is a veteran of a ham radio expedition to Manchester islands on the Ohio River. There it powered a TS-520 ham transceiver at about 350 watts maximum for the day. I'd refuel it about every hour or so. This power source has seen a lot of use and is very reliable.

---

You ask, "How in the world did you convert a 3 phase alternator to a single phase system?" In its original condition, it had 42 poles on the stator. The rotating field has 14 poles. (42 stator poles divided by 14 rotor field poles equals 3 phases, ... Hey! How 'bout that? ) Well, NJ8V helped me cut out every third pole on the stator of the alternator. This left 2 poles with a large space between them and the next 2 poles. I wound each of the 2 pole pieces as a single pole, for a total of 14 poles.

In this close-up shot, notice the two pole faces wound as one and where each third pole has been cut out. A small coil form was made out of plexiglass to wind the coils. I used epoxy glue to hold the coils in place, with fiber tape as an insulator. The coils are about 36 turns of #18 wire, all connected in series.

The only advantage of converting the alternator to single phase was that I could get the full 120 vac out of the windings. That was better than having to use a transformer or other method of getting 120 volts out of it. Besides, it was a good education!

---

**Here is a new welder/generator that I've just finished in February, 2000.  
It is a 100 ampere DC welder, powered by a B&S 8 hp gasoline engine.  
Click on it to go directly to this welder page.**

## Animated Engines

I have loved mechanical things since I was a kid. Engines in particular have always intrigued me. All my life I've pored over books, studying cutaway diagrams, hungry to understand how things worked. These pages are an attempt to share that magic.

Some of the animations are rather large, so you may need to **allow a few extra seconds** while each page loads. These pages use animated GIF files, so they require a fairly recent browser -- any but the oldest browsers will do. If the main illustration at the top of each page isn't moving, you'll need to update your browser for the full effect.

I hope you enjoy visiting my engine pages as much as I have enjoyed creating them.

Internal combustion

# AC Battery Chargers

This discussion centers on battery chargers that convert 120 volt AC power to 12 or 24 volt DC. There are a few different varieties available. In our opinion this is the **least** desirable option for charging batteries in a remote power application, but is often the **only** option if you are not willing to tinker with antique or home built equipment. Check out our previous pages about 12 volt chargers--gasoline engines that produce 12 volt power directly. Every time you convert power to or from 12 volt DC and 120 volt AC, there are electrical losses involved. The less conversion, the better!

## Options for AC Battery Chargers:

### Build Your Own!

We converted a dead Heart Interface inverter into a super powerful battery charger by extracting the transformer and connecting it through a large bridge rectifier.

[Click here to see plans for our home built charger, made from a dead inverter](#)

### Hardware Store Chargers

(auto parts store, too)

These chargers function quite well, but are not very efficient compared to the new solid-state variety. They are very easy to find, any hardware store or auto parts store will sell you one. And they work fine, BUT--the ratings are generally inflated by quite a bit. This is a problem with the new low-cost inverters available from Taiwan, too. It might SAY 1000 watts on the case, but that's not what you are getting. Shame on them! Usually what you really have is a 30-amp charger in a big case that's mostly empty space.

Let WEIGHT be your guide as to the true amp rating of this sort of charger--big ones should be extremely heavy because of the transformer inside. Also, this transformer tapers the charging

current into your batteries. When the batteries are nearly empty, the charger will put out nearly its full current, which will gradually get lower and lower as the batteries fill.

### Surplus Industrial Chargers

Made for charging forklift batteries, these machines are brutally expensive when new, and a great bargain if you can find them used. Some are set up for 24 volts. This can be a problem with both efficiency and heat buildup if used to charge 12 volt batteries.

### Inverters with chargers built in

This sort of charger is very convenient--when your generator gets up to speed, the inverter automatically switches your house over from battery to generator power, and uses the excess capacity from the generator to charge your batteries. While not as efficient as a solid-state charger, these are usually quality components. If the inverter's charger is rated at 50 amps, you can bet that it produces that rating when the batteries are empty. We've never seen one of these chargers that suffers from "ratings inflation" like the hardware-store variety above. Since it's transformer based, it will automatically taper off the charging current as the batteries fill.

### Solid-state chargers

The latest thing in battery charging, these chargers are lightweight (no transformer) and very efficient, but expensive. The only 2 brands currently available are from Todd and Statpower. And if they say "50 amp," you'll get 50 amp into empty batteries.. Charging current is controlled electronically for best efficiency. One note--with Todd chargers (the brand we use here), be careful to unplug the charger from the generator when starting or stopping it, otherwise the charger can be damaged over time.

# Home Built Battery Charger

## (made from a dead inverter)

---

The battery charger pictured here is a real beast. It will dump 60 amps into a 12 volt battery bank that is low, and will taper down to about 10 amps charging current as the batteries fill. Total cost, \$20!

The basis of this charger is dead 1000 watt inverter from Heart. A lightning strike fried the electronics in this unit, but the transformer was intact. The owner elected to replace it with a new model, and we picked it up for \$20. The inverter case made a handy case for the charger, too, because of the handles. The whole unit weighs over 50 pounds.

At the time, we did not have a large enough bridge rectifier available, so we built one out of 9 car alternator diodes connected in parallel to a heat sink. The bridge gets hot in use, but the diode bus bar is a piece of unistrut that's massive enough to dissipate the heat produced.

Close up of home built diode bridge

**home built diode bridge--note the insulated standoffs so the diodes don't ground to the case.**

**Here is the wiring diagram for the charger. Buying a bridge rectifier big enough to handle 70 amps would simplify construction...the home built diode bridge was the most complicated part of the project. Check our products page, we sometimes have large bridge rectifiers for sale.**

**Here is the circuit schematic for the charger conversion:**

# Battery Bank Care

Most battery banks need maintenance only 4 times a year or so. But after you first install your system, check the batteries every month for a while just to make sure. If the electrolyte level gets below the plates, your batteries WILL be damaged. I remind myself to do this by performing maintenance on the solstices and equinoxes--quite appropriate for a solar energy system!

## **CHECK OUT THIS GREAT, INEXPENSIVE BATTERY REFERENCE BOOK!**

**Secrets of Lead-Acid Batteries by Thomas Lindsay is one of the best reference books on the subject that we've ever seen. Plus, it's cheap, since he doesn't waste any paper talking about irrelevancies. Available on our products page for only \$4.95!**

**Equalize your battery bank about 6 times a year.** Don't do this with gel cells, only with regular "flooded" lead-acid batteries. Equalization is basically a controlled overcharge that extends your battery life by knocking deposits off the plates. It's usually easiest to do this with a generator. Charge the batteries at your normal rate, but don't stop when your meter shows full charge. Keep charging for 2 or 3 hours longer. If you care to monitor the process, you can take specific gravity readings 30 minutes apart and continue the process until the readings stop increasing.

**4 times a year you should turn off the main power switch and::**

- Check the electrolyte level. Do this when the batteries are -not- discharged, and wait a couple hours after charging for the hydrogen bubbles to disperse. The batteries should have full and low marks--sometimes the full mark is an inner plastic "shelf" with a hole in it to see the electrolyte level.
  - Wear safety goggles and rubber gloves
  - Fill **ONLY** with distilled water to the "full" mark
    - **DO NOT** add acid!
- Clean the battery tops with rags dipped in a baking soda and water solution. **DO NOT** let this cleaning solution get into the batteries--be careful of the vent holes in the caps on each cell, as cleaning solution can enter the battery here.
- Check for corrosion on all the battery terminals
  - If any terminals are encrusted in green "stuff" you should
    - Make **SURE** your main power switch is off. If you don't have a main switch, turn off the inverter, all load circuits, and all charging circuits.
    - Carefully disconnect wires from the dirty terminal and clean off the gunk with a wire brush. Don't breathe in the dust! Wear a mask if necessary
    - Apply anti-corrosion paste to the terminal (available at any hardware store in the electrical department)
    - Reconnect the wires
- Relax and smile. Enjoy the fact that you don't have to read by candlelight anymore, or that

you no longer pay bills to the power company! Your maintenance is done for the next 3 months.

# Battery Safety

Batteries demand lots of caution when you work around them or move them. They are very heavy, store enough energy to start a fire, are full of dangerous sulfuric acid, and emit explosive hydrogen gas. Fun stuff, eh? Here are some safety tips for working with your batteries. Note: These safety precautions are for standard lead-acid batteries, since nickel-cadmium batteries use a base--potassium hydroxide--instead of sulfuric acid for an electrolyte. Follow the manufacturers instructions instead of these with your NiCad batteries.

- Install your batteries in a vented battery box, they emit hydrogen gas when charging
- Never install electrical equipment in the same compartment as batteries due to explosive hydrogen gas
- No smoking around batteries for the same reason
- Wrap wrench handles in electrical tape to avoid shorting between battery terminals. A 6-volt golf cart battery can turn a wrench red hot in seconds
- Wear goggles and rubber gloves to protect yourself from sulfuric acid when moving or working on batteries
- Keep a box of baking soda and a jug of water around to neutralize any spilled battery acid
- **If you get acid on your skin, flush with lots of water**
- **In case of acid in your eyes, flush with water for 15 minutes and call a doctor**
- Make sure someone else is around when you work on or move batteries

# Battery Metering

With proper care, quality batteries that are sized correctly for your application will last for years. If abused, an expensive battery bank may last only months. Taking out too much power without recharging is what kills most batteries. Also, batteries that are low will freeze easily, while a fully-charged battery is good to at least 30 below zero.

Battery capacity is measured in ampere-hours (amp-hours). In rough terms, a 100 amp-hour battery can give out 1 amp for 100 hours, or 100 amps for one hour, or 20 amps for 5 hours. However, see the first item below--you would actually never want to use the entire capacity before recharging.

Meters can be as simple as a voltmeter to measure battery bank voltage and an ammeter to show net gain or loss of power, or as complicated as a digital amp/hour meter. **We sometimes stock older, unique analog meters (the kind with a needle), check our products page for availability.**

[Click HERE for information on building analog meters at home!](#)

## For maximum battery life:

- If possible, never use more than 20% of your battery bank's capacity. If your capacity is 1000 amp-hours, start your back-up generator when the meter shows -200 amp-hours (80% of capacity remaining).
- Never use more than half your battery capacity without recharging.
- If you use 75 to 80% of your capacity without recharging, your batteries WILL be damaged, even if they are "deep-cycle" batteries.

**To measure battery state-of-charge**, there are 3 possible methods.

- **By Voltage:** This method is the least accurate, but requires only a cheap digital voltmeter. It will not work for NiCads or Telephone cells. Analog meters (with a needle) are generally not

accurate enough for this.

- Wait 2 hours after any charging or discharging to take your measurement (use your disconnect switches to stop all charging or discharging if necessary)

- Measure DC voltage across the main positive and negative terminals (where the inverter and/or solar panels are connected to the batteries).
- Compare to this chart
  - As batteries age, this voltage reading will gradually get lower (or quickly, if they are abused)
  - Measuring voltage across each cell can help diagnose failed cells. Divide the 12 volt reading from this chart by 2 for 6 volt batteries, and by 6 for individual 2 volt cells to figure state of charge (or amount of damage) for the cell. Example: An individual cell would show 2.12 volts at 100% charge when new.

percentage of charge	12 volt battery voltage	24 volt battery voltage	specific gravity
100	12.70	25.40	1.265
95	12.64	25.25	1.257
90	12.58	25.16	1.249
85	12.52	25.04	1.241
80	12.46	24.92	1.233
75	12.40	24.80	1.225
70	12.36	24.72	1.218
65	12.32	24.64	1.211
60	12.28	24.56	1.204
55	12.24	24.48	1.197
50	12.20	24.40	1.190
40	12.12	24.24	1.176
30	12.04	24.08	1.162
20	11.98	23.96	1.148
10	11.94	23.88	1.134

Chart from the Trojan Battery company for Trojan L-16 batteries

- **By Specific Gravity.** This is the most accurate method, but the most messy. You do not have to wait 2 hours to take this reading. It will not work with gel cells or NiCads. You'll need a good battery hydrometer--it will look like a footlong glass turkey baster with a glass float and thermometer inside. It's available from us, or at some auto parts stores.
  - Wear goggles and rubber gloves! Keep baking soda and water handy in case you spill!
  - Open up one cell on each battery and suck out enough acid to float the float (or measure every cell if you are ambitious enough)

- write down the reading
- average all these readings and compare to the chart
- **By Ampere-Hours.** This is best method to measure state of charge, both in accuracy and ease of use. The only drawback is price--plan on spending \$175 to \$200 for an amp-hour meter. But compared to the cost of replacing a quality battery bank, this cost is trivial. This also makes it easy for people not familiar with your system to avoid abusing the batteries. Our system uses 12 telephone cells with a capacity of 1080 amp-hours. These batteries should never be discharged below 80%, so even my kids know to turn off the TV when the meter shows -216, and yell for Dad to go start the generator..
  - Amp-hour meters keep track of all power moving in or out of your batteries by time. The efficiency of your battery bank is calculated by the meter while the system operates, and is automatically corrected.
  - Amp-hour meters can sense when the batteries reach full charge, and automatically reset themselves to zero (full) when that point is reached.
  - Any positive reading of amp-hours refers to power that was generated but not stored by the batteries because they were full. This power is in effect wasted, but switching systems can be built to divert the extra power to run water pumps, etc.
    - An amp-hour meter measures power running both ways in the main negative power cable through a "shunt". Any circuit or equipment that is on the wrong side of the shunt (the battery side) will not be metered--this will make your reading inaccurate. Connect all load and charging circuits to the side of the shunt away from the battery bank.
    - The shunt must be big enough to handle -all- power the system can produce, including the inverter. A standard 500-amp shunt is big enough for most systems. A 100-amp shunt can usually be used in a small system with no inverter.

# A SIMPLE AMMETER

Here is a simple way to make a reliable, safe ammeter for ... ? I use mine to monitor power coming into/out of my batteries. Undoubtedly one could make many modifications; it would not be too difficult to convert this to a full function multi-meter. Mine shows DC amps, plus or minus 15. This meter is simple, and reliable enough to serve many applications. With just a little work, it could be a fine addition to any shop, or living room.

The meter consists of a wooden back, a long wooden needle(14" long), which pivots on a nail. To the bottom of the long wooden needle is a surplus computer hard drive magnet glued on with super-glue. You can get the magnet out of most computer hard drives, or...we sell them, between \$1 and \$12, depending upon the scale of meter you have in mind. (it would be great to make a BIG one)

**Pictured above is the surplus computer hard drive magnet. This is a NdFeB (Neodymium Iron Boron) rare earth magnet, the strongest permanent magnets currently developed. These are many times stronger than AlNiCo or ceramic magnets that we are all accustomed to, they make possible many new things! Without this magnet, this meter would not work nearly as well. The shape, strength, and polarization of these magnets make them perfect for a 0 centered ammeter. The steel back serves as a nice counterweight. Again, magnets similar to these can be found inside almost any computer hard drive, or...if you like, go to our products page and you'll find several sizes available.**

**Behind the hard drive magnet (attached to the wooden back) is a wooden peg, around which is a coil (3 windings) of 12 gauge romex (normal copper wire for wiring houses). In the picture below, I swung the meter such that you can see detail of the magnet, the pivot, the bottom of the needle, and the coil of wire that drives it.**

There isn't much resistance, the meter works well because of the extremely strong rare earth magnet. More windings on the coil could make the meter more sensitive, less windings would make it less so. It can also be calibrated/centered with a small weight on the back of the magnet or the needle. I have mine set up to read +/-15 amps, this is appropriate for my power consumption/generation. The meter shown in the picture is somewhat inaccurate, as the scale should compress, especially near the ends of the scale. Mine is accurate between 0 and 10 amps, after that it becomes conservative. Simple thing, I think it can make for a more attractive meter for monitoring power systems than most available...at very little cost, if one has a couple hours to spend on it! As somebody who enjoys making/using my electricity, I also enjoy watching it come and go. This meter is sensitive, and moves freely enough that it responds very noticeably to a small 12 volt car stereo, you can easily see it respond to music played at a reasonable level!

# Rewinding a fan motor to get a slow speed DC Generator

Chuck Morrison ©2001

## The electric power plant.

There are two types of generators that we can employ for our wind generator. In the automotive world, we know these as generators and alternators. Generators are properly known as dynamos. The main difference between them is that dynamos utilize a commutator to transfer power from the coils on the armature to the outside world. A commutator is a multi-part cylinder made of copper which allows the brushes to pull energy from the coils only when they are in one position relative to the magnetic poles. In essence, this allows you to "skim the top" of the electric cycles to produce DC. Usually, there is a commutator section for each slot in the armature, although there may be an additional slot. An alternator differs from this in that it has two slip rings instead of a commutator. The alternator produces AC current, which is then usually run through a set of diodes to produce DC.

From the searching you've already done, you are probably aware of how difficult it is to find a generator or alternator that generates an appreciable amount of power at ~300 rpm. How many rpms you need will depend on how many blades are on your turbine and how well they are designed and constructed, but 300 seems to be a good ballpark figure. So how is the search going? Find any 300rpm motors out there? I've heard that there are such motors out there being used for computer tape drives (big tape drives, small wind turbines) and battery powered floor washers (I've never seen a battery powered one myself). My own experience is that these things are rare. Most plentiful are auto and truck generators, alternators and fans.

The first thing to do is to wander around some junkyards and see what's available. Check out the name plates for voltage, current and rpm information. You can check the state of bearings, but I would advise replacing these even if they appear to be OK. They are used and you're proposing to put several million more revolutions on them. If you find a generator, motor or alternator large enough, you may decide to go with it, even though it's rated at relatively high rpms. Now you have a problem you must solve before you can use it. For wind turbine use, you have to get the thing to generate a decent amount of power at a usable voltage at a relatively slow speed. It would be preferable that this be somewhere around 300 rpm or lower.

## Lowering the rpms.

The motor/generator you have is rated at a certain voltage, amperage and speed. These are all tied in together and changing one of them changes the others. A generator rated at 12 volts at 1750rpm, will generate power above and below this speed, but will only supply 12 volts at or above 1750rpm. With a load that draws 12 volts, it will supply power to the load at 1750rpm and above, but not below. This is called the "cut in" speed for that voltage.

To change the cut in speed for a generator or alternator you can

1. Increase the field strength,
  1. Replace the magnets with stronger ones in PM generators
  2. Supply more power to the field coils in shunt generators and alternators. This may require replacing the field coils.
2. Increase the number of field poles,
  1. Replace the magnets with more magnets (in pairs) with the same flux. This may require resizing the armature coils.
  2. Add more field coils in shunt generators and alternators.
3. Increase the number of windings in the armature coils,
  1. More windings should give you more volts at a given rpm, all else being equal. You will probably lose power capacity if you have to reduce the size of the wire. Current is determined by wire size and since power (watts) = voltage x current (amps)... you lose if the current is reduced.
4. or a combination of the above.

PM generator/alternators are preferred by wind enthusiasts. I've rebuilt one for slower speed and was able to do by replacing the magnets and rewinding the armature coils. Let's use that experience to examine this subject.

The motor I found was a model 7600 from Electric Fan Engineering. It was rated at 12 Volts, 50 amps and was a four pole permanent magnet fan motor produced for heavy trucks. It had two rather noisy bearings, but ran very fast when connected to a 12 volt battery, or fairly slow connected to a 12 volt, 3amp battery charger - which was very hot after about 15 seconds of running this fan. I was able to get a reading of around 15 volts when running it off a 1725 rpm motor at roughly a 1-1 gearing. Calling EFE only gained me the information that it was rated somewhere around 2000 rpm. Below is a picture of the insides of this motor. The shell casing is ~8" in diameter (OD), although it isn't exactly round. Note the four large pole magnets inside the casing.

The photo doesn't show the brush assembly or the shell ends and bearings. The four magnets are  $\frac{3}{4}$ " thick and measure  $2\frac{1}{2}$ " deep by  $3\frac{1}{2}$ " long. The magnets are held in by double sided sticky tape and metal spacers. The entire motor weighed in at 45 lbs. The wire on the armature appears to be 15 or 16 gauge copper. It appears to have a rather complicated winding scheme which disassembling did little to demystify. I suspect that it utilized a frog leg winding scheme which is a combination of lap and wave coils. There were four wires coming from each commutator segment, completing two turns around 9 slots, giving a total of 8 turns (4 coils of 2 turns each). It was more complicated than this, but let's go with this simplified version to run through some calculations.

I did some quick calculations based on [Mick Sagrillo's paper](#), which gave the following for just rewinding and not adding magnets.

Volts	Amps	Watts	RPM	Wire Gauge	Turns per coil
-------	------	-------	-----	------------	----------------

12	50	600	1750	15	8
12	25	300	825	18	16
12	12.5	150	412.5	21	32
12	6.25	75	206	24	64

Since I had been really happy about finding a 600 watt motor, I was less than thrilled about putting all sorts of work into it and getting a 100 watt generator out of it. Now of course at higher speeds more power is produced, so this isn't 100 watts max. However, current is dependent on wire size and 24 gauge wire will handle a lot less of it than 15 guar. It will have larger heat losses, especially at only 12 volts. So while this may generate 12 volts of power at +/- 200 rpm, it isn't able to supply the power the original motor/generator could, speed not withstanding.

[Next - magnets](#)

# Rewinding the Armature

As it turns out, my reasoning was flawed concerning the windings and number of poles. According to the text books I was able to find, the coils should span 180 magnetic degrees, or from the north pole to the adjacent south pole. By adding magnets, but not rewinding the coils, I was using coils meant for 4 magnets, and thus spanning 9 armature slots ( $37/4 = 9$  and omit the remainder). This meant that each coil is now spanning 5 changes of polarity or 900 magnetic degrees. Turning the 20 pole generator without rewinding the armature yielded poor results. I thought it over, read a lot and decided I'd have to rewind the armature anyway.

A word about the steel spacers. I originally was going to put them facing the housing. However, in testing I discovered that the magnetic pull from the steel was considerable more than that from the ceramic magnet that it was glued to. I wanted that strength facing the armature. I also figured that if the air gap got too close, it would be easier to grind the steel down than the ceramic. As it turned out, the air gap is small, but when the casing is snugged up, the armature doesn't rub on the pole pieces.

## Adventures in rewinding

Before attempting to rewind the armature, I went to the local university library and took out a few books. The best of these IMHO was *Electrical Machines, Direct and Alternating Current* by Charles S. Siskind (McGraw-Hill, 2<sup>nd</sup> Edition 1959). Reading this helped me visualize what I had to do.

To begin with, I had to strip the old wire from the armature. This is easier said than done. I had hoped to trace the path of the old wiring, but this proved difficult. The wires were heavy and were varnished in place, making for a physically challenging task. It took the better part of a day to pull all the wires from the armature and my right arm was stiff for days afterwards.

When it was finally stripped of all wire, it looked like this:

The stripped armature showing the large copper commutator and the armature slots ready for new coils.

I left the plastic inserts in each slot to protect my own coils. I used the jig shown below to wind the new coils. I had no idea how many turns I'd be able to use and did a little trial and error before settling on 60 turns using 21 guage wire. I was *hoping* 21 guage copper wire would carry 10 amps or so at 60 to 90 volts retaining the 600 watt rating of the original motor at a much slower speed. Revisiting the tables from above, I made some rash assumptions and postulated the following, which turns out to be rashly optimistic, especially the part about gaining, not loosing, wattage.

Volts	Amps	Watts	RPM	Poles	Wire guage	Turns/coil
Original - 12	50	600	1750	4	15	8
Assuming - 12	50	600	354	20	15	8
Maybe - 60 to 90	12.5	612.5 - 900	354	20	21	60

Only testing would tell if I was totally out to lunch. It turns out that I was way off. See the [test results](#) to see how

far off this expectation really was.

In order to make 37 coils, I made the jig shown in the next two pictures. It is made from 1/8" masonite board, scrap 2x4 lumber, a few screws, a 1/4" dowel and a bolt. Epoxy was used on the end piece only, since it had to be disassembled 37 times to extract the coils.

The motor serves only to hold the spool of wire. It isn't plugged in and does not run. Here are two other photos of the winding jig. [View 1](#) and [view 2](#).

37 coils ready to be installed. Note the tape for holding the shape before installing. Each coil is 1/8" thick to fit into the armature slots. The tape is removed on installing so the wires can be moved around inside the slot. The coils are longer than the armature slots so they can go around each other.

The first six coils, lower ends installed. Tape secures the coils until they are installed in the slots.

View showing that each coil skips a slot. Wood strips secure each slot. Each slot contains the front of one coil and the rear of another. Room must exist for the coils belonging to the slot in the middle to cross between the two coils.

The semi finished back side of the armature. Note how the coils are bent over on each other to conserve space.

Commutator side of the armature, showing the connections to the commutator segments. There are two wires attached to each commutator section. When the last segment is connected, every segment is connected to every other electrically. I used [this wiring diagram](#) to determine the pitch (spacing) of the wire ends.

Side view before securing connections. The connections were secured by pounding on the slots holding the wires with a nail punch. I tried soldering, but my heat source wasn't strong enough. Since the slots in the commutator sections originally held much larger wire (15 vs 21 gauge) I wrapped the two wires together, pulled them through one of the two slots, and pounded a lot of brass to get a solid connection.

Next - [finished generator](#)

# Building a solar electric system

My entry into solar energy came as a direct result of my interest in wind energy. I started building a wind generator and purchased batteries so there would be something for it to charge. Then I ended up getting some solar panels because the wind generator wasn't finished. Learning more about how not to ruin batteries led me to purchase a charge controller. Then I had to get an inverter to be able to use all this energy. In the mean while I had to get a tower for the wind machine, install it, get the right kind of charge controller for it, get a diversion load for it, and so it seems to go on forever. It's a fun, if rather involved, hobby.

The 24 volt battery bank. Wieghing in at over 3000 lbs. These are lead cadmium telco UPS batteries. They are not meant to cycle more than 15% from full charge.

The PV combiner box and solar boost 3048 charge controller. These carry 48volts from the PV panels.

The Main disconnect box - 175 amps at 24 volts DC, and the 2.5Kw 24vdc/120vac inverter. This begins the 120 volt AC side of the system.

Here is the overall view of the system. The PV panels are outside the building on the left side. The wiring enters the combiner box and is fused with a 10 amp fuse per panel pair. A single pair (plus ground) leaves the combiner box and goes to the charge controller. 48 volts from the PV panels is converted to 24 volts and sent to the batteries via a 35 amp dual disconnect switch. The charge controller makes use of a temperature sensor connected to a battery terminal. Note that all wiring except for the shielded 2/0 guage wiring to the large Disconnect box and the system ground is in conduit.

Centennial Flight Celebration in Kitty Hawk, North Carolina: Wright Memorial (left), Under Secretary James E. Rogan with Apollo Astronaut Neil Armstrong, the first man on the moon (upper right), the failed attempt to recreate the first flight (lower right).

### Secretary Rogan Attends Centennial Flight Celebration

USPTO Director **James E. Rogan**, joined **President George W. Bush** and other members of the administration at a ceremony commemorating the centennial of flight on **December 17**. The Kitty Hawk, North Carolina event capped a year of celebrations honoring **Orville** and **Wilbur Wright** on the **100th anniversary** of powered flight. Under Secretary Rogan was invited to the event because of the key role the USPTO and the patent system played in the eventual commercial success of the Wright brothers.

From the beginning, the Wright brothers understood clearly that the credit for their work, and potential profits, would vanish quickly if they did not get a patent. Despite initial skepticism from the patent

office regarding powered flight, the brothers eventually prevailed. They were issued a patent three years and two months after the filing of their application. The validity of the patent was upheld by the courts. The Wright brothers patent and company were sold for \$1 million in 1915. After the sale, Orville Wright (Wilbur had died in 1912) continued to collect substantial royalties from several foreign and domestic companies from the patented invention.

Under Secretary Rogan, spent two days in Kitty Hawk participating in the many functions and seminars held in conjunction with the centennial event.

# MAGNETS

---

## Low RPM alternator tests with surplus hard drive magnets 9-13-99

---

In the effort to build my own low RPM alternator for small wind/water power applications, these are some of the tests I've performed and their results. First step is the magnets. I used surplus hard drive magnets which I salvaged from scrap computer hard drives. These magnets 1.4" long, .80" high, and .090" thick. They are nickel plated Neodymium Iron Boron magnets of impressive strength. I sell surplus magnets on my web site. In this test used some of my smaller ones, due to their seemingly unlimited supply.

Item #2 on my magnet web site

---

Next wound a coil from 23 gauge magnet wire. The coil is slightly under 2" long, and consists of 700 windings, with taps at 100, 200, 400, and 700 windings. The core for the coil is made from 20 2" long segments of enameled coat hanger wire, super glued together. This should reduce inefficiencies due to eddy currents through the core. I believe annealing the wire segments would probably improve performance, but I skipped that step here. The spool on which the wire is wound are made from paper, poster board, and super glue. There are certainly better materials to use here, although paper and cardboard worked just fine. The alternator I'm currently building will have spools made of phenolic sheet.

---

Next I took a gear, 5.5" diameter and placed two rings of surplus computer hard drive magnets on it. Each magnet has 2 poles on each face. 7 of these ones fit tightly together in a ring, having 14 poles. I placed two rings of magnets on the face of the gear, one ring containing 7 magnets(which fit together nicely), and the other ring containing 12 magnets(which don't fit as well). The inner ring of 7 magnets is a little over 3.5" diameter. The outer ring is a little over 5.5" diameter. I then placed the gear in a small metal lathe on which I performed tests at 3 different speeds.. I tapped the coil to a boring bar, so that I could adjust its position in relation to the two rings of magnets.

---

Next step was to turn it on, and test the different taps on the coil, at 3 different speeds. I used a 12 Volt, 5 watt light bulb as a load, and tested the voltage of each tap on the coil, at each speed, with, and without the load. The tests were done at 200, 400, and 600 RPM.

INNER RING(7 MAGNETS-14 POLES)  
200 Windings

	200rpm	400rpm	600rpm
Light off	2.3 Volts	3.4 Volts	5.5 Volts
Light on	2.1 Volts	3.2 Volts	4.8 Volts

INNER RING, 400 Windings

	200rpm	400rpm	600rpm
Light off	4.4 Volts	7.3 Volts	11.3 Volts
Light on	3.8 Volts	6.1 Volts	9.1 Volts

INNER RING, 700 Windings

	200rpm	400rpm	600rpm
Light off	6.5 Volts	11.1 Volts	18.6 Volts
Light on	4.3 Volts	7.0 Volts	10.5 Volts

## OUTER RING(12 magnets, 24 poles) 200 Windings

	200rpm	400rpm	600rpm
light off	3.2 Volts	5.5 Volts	9.5Volts
light on	3.1 Volts	5.1 Volts	9.1 Volts

## OUTER RING, 400 Windings

	200rpm	400rpm	600rpm
light off	7.8 Volts	11.8 Volts	18.6 Volts
light on	6.5 Volts	9.9 Volts	14.6 Volts

## OUTER RING, 700 Windings

	200rpm	400rpm	600rpm
light off	13.9 Volts	19.2 Volts	30.9 Volts
light on	9.3 Volts	10.8Volts	14.6 Volts

Considering this data, Its my guess that 400 windings is closest to ideal for charging 12 volt batteries. It surprised me, that in every test performed, the lightbulb did light-though it was rather dim on some. 1 problem with the test, is that the coil was tapped to a boring bar, attached to the compound rest of a rather cheap, old, and worn out lathe. As the machine ran, the coil would creep towards the magnets. Although I tried to keep the gap between magnets and coil consistent, I know this varied some throughout the testing. A slight change in gap has a causes a significant change in voltage. In another test, at 600 RPM with the light on and 700 windings used, output was at 18 volts. It was interesting, to be able to move the coil front/back, and side to side while observing the output voltage.

## IMPROVEMENTS?

There must be many improvements. I have no doubt a better iron core could be used. The length of the coil, I chose 2" off the top of my head, I doubt its perfect, but I'm using that because I am building an alternator that will employ two discs, each with a ring of magnets, on opposite sides of the coil. 2" seemed like a good distance. 23 gauge

wire was convenient, and seemed like a good starting point, though I have a feeling that fewer coils of thicker wire might work better. Stacking magnets? I didn't double up the magnets for fear of the lathe launching them like bullets off the gear. I'm sure that this would have a good effect though-but-it would add to the cost of an alternator. More coils-the coil is exactly big enough such that 7 of them could fit nicely in an alternator using the small ring of 7 magnets. At this point, seems to me like an alternator built with 7 coils hooked either in series or parrallel-(or a combination) would perform reasonably well at low rpm. I have no idea yet what the effect of adding a second spinning ring of magnets to the back side of the coil will be, but I'm sure it will be significant. Although already somewhat obsolete, (because of the base/bearing arrangement) you can see my current alternator project in the picture below. I intend to finish this one, and test the output. The next one will have a much improved bearing arrangement, larger discs, and more coils.

## HP Magazine

[Issue #98 Contents](#)[Download Current Issue #98](#)

Welcome to HomePower.com!

Home Power magazine, the hands-on journal of home-made power, grew out of our passion for renewable energy (RE). We're concerned about a world that is increasingly polluted. We're concerned about the high energy use and waste of "developed" cultures. And we're concerned that people are dependent and unable to care for themselves when it comes to energy. Renewable energy gives people control over their energy future by using energy that is provided daily by nature. New to Home Power... click [here](#) to learn about us!

##### Horoscope (by Astrocenter.com)

You, of all people, dear Capricorn, will recognize and appreciate the need for structure and stability on a day like today. Keep in mind that this practical energy may be working to take away some of the fun out of the equation. Though you may not recognize it at first, the fun in your life may be getting chipped away at, little by little, if you are not careful. Make sure you hold tight to the things that really give you passion and purpose in life. These are the keys to healthy living. - [Tomorrow](#) - [Professional Phone Consultation](#) - [Email an astrologer your question!](#)

### Yahoo! Privacy Policy

Yahoo! takes your privacy seriously. Please read the following to learn more about our privacy policy.

**NOTICE:** [Click here](#) for important information about safe surfing from the Federal Trade Commission.

### What This Privacy Policy Covers

- This policy covers how Yahoo! treats personal information that Yahoo! collects and receives, including information related to your past use of Yahoo! products and services. Personal information is information about you that is personally identifiable like your name, address, email address, or phone number, and that is not otherwise publicly available.
- This policy does not apply to the practices of companies that Yahoo! does not own or control, or to people that Yahoo! does not employ or manage. In addition, certain Yahoo! associated companies such as [Inktomi](#), [Overture](#), [Altavista](#), and [AlltheWeb](#) have their own privacy statements which can be viewed by clicking on the links.

### Information Collection and Use

#### General

- Yahoo! collects personal information when you register with Yahoo!, when you use [Yahoo! products or services](#), when you visit Yahoo! pages or the pages of certain Yahoo! partners, and when you enter [promotions or sweepstakes](#). Yahoo! may combine information about you that we have with information we obtain from business partners or other companies.
- When you register we ask for information such as your name, email address, birth date, gender, zip code, occupation, industry, and personal interests. For some financial products and services we may also ask for your address, Social Security number, and information about your assets. Once you register with Yahoo! and sign in to our services, you are not anonymous to us.
- Yahoo! collects information about your transactions with us and with some of our business partners, including information about your use of financial products and services that we offer.
- Yahoo! automatically receives and records information on our server logs from your browser, including your [IP address](#), Yahoo! [cookie](#) information, and the page you request.
- Yahoo! uses information for the following general purposes: to customize the advertising and content you see, fulfill your requests for products and services, improve our services, contact you, conduct research, and provide anonymous reporting for internal and external clients.

#### Children

- When a child under age 13 attempts to register with Yahoo!, we ask that he or she have a parent or guardian create a [Yahoo! Family Account](#) to obtain parental

permission.

- Yahoo! will not contact children under age 13 about special offers or for marketing purposes without a parent's permission.
- Yahoo! does not ask a child under age 13 for more personal information, as a condition of participation, than is reasonably necessary to participate in a given activity or promotion.

### **Information Sharing and Disclosure**

- Yahoo! does not rent, sell, or share personal information about you with other people or nonaffiliated companies except to provide products or services you've requested, when we have your permission, or under the following circumstances:
  - We provide the information to trusted partners who work on behalf of or with Yahoo! under confidentiality agreements. These companies may use your personal information to help Yahoo! communicate with you about offers from Yahoo! and our marketing partners. However, these companies do not have any independent right to share this information.
  - We have a parent's permission to share the information if the user is a child under age 13. Parents have the option of allowing Yahoo! to collect and use their child's information without consenting to Yahoo! sharing of this information with people and companies who may use this information for their own purposes;
  - We respond to subpoenas, court orders, or legal process, or to establish or exercise our legal rights or defend against legal claims;
  - We believe it is necessary to share information in order to investigate, prevent, or take action regarding illegal activities, suspected fraud, situations involving potential threats to the physical safety of any person, violations of Yahoo!'s terms of use, or as otherwise required by law.
  - We transfer information about you if Yahoo! is acquired by or merged with another company. In this event, Yahoo! will notify you before information about you is transferred and becomes subject to a different privacy policy.
- Yahoo! displays targeted advertisements based on personal information. Advertisers (including ad serving companies) may assume that people who interact with, view, or click on targeted ads meet the targeting criteria - for example, women ages 18-24 from a particular geographic area.
  - Yahoo! does not provide any personal information to the advertiser when you interact with or view a targeted ad. However, by interacting with or viewing an ad you are consenting to the possibility that the advertiser will make the assumption that you meet the targeting criteria used to display the ad.
  - Yahoo! advertisers include financial service providers (such as banks, insurance agents, stock brokers and mortgage lenders) and non-financial companies (such as stores, airlines, and software companies).

### **Cookies**

- Yahoo! may set and access Yahoo! [cookies](#) on your computer.
- Yahoo! lets [other companies](#) that show advertisements on some of our pages set and access their cookies on your computer. Other companies' use of their cookies is subject to their own privacy policies, not this one. Advertisers or other companies do not have access to Yahoo!'s cookies.

- Yahoo! uses [web beacons](#) to access Yahoo! cookies inside and outside our network of web sites and in connection with Yahoo! products and services.

## **Your Ability to Edit and Delete Your Account Information and Preferences**

### **General**

- You can edit your [Yahoo! Account Information](#), including your [marketing preferences](#), at any time.
- New categories of marketing communications may be added to the Marketing Preferences page from time to time. Users who visit this page can opt out of receiving future marketing communications from these new categories or they can unsubscribe by following instructions contained in the messages they receive.
- We reserve the right to send you certain communications relating to the Yahoo! service, such as service announcements, administrative messages and the Yahoo! Newsletter, that are considered part of your Yahoo! account, without offering you the opportunity to opt-out of receiving them.
- You can delete your Yahoo! account by visiting our [Account Deletion](#) page. Please [click here](#) to read about information that might possibly remain in our archived records after your account has been deleted.

### **Children**

- Parents can review, edit, and delete information relating to their child's Yahoo! account using tools offered by [Yahoo! Family Accounts](#).
- If a parent chooses not to allow us to further collect or use a child's information, parents enrolled in Yahoo! Family Accounts can delete their child's account by signing into that child's account and then visiting our [Account Deletion](#) page. Please [click here](#) to read about information that might possibly remain in our archived records after your account has been deleted.

## **Confidentiality and Security**

- We limit access to personal information about you to employees who we believe reasonably need to come into contact with that information to provide products or services to you or in order to do their jobs.
- We have physical, electronic, and procedural safeguards that comply with federal regulations to protect personal information about you.
- To learn more about security, including the security steps we have taken and security steps you can take, please read [Security at Yahoo!](#).

## **Changes to this Privacy Policy**

- Yahoo! may update this policy. We will notify you about significant changes in the way we treat personal information by sending a notice to the primary email address specified in your Yahoo! account or by placing a prominent notice on our site.

## **Questions and Suggestions**

- [Yahoo! is TRUSTe-certified](#). This certification applies to all English-language sites under the Yahoo.com domain. If you feel that your inquiry has not been satisfactorily addressed, you should contact [TRUSTe](#), an independent privacy organization. TRUSTe serves as a liaison with Yahoo! to resolve your concern.
- If you have questions or suggestions, please complete a [feedback form](#) or you can contact us at:

# An Easy to Build and Operate Induction Generator

Believe it or not, nearly everyone you know has at least one induction generator and probably more. That's right! You say that is impossible... well, read on!

Within every home in America there are motors that can be operated as generators. They may not be labeled as generators, but they will function just the same. These motors are often called "squirrel cage motors" and are in washing machines, dryers, water pumps and other devices too numerous to mention.

.....  
**Typical electric squirrel cage motors**

Besides being numerous and cheap, they will generate AC voltage of the purest sinewave. They use no brushes and do not produce any RFI.(Radio Frequency Interference) A motor converted to an induction generator will power flouresent and incandesant lights, televisions, vcr's, stereo sets, electric drills, small power saws and other items.

**OK, what is so great about it?** There is nothing complicated about the conversion, no weird rewiring, no complicated math...nothing! There are no brushes to wear out.

They can not be overloaded; if too much of a load is applied to the generator, it simply quits generating. Removing the load will usually cause the generator to start again. Speeding up the motor will help if it doesn't start right away.

**Yes, but... are there problems?** Well, there is no active voltage regulation, but keeping it within a tested load rating can keep it within any voltage parameters that you set. I feel that a voltage range between 105 and 126 volts is perfectly reasonable.

A motor converted to an induction generator will not start another squirrel cage motor unless that motor is about 1/10 of the horsepower of the induction generator. In other words, a 1 horsepower motor used as an induction generator will start a 1/10 horsepower or less, squirrel cage motor. **It is best to NOT use an induction generator to drive motors. The added inductance of the motor will cancel out the capacitive reactance of the capacitors and cause the generator to quit producing electricity.**

The generator will not start under a load. Not a problem! You shouldn't attach any load to a generator until it is at running speed. This is actually kind of a fail-safe feature.

So far, that is about all of the problems that I've found and I consider those minor.

# How do you convert one?

By adding capacitors in parallel with the motor power leads, and driving it a little above the nameplate RPM, (1725 RPM ones need to turn at approximately 1875 RPM, and 3450 RPM ones at 3700 RPM) the motor will generate AC voltage! The capacitance helps to induce currents into the rotor conductors and causes it to produce AC current. The power is taken off of the motor power leads, or the capacitor leads, since they are all in parallel.

This system depends upon residual magnetism in the rotor to start generating. Almost all the motors I've tried begin generating just fine on their own, with the appropriate capacitor connected of course! If it doesn't start generating, try speeding the motor up. That will usually get it going. However, it is extremely rare to find one that doesn't start.

If a motor doesn't start generating on the **very first try**, then apply 120 vac or even 12 or more volts DC to the motor for a few seconds. That will usually work to magnetize the rotor and your generator will **start by itself from then on**.

**It is important to not shut the generator down with a load connected to it.** This tends to demagnetize the rotor and can cause it to not self-energize. That is, the motor will turn, but it will not produce voltage. It is not a serious problem since the rotor can be remagnetized by following the instructions in the paragraph above.

I've only found one motor that would not consistently generate (out of a dozen or so that I've tried over the years) and it was one with a bunch of wiring coming out of it; it may have been a multi-speed AC motor. I had a 120 volt AC relay in the circuit that temporarily added a 200 uf **starting** capacitor across the permanent 160 uf running capacitor (Using the Normally Closed contacts) to get it generating. When 120 volts was produced, the relay contacts opened up and removed the 200 uf from the circuit. That worked, but it was not dependable. I just gave up on that one.

The capacitors used must be the type designated as "running" capacitors and NOT "starting" capacitors. Starting capacitors are used for a very short time, usually less than a second or two, and would be destroyed by being connected across the AC line continuously. Running capacitors are designed to be connected while the motor is powered.

**NOTE:** Make sure the caps say, "NO PCB's". PCB's aren't used anymore for capacitor construction because it was a dangerous chemical composition. If the caps are old, and you are not sure, don't use them. Be safe!

It is necessary to experiment to find the best value of capacitance to get one working. Start with about 150 to 200 uf for motors 1 horsepower and under. More capacitance equals more voltage output. The final value should be able to produce about 125 VAC when it is putting out 60 hertz with no load. Then plug in 100 watt light bulbs until the voltage drops to whatever lower limit you set. Mine will do about 1050 watts before dropping to 105 VAC.

**Typical Running Capacitors...GOOD! .....Starting cap...Bad!**

---

In the following example, I used a 1 horsepower motor from a Sears water pump that I bought at a junk yard for \$10.00. This motor was capable of operating off of 115 or 230 volts at 13 or 7 amperes respectively.

**Typical waterpump motor**

**Motor:** A. O. Smith 1 Horsepower : 115 / 230 VAC : 13 / 7 AMPS : 3450 RPM

**Capacitor:** 200uf 330vac. This was made by paralleling 4 capacitors that were 65uf, 35uf, 50uf and 50uf. All of these were rated at 330vac or better. All test results are from this capacitor set. (**NOTE:** The final version of this generator has 225uf of capacitance.)

**Output Capability:** This Induction generator has an no load voltage of 125.9 VAC at 60 hz. The generator successfully powered 1050 watts of lightbulbs with a voltage drop of 10.9 VAC to a full load voltage of 105 vac. During the power test, the generator was driven by a 1.5 horsepower electric motor and there was a loss of RPM when the load was increased. I attribute some of the voltage drop to this lack of driving power.

---

The ex-motor, now an induction generator is driven by a well used 3.75 HP B&S lawnmower engine. A total of 950 watts of lights were ran for about 15 minutes with the generator only getting warm. The voltage went from 126 volts open to 110 volts AC under this load.

Notice the capacitor set-up. Here I am trying a suggestion found in an old article, which stated that it is possible to use DC electrolytics connected in series, + to +, and - to - in an AC circuit. I have 4 capacitors rated at 850 uf, 400 VDC in series, for a total of 225 uf @ 1600vdc . The connection is like this:

AC Lead to motor 0-----+||-----+||-----||+-----||+-----0 AC Lead to motor

[Click here for schematic.](#)

Will it work? They seem to be doing just fine, with no sign of heating at all. If they fail or deteriorate, I'll post the info here on the web page.

***New!New!*** I used this generator for 12 hours continuously in the NC8V field day in very hot temperatures and adverse conditions on the weekend of June 26, 1999. The capacitors did ***NOT FAIL OR CHANGE*** in the least. So

I can recommend this use of DC capacitors as a viable option. Of course standard disclaimers apply!

---

**Top Trace: 60 hertz / Bottom Trace: Capacitor phase shift. Overlaid waveforms.**

These traces show the phase shift within the capacitor/inductance combination. The inductance is from the motor windings. Traces were made by feeding a 10 v p-p 60 hertz voltage through a 47 ohm resistance to the capacitor/inductance combination. The top trace in the left picture is the input voltage to the resistor while the bottom trace is across the capacitor/inductance.

---

**Waveform at 950 watt load.**

---

**Note the enlarged gasoline tank. I made this modification in mid June of 1999. This generator was used at the [NC8V field day](#) event and performed perfectly where it ran approximately 12 hours. This one gallon tank allows the generator to run for 4 and 1/2 hours without refueling.**

---

## **Notes on gasoline engines:**

Make sure you get a reliable gasoline engine. Nothing is more frustrating that to have to fight with the engine while you need electricity!

Nearly all the B&S engines that are used on lawn mowers with a direct connected mower blade depend upon this blade to act like a second flywheel for the engine. They have a primary aluminum flywheel inside the engine cover. The aluminum flywheel does not provide enough inertia to work without the blade. The symptoms are backfiring, jerking starter rope and

difficulty in starting. You will probably have to change the aluminum flywheel to a cast iron one. The cast iron ones are pretty common in horizontal engines that are used in rototillers, etc. Usually junk yards or small engine shops will have them. (Also, make sure the magnet matches the one on the original flywheel; they have either one or two magnetic poles which are very obvious by sight.) However, if the generator rotor has enough mass, it may have enough inertia to keep the engine running fine with an aluminum flywheel. Just experiment.

Go with solid state ignition if possible. Ignition points were fine in their day, but the solid state magneto's are great!

Make sure the speed governor works and that the engine is cleaned and serviced reguarly.

The small gas tank on these B&S will give you at least an hour of power. If you need longer running time, then find an engine with a larger gas tank. A gallon tank will give you lots of time with a small engine, probably over 4 hours or so before refueling. Check oil levels at each gas refill, etc.

**If you experience static on radios or TV's that you are powering by your generator:** Sometimes ignition static can be a problem. Rubber boots should be placed over the sparkplug wire so that there is no wiring uninsulated, and then simply cover the sparkplug wire with braided wire and ground it near the magneto coil. Also clamp it around the sparkplug metal base. That will cure it.

Static can be caused by the generator rotor bearings. (I have yet to have that problem!) But, just in case you do: Simply mount a little contact brush against the shaft of the generator rotor and that will successfully ground it and eliminate the static.

---

**Once again I've got to thank Dewey King, NJ8V, for his never ending patience and help with the mechanical hurdles! His expertise in**

## **machining leaves me bewildered.**

All disclaimers apply. I can in no way guarantee that you'll have the same success, but they do work. Be careful too! There is a lot of good ol' AC here and it can be dangerous. I'm not responsible for anything you do!

---

### **Misc.**

- A. This motor exhibits an internal resistance of about 1.5 ohms of AC resistance and .5 ohms of DC resistance.
- B. The capacitor current is approximately 11 amps. Remember, this current exists whether there is a load or not. However it is not 100% "real power", but it is capacitive, with the current out of phase with the voltage. The current,  $I$ , leads the voltage,  $E$ , in this case. The reason this current exists is to keep the generator "excited" by inducing current into the squirrel cage rotor conductors. Calculations seem to put the exciting power at around 55 watts.
- C. The reactance ( $X_c$ ) of the capacitor (200 uf) at 60 hertz is 13.3 ohms.
- D. The reactance ( $X_l$ ) of the motor is (3.8 mh) at 60 hertz is 1.4 ohms
- E. The capacitance and the inductance, being in parallel, does exhibit a resonance. This frequency is 183 hertz.
- F. The engine needs to turn this generator at about 3700 rpm to give 60 hertz output. **(If your motor is a 1725 RPM one, then you'll need it to turn at about 1875 RPM)**
- G. I don't have a clear understanding of exactly why this works... but it does!
-

### Guerrilla Solar Manifesto

We hold these truths to be self-evident, that all energy is freely and democratically provided by Nature, that utilities both public and private have no monopoly on the production and distribution of energy, that this century's monopolization of energy by utilities threatens the health of our environment and the very life of our planet.

- We, the Solar Guerrillas of this planet, therefore resolve to place energy made from sunshine, wind, and falling water on this planet's utility grids with or without permission from utilities or governments.
- We resolve to share this energy with our neighbors without regard for financial compensation.
- We further resolve that our renewable energy systems will be safe and will not harm utility workers, our neighbors, or our environment.

## Meet the Crew

► [Meet the Crew](#)

### [Richard Perez](#)

#### **Publisher & Digital Janitor**

While I facilitate the work of Home Power's editorial, art, advertising, production, sales, Web, and CD-ROM crews, my primary job is Digital Janitor. I maintain and upgrade Home Power's extensive computer systems, a monumental task. I also write articles and editorials. I've been living and working off-grid since 1970 with a photovoltaic/wind RE system. When I'm not working, I like tinkering with Macintosh computers, amateur radio (N7BCR) and electronics, and watching movies with my sweetheart, Karen.

My goal is to change the way people make electricity. Small-scale renewable energy can solve many of our environmental and human problems.

### [Karen Perez](#)

#### **Publisher & Business Manager**

My duties at Home Power include managing the money, paying the bills, keeping business ducks in their proper rows, being a database grunt, doing weird business research (paper, trademarks, UPCs, distributors, etc.), cooking for the crew, and acting as mediator and den mother. My love and joys are critters (currently three dogs and eight cats), gardening, playing with string (knitting, needlepoint, etc.) while listening to audio books or watching movies, loving my bear, and reading.

### [Joe Schwartz](#)

#### **CEO & Technical Editor**

My work life with Home Power is happily schizophrenic. In the office, I help organize the magazine's direction, projects, and crew. I write articles and equipment reviews, shoot photos, and edit text and graphics for technical accuracy. In the field, I install renewable energy hardware for testing, and collect performance data. I'm finishing up my licensing requirements for Oregon's Renewable Energy Technician program. Further afield, I'm busy homesteading an off-grid piece of land east of Ashland,

Oregon. I drive a biodiesel pickup, and I don't use petrol fuels for cooking, heating, or electric backup. In my spare time, I play guitar and ramble about in the backcountry.

### [Ben Root](#)

#### **Art Director**

My degree in graphic design prepared me for the workplace, but not for the shock of our ethic-less economy. I often found myself designing pieces to promote the very aspects of society that I think are its largest problems. Graphic design is about communication, and I didn't believe in what I was being paid to communicate. After selling everything but the VW van, and spending a magical summer in Colorado studying at Solar Energy

Want to make **40%**  
more energy...

**Follow The Sun**

[www.wattsun.com](http://www.wattsun.com)

**RE Directory**  
Find an RE business

International, I had a mission. By doing design, layout, and illustration at HP, I now have something of value to communicate information that interests me and benefits humanity and the planet.

**Linda Pinkham**  
**Managing Editor**

My job is to make sure the editorial and advertising components of the magazine are brought together into a finished and quality product. I am an editor, the keeper of the style guide, and the ring mistress of proofing. I focus on the details and keep track of corrections and suggestions from our editors, authors, and advertisers, without losing sight of our goal. I live and garden on four acres amongst the pear orchards outside of Medford, Oregon with my husband, three dogs, numerous cats, and a horse. We recently installed a 2.1 KW (rated) grid-intertie PV system. When I m not watching the meter spin backwards, I like to go backpacking in the Siskiyou and Cascades.

**Connie Said**  
**Advertising Manager**

I joined the HP staff in 1999 after finishing my degree in anthropology. My primary job is to manage all aspects of HP s advertising accounts, beginning with ad sales all the way through to final publication and billing. I am continually inspired by the passion our advertisers have about changing the way the world makes energy. I live with my 16-year-old daughter, who tells me to breathe as she jumps off mountains to go paragliding. My son is a grad student in engineering at Stanford University and likes to ski, very fast. My children are my joy, and they keep life interesting! My current hobby is collecting and growing heirloom seeds, and being part of a seed exchange to help preserve our plant biodiversity.

**Rick Germany**  
**Chief Information Officer**

I m responsible for all aspects of information technology (IT) and systems, including HP s Web site. I have more than ten years experience in Internet technologies and database integration. My goals include re-engineering Home Power s business processes and IT infrastructure to make them more productive and efficient for the end user and the HP crew. My job allows me to work with technology while supporting the growth of energy technologies that benefit our planet. Yes, I m a geek with a conscience, and a dabbling activist. When I m not plugging away at the computer, I enjoy exploring the outdoors with my wife near our home in beautiful Ashland, Oregon.

**Ian Woofenden**  
**Senior Editor & Word Power Columnist**

My primary job with Home Power is to edit the articles and columns. I take the rough text and try to make it clear and readable for you. I really enjoy working with the authors. Later I proofread the articles, columns, and other text to find the bugs we missed in edit. I write Word Power, do an occasional interview, answer reader inquiries, put together the Letters and Q&A sections, and evaluate articles. And I try (in vain) to keep up with the rest of my over-full life, which includes putting up wind generators, coordinating SEI workshops, trimming trees, singing, and trying to keep my large, off-grid family busy, fed, and laughing.

**Eric Grisen**  
**Graphic Designer & Article Submissions Coordinator**

I work with images, words, and tools at Home Power. I split my time coordinating and soliciting new articles for the magazine, and working on the magazine's layouts, illustrations, and ads. I also write and work on progressive construction and RE projects. My publishing background includes reporting for newspapers, writing for whitewater paddling magazines, and managing editorial projects at a large publishing house. I enjoy traveling with my partner Tiffany, making our own biodiesel from waste vegetable oil, kayaking, mountain biking, Macintosh computers, recycling everything, stinky dogs, and staying active in local environmental and political arenas. I live with renewable energy and telecommute from the Siskiyou Mountains in Williams, Oregon.

#### [Michael Welch](#)

##### **Senior Research Editor & Power Politics Columnist**

My jobs at Home Power include editorial researcher and political commentator. I also answer most of the e-mail from our readers, and assist the editorial staff with indexing, editing, proofing, and other assignments as they come up. In 2003, I celebrated my fourteenth year of involvement with Home Power. My other work is a volunteer position with Redwood Alliance, a nonprofit that works strictly on energy issues. I do most of my work from Arcata, California. The rest of my life is well filled, including enjoying my wonderful daughter, Emily, a future solar bozo.

#### [Marika Rose Kempa](#)

##### **Customer Service/Circulation**

My duties at Home Power include sales of subscriptions and products, database management, and general office work. Being raised in the country, I was shown by my parents how to respect nature. My five siblings and I learned how to make our environment a playground. Away from work, my husband and I enjoy taking our three dogs camping and hiking. I am proud to be part of a company that makes a difference in our world.

#### [Shannon Ryan](#)

##### **Customer Service/Circulation**

I'm a relative newcomer to Home Power and love working for a company whose mission is to help preserve the planet and its resources. I help in our office doing circulation-related tasks, such as answering calls about subscriptions and other customer service matters. I pack orders for our products, back issues, and miscellany. After hours, I love gardening, walking in Oregon's beauty, learning to play the guitar, and spending time with my two rascally parrots. I'm passionate about animals, wildlife, and protecting our dwindling resources. I support various environmental groups attempting to constructively change the present course.

#### [Scott Russell](#)

##### **Marketing Director**

The newest crew member, I'm devoted full time to expanding Home Power's reach and making sure that we keep up with the diverse needs of a rapidly evolving readership. This means analyzing survey data, managing distributor relationships, creating marketing materials, juggling logistics for energy fair exhibitions, etc. I come from a broad background in business administration, information management, RE retail sales, and system installation. Recently back from a six-month stint doing PV work in Nepal, these days I'm busy nursing my very first crop of Oregon veggies, sussing out the local bike routes, and trying to remember the names of the crew's myriad dogs.

**AJ Rossman**

**Data Acquisition Specialist**

I am excited to have just joined the Home Power crew to help with data acquisition and product reviews. My academic background is in electrical engineering, geology, and environmental engineering. I teach a renewable energy design course at the University of Vermont, where I am a Ph.D. candidate researching the applications of renewable energy for groundwater remediation. I am also the president of Draker Solar Design, LLC, an electrical and ecological engineering firm that specializes in environmental data acquisition and display. My wife Kathy and I live in Burlington, Vermont and are eagerly awaiting the birth of our first child.

**Ken Olson**

**Solar Thermal Technical Reviewer**

I review solar thermal articles for Home Power. Practical training in solar energy has been my full-time occupation since 1981. At Solar On-Line (SöL), I teach practical workshops and on-line distance courses. I co-founded Solar Energy International in 1991, and have trained PV technicians for the World Health Organization since 1989. In 1999, I took my family (Barb, Kristin, Sander, and Kaitlyn) to Oaxaca, Mexico for a school year and a change in perspective. We discovered a new way of looking at things and have yet to find our way home to Colorado. My goal is to help more people use solar energy for a cleaner, safer, more prosperous, and peaceful world.

**Chuck Marken**

**Solar Thermal Editor**

I am a licensed electrician, plumber/gasfitter, and HVAC contractor, and I edit and author selected HP articles for technical accuracy. I started installing solar heating systems in 1979 and PV in 1983. New Mexico's multiple climate zones gave our business the opportunity to install and service virtually every kind of solar energy system. My wife Juanita and I have been married for 31 years, and our house and water are heated with solar energy. Our shop is also solar heated, and we use PV to offset utility electricity usage. Whitewater rafting, photography, video editing, cantina ambiance evaluation, and fooling with computers round out my life.

**Smitty**

**Solar Thermal Technical Reviewer**

I assist Ian and Linda by reviewing solar space and water heating articles for technical errors and clarity. I also contribute to What the Heck? features, Tips from the Pros sidebars, and Q&A answers. I actually wanted the HP janitorial position, but that was already taken. So they said, Why don't you clean up articles instead of bathrooms? I figured I've got to start somewhere, and said OK. When not adding to my 26 years in the industry, I put on my starving artist hat and add to my scar collection by playing with lava (blowing glass).

**Shari Prange**

**Transportation Editor & Author**

I grew up in Illinois, and moved to the San Francisco Bay area in 1978. In 1982, my VW was towed into Brown's Auto Service, home of Electro Automotive. By 1983, Mike Brown and I had joined both our personal and business lives. My auto education was on-the-job. In 1988, I put my background as a writer to use as Mike and I coauthored Convert It. My niche is taking technical information and turning it into simple language that a

nontechnical person can understand. We live and work in the Santa Cruz mountains, with our two cats and a boa constrictor. We solicit and consult on alternative transportation articles for HP.

**Mike Brown**

**Transportation Editor & Author**

I'm a Nebraska native, and I studied engineering briefly at the University of Wyoming before settling in the San Francisco Bay area in 1965. I worked as a mechanic at various auto dealerships, but my specialty was Volkswagens. In 1975, I opened my own auto repair shop and gas station. During the gas crisis of 1979, a customer asked me to build an electric car. I discovered a dearth of conversion parts suppliers. So I founded Electro Automotive, and eventually closed my gas car repair business to work full time on electric cars. I now live in the Santa Cruz, California area, and run Electro Automotive with my wife, Shari Prange.

**Kathleen Jarschke-Schultze**

**Home & Heart Columnist**

I had a great childhood in a large family in California's Napa Valley. Checkered past: Psychiatric Technician, EMT, Owner/Rider of a BMW R90/6, Restaurateur, and On-Grid Consumer. Now: Mail-Order Bride, Homesteader, Bee Wrangler, Organic Gardener, Vermi-Composter, Rose Rustler, Garlic Grower, Haus Frau, Cookbook Collector, Solar Cook, Basket Weaver, Self-Proclaimed Vidiot, Raconteur, Avid Reader, International Author, Workshop Presenter, RE Appliance Queen, Tai Chi Student, Trekker, Devoted Dog Mom, Tarot Reader, Fairy Sister Energy Park Electric Co. at OCF, Ham KB6MPI, Sainted Wife of Bob-O, Home Power's First Hired & Retired, Renaissance Woman, Optimist, Survivor.

**John Wiles**

**Code Corner Columnist**

I am a program manager at the Southwest Technology Development Institute at New Mexico State University. I assist the PV industry, electrical contractors, and electrical inspectors in understanding the PV requirements of the National Electrical Code (NEC). I drafted the text for Article 690 in the 2002 NEC Handbook, and serve as secretary for an NFPA-appointed task group involved with Article 690. I installed my first PV system in 1984, and live in an off-grid, PV/wind-powered home (permitted and inspected, of course) with my wife Patti, two dogs, and two cats.

**Don Loweberg**

**Independent Power Providers Columnist**

I was born in 1943 in Los Angeles, California. After being in the army, I completed an MS (Physics) on the GI bill. My wife Cynthia and I own and operate Offline Independent Energy Systems, and have been in business since 1983. The company is a licensed California contractor, specializing in the sale, design, installation, and service of RE systems. We have lived off-grid for 22 years with a solar and microhydro system. I research and write the Independent Power Providers column in HP. I also teach algebra part-time at a local junior college, and sit on the boards of IPP and CalSEIA.

## Writing for Home Power

*Home Power* is a user's technical journal. We specialize in hands-on, practical information about small-scale renewable energy systems. We try to present technical material in an easy to understand and easy to use format. Here are some guidelines for getting your renewable energy (RE) experiences printed in *Home Power*.

### Informational Content

Please include all the details! Be specific! We are more interested in specific information than in general information. Write from your direct experience—*Home Power* is hands-on! Articles must be detailed enough that our readers can actually use the information. Name names, and give us actual numbers, product names, and sources. If you are writing about someone else's system or project, we require a written release from the owner or other principal before we can consider printing the article.

### Article Style & Length

*Home Power* articles can be between 350 and 5,000 words. Length depends on what you have to say. Say it in as few words as possible.

We prefer simple declarative sentences that are short (fewer than twenty words) and to the point. We like the generous use of subheadings to organize the information. We highly recommend writing from within an outline. Check out articles printed in *Home Power*. After you've studied a few, you will get a feeling for our style.

We edit all articles for accuracy, length, content, organization, and basic English. You can help by keeping your sentences short, simple, and to the point. Our editing crew will make your text shine.

### Photographs

We can work from good photographic prints, slides, or negatives. We prefer 4 by 6 inch color prints with no fingerprints or scratches. Do not write on the back of your photographs, since the ink can transfer to the front of the next photo. Please provide a comprehensive caption and photo credit for each photo. Include some vertical format photos—you might even find your system on *HP's* cover. People are nice in photos; a fuse box is only so interesting, even to solar nerds.

Digital photos should be at least 280 pixels per inch (ppi) at the final printed size. This means that a column width photo should be 1,000 pixels wide or more. A full page width photo should be at least 2,300 pixels wide. Basically, set your digital camera at its highest resolution, and crop thoughtfully. We prefer Photoshop files, but we can handle the following formats in descending order of preference—EPS, TIFF, and JPEG.

### Art, Schematics, & Tables

System articles must contain a schematic drawing showing all wiring. Our art department can make gorgeous diagrams, charts, and schematics from your rough sketches. If you want to submit a computer file of a schematic or other line art, please call or e-mail us first.

For system articles, we require a load table listing all loads, with wattage and run time. We also require an itemized cost table listing each system component and its cost. We prefer to have the tables come to us in Excel format. But we can use them from any word processor or spreadsheet

▶ [Writing for HP](#)

**RE Directory**  
Find an RE business

format if they are saved as "text only," with tabs as the delimiter between data.

### Computer Talk

We can take text from most word processors. Save all word processor files in "TEXT" or "ASCII TEXT" format. This means removing all word processor formatting and graphics. Use the "Save As Text" option in your word processor.

If you want to send files larger than 5 MB (such as digital photos), use removable media and snail mail it to us. We can read ZIP disks (either Mac or IBM) and CD-ROMs. You can also FTP your large files to us at [ftp.homepower.com](ftp://ftp.homepower.com), to the "incoming" folder. Please let [ben.root@homepower.com](mailto:ben.root@homepower.com) know after you have sent us files via FTP.

### Putting It All Together

We get many more articles submitted than we can print. The most useful, specific, organized, and complete get published first. Here are the basic components of a great *Home Power* article:

- Clearly written, well organized, and complete text, with a strong introductory paragraph, subheads for each major section, and a strong closing paragraph.
- Photos (plenty) with comprehensive captions.
- Cost table.
- Load table.
- Other tables, charts, and diagrams as appropriate.
- System schematic.
- Complete access information for author, installers, consultants, suppliers, and manufacturers.

Have any questions? Give us a call Monday through Friday from 9 to 5 Pacific and ask. Or send e-mail. This saves everyone's time. We hope to see your RE project in *Home Power* soon!

### Home Power Index - Issue #1 - #97

You are searching the index of past articles in Home Power magazine. We do not make these articles available by download. Many back issues are still available in magazine hard copy. All are included in the annual CD-ROM's which comes out each June. You can purchase our CD-ROM's [here](#).

However, some of these articles are available for free download, either in the [RE Components of our Education pages](#), or in the various subcategories of our [Magazine Downloads page](#). If you do not find the article you are looking for in either of these places, then it is not available for download.

## What the Heck?

Do you stumble on terminology and technical details in Home Power articles? Do you ask yourself, What the heck is a disconnect? or, What the heck does this dude mean by utility interactive inverter? You're not alone. We get lots of e-mail from new readers who read our articles but don't understand what the renewable energy (RE) pieces and parts are.

What the Heck? cuts through industry jargon and gives readers simple explanations of esoteric hardware terminology. They're written by in-the-know renewable energy professionals in easy-to-understand language. And if you have more questions, you can e-mail the authors they are there to help.

1. [Non-Islanding Inverter](#)
2. [Overcurrent Device](#)
3. [Differential Control](#)
4. [Disconnect](#)
5. [Amp-Hour Meter](#)
6. [Charge Controller](#)
7. [Inverter](#)
8. [Thermal Sensor](#)
9. [Load Center](#)
10. [Relay](#)

If you have an idea for a potential What the Heck?, please send it to [submissions@homepower.com](mailto:submissions@homepower.com). We'll try to get your idea covered in a future What the Heck?

## Reader's Marketplace

Sell & Buy your RE-related equipment here.

[Submit](#) a listing today.

Home Power Reader's Marketplace Rates:

25¢ per CHARACTER, include spaces & punctuation. \$20.00 minimum per insertion. All listings are published in both the print and web versions. Please send a check or Visa, Mastercard, American Express, or Discover card data with ad. Please, no money orders. We do not bill listings, they must be paid for in advance of publication. Your cancelled check or credit card bill is your receipt.

Help us prevent fraud! Home Power listings from individuals must supply serial number(s) for equipment being sold. Businesses must supply published phone number(s) and physical address. While Home Power is doing everything we can to prevent fraud, we can assume no responsibility for items being sold.

HP's Reader's Marketplace:

**HYDROELECTRIC SYSTEMS:** Pelton and Crossflow designs, either complete turbines or complete systems. Assistance in site evaluation and equipment selection. AC Systems for standalone or grid interconnect operation. Manufacturing home and commercial size turbines since 1976. Send for a free brochure. Canyon Industries Inc., P.O. # Another homebrew windmill from Volvo parts!

This page is about another homebrew windmill I built using the front strut, hub, bearings, and disk brake assembly from a Volvo 240. The Volvo 240 was built, and sold in large numbers worldwide from 1975 to 1993! There should be lots of cheap parts out there. Surely this design could be adapted to many front strut assemblies. The alternator is very similar to others and if you look at our other experiments, you'll see many similarities. There are a few points of construction which are not addressed in detail on this page, as many elements of it are redundant. Should anybody want further detail, they should read our other pages about the Volvo disk brake alternator, and other alternators we've made.

[Para Español, traducción de Julio Andrade.](#)

Pictured above is the front strut assembly. The only part not shown in this picture is the brake disk itself, which is necessary to make the armature for the alternator. The strut assembly, in the car, contains the strut (a shock absorber), front wheel bearing, hub, and brake rotor. It serves for the basic frame of a compact, and reasonably powerful wind generator. Once the strut is removed, it leaves a steel tube, which fits over pipe at the top of the tower. The wheel spindle is not at a perfect right angle to the tube in which the strut fit, so the prop will be canted back a few degrees from the mast. This may not be ideal in a windmill... Im not sure really - but I doubt it hurts much, and I suspect that more wind comes "down from the sky" than "up from the ground"! So it may be a good thing. It does allow for the blade to be very close to the pivot at the mast, yet well out of the way from the tower. It's actually such, that with a 7' 6" prop, part of it at the very top runs downwind from the mast! Considering that, and how close the prop is to the mast, the tail can be mounted much closer to the alternator than normal - which allows for a short, and stubby windmill! It's also good that the alternator can be based upon the very strong tapered wheel bearings. I feel confident, that if this assembly is strong enough to support the front wheel of a Volvo, it's more than strong enough for a windmill of this size.

The existing studs are knocked out of the wheel hub with a hammer, and replaced by bolts long enough to accommodate the armature, and the prop. A spacer (not shown) has to be made to hold the brake rotor out. The stator will replace the backing plate, and it is much thicker. The magnets in the rotor will also add thickness, and there will have to be somewhat of an airgap between the stator, and the armature (the brake rotor). The spacer will have to be thick enough to make room for all these things.

The stator is made up from a disk of 3/4" plywood 11.5" in diameter. In the center of it I cut a hole (3" dia) with a holesaw. This hole will allow room for the wheel hub. The steel laminates lay into a slot which is cut into the plywood 1/4" deep. The slot is a ring, inner diameter is 9.25" and outer diameter is 10.25". The laminates are made up of strips of cold rolled steel sheet metal, they are 1/2" wide, so they stickout of the stator by 1/4". The steel strips are first coated on 1 side with a coat of insulation - I used plastic tape, and then packed tightly into the slotted plywood disk and epoxied tightly. After they are glued in, I apply another coat of epoxy over the top - and especially around the sides. This insures that the coils will not short out to the steel laminates and they will be clamped on very tightly.

Pictured above is the plywood stator bolted on to the strut assembly. It bolts on exactly in place of the backing plate (the sheetmetal plate on cars which covers the backside of the brake rotor), in fact - I left the backing plate in place and put the wooden stator on top of it, because it fit perfectly inside and I figure the backing plate may provide some protection to the wood against weathering. The bolts that used to hold the backing plate on are too short to go through the plywood stator, but I found that the bolts which hold the ball joint to the strut assembly are exactly the right length! So.. if anybody tries this - save those bolts and try to find a strut assembly with the ball joint attached!

Above you can see the brake rotor with magnets installed. There are 20 magnets in this one, each one is 1.25" diameter X 0.5" thick. Its important that they be perfectly spaced. I cut a shallow slot (about 1/8" thick) in the brake rotor, with inner diameter of exactly 9.25" and outer 10.5" which holds the magnets in place. I spaced the magnets out perfectly, and epoxied them in place. This finished assembly is the "armature".

I made a simple coil winder to make the job easy and the coils consistent in size/shape. It was a quick job to wind up 20 coils. Each coil in this alternator has 20 windings of AWG 14 magnet wire. At this point, it should be pointed out that this is a "Single Phase" machine. It could probably be more powerful and offer some advantages if it were wound as 3 phase or even 2 phase - but this gets more complicated and it becomes difficult for me to maintain a thin enough airgap. So far I've had good luck with single phase, and I believe that this alternator will do an adequate job of getting a reasonable amount of power out of the 7'6" diameter prop.

Once all the coils are made, they are laid out over the laminated steel ring on the plywood stator. They must be perfectly spaced around the circle. Once I was sure all 20 coils fit properly, I took them all off and laid a thin coat of epoxy over the steel laminates. I then put the coils back on - and exactly in place, and cover all the coils with a generous coat of epoxy. The assembly then gets covered with wax paper, and I used another disk brake rotor to lay over the wax paper - although anything which is flat, large enough - and none-flexible should work. I put C clamps around and clamped the steel rotor down over the coils. Once all the clamps are reasonably tight, the thickness of the "sandwich" is measured and the clamps adjusted until the stator is the same thickness all around. This will insure an even airgap when the alternator is complete.

Except for hooking up the coils, the stator is finished in the picture above. The only other thing I did later was coat the entire surface of the wood with epoxy to help the plywood stand up against the weather. This is a good time to carefully strip all the wire ends on the coils. As with other machines I've made, it turns out best to divide the stator in half, and hookup 10 coils in series on each half - then, those halves are hooked in parallel. This allows the alternator to reach cut in voltage (12 volts) at around 250 rpm. It would probably be better to use a heavier wire (like AWG 12 maybe) and make each coil only 10 windings, and hook all 20 in parallel, but this works fine.

The prop is 7' 6" in diameter, and for simplicity and lack of patience I made it a "2 blader". As it turns out - I've had a few problems getting it balanced well and it does vibrate some when it yaws. I'd have probably saved time in the end to make it a "3 blader". The prop is made from normal - mostly knot free 2" X 10" lumber (1.5" X 9"). At the tips, it's 1/2" thick at the thickest part of the airfoil, and the pitch is 5 degrees. At the hub, its the full 9" wide and the pitch is... as steep as the board will allow! Most of the other props Ive made were made from 1" thick or 3/4" thick lumber and worked reasonably well, however - this is the best one yet, it starts up real easily in the lightest breeze and I believe the extra work involved working the 2" thick boards pays off. Pictured above is the process of chizeling out the board. I first cutout the basic shape of the prop, and then draw lines so I know exactly which material to remove. I can cut down to the lines and the wood chizels out easily and quickly. It took about 4 hours to make this prop and it works great.

As stated above, using this assembly, with the prop canted back away from the mast - allows for a very short tail! On this the tail is supported by 2 bolts on a small frame I welded up from rhee-bar. It's very strong. The tail is cutout from 1/2" thick plywood.

All finished up. The performance of this alternator is very similar to the other Volvo disk brake alternator shown on this page. In 30mph winds I see about 50 amps, and I have seen over 100 amps in high winds. I like this one best as it was much quicker and simpler to build - the strut assembly provides a good start!. The finished project is an unusually short - and somewhat "cute" windmill! I built this for installation at my own house, and at the time of writing this page it's been up for about 3 weeks. I'm impressed with its performance, and I've seen it survive some incredibly strong windstorms. We live in a gusty... mountain environment - we rarely see sustained, constant strong winds. I've had no problems with needing a furling - or other system of protection to keep these from blowing up in high winds. It seems they can be built strong enough to hold up - and if they don't, they are usually an easy fix. However - in areas which do have high, sustained and constant winds, a furling system of some kind may be needed simply to keep the alternator from overheating! I'm not sure... one day I'll have to stick one of these down on the plains somewhere and see how it holds up!

# Alternator and Generator Comparison for Wind Power

[| Vehicle Alternators](#) | [| Homemade PM Alternators](#) | [| PM Converted Induction Motors](#) |  
[| DC Generators](#) | [| DC Brushless PM Motors](#) | [| Induction Motors](#) |

[Para Español, traducción de Julio Andrade.](#)

## Vehicle Alternators

- **Advantages:** cheap, easy to find, pre-assembled.
- **Disadvantages:** high rpms required, gears or pulleys needed, low power output, slip rings need maintenance.
- **Suitability for Wind Power: POOR**

The biggest problem with using car alternators for wind power is that they are designed to rotate at too high a speed to be practical in wind power applications without significant modifications. Even a small, seemingly fast windmill might do most of its work at 600 rpm, not nearly fast enough for a car or truck alternator. This means that gearing up with pulleys or other methods is needed, so lots of power is lost to friction--a big problem with wind or water power, but not a problem with a gasoline engine. Check out how useful car alternators can be for building a small gas-powered charger [HERE.](#)

A standard car or truck alternator is electromagnetic-- meaning that some of the electricity produced by the unit must be used internally and sent to the armature through brushes and slip rings to make the magnetic field. Alternators that use electricity to generate the field current are less efficient and more complicated. They are quite easy to regulate, however, since the magnetic flux inside can be changed by adjusting the field power.

Also, the brushes and slip rings wear out, requiring more maintenance. Car and truck alternators can also be rewound to produce power at lower speeds. This is done by replacing the existing stator windings with more turns of smaller gauge wire. This project is not for the faint of heart, but check our [PRODUCTS](#) page for the inexpensive booklet *Alternator Secrets* by Thomas Lindsay if you are interested. The booklet is invaluable for any alternator experimenter! Also, some alternator/electric motor shops may have the knowledge to do this for you.

# Homemade Permanent Magnet Alternators

- **Advantages:** Low cost per watt of output, very efficient, huge power output possible, extremely sturdy construction
- **Disadvantages:** A time-consuming, somewhat complicated project, machining needed.
  - **Suitability for Wind Power:** GOOD

**Homemade Volvo Brake Disc PM alternator, 800 watts, \$150!**

[Hugh Piggott](#) in Scotland was the pioneer in building permanent magnet alternators from scratch. Much of our inspiration came from his designs. Thanks Hugh!

Our experiments have consistently shown that homemade PM alternators are the most powerful and cost-effective solution for building a wind generator. Their low-rpm performance is excellent, and at high speeds they can really crank out the amps thanks to their efficiency. Our more recent PM alternators have been based on Volvo disc brake assemblies, which are very sturdy and have thrust bearings built into the unit. Our larger units are "Disc" or "Axial" designs...a flat plate of magnets rotating next to a flat plate of coils. Our smaller PM alternators are "Radial" designs, where the magnets are fastened to the outside radius of the armature. Since all alternators produce AC, the output must be converted to DC with bridge rectifiers for battery charging.

Our designs to date have been single phase for ease of construction. Three-phase alternators have some advantages (they are somewhat more efficient, and make better use of available space), but

they are somewhat more difficult to build.

With a 7 ft diameter prop, our Volvo brake designs can put more than 60 amps into a 12 volt battery in a 30-mph breeze--that's about 700 watts. We've seen the Volvo design peak at over 100 amps during high winds! This gives these homebrew designs a big advantage over similar-sized converted induction motors, which become inefficient quickly and top out at 20-25 amps output with a 7 ft. diameter prop.

Check out all of our PM alternator projects on our [EXPERIMENTS](#) page!

## Induction Motor Conversion Alternators

- **Advantages:** cheap, easy to find, fairly easy to convert, good low-rpm performance.
- **Disadvantages:** power output limited by internal resistance, inefficient at higher speeds, machining needed.
- **Suitability for Wind Power:** OK

**Armature converted with permanent magnets**

A normal AC induction motor can be converted into a permanent magnet alternator at very low cost. Our experiments have shown that these conversions produce significant power at very low speeds, but become inefficient quickly at higher power levels.

An induction motor has a center core with no wires in it, just alternating plates of aluminum and steel (it will look smooth from the outside). If you rout a groove in this center core to accept permanent magnets, the unit becomes a permanent magnet alternator! We sell super-powerful neodymium magnets that are shaped and polarized perfectly for this application--check our products page.

In practice, our wind generators made with these do quite well until they reach 10-20 amps of output. At this point, they become inefficient quickly--it takes a large increase in windspeed to make only slightly more power, and the rest is wasted as heat inside the unit. The induction motors are wound with wire that's simply too thin for generating large amounts of power. In our tests, DanB's PM induction motor conversion windmill peaks at around 25 amps in 30 mph winds, with a 7-foot

diameter prop. By comparison, a 7-foot prop on an efficient PM alternator made from scratch gives peaks of 50-60 amps in similar winds! Converted motors also have the tendency to "cog" when starting...you can feel the resistance when you turn the shaft. This affects low-speed startup somewhat.

If the lesser output in high winds is acceptable to you, these units can make for a pretty easy wind generator project. Look for AC induction motors of the lowest rpm rating possible. 3-phase motors will perform better than single phase. Since alternators produce alternating current (AC), the power must be converted to DC with bridge rectifiers.

[Tips and photos--converting an AC induction motor into a permanent magnet alternator.](#)

## DC Generators

- **Advantages:** Simple and pre-assembled, some are good at low rpm.
- **Disadvantages:** High maintenance, most are not good at low rpm, large sizes very hard to find, small ones have limited power output.
- **Suitability for Wind Power:** POOR to OK

Generators make DC current, and batteries need DC for charging. Generators were used in automobiles until around 1970, when alternators became more practical (due to the availability of cheap, small diodes). Even old car generators must spin too fast to be practical for wind power, but there have been many good plans for modifying them. Check out our [PRODUCTS](#) page for the *LeJay Manual*, which contains many useful, though involved, plans for doing this. Generators are fairly complex compared to alternators. They must have brushes, and complex commutators.

Brushes require maintenance, and commutators can wear out. For most purposes, alternators are more practical today, although generators do have certain advantages at times. Certain low rpm DC motors can be purchased as surplus and work very well as 12 volt low rpm generators. These are from old mainframe computer tape drives, and are sometimes available in local and mail-order electronics stores, and on Ebay. Check out [Our tape drive motor page HERE](#). They don't make a whole lot of power...you can expect only 100-200 watts of output...but these motors are almost a science project in a box! Slap on a frame and a 3-4 ft prop, and you have a small working wind generator.

**Surplus tape drive motors can make a quick and easy generator for small windmills**

## Brushless DC PM Servo Motors

A brushless DC permanent magnet motor is really just a permanent magnet alternator! A special driver circuit provides AC power that is in phase with the rotation. If you are able to find a large one of these surplus, it's possible you might have an excellent start for a wind power project. They are used in robotics and precision control applications, and some use Nd-Fe-B magnets for high torque in a small space. As with surplus tape drive motors, we would not trust the bearings to stand up in a wind power application...add more bearings so you don't ruin the motor's original front bearing.

We have not yet been able to locate any of these surplus for experimentation. If you have tried this, or have more information on sources, please [Email](#) us! However, we do have a small version...our [Homemade anemometer](#) uses a small surplus brushless DC PM motor, which is available for cheap on our [Products](#) pages.

The inside layout of our tiny Brushless PM DC Motor looks just like the [Wood 103's](#) alternator!

## Induction Motors as Alternators

It's possible to make a 3-phase induction motor produce electricity, either 3-phase or single phase. This requires a controller and capacitor. The generator must run at a fairly constant speed. For this reason, this type of generator is more suitable for constant-speed hydro power installations than for wind, where speed varies--though it can be done. We have not experimented with this technique yet, since we don't have a suitable hydropower source. For more information, check out the book *Motors as Generators for Micro-Hydro Power* by Nigel Smith.

# Witte engine battery charger

This is a brief page about a very effective battery charger I built from an old Witte log saw engine. This type of engine is often referred to as a "stationary" gas engine, most of them were built between 1900 and 1940. Unfortunately most of them were melted down for their cast iron during World War 2. Although I am unsure, I believe this to be a 1.5 horsepower engine, and it is a good match for a Delco alternator with a 14" pulley! This motor runs full throttle at about 300 rpm. The alternator is what folks call a 1 wire alternator. It only has 1 wire to worry about! The regulator is built in and its real simple to hook up. These are often sold as retrofits for tractors, old cars, etc and should be available at most parts stores for around \$50. It's rated 55 amps, and with this setup I get between 40 and 50 amps output!

Witte built this engine in the mid 1920's, specifically for use in a log saw. (see picture above!) This application explains the angled top on the water hopper. These type of motors, although very heavy have the advantage of developing reasonable horsepower at very low rpm (around 300 rpm). They also require a little more attention than the normal small engine. One must be careful to see they always have water in the hopper, oil in the oiler, and grease in the grease cups. Past that, they are reliable, quiet(with a good muffler) and lots of fun to watch. Although they are collectible, and might seem expensive, the price is reasonable when you compare them to a new engine this well built. Surprisingly, parts and support for engines of this type are real easy to find. Check out some of the links off our links page! To make a nice, slow running generator like this with a modern engine, one should look in the 8 - 10 horsepower range.

Since building this generator, I have not used my 120VAC generator. This is capable of putting 600 watts, into my batteries, which is adequate to make up quickly for large loads off my inverter. I'll admit, it's a little work in the morning to start it, but once started it can run for many hours with no maintenance short of adding water. It seems to use about a gallon of fuel every 4 hours, not bad in my opinion...a LOT better than my old Honda generator (which quit after two years) which pounded itself to death charging batteries with a battery charger. Although antique engines may not be everybody's preference, a good slow running charger like this should be an important part of any "off the grid" battery powered system. Something like this, a good battery bank, and a strong inverter can go a long ways!

# Converting common induction motors to low rpm alternators

Induction motors are commonplace, you'll find them on tools, furnaces, blowers...etc. It is possible to convert them into effective brushless low rpm alternators by installing permanent magnets in the armature. We have performed experiments installing surplus computer hard drive magnets into the armatures. Undoubtedly, a "surplus" magnet is probably not optimized for the application, but the results have still been promising and we think it might be a cheap, quick, and practical approach to building a low rpm alternator. Unless extremely creative, one would probably need to have, or find somebody who does have, a metal lathe...that makes it a half hour project.

[Para Español, traducción de Julio Andrade.](#)

**NOTE 06/25/2003 -- We've stopped experimenting with these conversions. They work, but the windings of the motors are just not made for producing lots of power. The resistance is way too high, which makes them VERY inefficient once they reach higher speeds. They also cog, which causes slow startup. We've found**

**that it's the same amount of work to build an efficient alternator from scratch as it is to convert an induction motor, and the home-made alternators perform MUCH better. You can see some of our latest, most powerful, and most efficient from-scratch PM alternators on our [HERE](#).**

## **Magnets**

**Pictured above are the magnets we've used, though undoubtedly any small magnets could be arranged to work reasonably well. The magnets we used are rectangular, and arched such that 8 of them fit to form a ring approx. 3 3/4" diameter (pictured above), which seems to be a fairly good match for induction motors from 1/2 hp to 2 hp. The magnets come out of a computer hard drive, ours are surplus, and are available from our products page. They come magnetized with either the North or South pole on the concave surface. These are NdFeB (Neodymium Iron Boron) magnets, of extremely high grade - much stronger than normal ceramic or AlNiCo magnets.**

**UPDATE 6/25/2003 -- These magnets were surplus, and they have SOLD OUT. We cannot get any more. We do have some rectangular block magnets that should do the trick, and still fit inside the armature....you'll just have to turn out the slot differently. You can check out of magnet selection [HERE](#).**

## The Armature

The armature will need to have a slot cut, to accept the magnets. We think they should press in fairly tightly, and then glued applied(epoxy is probably best). Odds are the curvature of the magnets won't match up perfectly with the diameter of the armature, so the slot needs to be deep enough so that the highest point of the magnets is flush with the surface of the armature. In the armature above, there are 6 magnets used. We used feeler gauges to even up the gap between the magnets.

Undoubtedly one could drill out the armature to accept disc magnets, but disc magnets are not ideal, and some performance would be compromised. Of course, the number of magnets used depends upon the number of poles in the motor. A 3600 rpm motor would have 2 poles, 1800 rpm 4 poles, and 1200 6 poles. Voltage is dependent upon the speed at which the magnetic field changes, so...the more poles, the better candidate the motor would be for a low rpm alternator. The lower the rated speed of the motor, the better it will work at low rpm. In our tests, we always used the same number of magnets as poles, except in a 2 horsepower motor, which had 4 poles. In that motor we installed 8 magnets, but in sets of two such that there were 2 North and two South poles on the armature.

## Results...

The first motor we tested was a 1/2 hp furnace blower motor, rated at 7 amps and 1050 rpm. It had 6 poles and we installed 6 magnets in the armature, equally spaced. It cogs(when the magnetic field locks in with the slots in the motor stator) enough such that it is difficult to turn the shaft of the motor. It hits charging voltage(12 volts) at approx. 80 rpm! At 400 rpm, it will charge 12 volt batteries at

over 10 amps. We tested this with a wind generator propellor - [click here to see more on that!](#) Basically, it worked fairly well, but the wind speed had to hit about 10 mph before the propellor would start turning. Once it started turning...it kept spinning and generated well. We also hooked this one up to a bike- it would easily put 10 amps into the battery with pedal power. I suspect this one would probably peak at 15-20 amps, but it becomes inefficient after about 10. This could be changed if one could make a regulator which would take the coils in the motor(alternator) out of series and put them in parallel at a certain rpm. Another drawback of this motor...it was a fairly cheap furnace blower motor, with bronze bushings, it might last longer with higher quality bearings.

The second motor was a 2 hp single phase 1800 rpm, rated at 15 amps. In this motor we installed 8 magnets. Oddly, these computer hard drive magnets just happen to be a perfect fit, there are no gaps, and no overlap - the diameter of the ring is exactly that of the armature. The magnets on this motor are in sets of 2, so...we put 2 magnets with North up, then 2 magnets with South up...etc, so that there are 4 magnetic poles on the armature. This alternator doesn't cog nearly as bad as the first one, and would certainly work well on most windmills. It doesn't reach charging voltage until about 150 rpm, but...at 400 rpm it charges my batteries at over 15 amps, and would probably be efficient up to 20-30 amps.

Both of these test alternators become very difficult to turn by hand if the wires are shorted...even a couple of rpm by hand will produce a very noticeable spark at the leads. This might be an excellent alternative, considering the difficulty and labor required in making an alternator from scratch. Considering just how slow these alternators are charging, they may have the most potential of any low rpm alternator we have yet to run across. We'd like to know what other folks have done in this area, so please send us an email if you have any ideas/experience.

# HOMEBREW WIND GENERATOR

---

This page is about a windmill experiment. The windmill was built for under \$100, and although there is certainly much room for design improvement, it works fairly well and should provide some data to other folks who'd like to build their own from scratch! If time is money, and one has more money than time, it might be wise to buy a commercial machine, there are many good ones starting from about \$500 on up, however to build one at home is fun, and it can save a lot of money! It's my hope that "experts" (folks more knowledgeable than myself on this topic) will review this page and offer suggested improvements on our discussion board! This page will break down the components of the machine and in the end I'll discuss what I know about its performance!

## The Propeller

The propeller for this machine is a 3 bladed design. Although a 2 blade prop is simpler to build, they have the disadvantage of being harder to start. The other drawback is that when the wind changes direction, a 2 blade prop tends to vibrate

quite a bit while turning. This is hard on the prop, and the generator bearings. I made my prop out of spruce 1" X 4" boards. I tried to pick 3 boards which were knot free, had good vertical grain and seemed to have similar density. (they weighed about the same). Of course other types of wood could be used, this is what I had available. I've made very good props from redwood, ponderosa and lodgepole pine with no problems. I used 1" X4" (actually - it was planed down to about 3/4" X 3 1/2") because I wanted the prop to be light weight, I think this helps them start faster and preserves the bearings on the generator. It seems consistent with props I've seen on small commercial windmills. I carved my prop real fast, took about 2 hours. Undoubtedly, had I spent more time I'd probably have a better prop, but...I have seen folks spend a week on this stage and I feel it can be a fairly quick and simple project. I used "intuition" on both the pitch of the prop, and the airfoil shape. I simply marked 1/4" down on the thickness of the prop, so that over the 3 1/2" width the low end would be 1/4" below the high end. There is a LOT of information on prop carving, airfoil details etc on the Internet. The Lee-Jay manual, published in the 1930's also has good simple instructions for both propeller carving and building a windmill from scratch. See the picture below....

Once roughed out, I weighed each prop and planed them down so they were the same. I then bolted them together, two at a time, and further planed them down so they were reasonably balanced. Once all three blades were the same weight, I painted them, and bolted them to a hub (an old gear about 8" diameter). Once on the hub, I could put the whole assembly on a shaft, and spin it. I would observe the place in which the prop stopped, if it had tendency to stop in 1 place more often than others, I would plane down the heavy side(s) until it seemed perfectly balanced. (of course I had to paint those spots again!). The whole process of building this prop, and balancing it took less than 4 hours. It should be noted that all 3 blades, after being balanced, were NOT of the same thickness. At the tip, they varied from in thickness by over 1/8"! This could have been prevented by finding better wood, and taking more time in the initial carving of the prop. The main tool I used for carving this prop was a power planer. It should also be noted, this prop has NO twist, the pitch remains the same from the hub,

to the tip. Although unsure, I do not think this hurts, especially in a small machine. Total prop diameter is approx. 6 1/2'...although, to be honest, I never measured it! This is the same propeller I tested on my model A ford. [Click here](#) to check out that page! . It worked so well on the Ford test, that I figured it would hold up on a windmill. The only modifications I made since that test was to cut about 8" off the diameter and further balance it.

## The Alternator

The alternator used in this windmill is a 2hp induction motor which I took off a Taiwanese milling machine. I took it apart, and cut a slot into the armature with a metal lathe so that I could insert 8 Neodymium rare earth magnets, thus turning the induction motor into a permanent magnet low rpm alternator. The magnets are rectangular in shape, and curved such that they seem to be a good fit in the armatures of most induction motors 1/2hp on up. I cut a slot in the armature so that when pressed all the way down, the highest point on the magnets is flush with the outer diameter of the armature. The slot is cut so the magnets are a tight fit, and the magnets are glued in with epoxy. This is a 4 pole motor, so it requires 4 alternating poles in the alternator. To accommodate 8 magnets, I had to insert them in pairs, with two magnets of identical polarity beside each other. These particular magnets are surplus from computer hard drives and are available with both North, and South on the convex surface. See a picture of 8 of these magnets in a ring below. You'll find these same magnets for sale on our products page.

The alternator is wired so that it hits 12 volts at approx. 160rpm. Had I wired the motor differently it could have hit charging voltage at 80 rpm, but I was afraid this would limit the current too much. Of course, the output here is alternating current and it must be rectified before charging batteries. I used a 40 amp bridge rectifier to reach this end. We also offer large bridge rectifiers on our products page. It is very important that when using a diode, or a bridge rectifier in this application that it be attached to a suitable heat sink, or else it will get too hot and burn up! [Click here](#) to see our experiments page about converting induction motors into low rpm alternators.

## The Tower

The tower is probably the MOST important part of any wind machine, and is often the most neglected....this is probably the case here! I put this up in the middle of Feb, it was very cold, the ground was very frozen and I didn't have the ability to pour a proper concrete pad which I think would make for a nice tower base. I also have the disadvantage of being in a forest, with no level ground. Although this works OK, I feel a much higher tower would be appropriate. My windmill currently sits 36' feet above the ground. I removed one large pine tree, as I thought that would be the best place for the tower. I cut the stump off about 3' high, and notched it with a chain saw. The mast is made from a lodgepole pine. The base of it was drilled through so that it could pivot in the stump. The top of it has a steel assembly made from pipe, to allow support and pivoting of the windmill. I while assembling the windmill the tower was

supported off the ground by a small tripod made from lodgepole pine. A larger tripod was used for raising it. The tower is supported by 4 guy wires of 1/8" diameter aircraft cable with turn buckles on the ground for adjustment.

I simply used a truck, a long cable, and the large tripod to raise the mast, it went smoothly!

## The windmill chassis and tail

The windmill is really very simple. I started with a 3/8" thick piece of steel to which the alternator could be bolted. To that I welded a pipe, which fits over a smaller pipe on the top of the tower - this is what the windmill pivots on. There are no slip rings in this machine, I simply ran enough aircraft cable so that the machine could pivot several times before it gets tight. The power line from the alternator is slightly longer than this cable, the idea being that the aircraft cable will get tight just before the power cord. The tail sits back about 4' from the pivot, and is bolted into angle iron. Two 1/2" diameter steel rods serve to further support the tail. In home built windmills I've seen...tails breaking off seems a common problem. This part needs to be strong, and a well balanced prop will also help prevent metal fatigue. I offset the tail, and the alternator slightly from the pivot, in hopes that it would turn out of the wind should it get too fast. This was done intuitively, I have no specific data on how to do this right, but it was my intention to move in the direction of several home-built windmill I've seen before. See Hugh Piggots design!

## Performance

So far, so good. The alternator has a slight cogging affect, which keeps this machine from starting easily at low wind speeds (below about 10mph). This could be solved by a bigger prop, wider blades, or...more blades! I think should I try to improve this I

will use wider blades. Once started it keeps spinning well at very low speeds. We have very gusty winds, the direction changes frequently so it is difficult for me to offer specifics on output vs wind speed. Best output I've seen in high winds is approx. 25 amps, though typically it puts out 5-15amps (into my 12 volt batteries) in low, to medium wind speeds. It is possible that a regulator could be made with a matching transformer or possibly a linear current booster that would better match the load to the alternator and provide significantly more output, I've not tried this yet. This machine does perform much better than smaller ones I've made using surplus DC tape drive motors, and so far it has held up well to extremely high winds. It does seem to turn out of the wind somewhat in extreme conditions, although I doubt it needs to.

Again, building these at home is fun, and rewarding. Lots more fun, in my opinion than buying an expensive new machine! I hope that folks provide input about their own machines, and their comments about this one! This machine, although fairly quick and easy to build, is a culmination of several experiments....the prop, the alternator, the tower. Please check out our products page for a few of the items I used to build this machine and some interesting books!

### **April 8 update**

After about 8 weeks up, there was a breakdown! On the radio they were predicting 80+mph winds. I took care to go out, make sure all the guy wires were good and tight and did what I could to help insure its survival. At about 4pm I woke up to a most unpleasant sound. Although still running, and pegging the 20 amp meter it definitely had a problem. Turns out she threw a blade in extremely high winds. Considering the lack of time I put into them, it really came as on surprise and I was grateful for the data.

I found the piece of broken blade only 20' from the base of the mast. Turns out, the

blade definitely had a crack in it, before I even raised the windmill, I could tell by the paint which had seeped into the wood. The other two blades were still in fine shape, suggesting that the design would have been good, had I taken more care to use better wood in making the prop. This was especially surprising considering how long the machine ran in extremely high winds, with only two blades!

Rather than replacing the one broken blade, I decided to make a new prop all together. It's slightly larger, the diameter being just over 7 feet. These new blades are 4" wide at the hub, and 3" wide at the tip. The wood is much stronger. The pitch is similar, although this new blade has a little twist to it. Although it's been up for less than 24 hours, I can already tell it starts much easier. It's still real quiet even at high speeds. It should make for an interesting test, the tips of this new blade are only 3/8" thick. The blades are of good vertical grain pine, each one weighs exactly 11 oz.

Other good information from this breakdown...the tower. It came down and went back up very easily with no problems at all. I simply used an A frame built from lodge poles, my truck, and a cable. Total down time, 4 hours, thats how long it took to lower it, build a new prop, finish it and get her back in the air again!

In conclusion, I believe, judging from the improvements on the new props that this machine will probably hold up well over time. In watching it for a few weeks now it seems to do a find job producing up to 400 watts. In "normal" winds it produces between 100 and 200 watts. It seems to outperform some small commercial windmills, which I have also had opportunity to watch. It's very quiet even in high

winds. Overall I would say this experiment has been a good one! Please email us with comments, questions, or suggestions.

# Computer tape drive motors

These may well be the best, most inexpensive, ready to go low rpm DC generator out there. They are *not* ideal for wind and hydro power, but they are very convenient! Check out our [Choosing an Alternator or Generator](#) page for more details on their advantages and disadvantages. Expect a maximum of 200 watts from the larger versions (about 4 inches diameter by 8 inches long) and 100 watts from the smaller ones. They are surplus, from large mainframe computer tape drives. The supply seems to be getting scarce--we had a few in stock at one time--but they sold out quickly and we have not been able to obtain any more. They seem to come in many sizes, the larger ones usually having higher output. We've built and seen many very successful wind generators made from these, usually capable of 150 watts at best. They seem to be well built, have robust bearings and can hold up for years. The bearings are not really designed for a thrust load, so adding another bearing and shaft might be wise. They are DC motors, so they do have brushes which do wear out. Some of these will generate 12 volts at less than 300 rpm! Even simply shorting out the leads makes them difficult to turn by hand (a good sign for a low rpm generator). These generators have 4 ceramic grade permanent magnets in them. Maximum current before demagnetization occurs is 24 amps. Weight, 10 lbs. +/-.

## Current Best Bets for obtaining these motors:

[Ebay](#) -- around \$50, lots available  
[C&H Sales](#) -- around \$60, available

## Surplus Sales of Nebraska (no website)

Local electronics stores -- many small mom and pop electronics stores have a couple of these around.

Our experience....a windmill with one of these might need taken down once every two years to replace the ball bearings and brushes. One of our neighbors built a very simple hydro system, out of a squirrel cage fan and one of these. They are also well-suited for direct connection to a small pelton or turgo wheel for hydro power, a bicycle for human power, a circular wire cage for dog or cat power...

**In a battery-charging application, you will need a heat-sinked diode in the circuit, otherwise the battery will simply spin the motor. We sell 35-amp diodes on our products page.**

Our test results from these motors appear below. Please note that these tests were approximate--the lathe we used for testing them started to bog down at about 9 amps. In our experience using these for windmills, they can produce much more current than this. The voltages given are OPEN CIRCUIT, the amperages were measured while connected to a battery bank. As with any generator or alternator for battery charging, the battery bank will hold the generator's voltage down to its own level during charging, until the batteries fill. At that point, you need some sort of regulation that does not allow a wind generator or hydro plant to overspeed and 'freewheel' -- in other words, a load of some sort must be kept on the motor after the batteries fill. These motors are ideal for charging 12 volt battery banks!

RPM	Large Motor Volts	Large Motor Amps	Small Motor Volts	Small Motor Amps

# The Wood 103

## All-Wooden Wind Generator

Built in a day

**Our article about this silly Wooden Windmill was published in issue #88 (April/May 2002) of Home Power Magazine! You can [Download the entire Wood 103 article HERE](#) in .PDF format. You'll need [Acrobat Reader](#) to view it. *The***

## ***article goes into much more detail than the text below...Please refer to it first!***

---

**UPDATE (05/22/2003): We are now completely SOLD OUT of Item#7, the magnets we used to build this project.**

**They were surplus, and we can't get any more. We do have other magnets that could be used with a little adaptation of the design....check out NdFeB magnets on our [Web Shopping Cart](#).**

---

This page is all about a rather silly, quick project where in about 1 day I built a small wind generator using the following items, and nothing else....

- (1) Wood
- (2) Copper wire
- (3) Surplus Neodymium magnets
- (4) Dirt
- (5) 10" piece of 3/8" steel shaft
- (6) Two bolts, but these are optional.

...and that's all, unless we count glue, and linseed oil which I used for finishing. Initially the project started out to simply be an alternator experiment. Once I had the armature finished and a couple of the coils wound on the stator, I realized it was definitely going to be a successful one, so I decided to build it into a small wind generator. Mostly simple tools were used, although a band saw, wood lathe, and drill press came in pretty handy.

Pictured above is one of the magnets I used. These are surplus magnets from computer hard drives, one of my favorites for alternator experiments. They are about 1.75" long, 1.4" wide, and a quarter of an inch thick. 8 of them will fit together to make a ring. **We no longer have these magnets in stock. They were surplus, they are sold out, and we can't get any more. But this design could easily be adapted to use different size or shape NdFeB magnets.**

Above you can see the armature for the alternator. I simply laminated wood until I felt it was thick enough to hold the magnets securely. After they were glued together, I lathed the armature down to match the diameter of a ring of 8 magnets, I cut a slot so the magnets could be pressed/glued in. Epoxy is probably the best glue for this. In the center I drilled a hole and glued/pressed in the 3/8" diameter shaft. Keep in mind, this alternator has 8 poles, and the magnets must have alternating poles facing out.

Pictured above you see the wooden pillow block bearings. I simply drilled a hole, slightly under 3/8" diameter, and then using a gas stove, heated the shaft to almost red hot, and forced it through the holes. This makes for a good tight fit, and it serves to harden the wood, and the inside of the holes has a layer of carbon, which makes for a better bearing. These bearings are from pine, certainly a harder wood would work much better! In the top of the pillow blocks I drilled a small hole so that the bearings could be oiled/greased. Once the alternator was assembled, there was no play in the shaft at all, and it turned freely. Even after several hours of hard running, the bearings are holding up well. It's interesting information, although I would certainly encourage anybody building a windmill to use steel ball bearings. I just did wooden ones for the sake of fun, and simplicity. Odds are, on a slow running machine, like a slow water wheel, wooden bearings, properly made could last for years. This is actually a high speed windmill and I should think these would wear out quickly.

The stator, on which the coils are wound was cut from two pieces of 2" X 4" lumber. The inner diameter is 1/2" larger than that of the armature, and to the sides are thin plywood pieces with holes drilled for winding the coils. Inner diameter of the plywood pieces is only slightly larger than the diameter of the armature. This allowed for "hollow coils" into which I would have a "dirt" core to attract the magnetic field through the coils. These coils are wound with #22 AWG enameled copper wire, each coil is 100 turns. The coils are wound in opposite directions.

I dragged a magnet around in the dirt of my driveway, so that it would attract the magnetite sand. Pictured above you can see the pile I used, with a stack of magnets demonstrating its magnetic properties.

The dirt was mixed with epoxy, so that I had a thick paste. I simply spooned it inside the hollow space in the stator. This makes for a reasonable core, and although it does not work nearly as well as steel laminates, it's much easier. Making steel laminates is a nearly impossible task without significant time and tooling. The magnetite paste does a good job of attracting the magnetic field, and is non-conductive so eddy currents are not a problem.

The completed alternator! I was real surprised by the performance. I could easily spin it up with my fingers to produce over 12 volts. Attaching a cordless drill to the shaft, it would light up a 25 watt 12 volt light bulb easily! Although this may not seem breath taking, I thought it was, considering the simplicity of the project! It was at this point I decided it deserved a windmill for testing!

To stay with the "style" of the project I decided to build the whole windmill out of wood, it's a fairly simple design and should be self explanatory. It's glued and pinned, with wooden dowels, no bolts are used except to bolt the alternator on it. I cheated there.

The prop is wooden, made from 1" X 4" lumber. Each blade is 3.5" wide at the base, 2.5" at the tip, and 2' long, for a total diameter of 4 feet. The pitch of the blade is 10 degrees at the hub, and 6 degrees at the tip. The hub is simply made from 2" thick wood, and glued to the shaft with epoxy. The blades are held on by one small nut at the end of the shaft, and several wooden pins. So far its held up well! Hope I never feel like taking it apart, because it would be nearly impossible...

So there it is, all finished up! I took it for a test drive in the model A Ford. I didn't want to break it, so I never took it over 25 miles per hour, but it seems to perform well (considering). In a 25 mph wind it produces about 60 watts (5 amps into a 12 volt battery), so I think I can give it an optimistic rating of 100 watts...not bad for a 1 day project made entirely of wood. Obviously, it's not made to hold up over the long term, it was merely a fun little test, but I think the alternator provides some interesting data. I feel pretty sure now that with little work one could definitely build a very useful alternator completely from scratch. By simply increasing the diameter some one could get a LOT more output from a very similar machine. Of course, using better bearings would be wise, but I like the use of wood, because it is a material which is widely available, and easily worked with the simplest of tools. Thanks for dropping in and letting me show off this silly windmill!

# The Wood 103

## A Wooden 100 Watt Wind Generator

Dan Bartmann  
& Dan Fink

©2002 Forcefield

The Wood 103 was built mostly of wood in just a few hours, with very little number crunching. Producing 100 watts in a 30+ mph wind ain't bad for a weekend project!

**T**he initial goal of our project was to build a functional, permanent magnet alternator from scratch, primarily out of wood. When the alternator was together and working, it became clear that wind was the logical energy source for it. This unit (we call it the “Wood 103”) is not intended to be a permanent addition to a remote home energy system, but a demonstration of how simple it really is to produce energy from scratch—and to be a bit silly!

Many homemade wind generator designs require a fully equipped machine shop to build. Our wooden version, built in a day, can be made with mostly local materials and simple hand tools in any remote corner of the world. The alternator design is well suited to hydroelectric, human, or animal power. We plan to use it for a series of magnet and electricity demonstrations at

local schools, and for future experiments with different energy sources, windings, cores, poles, and rotors. This project will cost you only US\$50–75, depending on what you pay for magnets and wire.

### Alternator Basics

Electricity is simply the flow of electrons through a circuit. When a magnet moves past a wire (or a wire past a magnet), electrons within the wire want to move. When the wire is wound into a coil, the magnet passes by more loops of wire. It pushes the electrons harder, and can therefore make more electricity for us to harvest.

The magnetic field can be supplied by either permanent magnets or electromagnets. All of our designs use permanent magnets. In a permanent magnet alternator (PMA), the magnets are mounted on the armature (also sometimes called the “rotor”), which is the part that spins. It is connected directly to the wind generator rotor (the blades and hub). There are no electrical connections to the armature; it simply moves the magnets. Each magnet has two poles, north (N) and south (S). The magnets are oriented in the armature so that the poles alternate N-S-N-S.

The Wood 103 has three, 2 foot, hand-carved blades, creating a swept area of 12.5 square feet.

The other half of a PMA is the stator, which does not move. It consists of an array of wire coils connected together. The coils in our stator alternate in the direction they are wound, clockwise (CW) and counter-clockwise (CCW). The coils and magnets are spaced evenly with each other. So when the north pole of a magnet is passing a clockwise coil, the south pole of the next magnet is passing the counter-clockwise coil next door, and so on.

The coil cores are located inside or behind the coils, and help concentrate the magnetic field into the coils, increasing output. The cores must be of magnetic material, but also must be electrically nonconductive to avoid power-wasting eddy currents. The air gap is the distance between the spinning magnets and the stationary coils (between the armature and the stator), and must be kept as small as possible. But the spinning magnets must not be allowed to touch the coils, or physical damage to them will occur.

**Permanent Magnet Alternator**

The more loops of wire that each magnet passes, the higher the voltage produced. Voltage is important, since until the alternator voltage exceeds the battery bank voltage, no electrons can flow. The sooner the alternator voltage reaches battery voltage or above in low winds, the sooner the batteries will start to charge.

Increasing the number of turns of wire in each coil allows higher voltage at any given speed. But thinner wire can carry fewer electrons. Using thicker wire allows more electrons to flow, but physical size limits the number of turns per coil. This also explains why enameled magnet wire is always used in coils. The enamel insulation is very thin, and allows for more turns per coil than does thick plastic insulation. Any alternator design is a compromise between the number of turns per coil, the wire size, and the shaft rpm.

The electricity produced by an alternator is called "wild" alternating current (AC). Instead of changing direction at a steady 60 times per second like standard AC house current, its frequency varies with the speed of the alternator.

Since we want to charge batteries, the wild AC is fed to them through a bridge rectifier, which converts AC to DC (direct current) for battery charging. The alternator may produce much higher voltages than the battery bank does, but the batteries will hold the system voltage from the wind generator down to their normal level when charging.

### Design

We had successfully converted AC induction motors into PMA wind generators before. But starting from scratch was truly a first-time experiment. Our design choices for wire size, number of windings, number of poles, blade pitch, and other factors were intuitive rather than calculated.

Every wind generator, waterwheel, and alternator we've built has produced usable energy, no matter how strange the design. The trick is matching the generator, rotor, and energy source. You can do a lot of study and calculation to get there. But if the design is quick, cheap, and easy to build, why not just make adjustments by observing the unit's performance?

If you try this project and change the wire size, magnet type, rotor design, and stator cores, you'd still be making usable energy and have a great starting point for further research. Just change one thing at a time until the unit performs to your satisfaction. We're aware that many design improvements could be made to the Wood 103—and we hope that others will experiment with variations.

### Wooden Alternator

The biggest problem with building most wind generator designs at home is the need for machine tools—usually

### Wood 103 PM Alternator: End View

## Materials Used

The materials we used are not hard to find:

- Wood, the harder the better. We used pine since it was locally available.
- Copper magnet wire, about 100 feet (30 m), enameled #22 (0.64 mm diameter).
- Eight surplus neodymium-iron-boron magnets, four with the south pole on the convex face, and four with the north pole on the convex face.
- Dirt (magnetite sand).
- A 10 inch (25 cm) piece of 3/8 inch (9.5 mm) steel shaft with a nut on the end to hold the hub on.
- Two, 3/8 inch by 2 inch (9.5 mm x 5 cm) bolts, but these are optional.
- Bridge rectifier, rated for least 15 amps, 100 volts.
- Other supplies—glue and linseed oil.

at least a metal lathe is required. Headquarters for our business, Otherpower.com, is high on a mountain, 11 miles (18 km) past the nearest utility line. We are lucky enough to have basic tools up here, but many folks around the world don't. That's the main reason we used so much wood in this design.

It's possible to build human-powered woodworking tools in almost any location. With some patience, only simple hand tools are required for this project. If you want to build it in a day, though, a lathe, drill press, band saw, and power planer can be very helpful!

### Building the Armature

The key to the Wood 103's armature is the neodymium-iron-boron (NdFeB) magnets. They are the strongest permanent magnets available. Ours are surplus from computer hard drives. They are curved, and measure about 1 3/4 by 1 3/8 by 1/4 inch thick (44 x 35 x 6 mm). Eight fit together in a 3 7/8 inch (9.8 cm) diameter ring. That's why we chose this particular diameter for the armature.

The magnets are available with either the north or south pole on the

**The wooden armature holds eight NdFeB (neodymium-iron-boron) magnets arranged in alternating polarity around its perimeter.**

convex face. For this project, you will need four of each configuration. Don't start tearing your computer apart to get these, though! They are from very large hard drives, and you won't find any inside your computer. Check the Access section at the end of this article for suppliers.

To construct the armature, we laminated plywood circles together with glue. The  $3\frac{7}{8}$  inch (9.8 cm) diameter wooden cylinder is  $3\frac{3}{4}$  inches (9.5 cm) long, with a  $1\frac{3}{4}$  inch (4.4 cm) wide slot cut into it  $\frac{1}{4}$  inch (6 mm) deep to tightly accept the magnets. To assure that the magnets would be flush with the armature surface, we cut the plywood disks a bit oversized, and turned them down on the lathe to the proper diameter. The same procedure was used to cut the magnet slot to exactly the right depth.

Using a firm grip, we carefully press-fit and epoxied the magnets into place. Remember that these magnets come in two different configurations—north pole on the convex face and south pole on the convex face. The magnets must have alternating poles facing out, and this is how they naturally want to align themselves.

Next, we drilled the shaft hole through the center of the armature using a lathe, though it could certainly be done with a hand drill if you are careful to align it perfectly. We roughed up the surface of the shaft with a file before epoxying it into the hole. It should be a very tight fit—we had to gently tap it through with a hammer. This may not be strong enough, and it might be wise to actually pin the armature to the shaft. Time will tell!

#### **Construction without a Lathe**

We did cheat by using a lathe to shape the armature, but a coping saw and sandpaper would work just fine. If a lathe is not available, our suggestion is to first cut out the disks, making sure that some of them (enough to

## **Safety Warning!**

The large NdFeB magnets in this project are extremely powerful, and can be dangerous. They are brittle, and if allowed to snap together from a distance, they can break and might send sharp shrapnel flying. They are powerful enough to cause painful damage to your fingers if you allow them to pinch you, and can cause malfunctions in cardiac pacemakers if brought too close.

Use safety glasses, gloves, a firm grip, and Zen-like concentration when handling these magnets. Do not get them anywhere near televisions, computer monitors, floppy discs, videotapes, credit cards, etc. They are not toys, and should be kept out of reach of children!

stack up to  $1\frac{3}{4}$  inches; 4.4 cm) are  $\frac{1}{4}$  inch (6 mm) smaller in diameter than the rest. Once assembled, the armature will then have a recessed slot for the magnets.

Otherwise some means of "lathing" the slot will have to be devised. It could be done on the alternator's pillow blocks with a sanding block mounted below, or in a drill press. It would also be wise to first drill a shaft hole into each plywood disk, and then assemble, glue, and clamp all the plywood disks together on the shaft before turning.

#### **Building the Pillow Blocks**

The pillow block bearings were made from pine, since that's the hardest wood we have available up here on the mountain. Certainly hardwood would be much better. First we drilled a hole slightly under  $\frac{3}{8}$  inch (9.5 mm) diameter in each pillow block. Using a gas stove burner, we heated the shaft to almost red hot, and

**Pillow blocks support the armature. Charred wood creates "carbon" bearings for the shaft to spin on.**

forced it through the holes. This gave a good tight fit, hardened the wood, and made a layer of carbon on the inside for better lubrication. We drilled a small hole in the top of each pillow block, down into the shaft hole, so the bearings can be greased.

After pressing the hot shaft through the pillow blocks, we were very pleased with how freely the armature turned and how little play there was. In a slow waterwheel design, wood/carbon bearings would probably last for years. This wind generator is actually a fairly high-speed unit, and real ball bearings would be a big improvement. Such bearings could be easily scavenged from an old electric motor of any kind. Wooden bearings were certainly simple, fast, and fun though!

### Building the Stator

The stator, on which the coils are wound, is made up of two identical halves. Each half is made from 2 by 4 inch lumber, 6 inches long (5 x 10 x 15 cm). A semi-circular cutout with a 5 inch diameter (12.7 cm) was made on each half. The tolerances are pretty tight, but this allows more than a 1/2 inch (13 mm) to fit the coils and core material inside.

On the sides of the 2 by 4s, right over the cutout, we glued thin (1/8 inch; 3 mm) U-shaped plywood “half disks,” which have an inner diameter of 4 inches (10 cm) and an outer diameter of 6 inches (15 cm). They have slots cut large enough to accept the coils. These were made with a hand saw, 3/8 inch (9.5 mm) drill bit, and a rat tail file. The coils are wound in these slots, and the space inside and behind the coils is filled with the magnetite core material. There are four coils on each half of the stator, and they must be evenly spaced.

Our twin stator halves are wound with #22 (0.64 mm diameter) enameled copper magnet wire. Magnet wire

**The two stator halves—one wound with 100 turns per coil, and one ready to be wound.**

### Stator Construction

of this type is often available from electronics stores or electric motor repair shops. Each stator half contains four coils. Each coil is 100 turns, and every coil is wound in the opposite direction as its neighbor. It's important to wind the coils neatly and tightly, using a wooden dowel to carefully press each winding loop into place.

Most common alternators use thin steel laminates as cores, to help concentrate the magnetic field through the coils. Magnetism in motion pushes the electrons around in the steel too. The laminates are insulated from each other to block these eddy currents, which would otherwise waste energy.

These laminates are difficult to make in a home shop, so we chose dirt as our stator core—actually magnetite sand mixed with epoxy. It is not as effective as real laminates, but was very easy to use, and available for free by separating it from the dirt in our road. We mixed the magnetite with epoxy and simply spooned it into the open cores. If the cores were left empty (an “air core”) the alternator would still work, but with much less power.

Magnetite is a common mineral, a type of iron oxide. It is a byproduct of some gold mining operations, and can sometimes be purchased. As an alternative, we simply dragged a large neodymium magnet (just like the ones we used for the armature) around on our local dirt road on a string for a while, attracting all the ferrous sand, which stuck to the magnet.

**Magnetite sand collected from Dan's driveway by dragging a magnet around on a string.**

**The stator cores are filled with a mixture of epoxy and magnetite sand.**

**An exploded view shows the armature, stator, and pillow blocks ready to assemble into an alternator.**

We separated this somewhat magnetic sand into a pile, sifted it through a window screen, and sorted that with the magnet one more time. The remaining black sand sticking to the magnet was nearly pure magnetite. A quick test of any local dirt pile with a neodymium magnet should reveal whether your sand contains magnetite. If not, try dragging the magnet along the sandy bottom of a local river. Any deposits of black sand on the river bottom are most likely nearly pure magnetite.

The clearance between the stator coils and the armature surface is very important. It must be extremely close (within  $\frac{1}{16}$  inch; 1.5 mm) without allowing the magnets in the armature to touch the stator. Our model is actually a bit sloppy—the clearances are more like an  $\frac{1}{8}$  inch (3 mm). Tighter tolerances would produce more power.

**Wiring Configuration**

The completed stator consists of two identical sets of four coils. For our wind generator, we connected the stator halves in parallel for more current (amperage). Connecting them in series would double the voltage produced, but halve the amperage. For low wind speeds, a series connection would be the best—the alternator would reach charging voltage at slower speeds. At higher speeds, a parallel connection is optimum for producing the most amperage.

An ideal system would contain a regulator that switched the stator connections from series to parallel when the unit began to spin fast enough. As is the case with many

homebrew and commercial wind turbines, we eliminated this entirely, sacrificing a small amount of efficiency for much greater simplicity and reliability. Many people have experimented with such regulators, both solid state and mechanical.

**Alternator Performance**

We were really surprised by this alternator's performance. We could easily spin it with our fingers and get 12 volts or higher. A cordless drill attached to the shaft would light up a 25 watt, 12 VDC light bulb easily. This might not seem breathtaking, but considering the simplicity of the project and one-day construction time, we were quite impressed.

Our 100 watt rating for the Wood 103 is probably right on, considering the performance we got during testing,

**The finished alternator, ready for a power source.**

Almost ready—the wooden frame and tail are attached.

and the way commercial wind generator manufacturers rate their products. Our data acquisition system was pretty simple—multimeters and people with pencils and paper to watch them and record measurements.

With a series connection between the stator halves, the unit reached charging voltage for 12 volt batteries at around 300 rpm. With the stator in parallel, it took around 600 rpm to start charging. When installed on our wind machine, the parallel connection gave us 4.8 amps output in a 25 mph (11 m/s) wind.

### Building the Frame

To stay with the style of this project, we chose to build the rest of the wind generator out of wood too. It's a very simple design and should be self-explanatory. It's all glued and pinned with dowels. No bolts are used except to connect the alternator to the frame. We admit that we cheated here!

We did not make any provision for overspeed control, since this was intended to be a demonstration unit for all energy sources, not just wind. A canted tail and spring assembly could be added to control speed during high winds. And of course, making the frame out of surplus steel or aluminum angle would give great improvements in durability.

We also did not include slip rings for power transmission as the wind generator yaws. Instead, we used flexible wire for the first few feet, letting it hang in a loose loop. A piece of aircraft cable cut slightly shorter than the power cable was attached, so if the power wire gets wrapped around the pole too tightly, the connections won't pull loose.

Our normal winds are usually from one direction, and designs without slip rings seem to work fine up here. Wrapping the power wire around the pole is only rarely a problem, and this strain relief cable prevents any damage. Our experience is that if the power cable does wind up all the way, it will eventually unwind itself.

### Designing the Rotor

The "rotor" here refers to the blades and hub of the wind generator. We don't profess to be experts in blade design. Once again, we chose our starting point intuitively rather than trying to calculate the proper blades to match our alternator's power curve. Since the blade carving process took us less than an hour for the whole set of three, we figured that any design changes would be quick and easy to make. However, because we glued the blades to the hub, a new hub will be necessary for any blade changes.

There's a great deal of information out there about building blades. Hugh Piggott's Web site and his *Brakedrum Wind Generator* plans are some of the best sources around.

The rotor was built from  $\frac{3}{4}$  inch by 4 inch (19 mm x 10 cm) pine lumber. Each blade is  $3\frac{1}{2}$  inches wide at the base and  $2\frac{1}{2}$  inches wide at the tip (9 x 6.4 cm). The three blades are 2 feet long (0.6 m), for a total diameter of 4 feet (1.2 m). The pitch of the blades is 10 degrees at the hub, and 6 degrees at the tip.

The hub is made from 2 inch thick (5 cm) wood, press-fit and glued to the roughed-up shaft with epoxy. The blades are held onto the hub by one small nut at the end of the shaft, and several wooden pins with glue.

### Carving the Blades

To prepare the blades for carving, we simply drew a few lines so that we knew what material to remove. Each blade starts out life as a 2 foot (0.6 m) long, 1 by 4 (2.5 x 10 cm). Starting from the leading edge of the blade at the hub, we simply used a protractor to lay out how far into the wood 10 degrees of pitch would take us at the trailing edge—about  $\frac{5}{8}$  inch (16 mm).

At the tip, the pitch is about 6 degrees, so we removed about  $\frac{3}{8}$  inch (9.5 mm) of material on the trailing edge. We made both marks, and connected the two with a line. We then simply took a power planer, and followed the cut depth line all the way up the blade.

### Blade Cross Section

excellent testing facility for wind turbines. It has a perfectly accurate speedometer, which has been carefully checked by the Fort Collins, Colorado Police Department's radar machines!

For better accuracy (or if you don't have a power planer), you can use a hand saw to make cuts across the blade every inch or so, down to the cut depth line on the trailing edge and not cutting at all on the leading edge. Using a hammer and chisel, it's easy to break out the chunks of wood to the proper depth. Then smooth the blade down to the proper angle with a hand plane. When the saw kerfs disappear, the blade pitch is correct.

The blade width taper occurs on the trailing edge. We simply used a saw to cut the first taper, and used that first blade as a template for cutting the others. No calculations were made for the airfoil shape on the other side of the blades. We picked a likely looking profile and started cutting with the power planer. A hand planer is fine for this process, too. After everything looked good and even, we sanded the blades and treated them with linseed oil.

**Balancing the Blades**

To avoid vibration problems and enable easy starting, we made some effort to balance the blades. We considered them reasonably balanced when each blade weighed the same (about 8 ounces; 227 g) and had the same center of gravity. Adjustments can be made quickly with a planer.

Once this is done, and all three blades are assembled on the hub, balance can be double-checked by spinning the rotor and making sure it has no tendency to stop in any one place. This is a quick process, and we certainly were not concerned about great precision here. As it turned out, a small effort in balancing the blades yielded good results, and the machine seems well balanced and vibration free.

Truly, one could write an entire book on blade design, and it can get complicated. Don't worry, though. It is possible to make a very basic blade that will work quite effectively. Often a simple blade with a constant 5 degree pitch from hub to tip and a reasonable airfoil on the backside will work very nicely. If you are interested, explore the books and Web sites listed at the end of this article for more information on blade design.

**Testing**

For testing, we strapped the Wood 103 to our trusty Model A Ford. The Model A serves as a reliable daily driver, and with the bracket we made, it makes an

We carry a 12 volt battery, a voltmeter, an ammeter, and pencil and paper in the test vehicle. On a still day, we can observe the speedometer and take accurate windspeed versus output measurements on any wind turbine. We've used this rig with props over 8 feet (2.4 m) in diameter. The cost of a good Model A (about US\$4,000 if you don't mind a jalopy) is *not* included in the price of this project!

Wind generators should be installed high above human activity. For testing purposes, we've run our generator on low towers within reach of people, and on our Model A. Wind generators have parts that spin very fast! The blades could probably take your head off in a high wind if you were silly enough to walk into them. Make all installations well out of reach of curious organisms. You should treat any wind generator with a great deal of respect. This is not a joking matter, though we always shout "Clear prop!" before we fire up the test vehicle...

**Model A Ford—a high tech test vehicle for a high tech wind machine.**

**The next generation—the WoodAx is for permanent installation, and produces upwards of 300 watts in 30 mph winds.**

### Improvements

Many improvements could be made to this design. But the intention was to use mostly wood and hand tools, and keep it fast and simple. The wooden alternator is easy and quick to build, but for longest life, it would need to be protected from rain and snow. Maybe a small shingled roof over it?

Using real ball bearings would help friction loss and longevity a bunch. A metal frame and tail would improve high-wind survivability significantly. A furling system to keep the Wood 103 from destroying itself during a gale would be a great addition too. We plan to experiment with many improvements, and we hope this project piques the interest of others too.

### Trade-Offs

Designing and building a permanent magnet alternator involves a long series of trade-offs. For example, thicker wire in the windings would give more possible current, but less room for windings and hence lower voltage at the same rpm. Ceramic magnets might be cheaper, but would give far less power than neodymium magnets.

Series wiring on the stator would allow lower rpm at charging voltage, but parallel gives better charging current—and a regulator to switch between the two would be complicated. Using steel laminates instead of air or dirt stator cores would produce more power, but laminate production is extremely difficult.

The trade-offs involved in designing a complete wind generator (or water turbine, or bicycle generator) are even more lengthy and complicated. Wind speed, rotor diameter, number of blades, blade pitch, width and twist, optimum rpm for your winding configuration, generator diameter, and number of poles all factor into a perfect final design.

### Improvise, But Do it!

We've tried to demonstrate how easy it is to produce electricity from scratch. Don't let yourself get hung up on complicated formulas, calculations, and machine tools. Even if you make many changes to this simple design, you'll still almost certainly have a unit that makes usable energy for charging batteries.

Then, you can make small improvements until it performs exactly right for your application. And it could be powered by wind, falling water, a human on a bicycle, a dog on a treadmill, or a yak in a yoke!

# Homebrew 700 Watt Wind turbine

We made a deal with our good friend Ward. Going into Dec, with only one solar panel, it seemed maybe he could use a bit more power! We agreed, that if he'd foot the cost of the tower, and wire, and help in the construction, we'd offer the shop space, parts, and some help to build a new wind turbine from scratch. It's an experimental design, and the alternator is designed around the front wheel assembly of an old Volvo 122s. [Click Here](#) to read about details and the construction of the alternator! Although it's not terribly efficient, we see about 60 amps into a 12 volt battery in a 40mph wind - so it makes significant power.

[Para Español, traducción de Julio Andrade.](#)

Please be patient, this page has a lot of pictures!

## The Alternator

It's a radial alternator, designed around a volvo disc brake, wheel hub, bearings, and spindle. The Volvo wheel bearings make for a very tough unit, which should hopefully stand up to severe abuse! The studs which used to hold the wheel on were replaced with much longer bolts, so that the prop could bolt on the disc brake in place of the wheel. Again, please see the page about the alternator for further details about building it, and testing it - and some discussion about problems it has!

## The Propeller

We actually had to make two props for this, since we accidentally dropped the machine in our first attempt to raise it! [Click here](#) to read about that failure! The first prop we made out of the very best, vertical grain knot free fur. The second prop we made out of some fairly clean Lodgepole pine we had on hand. Both worked well, the 2nd prop actually runs somewhat quieter due to reduced thickness. Otherwise, they are about the same and this page will document only the creation of the 1st one!

The prop is a 3 blader, 8 feet in diameter. The pitch at the tip is 4 degrees, at the hub it's about 8 degrees. At the hub, each blade is 7" wide, and at the tip they are 3.5" wide. The blades are 7/8" thick at the hub, and 5/8" thick at the tip. The airfoil is of an "intuitive" design, and the thickest part of the prop (the high point of the airfoil) is about 35% of the blades width, from the leading edge. Near the hub, we made relief cuts with a crosscut saw, and chiseled down to the line. After the first 6" away from the hub are chiseled out, it was an easy matter to finish the rest of the prop with a power planer.

Once the blades were roughed out we had to balance them. The system I usually use (and please...any experts with a better idea let us know!) involves two things. I first find the blades center of gravity (the point at which the blade balances) and then weigh the blade, at that point. We didn't have a scale on hand which was sensitive enough, so we made a simple scale from some bandsaw blade! (show in picture above) I'm not in the habit of adding weights to blades (though I probably should be), but instead we plane material off the blades, untill they all weigh the same and all have the center of gravity located at the same location. It usually goes fairly quickly and I've always had good results with this system. It is true, that when finished some blades might be slightly thicker than others, but if each one is made from fairly similiar wood, which has similiar density, then the blades all turn out very close.

The hub for the prop consists of 2 10" diameter 1/2" thick plywood discs. One of them is routed out, into a ring (6" inner diameter)- so that into it we could inlay a 1/2" thick Aluminium disc, which was drilled out to accept the "studs" by which the prop would be bolted to the alternator. Once all the blades were finished, we coated both plywood discs with epoxy (on the inside) and laminated the discs together with the blades on the inside. The whole sandwich was tightly screwed together with a bunch of 1.5" wood screws.

Once the epoxy dried, we finished the prop with "Super Glue" - from a spray bottle. Neat way to put a tough finish on wood, but horribly toxic and very expensive! (about \$50!). As it turned out, we smashed this prop and the next prop we simply finished with a thick coat of Linseed oil.

## The chassis

It's very simple. About 5' of steel sign post make up the machine. The alternator is welded to the front of it. Even though it is welded on, all the important parts can still be removed, everything except for the wheel spindle, which should never wear out. The alternator's armature (brake disc) is removed easily with one cotter pin and 1 bolt. The stator can be removed by removing 4 bolts/nuts.

The tail I cut from thin sheet metal, which is bent, and folded over on the back side. Since I have no tin snips, we cut the tail out with an angle grinder. The tail is bolted to the signpost, and 1 heavy steel bracket is bolted to the top of the tail for reinforcement. As it turns out - this is inadequate. I've seen this machine running now for a couple weeks, the tail is NOT longed for the world. It should have been much stronger. We'll take it down soon and fix it.

\*\*\* update - since written, the tail has been replaced twice! 1st one too thin, 2nd one too heavy and large, the new one is smaller and made of plywood which is bolted to the frame \*\*\*

A 2.5" diameter pipe, about 20" long serves to mount the machine to the mast....it slips over a 2" pipe. A couple reinforcements are welded between the sign post, the pivot, and the alternator. It's very simple. I have no system of "overspeed" protection. We've made some good windmills up here without it, and many have held up for the long term. I'll be honest, I've seen this machine run in 80+ miles per hour now. Although it held up well, I would be a little more comfortable with some system of high wind protection, not only for the sake of the turbine itself, but also for the tower. I'll definitely look into some system of governing the next time I make a prop 8' or larger. This wind generator also has no slip rings (the commutator/brush assembly which allows power to flow from the wind generator (which pivots) to the mast). I've never made one with slip rings and it's never been a problem! Although slip rings are nice, they add some work to the project and they are not necessary. This machine has a piece of aircraft cable, which is tightly tied to the wind generator frame, and the mast, and allows for the machine to turn about 4 revolutions either way, before the cable gets tight. The power line, is even slightly more slack than this aircraft cable, so the power line can never get pulled tight. I, and my neighbors have built several machines this way. It has never failed, and you'll rarely if ever see the cable tight such that the machine cannot yaw in the wind. It's

a lot simpler, and probably less likely to fail than slip rings.

## The Test!

I bolted a piece of the same sign post we used to make the windmill onto the front of my '70 F250, and made some U clamps so that a 2" diameter pipe mast could be fitted. See in the picture above, I am wiring the alternator up for testing. This serves as an excellent test rig. On the passenger floor of the truck is a 12 volt battery, and enough meters on the seat to record what's going on! By watching the meters and my speedometer, and a still day, one can record good information about how the machine performs.

This windmill is a bit hard to start, it takes about 12 miles per hour for a couple seconds to really get it spinning good. When I made the alternator, I soldered the coils together in series in two sets of 9. The two "halves" of the stator could either be hooked in series (for the highest possible voltage) or parallel (for half the voltage and twice the current). When all 18 coils were hooked in series it had difficulty ever charging over 30-35 amps. I realized that there was very little lost (if any) at low windspeeds, and much gained at high windspeeds, to hookup the alternator with the 2 sets of 9 coils hooked in parallel. Again, it didn't start really spinning well until it saw 12mph for a couple seconds. After that the wind could slow and it would produce around 5 amps @ 10mph, about 20amps @ 20mph, about 35amps @ 30mph, and about 60amps @ 40 mph. At 40 miles per hour, there were wires melting into the seat of my truck and the cab smelt of burning diodes. I've never seen better than 60 out of it, and my guess is that is close to the limit unless some changes were made to the alternator.

## The Tower

As stated above, we failed in our first attempt to raise this, which resulted in a broken base, broken prop and a bent mast. In retrospect, it's a good thing we did forget to tighten guy wires, because had we put the mast up in it's original form, it would have surely failed.

Ward opted for a tower made from steel pipe. It's made up of sections of pipe, which fit tightly together. The bottom 15' is 3" diameter steel pipe, into which another 15' of 2.5" section is slid (About 1' overlap) and into that an 8' section is slid. It fits very tightly and all the joints were welded. At two points on the tower (15' from the base and 30') we welded links of chain around the mast so that the guy wires could be attached. The base was a "Simpson Strong Tie" bracket, which Ward had laid into a fairly large concrete base. At the bottom of the mast, I welded a small pipe, so that the mast was loosely hinged to the base on a 1/2" dia blot. At the bottom of the mast was welded a 2" pipe, 8' long to serve as a jin pole. The jin pole is reinforced with one steel brace at the bottom and a cable which runs up the jin pole 6' and up the mast 15'. Upon raising the mast (1st time) the jin pole immediately started to bend. We got it up a bit, and it stopped bending. We got it almost all the way up, and it fell to the side, because we had forgotten to tighten the guy wires on one side. The Simpson "strong tie" bracket was torn to pieces, and the top 8' of the mast was bent, and the prop was destroyed.

Otherwise, the alternator and everything looked fine. We stayed up late, made a much stronger bracket, and a new prop. Next morning we ground the old bracket out of the concrete, and bolted the new one on using 1/2" bolts and a rock drill so it would be set well in the concrete. It was obvious at that time, that the 2' pipe on the top 8' of the mast was NOT strong enough, it was easy for us to bend it back straight - by hand. We cut a piece of 2.5" pipe, 6' long, and slipped it over the existing 2" pipe - making the top section of the tower much stronger, and leaving only enough 2" pipe sticking out for the wind generator to fit on. The jin pole was straightened out and we reinforced it by welding 2 fence posts (which we had on hand) to it. Next time we raised it, we made sure to tighten the guy wire clamps, and things went smoothly with no problems.

## Inside the house!

Pictured above is the "inside" part of Wards "utility" system. The wood stove heats his whole cabin with no problems. The windmill runs through a couple of bridge rectifiers mounted to a heat sink on the wall. The antique ammeter shows any power coming in from the windmill. When the windmill has the batteries topped off (which doesn't take long), the power is diverted into the antique parabolic space heater, which is bolted to the wall to the right of the heating stove. Although this doesn't make much heat, it does make some on windy nights, and it keeps the windmill from running too fast (at least, that's the idea...).

## In Conclusion

The total cost of this installation came in around \$500, most of that was for the pipe tower, and the expensive extension cord Ward purchased to bring the power into his house from it. The windgenerator itself cost around \$200, including Volvo parts, magnets, glue....everything. Had we used a wooden tower (which I think would've been stronger) and less expensive wire the whole project could've come in around \$250-\$300. It's a pretty powerful windmill for that price! It does have some problems which I'm sure time will sort out. It would start easier if I'd picked better metal for the laminates, I used bandsaw blade material, and it's hystoreses makes the machine a bit hard to start in low winds. It surely also creates inefficiencies. If this were not the problem that it is, I would be able to decrease the airgap between the armature and the stator greatly, and it's output would be significantly increased. Read more about that in the [alternator page](#). The tail came apart, so a stronger tail than described above is necessary. I've watched it in super high winds and it seems to

hold up well otherwise. The tower looks a little rickety in high winds - I'd surely do no less next time, in fact...I'm tempted to further reinforce this tower! Although I believe an 8 foot prop, with no overspeed protection is risky, it's very strong and I believe no overspeed protection is needed. The bearings are more than strong enough and in watching the machine I believe it'll hold up! Only time will tell. If it were any larger, it would need some overspeed protection for sure. Otherwise, I have no complaints. The prop is very quiet, you cannot hear it at all till the machine is producing over 30 amps! I've seen it make 700 watts at 12 volts in high winds. I believe if the alternator were improved, with a better core material and a much smaller air gap, it would be capable of at least 1000 watts at 12 volts, probably much more at 24v. So, soon...I'll try to make one like this with some of these improvements in mind.

Be sure to check out [Hugh Piggot's](#) site! He's a pro at making homebrew windmills.... all of the problems I'm having are ones he's solved and his plans are excellent. You'll find some excellent alternator ideas, a good overspeed protection system, lots of info on blade design, and fun reading! Also be sure to check the many resources available on our [Links](#) page and feel free to email, or use our discussion board if you have any questions or comments about this stuff!

## Update! Jan 2002

This wind turbine has been up and down a couple times now. 1st failure - as you may have seen, we forgot to tighten the guy wires on one side and it fell over breaking the prop. 2nd failure, the tail cracked and blew off! We replaced it with a large (About 25" diameter) old circle saw blade, from an old shingle mill. It ran for a few weeks very nicely, and then in one night of ferocious winds, we woke up to a broken prop, a bent mast, and a missing tail! Not sure exactly what led to what, but - I'm starting to think we should seriously consider some way to shut it down in high winds! Again - the alternator held up fine though. We made a new 8' 6" two bladed prop for it - it's of very strong wood and somewhat thicker near the hub. We also built a new stator for the alternator, replacing the bandsaw blade material with 1/2" wide strips of 22 gage cold rolled sheet metal (which is a LOT better than bandsaw blade!). I rewound the stator with 18 coils of AWG 14 magnet wire, and I doubled up the magnets. (so the magnets are now 1.5" diameter X 3/8" thick). We've yet to raise it - still have to straighten the mast, but we have tested it's performance on the nose of my truck. It does somewhat better, and the prop seems to run a little slower (which is good). Kicks in around 10mph doing 5 amps and quickly rises to around 70 amps at 35 mph! I figure the odds be 50/50 that it will blow up in a high wind once we raise it!

# Low-RPM Disk Alternator

**The completed unit. It's already been attached to a homebrew wind generator with an 8-foot diameter, 3-bladed rotor--and is up and flying! [See it HERE!](#) We've already seen peaks of over 60 amps into a 12 volt battery bank, and it survived 60-mph winds last week. Steady output of 30 amps in 28 mph winds, and reaches charging voltage at around 12 mph.**

After building a couple of reasonably successful alternators out of wood, I thought it would be fun to make one utilizing steel behind the magnets, and some sort of steel laminates. The most recent [wooden alternator](#) I built works great, but the lack of iron behind the magnets and coils severely limits its maximum output and may cause inefficiencies, especially at higher output levels. Iron behind the magnets nearly doubles the magnetic field density through the coils. Putting steel laminates behind the coils has the same effect, again nearly doubling the field density through the coils. The wooden pillow blocks and ball bearings in the wooden alternator also limit its strength and durability. This alternator uses a rock-solid Volvo wheel bearing, which is built to take thrust forces and abuse, and will hold up well to weather.

## **Parts/supplies required to build this alternator**

Front wheel assembly from Volvo 122s, including wheel spindle, wheel hub, bearings, and brake disc.

3 square feet of 1/2" thick plywood

5 pounds AWG 16 Magnet wire

18 NdFeB disc magnets, 1.5" diameter X 3/16" thick

1.5" drywall screws

Epoxy (lots of it!)

A bunch of steel banding material for the laminates (I used bandsaw blades!)

This alternator is built around the front wheel/disk brake assembly from an old Volvo 122s. I chose the Volvo parts simply because I had them on hand; this concept could easily be adapted to any front disk brake assembly. Odds are, another type might even work out better. The main advantages to using the front wheel hub and brake disk disc from a vehicle are: 1) Very strong bearings - the front wheel bearings are tapered bearings, they hold up well to thrust. 2) A nice steel disc to put the magnets on! 3) Cost, and time saved. Building this from scratch would be fairly expensive and involve a fair amount of machine work. Here, in one cheap package from almost any junkyard many

of the problems are solved.

This is the only machine work involved, very easily done by any automotive machine shop, or anybody with a metal lathe. I cut a slot 1.5" wide in the back of the brake disk very near the outer edge. (I left about 1/16" steel on the outer edge) This slot serves to hold the magnets in. It might not be needed, but at high rpm there is risk of the magnets flying off. This slot should hold them in tightly.

The magnets are N40 grade NdFeB rare earth magnets (available from our shopping cart). In this alternator, I installed 18 magnets. I put them all together side by side, and measured the gap. I then divided the gap and it turned out that there should be exactly 0.08" gap between each magnet. Wooden kitchen matches fit the bill, so I spaced the magnets evenly using kitchen matches! At a later time, after the magnets and brake disk are cleaned carefully, the magnets are epoxied down in the slot, and the kitchen matches removed. **One safety note: At this point we have 18 VERY powerful magnets stuck down to a perfectly flat surface, making for one heck of a strong magnetic assembly! Should this get stuck to another flat, steel surface, it could be IMPOSSIBLE to remove! If your fingers get stuck between the armature and another metal surface it would probably SQUEEZE them right off - so be careful if you try to build this, and keep it in a safe place!**

Pictured above is the beginning of the plywood stator. It is made out of laminated plywood discs. The total thickness is 1.5". The top layer, which is 1/2" thick, has a slot 1" wide at about 10" diameter so that steel laminates can be epoxied in. Over that will be the coils. (you'll see this later in the page!)

I made the "steel laminates" from old rusty 1/2" bandsaw blade. The reason for thin pieces of steel (laminates) is to prevent the low voltage, high amperage eddy currents which would be very problematic with a solid steel core. I annealed the bandsaw blade in a wood stove, hoping to make it more flexible and a better magnetic conductor. My thought was that coiling it up and sticking it into the stator (in the slot described above) would serve as a good magnetic conductor so the field density through the stator coils would be maximized. In retrospect, bandsaw blade is NOT the best choice. Although the alternator works well, the bandsaw blade I used is a relatively high carbon steel, and makes for a pretty good permanent magnet! So - although eddy currents are not a problem, the Neodymium magnets in the armature actually magnetize the metal, creating a noticeable drag on the machine. It's called "hysteresis," and it's definitely something to avoid in the steel laminates of an alternator. Anyhow...in tests, even after I built a complete windmill from this alternator, it still starts up reasonably well and produces plenty of power, so this setup, although not ideal, still works fine. In the future, I will find better metal to use than bandsaw blade. The main point here is that coiling up thin strips of metal behind the coils makes for a simple solution to the problem of having steel laminates behind the stator coils.

Pictured above you can see the plywood stator, with the steel "laminates" (strips of bandsaw blade) glued into the slot. Each layer of metal should be insulated from the ones next to it in order to preven eddy currents. Eddy currents in a steel core are very low voltage, high current in nature. With that in mind, I assumed that simply the corrosion on the bandsaw blade and the epoxy resin which I used to glue them in would provide good enough insulation. I believe it did - however, it would be "safer" to actually put a thin paper insulating material such as masking tape between each layer of metal banding to ensure that significant eddy currents do not develop.

Above is pictured Ward (my neighbor who we are building this machine for) winding coils on the same coil winder I made for the [wooden alternator](#). Each coil in this machine is 30 windings of AWG 16 magnet wire. The coil winder we used probably wound the coils a little taller than needed, so the unit could be improved by making the coils a little smaller. (In other words, these coils came out about 1.5" wide, and 2.5" tall - there would be less resistance in the stator if the coils were only 2" tall and some wire could have been saved) After each coil is wound, it is carefully set aside to be glued and clamped over the top of the stator at a later time.

Ward works well with his hands, but....the coil winder I made was quickly built, for a different machine and really only meant to be used once. He got a bit impatient with constantly gluing it back together, and its rather crude performance. After winding the last coil he threw it in the stove, so - our next alternator is bound to turn out a little better and we should get through the coil winding phase with hopefully a little more patience left over!

As I stated above, the coils come off the winder in rather delicate condition, and rough in appearance. The next step is to line them up around the stator and put them in exactly the right place. Since there are 18 coils, each one must occupy a 20 degree arc around the stator. This is actually easily estimated by first perfectly aligning the magnets around the armature (the brake disk), placing all the coils down around the stator (pictured above), and then placing the brake disc down over the stator, making sure that there is 1 coil located exactly under each magnet. Sometimes it was necessary to squeeze the coils by hand so that they would fit in the space provided. Once everything is lined up properly, I "tacked" the coils down with super glue so they would stay in their places.

Once the coils are tacked in place, I generously covered them with epoxy and layed wax paper over the top. I took a 12" diameter disc of plywood, and layed that over the wax paper. Then I took the brake disk (which is 11" diameter), centered over the stator, and clamped the whole thing together tightly. It is very important! When clamped, the thickness of all the coils around the stator should be the same. Otherwise, when completed the gap between magnets and coil will be wider in one part of the alternator than another. So, when one side had thicker coils than another, I would simply adjust the clamps until it was about even all around. As it turned out, I somehow missed and one side of this alternator does have coils about 1/8" thicker than another side...but it works fine anyhow!

While I had the glue out, I glued the magnets into the brake disk at the same time. Once the glue set up partially, I removed the matchstick spacers.

Above is pictured the stator, mostly complete, with the coils smashed down tightly and glued well. At this point, I coated the assembly (plywood front and back) with epoxy to weather proof it as best I could. I divided the coils in half, hooking 2 sets of 9 coils together in series and figured I would decide later whether to hook the two halves in series or parallel - this was not decided until a prop was made and I actually got to test it in known windspeeds.

When originally used on the car the wheel hub was in direct contact with the brake disk, which allowed for the brake disk to fit well with the brake caliper and the backing plate.

In this application, the backing plate is replaced by the stator, which is about 2" thick when you account for the thickness of the wood plus the coils! So I had to make a spacer which would allow for the brake disk to sit about 2 1/2" out away from the wheel hub in order to allow space for the wooden stator. Pictured above is that spacer, which I made out of some kind of white plastic that I had on hand (maybe Nylon but I'm not sure). In a bind, it could probably be made from wood - a hard wood like Maple or Oak would probably be fine. A machinist with lots of goodies on hand and a lathe could make it real nicely from Aluminium. If that is not available, it could be made from wood with a bandsaw and a drill press.

Pictured above, all the parts are assembled except for the armature. Note the long bolts sticking through the hub and spacer. These will hold the rotor on, and the armature will not be held down tightly until the rotor is tightened. Although other systems might work, in this case I decided to lightly tack weld the bolt heads to the wheel hub on the bottom, since it would be impossible to hold them with a wrench once the brake disk (armature) was installed.

So that's it, all finished up! At this point it becomes obvious that it will be an effective low rpm alternator. There is slight drag from the hysteresis problem of magnetizing the steel bandsaw blade as described above, but it isn't too bad. It spins fairly freely, and when the leads of the stator are shorted out it locks up and becomes very difficult to turn. When the stator is hooked up with all 18 coils in series, it is easy to spin it up to about 15 volts by hand. Next step is to chuck it in my lathe and get some real test results.

Pictured above is the "test rig." It's somewhat limited by the motor on my lathe - the max speed I could test it at was 500 rpm, and even at that speed it loads up the motor and slows it down. The problem is that my lathe only has a 1/2 hp motor on it. The reason for this is that I run my whole shop off my batteries and a "cheap Chinese" inverter! Someday I'll upgrade to a 1 hp motor, which my inverter should barely run...but for now my tests are limited.

I have an accurate tachometer (a DC generator hooked to a well-calibrated meter), a voltmeter, an ammeter, and a 12 volt battery for performing reasonably accurate tests.

Above are pictured the results. For this test, all 18 coils in the stator are hooked into series. It appears that the numbers (amps into the battery) are climbing quickly above 300 rpm, but unfortunately I could not make tests above 500. As shown in the picture, open circuit voltage is about 1 volt per 12 rpm. Shortly after making these tests, we built the windmill and put it on a "test mast" which was bolted to the front of my truck. In testing it became clear that the unit (with all coils hooked in series) became inefficient above about 30 amps (into a 12 volt battery), so we divided the stator into two sets of 9 coils in series, and wired the two sets of 9 in parallel. In this configuration, we lost very little at low windspeeds (it still put out power at 10 mph!) but saw 60 amps (about 700 watts) into the 12 volt battery at 40 mph. More information about these tests will soon be available on the follow-up webpage about the windmill we made from it!

In conclusion, I think this is a great way to make an alternator. Keep in mind that I put this together as I went, without a plan! Several improvements could be made. As tested, the average gap between coils and magnets in around 1/4"! With better core material and careful attention payed to the thickness of the coils, this gap could be reduced for improved output. Overall it's dirt simple, super strong and the output seems reasonable. The bearings in the Volvo wheel hub are huge, and should last practically forever. The cost? The magnets would run about \$100, the wire about \$40, the glue about \$15, and hopefully a wheel assembly could be had for next to nothing. It's not a bad price for an effective alternator probably capable of 1000 watts. Again, in the future I would NOT use bandsaw blade. The best bet would be to find the very same metal used in motor laminates, although I have a feeling that hot rolled sheet metal is not a bad way to go.

There's a good chance that the steel strapping material used to hold stuff down to pallets would also work fine. Overall, it's a good way to build a tough, useful alternator with minimal tools and highly available materials.

I owe some thanks here for the ideas involved!

Be sure to check out [Hugh Piggot's](#) site. His brake drum windmill inspired me to consider making use of available auto parts. His design is well proven, and probably the most popular "home brew" windmill plan available at this time. Hundreds have been built. He has recently been building a different sort of "radial" alternator - visit his page to check that out!

Dragon's [Wind Stuff Now](#) page has a very similiar 3 phase radial alternator, with details about the construction. His page is full of useful formulas, products and information, and his correspondance with me has been helpful and inspiring! Be sure to check it out!

# The New Wind Generator is Flying!!!

**Yeee-HAH!!!! This may be a world record in fast recoveries...this mill smashed to the ground during erection less than 24 hours earlier, destroying the rotor and base hinge, and damaging the pole. After a 6-hour late-night rotor-building seminar and a bit of welding, it lives again. Of course, the erection of this wind generator immediately caused a complete, still, dead calm. And we worked all morning preparing it, freezing our \*\*\*es off in 40 mph winds! Launching a new wind generator seems to cause an abrupt stoppage of wind, no matter what the weather forecast says.**

**[See the whole sorry fiasco of the smashed windmill HERE!](#)**

**A new series of pages is in progress detailing every aspect of the design and construction of this new machine. Watch the Otherpower message board for details! We got 60 amps at 40 mph in tests...and a good 20 amps at 25 mph. The alternator is based on a Volvo disc brake, it has 18 homemade coils of #16 AWG magnet wire and 18 Neo magnets. The machine is on a 35 ft steel pipe mast, with an 8-ft. dia. 3-blade rotor.**

**MORE SOON!**

# OOOPS!

## Always remember to tighten your cable clamps!

---

**The windmill ready to be raised...everything looks A-OK. The mast is 35 feet high with 3" steel pipe at the base, and a 1 1/2" pipe jin pole with a brace welded to the bottom. The windmill has an 8 foot 3-bladed rotor, powering our homemade permanent magnet alternator (in tests, 60 amps in 40 mph winds!).**

OOOPS - Always remember to tighten your cable clamps!

**We just about got it up! Note that the end of the jin pole bent from the stress, but held on past its point of maximum stress, enough to get things vertical. Everything appears to be going good, BUT SOMBODY FORGOT TO TIGHTEN THE CABLE CLAMPS ON ONE THE SIDE GUY WIRES. Everything tilted hard to the side opposite the unfastened guy wire, and the mill came crashing to the ground. No injuries to humans, dogs or trucks.**

**Fortunately, there was no damage to the alternator itself. The cowling, made from a plastic bucket and wooden spacers, saved the alternator's stator coils! Ward's nice rotor, lovingly crafted with flawless, knotless and very expensive Douglas Fir and finished with about \$40 worth of cyanoacrylate, is toast. Though one blade did survive!**

**The moral of the story?** Double check ALL your guy wires, anchors and cable clamps before starting to erect a windmill! And don't drink beer during or immediately prior to the erection. We plan to sue the breweries involved. ;-)

We are starting into another set of blades tonight. We plan to fix the hinged base (it was ruined also) tomorrow by drilling into the concrete and pinning in a new baseplate. So maybe in the next couple days we'll be able to try again!

**UPDATE! [We got it raised and flying. See the pictures HERE!](#) The problem now is that the wind has quit entirely, despite forecasts of 60 mph winds. Maybe if we loosened the bolts that hold down our solar panels, the wind would come up again!**

# Wooden Low-RPM Alternator

After building the [all wooden windmill](#) I felt inspired to make a larger and sturdier version. The following page offers a brief description of building the alternator and testing it. I designed this alternator WHILE I was building it, using mostly intuition and working around supplies available. Undoubtedly many improvements could be made. If you have any ideas or thoughts about this, please share with us via email or our discussion board!

[Para Español, traducción de Julio Andrade.](#)

**Initial test results--wired in series, reaches 12 volts for charging at 120 rpm, with 6 amps charging current at 300 rpm. Wired in parallel, reaches 12 volts at 240 rpm, with 12 amps charging current at 350 rpm. At 500 rpm it produces about 500 watts. Unfortunately this is the limit of our current testing rig--we need to build a bigger one. More tests and a chart to come!**

## Parts and supplies used

To build the alternator I used the following:

10" long piece of shaft, 1/2" diameter.

2 1/2" inner diameter ball bearings

18 surplus NdFeB rare earth magnets

3/4" plywood

5 Pounds 18 AWG magnet wire

1 1/2" drywall screws

3" deck screws

Epoxy

Super Glue

Fiberglass resin for final finishing

I cut out 5 plywood disks on a bandsaw, 9" diameter. In the center of each disc I drilled a 1/2" hole. These disks are laminated on the shaft to build up the armature. In order to hold the armature securely to the shaft, I drilled a hole about 4" from one end

1/8" diameter, and inserted the a pin, 4" long. On one disk I routed a slot, 4" long and 3/16" wide, 3/16" deep, to accept this pin so that it would be locked to the shaft. I generously coated the plywood discs with wood glue and clamped them together on the shaft, then screwed them together with 3" wood screws.

On the metal lathe (a wood lathe would work fine) I evened up the armature so that the diameter is approx 8.75". In the center of the armature I cut a slot 3/16" deep exactly wide enough to accept the magnets (1.74"). The magnets are laid in with alternating poles facing up. This particular magnet is available with either North or South on the outside. This alternator requires 9 of each variety. The diameter is such that the magnets stick out from the wooden surface of the armature, so the total diameter, magnets included of the armature is just short of 9.25". These magnets have an arc much more acute than that of the armature, so it looks kind of "lumpy"! I don't think this is a problem. Custom magnets simply cost too much, it often pays to work with that which is available. In order for 18 magnets to fit around the armature, there is a small space between each magnet (approx 0.10"). For spacers, I used 1" drywall screws, which were removed after the glue dried. Since they are tapered at the top, simply screwing them in deeper provides for a larger gap between the magnets, so...with a little patience, it is easy to adjust the screws and get the magnets evenly spaced around the armature.

Once all the magnets were pressed in place, properly spaced with screws, I glued them in with epoxy. As a clamp, I simply tied a rope around the magnets and tightened it with a stick through the knot. When the glue started to set up hard, I removed the screws and applied a new coat of glue over the entire surface of the alternator. This not only aids in holding down the magnets, but it will protect the alternator from moisture.

The stator (that part which will eventually hold the coils of wire) is built up of 3/4" plywood. The inner circle has radius of 5", which leaves room for coils between it, and the armature. The magnets protrude from the wooden alternator approx 1/8", so this allows for coils to be approx 3/8" thick and have close clearance with the magnets. A very small gap between coils and magnets is important, especially if the coils do not have a ferrous core. I cut pieces to build up the stator from the plywood and glued them together, clamped them tight and screwed them together with 1 1/2" drywall screws. Each piece is made up of 3 laminates, for a total thickness of 2 1/4".

The shaft is supported by pillow blocks, also built up from 3/4" plywood pieces. I cut holes with a 1 1/2" hole saw to accept the bearings. Of course, the bearings have 1/2" inner diameter to accept the shaft. The outer diameter of the bearings is roughly 1.6" inches - a very tight press fit into the holes in the plywood. I coated the outside of the bearings with epoxy and pressed them in with an arbor press(a vice, or hammer should work fine too), as deep as possible so that I could still tighten the set screws. I was pleased with how well they fit the holes, and how straight they pressed in. I believe I got a little lucky here!

I built a simple coil winding device to speed production. It has a crank on one side, and a spool on the other. I used a long bolt as a shaft, and the end of the spool is held on with a nut. Each coil is wound on the form, then the nut is removed...so that the end of the spool comes off and the coil can be removed. It went very quickly! Since the alternator has 18 magnets, I wound up 18 coils. The coils are of AWG 18 enameled magnet wire, each coil has 50 wraps. The coils are approx 2.75" X 1.5" on the outside, and the hole in the middle is approx .5" X 1.5"....as per the size of the spool on the winding machine. I thought this was an appropriate size, considering the size of the magnets. Really - it's somewhat of an intuitive guess...

When the coils come off the winding machine, they are fairly loose, and delicate. I handled them carefully before gluing them into the stator laminates.

In the above image you can see all the parts of the alternator ready for finishing and assembly.

For the first step in attaching the coils (not shown in any pictures) I measured out their proper location (they must be spaced evenly) and lightly tacked them in with super glue. Then I generously coated them with super glue (epoxy would also work fine...it would just take longer), covered them with wax paper, and clamped them in using a form I cut from wood. This form forces them into exactly the right diameter to fit around the armature. Once the glue was dry, I removed the clamp, the wooden form and the wax paper, and was pleased to find they fit very well! In the future, I may fill the center of these coils with a mixture of magnetite sand and epoxy - this would help conduct the magnetic field through the coils, and increase the current output of the finished alternator. For now, I'm very curious to find out how it performs with nothing but air between the coils. There is also an advantage to "air cores" inside the coils--the alternator will not cog at all until under a load, which eliminates much vibration and will help the alternator start spinning in some applications. Cogging is a problem in permanent magnet alternators, especially for wind generators.

After the coils are glued in, all that remains is sanding and finishing. Thankfully I had some help from our head of research, development, and particle physics....Maya!

All the parts were generously coated with fiberglass resin - kind of like epoxy, it makes a thick, plastic coat and should make the alternator practically waterproof for years to come. The only drawback...it stinks real bad! You can get this stuff at any hardware or auto parts store. Difficult to see in this picture, but...the base of the alternator has wooden dowels in it, so that all the parts can be exactly located in their proper position whenever the unit is assembled. This allows for easy assembly and disassembly. When making the base, I put the parts together so that it spun easily--the coils were as close as possible to the magnets, and nothing rubbed. Then, I tacked the whole alternator together lightly with super glue and drilled 1/4" holes up from the bottom of the base into the pillow blocks, and both stator halves. I then glued into the base 1/4" dowel pins which assure that whenever assembled, all the parts will fit exactly into the right places.

After the fiberglass resin set up, I assembled everything on the base. Everything fit well--the clearance between coils and magnets was excellent. Once all looked good, I screwed it together from the bottom with 3" deck screws. It seems very sturdy--nothing moves, rubs or vibrates that's not supposed to! At this point I wired all the coils on each stator half into series. The coils must alternate in the direction they are wound. It can seem confusing! Trial and error isn't the worst way to be sure it's properly wired. Simply spin it slowly by hand, and start measuring voltage, starting with one coil, and being certain that the voltage increases with each additional coil which is wired in series.

All the coils on each half of the stator are wired together in series. At that point, each half can be hooked in either series or parallel to most appropriately match the load with the alternator. Above is pictured the good old Taste Test, a sure fire way to test any battery, or generator, as long as it stays below about 10 volts! (otherwise it hurts--don't try this at home!)

I don't have proper equipment to fully test this alternator. The best tool I have, since it will not fit on my lathe, is a hand drill with a 1/2" chuck. With a meter which reads frequency, I am able to accurately tell rpm. When both halves of the stator are hooked in series, the alternator will reach 12 volts at approximately 120 rpm. At approx 300 rpm, it charges approx 6 amps into my batteries (this is the limit of my hand drill!).

When I hook both halves of the stator in parallel, it hits 12 volts at approx 240 rpm, and at approx 350 rpm it's charging slightly over 10 amps into my 12 volt batteries. In the picture above you can see the frequency meter, and the large wooden ammeter on the wall. Clearly the limiting factor here is the power of the hand drill. I'll post a chart when I build a good alternator test machine and get some better results! All things considered here, I'm very pleased with the results.

I was curious what the output would look like on the scope, considering the close proximity to one another of the magnets, and the "lumpy" armature. Keep in mind, what is shown above on the scope, is Alternating Current, directly out of the alternator. In order to be useful in battery charging, it must be rectified into Direct Current. To do this a "bridge rectifier" (a simple arrangement of 6 diodes) must be used.

Shown above is the "rectified" output of the alternator. This is useful for battery charging, but - you'll notice how "lumpy" the Direct Current looks on the scope. Although this rarely causes problems, occasionally this sort of Direct Current will cause problems with radio and television reception (you'll hear a whine). To help smooth out the Direct Current available here, a capacitor can be used.

See above the nice, flat DC output after a capacitor is hooked up between Pos and Neg outputs.

Just for fun...I hooked it up to my stereo! This is a CD player, hooked to a '50's Fisher vacuum tube preamp, hooked to a Dynaco Stereo 70 vacuum tube power amp. If you add up the numbers on the back of these...it totals over 300 watts. To my amazement, this wooden alternator lit up the tubes and the CD player...played music and sounded just fine, when powered by the electric hand drill! The hand drill is rated to draw maximum current of about 3.5 amps...so this is a reasonably efficient transfer of power!

In conclusion... This whole thing took about two full days time, about \$100 in magnets and \$30 in magnet wire. (The shaft and bearings I had on hand) Not a bad price for an effective low rpm alternator. It was also fun, and the information obtained is useful. Using premade pillow block bearings would probably be wise, especially if one intended to really use the alternator! There are certainly easier ways to build alternators which would be just as, or even more effective. To build this really requires a lathe, bandsaw, drill press...etc. If one built a similiar machine using a disk type armature instead of a cylinder, it would be much simpler. I stuck with this design only because it seemed fun, looked neat - and was based upon my earlier wooden windmill. Keep your eyes peeled for our next alternator..it'll be even easier to build and much more effective. Overall though, I'm surprised with the performance fo this unit, considering it contains nothing but air between the coils and wood all around. Wood is a lousy conductor of magnetic fields! **Just goes to show...it doesn't have to be optimal, it just has to work!**

It seems that there may be some argument for not worrying too much about steel

laminates, or ferrite cores in the coils, and simply adding a few more magnets and wires and settling for a somewhat larger machine. One immediate benefit of having "air coils" is obviously the complete lack of cogging, which, if used in a windmill should result in a machine that starts very easily. I have no idea at this point what the maximum output of this alternator might be, but preliminary tests are impressive in my opinion! One could build a fine wind or hydro plant with such a machine. As with all our other alternator "experiments"...it is truly the magnets which make it possible!

Without these super high quality magnets, this alternator would not be nearly as effective. With normal ceramic or AlNiCo magnets, one would have to go to much greater lengths to build a alternator which efficiently produces this kind power at such low rpm.

# Regulator for Permanent Magnet Alternators

[Click the Photo](#)

to check out a 15-second MPEG movie (343K) which shows the regulator in operation. Watch close, and you'll see the sudden change on the voltmeter as the regulator changes the wiring of the stator from series to parallel. This is clearly visible both on acceleration of the alternator and deceleration.

This page results from an effort I made to regulate the voltage from permanent magnet alternators. In making wind generators it is important to start with a good low-rpm generator/alternator. Generally, good low-rpm generators require permanent magnets to supply the field. The main reason for this, of course, is if the field of a generator is supplied by electromagnets, they require electricity (inefficient) and simply the space required by copper wire can make it impractical. By using permanent magnets, it is possible to have many strong magnetic poles, packed into a

small space so that fairly low rpm can offer a fairly high output voltage.

The disadvantage of permanent magnet generators is that they are difficult to regulate over a range of rpm. In a normal generator or alternator, the voltage is regulated easily, by adjusting it to the field windings. In a permanent magnet machine, the strength of the field is predetermined and fixed simply by the strength of the permanent magnets used. When charging batteries, as in the case of most wind generators, the machine might be very efficient at a certain speed, but at high speeds most of the work done by the propeller is wasted by simply heating up the windings in the generator! For example, in this alternator which I used in this experiment, if all the coils are hooked into series, at 120 rpm it hits 12 volts, open voltage. At 1200 rpm, it's around 120 volts! When charging batteries (12 volts) it runs fairly efficiently at 200 rpm charging around 5-6 amps into the batteries. At higher speeds, it charges only a little more, and most of the work into the shaft of the alternator serves only to heat up the windings in the alternator.

If the alternator could be wired differently at higher speeds only, then it could serve efficiently at a wider range of rpm. This voltage regulator works in the following way.

The alternator stator is divided into two halves. Depending upon the speed of the alternator, the two halves will be hooked either in series (at low speeds) or in parallel (at high speeds). Such a regulator on any permanent magnet alternator could increase the usable output significantly at both low and high speeds. There is certainly argument that "simpler is better" and it may well be worth the lack of trouble to leave certain machines completely unregulated in the spirit of simplicity and reliability, but - I've thought about this problem for a while since making windmills and this is one possible alternative.

The regulator is really very simple. It consists of a set of contacts which in one position wire the stator in series, and in the other wire the stator in parallel. The whole thing is controlled by some magnets, in close proximity to an Aluminium (Copper would work even better) disc which is mounted to the alternator shaft. Of course, magnets are NOT attracted to Aluminium (or Copper), but...both are very good conductors. Spinning the disc in close proximity to magnets generates current, which is shorted out and has no place to go. This is called the "Lenz Effect." The magnets are pulled (and repelled) by the disc. It is the "pulling" force which is used here. Once the alternator is going a certain speed, the magnets and the electrical contacts they are attached to are physically pulled up to connect to the contacts above - thus re-wiring the two halves of the alternator stator into parallel, halving the voltage and doubling the current. This works exactly like a mechanical Relay, except it is triggered to switch by the Lenz Effect instead of an electromagnetic coil.

Above are pictured the contacts involved. They are carbon graphite, the same stuff they make motor brushes out of. I cut out the pieces on a saw, and they are arranged to hook two separate lines (the halves of the stator) into either series (for low rpm) or parallel (for high rpm). The piece with the brass contacts is the moving part and hooks directly to the stator. All the parts are made from plywood. The carbon graphite pieces are super-glued on. I drilled holes in the brass contact and pressed brass rod through them. All were sanded flat with the belt sander. It's very important that they be flat! This would've worked a lot better had I made the brass contacts somehow spring loaded, or flexible, so they could always be assured of making good contact with the carbon. As it is, I'm surprised that it works at all...it actually so far, works very reliably.

Again, a picture of the moving contacts. Notice the magnet in the center of the block. The rod (1/8" steel) that serves to move the block up and down, is attached **ONLY** by the force of this magnet. This allows for some flexibility between the block and the rod, to aid in making good contacts between the brass and the carbon. For my first try, I drilled out the block and the rod fit tightly into the brass contact block. I had real troubles getting it to work, and this "flexible magnetic coupling" solved the problem.

Above are pictured all the parts of the regulator, it's really very simple!

The photo above shows the regulator mounted to the back of the alternator. The Aluminium disc fits just perfectly between the back of the regulator and the magnets. The regulator works pretty well, though lots of little things could be done to adjust it. Changes which would affect performance include: More or less weight on the moving parts, a thicker(or thinner) Aluminium disc, more or less magnets near the disc, and distance between the disc and the magnets. Another thing I did to it (not shown in any pictures) is include a small magnet and a washer which it was attracted to, which serves to pull down on the moving contacts. It helped to insure a tight contact at low rpm, and also a much faster switching action! It actually makes a fast clicking sound, and it never floats between the contacts. As it is adjusted now, when the altnerator comes up from 0 rpm the stator is hooked in series, until it hits around 300 rpm (about 30 volts. It then changes to parallel, and the voltage drops to around 15 and available current doubles. The curve is different on the way down, due mostly to the magnet which holds the bottom contact tightly together. It stays hooked in parallel down to about 10 volts, and then switches back to series and the voltage jumps back up to around 20.

Again, there are a bunch of adjustments that could be made. Simple improvements should definitely include some spring loaded contacts - or some sort of flexibility there. Although my contacts worked in testing, slight wear could render the contacts I made useless. I believe that for currents over 10 amps they should be larger. I was surprised at how hot the carbon graphite got when charging my batteries at 15 amps! Overall though, I think if scaled up some and well made, this sort of regulator could

squeeze a good bit of extra power out of an otherwise unregulated alternator, giving better startup performance (starts charging at a lower rpm) and better high-speed performance (halving voltage to double current).

I know there are some alternative, solid-state approaches to solving this problem--but they involve high-power semiconductors, which I can't fabricate in my shop! As we learn more about other approaches we will certainly post information and links.

Please let us know via email or our discussion board if you have any ideas or experience with regulating permanent magnet alternators.

# Wind Generator Testing

There is some advantage it seems to being able to test windmills, close to the ground, and find out exactly their output, and durability. We built a simple bracket of wood, and tied it onto our '30 tudor. This way we could monitor exact windspeed, and take down information. So far we used it to test only a 7' diameter 3 bladed prop, attached to a alternator built from an induction motor. The

results were definitely interesting, and the ride exciting. I didn't feel safe much over 20 mph, at which point the output was about 12 amps into a 12 volt battery. I doubt this prop, or the hub to which it was attached would have held together much past 20. At any rate, it's fun, exciting, and an excellent way to get information about a systems performance. It helps to have a co-pilot to monitor speed, voltage and amperage, and to jot down measurements.

***Do this only on a deserted country road. It would NOT be wise to let anyone pass you, either! Don't be surprised at the strange looks you receive, too!***

# THE WOOD-AX

We've had lots of response in regard to the [wooden windmill](#) I built last spring. It was built almost completely from wood, and was actually capable of around 100 watts of output. It was good for fun, and demonstration - but only barely produced usable power and due to the wooden bearings and small shaft, it was not really suitable for permanent installation. This page is about a recent windmill I made, mostly from wood, and capable of about 3 times the output. Although mostly wooden, the ball bearings and thicker shaft should allow it to stand up to the elements for some time to come! The alternator is of an axial design. It's a smaller version of the [VOLVO DISK BRAKE ALTERNATOR](#) I built in the fall of 2001. It produces 200 watts in a 30mph wind - maybe not the most efficient wind generator in the world, but nice, simple and reasonably effective!

[Para Español, traducción de Julio Andrade.](#)

## Stuff I used

12" long 3/4" shaft

5 1/2" diameter steel gear for the armature

2 3/4" ball bearings on pillow blocks

AWG 18 magnet wire - about 2 pounds

12 NdFeB magnets, 1" diameter X 3/8" thick

Some plywood and other lumber

lots of epoxy, wood screws and linseed oil

I cut a slot in the gear 1" wide, and about 1/8" deep to hold the magnets in. The magnets must be evenly spaced around the circle, and once they were, I glued them in with epoxy. This is very similiar to the Volvo disk brake alternator I made - so check that page out for more detail. The polarity of the magnets around the circle alternates, so each magnet has the opposite pole up as its neighbor.

The stator (part that contains the coils and does NOT move) is made up from plywood laminates. It includes 2 disks, each 6" diameter with a 1" hole through the center (to allow the shaft to pass through). There are also semicircular pieces which sit on the top to provide a cavity for the steel laminates to be glued in. The cavity for the laminates has a rough inner diameter of 4.5" and outer diameter of 5.375" - basically, it is immediately behind of the ring of magnets on the armature and a hair less than 1" wide.

Show above is the plywood stator, glued, and screwed together. You can clearly see the cavity into which the laminates will be glued in. The laminates are made up of 1/2" wide strips of 20 gage cold rolled steel sheet metal. The strips I used are 4' long, and before installing them, I covered 1 side of each strip with tape so that each piece would be insulated from the one beside it! This is very important to reduce eddy currents.

Pictured above you can see the stator, with the laminates glued in. I glued the strips in with epoxy, and when I could no longer fit 4' long coils in the slot, I started cutting shorter segments and tapping them in with a hammer. Unfortunately, gluing these in with epoxy is a nasty, sticky messy job, and I wish I could find a "nice" way to do it - all I can say, wear some rubber gloves and don't try gluing these in until you have a lot of patience! After the laminates are glued down, it is important to cover the whole surface of the laminates with a coat of epoxy. This provides some insulation between the laminates and the coils and makes it less likely that the coils should short out to the laminates! If 2 coils shorted out to the laminates - in the process of gluing/clamping them down - it would ruin the alternator.

The coils are glued (with epoxy) on top of the stator - right over the top of the steel laminates. Before making the coils I made a very simple winding form - simply a handle, with a small plexiglass form on top (where the coils would be formed), and a cap, which is held on with a nut. I could hold it in one hand, wind the coils with the other, and when the coil is done the top is removed so the coil can slide off.

Above is shown the same coil winder with a finished coil on it. Each coil is made up of 40 turns of AWG 18 magnet wire. Once the coils are finished, I twisted the ends tightly together before removing them from the winder.

The coils are layed out in their places on top of the stator. It's very important that they be in exactly the right spot. One could lay out with a pencil exactly where they go, but I simply put a coat of epoxy down, lay out the coils as shown above, and then put the armature over them and carefully line up each coil with the magnet above it. This is not the most precision way of doing things - but it's quick, simple - and I've had fine luck with it so far. Once the coils are tacked in place, they are generously coated with epoxy. I cover the whole stator with wax paper, and clamp the coils down very hard - the point being to make them as thin as possible, as the gap between magnets, and the steel laminates behind the coils must be kept to a minimum! In the case of this alternator, the coils were smashed to about 1/4" thick. The thicker they are, the less effective the alternator will be, and a little difference in coil thickness will result in a big change in alternator performance.

Once the coils are glued down nice and flat and thin - the alternator is pretty much finished except for the base. In this case, the windmill is made from solid walnut, about 2.5" thick and 6" wide. The pillow blocks are bolted down to it, and the stator is glued, and screwed to the front of it. The shaft passes through the stator, and the armature is set on the end. It's important to keep in mind that the armature is full of very powerful magnets, and it's attraction to the steel laminates behind the coils (or anything else made of iron or steel) is very strong! So - the shaft must first be tightened down at the ball bearings. Then, a spacer (I used a compact disk) should be placed over the coils so that the armature can never touch them. Then, the armature is placed on the shaft, up against the spacer and the set screws tightened. Once everything is tight, then the spacer can be removed. Again - I used a compact disk, so the gap between the magnets and the coils just over 1/16". The gap must be kept as small as possible. Once all this is together and tight - it should be possible to test the alternator! One should easily be able to spin it up to around 6 volts by hand. Although the alternator is functional - it's not quite ready for the abuse a prop would put on it. Some further insurance should be added to make sure nothing can move - set screws are not enough! In my case, I welded a small tab on the shaft just in front of the rear bearing so the shaft could not be moved back, and I welded the armature (The gear) to the front of the shaft. These were light, "tack" welds. A better job would be to use key slots and keys, and make spacers - although welding is quick, easy - and it still allows for complete disassembly of the machine. Should the shaft need to be seperated from the armature, the welds are such they could easily be ground off.

The prop is a simple "two blader", 4' long and pitched 5 degrees at the tip with a likely looking airfoil on the back side. Again - I'm no expert at prop design, seems like everything I put up works reasonably well though. Two blad props are quick, and easy. This one is made from a board 1" thick and 6" long, made from lodgepole pine. The blades are 2" wide at the tips, 4" where they meet the hub, and the part in the middle that bolts to the hub is 6" wide. The picture above hopefully explains this.

Check out some of our other wind generator pages for a little more info on prop making! Or...for a lot more info - find our links page and check out Hugh Piggots website! Again, this prop is pitched 5 degrees at the tip, and as steep at the hub as a 1" thick X 4" wide piece of wood will allow! (the wood I started with is 6" wide, but only at the hub, as soon as the "blade" starts - I cut it down to 4". Most of the blades are quickly knocked out with a power planer - or a hand planer, but near the hub it is necessary to chisel as a planer will not fit in there! I make lots of relief cuts with a handsaw, down to the depth which I must chisel, and the material comes off quickly and easily.

I drilled and tapped the armature to accept two bolts, with which the prop would be bolted down. The prop should be balanced well to avoid vibration, which would result in power loss and stress to the whole machine. A small 2 blade prop is easily balanced by simply hanging it from it's center. It will be obvious if one side is heavier than the other, and material should be removed until both sides weigh the same. Once balanced, the prop, and the rest of the wind generator are coated generously with linseed oil. It may not be the best finish, but I have lots on hand...

To test it we simply put it on the mast which I keep mounted to the nose of my '70 F250 and go driving on a still day! We had wonderful results when we tested this, all of our test results came out very consistent - they all fall exactly on a nice curve which we plotted on graph paper. In the truck, we carry a 12 volt battery, a volt meter, and an ammeter. We watch the speedometer, vs system voltage (between 12-15 volts volts when charging) and the ammeter. Here is the bottom line...

It takes about 15mph to get it running, but then once spinning - we could slow down and it would continue to spin and produce power all the way down to a 10 mph wind.

It's a fun little windmill! Nice, simple and small - and actually somewhat useful!  
We're installing this machine at my parents weekend airstream trailer to keep the batteries topped off. It's a good size for a small, remote power system that mostly gets used only on weekends.

# Science Fair Wind Generators

The frame is made of PVC pipe, the tail from a video game CD, and the rotor from a computer fan. The generator is a small DC hobby motor. It will light a small bulb using an electric window fan for power.

## How to build some very simple demonstrations of wind-generated electricity

**UPDATE 12/2003 -- we have received all kinds of email about this project! Some folks have been successful ([CLICK HERE](#) to see pictures and graphs....) and others have had trouble. In almost all cases the problem is finding a suitable little motor.....if the motor needs very high rpms to generate power, it won't work for this experiment. Testing the motors you have available by spinning them by hand into a voltmeter will give you a good idea of if it will work or not. You want good voltage at low rpms.**

**You might also want to check out our Hamster-powered alternator. Since Skippy the Hamster could only produce low rpms on his wheel, [we custom-built this little alternator](#) to work in the 40-60 rpm range. This makes it very suitable for wind or hydro experiments.**

The intention of this project was a quick, small and easy windmill that would be buildable by a kid with very little adult supervision. It seems to be science fair season all year 'round up here at Otherpower.com headquarters. We get many requests for information about science fair projects,

and hope this page will help kids and adults alike...at heart, all the Otherpower.com staff are kids!

As a result of the experiments, we've come up with a variety of different ideas for science fair projects. The current projects on this page are very simple thanks to the use of small DC hobby motors as generators. The only test equipment you'll need is a cheap DC multimeter, available for \$5-\$15 at Radioshack. These projects are suitable for even a 3rd-grade science project (with adult supervision, of course). We hope to add some more complicated wind projects in the near future, involving more advanced students building their own alternator by winding coils, attaching magnets, etc. For more detailed research information regarding wind power (you'll need lots of background information for a science fair project!) we suggest searching [GOOGLE](#) for 'wind power,' and checking out some of the web pages listed in our [Wind Links](#).

### **The Basic Parts of a Wind Generator**

Even in a giant commercial wind generator that puts out thousands of watts of electricity, the basic parts are still pretty much the same as in a toy wind generator!

- **Rotor**--The blades and hub (the part that holds the blades on), which begin to spin when the wind gets above a certain speed. This is called "start-up" speed. The blades get their energy from slowing down the wind, extracting energy from it. Most commercial wind generators have 2 or 3 blades. Some only have 1 blade, and a counterweight for balance! More blades make a wind generator start up more easily in low winds, and give higher torque but with a lower rotation speed. Fewer blades mean harder start-up, but better performance at high wind speeds and faster rotational speeds. The backs of the blades have an 'airfoil' on them, shaped just like the top of an airplane wing or the front of an airplane propellor. This airfoil provides lift, which allows the blade tips to spin at a speed that is FASTER than the actual wind speed.
- **Generator**--The component that makes electricity when it is spun by the rotor. Some wind generators produce alternating current (AC), in this case the component is an 'alternator.' Wind machines that produce direct current use a 'generator.' In both cases, however, the electricity is produced by magnets moving quickly past coils of wire--or coils of wire moving quickly past magnets. The hardest part of selecting a generator for a commercial OR toy wind generator is the rotation speed required to put out the amount of electricity you need, at a certain windspeed. More on this later!
- **Tail and Yaw Bearing**--To effectively slow down the wind and harvest power, the wind generator must always face directly into the wind. The tail (properly called a 'vane') lets the wind itself point the machine correctly, and the yaw bearing is simply the assembly that lets it rotate.

### **Fan Power versus Wind Power**

The first consideration is, what do you want to DO with the wind generator? For our simple projects here, the objective is to make just enough power to light up a small flashlight bulb using wind provided with a multi-speed electric window fan...since for a science demonstration you'll probably be in a classroom or gymnasium. And of course remember the well-known 'wind anchor' phenomenon--as soon as you erect any size of wind generator, all natural wind will immediately stop for at least a few days!

If your project allows you to use outdoor air flow such as an actual windy day or a vehicle, it will be much easier -- and all of the designs presented here will work. Even strange, unique, and silly designs will still start up and function with enough wind!

If your project must work indoors with a fan for power, you must design the unit to start up in very low winds. The air flow provided by a fan is VERY turbulent--it is difficult to make a toy windmill spin fast enough to make enough power. A combination of a many-bladed rotor and a free-spinning generator are needed to get enough rpms to light a bulb.

### Choosing a Rotor

We recommend having 3 or 4 rotors of different kinds and diameters available for testing. This will prevent multiple trips to the hobby store during your design and testing!

- **Model Airplane Propellers**--One of the simplest options is to buy an inexpensive (\$3 to \$6US) plastic or wooden 2-bladed model airplane propeller, and mount it backwards. It will style your machine like a commercial wind generator. Good sizes range from 8 to 12 inches in diameter. In a wind generator, the flat sides of the blades face into the wind, and the airfoil sides face away from the wind, the OPPOSITE of an airplane propeller. However, a quick experiment shows the problem with reversing the propeller...suspend the propeller on a straightened paper clip, and blow on the flat sides. The airfoil is pointed the wrong direction...it's opposite the direction of rotation! However, upon close inspection of the propeller, you'll also see that the airfoil carved into it is very minimal...just barely an airfoil at all. Because of this factor we've found that model airplane props still work just fine for this experiment. However, they are hard to get started with an electric fan because of having only 2 blades. You should be able to get one started at around 15-20 mph in a vehicle or in the wind, depending on the generator and prop size.

**Windmill built with 2-blade model airplane prop mounted backwards. Though this unit works while testing in the wind or from a vehicle, it will NOT start up in the wind from a box fan...for that you need to use a computer fan blade prop.**

- **Computer Fan Blades**--These multi-bladed units are an excellent and cheap option. The multi-bladed design allows them to start up very easily, at mere walking speed or in front of an electric box fan. Old computer fans are easy to scrounge up for free, and are also available at electronics stores. A diameter of 4 to 6 inches will work well. The hardest part is removing the blade from the fan assembly...since the assembly has to turn into the wind, you can't really use the bracket that contains the fan. Adult supervision is required for removing the fan blade, it may take some cutting and prying. But it's well worth it!
- **Portable Fan Blades**--Removed from cheap desktop electric fans, these usually have 4 or 6 wide blades, and also work very well. A diameter of 4 to 6 inches is just right. Again, supervision is needed for removal!

### Choosing a Generator

By far the simplest and easiest choice for a generator is to use small DC hobby motors, available at any local or mail-order electronics store, including Radio Shack. Once again, we recommend having a variety on hand for experimentation. They work as motors when you apply electricity to them, but they ALSO work as generators when you spin the shaft! Get a variety of different voltages and speeds if possible. Lower-voltage versions (such as 3 volts) start up the easiest, but their output will be limited to 3 volts at high speeds. 12-volt versions will make the most power, but may be harder to start up. Anything in between works just fine too! **The key thing with selecting a hobby motor is to buy the ones that have a toothed sprocket already attached to the tip of the shaft.** This will make securely mounting the rotor MUCH, MUCH easier for you. See picture below.

**Be sure to get hobby motors with a sprocket like this already attached -- it makes things MUCH easier!**

### Initial Assembly and Testing

Better to make sure things will work right for you before assembling the whole thing with glue! Carefully drill a hole in the EXACT CENTER of the fan blade hub, slightly smaller than the diameter of the sprocket. You want the teeth of the sprocket to catch the plastic or wood of the blade hub. Gently heating the plastic of the hub with a match will soften it and make this operation simpler, and allow you to test it before gluing it in place.

Now, connect the wires from the hobby motor to your DC voltmeter. Set up your fan, turn it to low speed, and hold the motor and blades up to the fan. Wear gloves and eye protection for this

operation! Once the blade comes up to speed, record the voltage you get. Turn the fan up to high speed, and again record the voltage you get. This information will allow you select your lightbulb for the demonstration.

Radio Shack has a huge variety of flashlight bulbs in different voltages. LEDs can also be used, but must be hooked up with the correct polarity. LEDs also light up with much less electrical current than incandescent flashlight bulbs. The polarity doesn't matter with flashlight bulbs however. Either one will burn out if you apply too much current from your wind generator! Pick a bulb that has a rated voltage very close to the **MAXIMUM** voltage reading you got, with the fan at highest speed.

Attach the bulb to the circuit in place of the voltmeter, and try the test again. If all goes well, the bulb should glow brightly at the fan's top speed, and glow dimly at lower speeds. This will let you show differing power output with different wind speeds. At this point, you are ready to assemble the final version of the wind generator.

### **Final Assembly**

**Details of frame construction are visible here, including the yaw bearing**

Our frames were built using PVC pipe and fittings. Since hobby motors come in different sizes, you'll need to pick a pipe diameter that allows you to slide the motor into a pipe end or fitting. In our designs, the motor fits into a PVC elbow fitting, and is held in place with epoxy putty. Once you find which pipe diameters you need, purchase a variety of components -- 2 or 3 feet of pipe, and a

few elbows, caps and reducers. Generally, the pipe and fittings fit together tightly without the use of glue, but you might wish to use PVC cement on your machine after it is together and working.

The yaw bearing can be built a number of different ways. Be sure it allows the machine to turn freely or it won't yaw into the wind correctly. Our design was very simple -- we ran a 4" long bolt down through the top, fastened underneath the yaw bearing to a pipe cap. There are undoubtedly many easy ways to improve this -- we simply used what fittings we had available to make things quick and easy.

**Top view showing yaw bearing bolt**

The tail should be made of thin plastic, and can be of a variety of shapes and sizes. Look at pictures of commercial wind generators for good ideas on proportions and lengths. The dimensions and shape are not critical--we found that a Playstation 2 CD made a fine tail, and it expresses DanF's opinions about kids, videogames, books and science experiments quite ironically!

To mount the tail, use a hand saw to carefully cut a vertical groove in the back of the right-angle pipe fitting into which your motor will mount. The groove should be wide enough for your tail material to slide into.

Securely connect your power wires to the connectors on the hobby motor. Depending on the kind of connector, it might be best to solder them on. Adult supervision needed for this please! Then, run the wires down through the 90-degree pipe fitting, and out a small hole you've drilled in the side of it.

Securely fit the motor into the fitting. You'll have to choose the size of pipe you use depending on the diameter of the motor you selected; that's why we don't give specific diameters of pipe here. Use a thin 'rope' of epoxy putty to secure the motor in place. This is the kind of epoxy that comes in a stick, and feels like modelling clay. You simply knead the 2 parts together until they blend, lay it in the gap between the motor and the fitting, and wait for it to set.

The easiest solution for how to run the wires is to mount the lightbulb directly to the upper frame or tail of the wind generator. If you want to have the lightbulb separate from the wind generator or want to use a voltmeter for your demonstration, just make a loose loop of wire near the yaw bearing, and use tape or a cable tie to keep it from hitting the rotor as it spins. This loose loop can wind itself

up around the pipe mount, but will also unwind itself when the wind (fan) changes direction.

## **Experimental Ideas**

There are a variety of different experiments that can be performed once your wind generator is operational. You can change the fan speed to show the increase in power using your voltmeter or by how bright your bulb or LED lights up. You can change the facing of the fan to show how the tail makes the unit yaw into the wind. If you want to charge small batteries with your unit, you'll need a small diode, available for under a dollar at Radioshack. Get a diode rated at around 1 amp. The diode acts as a one-way valve for electricity--without it, your batteries will simply spin the motor and prop. You want the power to flow into the battery, but not out.

A great way to test a small windmill is with a vehicle -- that way you don't have to buy or make an anemometer to measure windspeed. If you do test in a vehicle, either build a mount in the back of a pickup truck, or have someone hold the unit carefully out the car window. This could be somewhat dangerous! The person holding the unit should wear thick leather gloves and eye protection in case the prop flies off! If the unit starts to become unstable, have the driver slow down immediately. It helps immensely to have a third person in the vehicle to write down the speed of the truck as the driver calls it out, and write down the voltage reading at each speed.

**We urge you to have fun with your project and hope our ideas have helped. However, PLEASE be safe in your experiments and wear eye protection and gloves when you are near spinning props! And remember, adult supervision is required.**

### **About the project that was previously pictured on this page**

In that project, we attempted to use a small Brushless DC motor as an AC alternator to power a small bulb. However, the motor was incapable of producing enough current after rectification to DC with a diode bridge. That's why we switched to using DC hobby motors. We are also working on some more complicated science fair wind generator projects, with homemade alternators and carved wooden props....an example of which is shown below.

Not much more than a handsaw, chisel, and sandpaper is needed to carve a 16 inch prop!

## Science Fair Wind Generator

By [MikeR](#), Section [Homebrewed Electricity](#)

Posted on Fri Nov 21st, 2003 at 05:41:23 PM MST

[Wind](#)

I am a fifth grade girl who built this.....

Hi, my name is Kathryn. I saw the small wind mill on your experiments page and decided to build a wind generator for my science fair project. My project was to find if different rotors make a difference and if so which rotors worked best. I used airplane propellers mounted backwards. I compared several pitches of two blade props, one three blade prop, and one blade from a desk fan. I used a hobby motor from Radio Shack for the generator. We tested it by mounting it out in front of my dad's car. It didn't make much power, but the purpose was to compare rotors. Here is a picture of my wind generator flying above my treehouse.

Here is a summary of the data results.

This was a really cool project and a lot of fun. Oh, by the way, I got 100! Now I want to build a bigger one.

Thanks for the great website.

hello Kathryn!

i must say and i think that all will agree that your little genny is quite impressive. it is not so much the output that counts, but the experience of building it and bringing your ideas to a useful purpose. oh, and those few watts that you did get, well it may not charge a very big battery, but it was plenty to brighten my life a little.

keep having a great time! zubbly

Re: Science Fair Wind Generator ([none / 0](#)) (#2)  
by DanB on Fri Nov 21st, 2003 at 07:01:08 PM MST

Thats super...

so am I to understand that the 2 blade prop with the flattest pitch wins here?

Pretty neat... as neat as the windmill is the good data you got on different prop configurations. Congratulations!!!!

Re: Science Fair Wind Generator ([none / 0](#)) (#7)  
by MikeR on Sat Nov 22nd, 2003 at 07:23:23 PM MST  
([User Info](#))

Dan,

Yes, the two blade prop with three inch pitch produced the most power. Maybe one with a lower pitch would be better, but I didn't have one to test. Also I learned that the airfoil on the back of the prop is backwards with the sharp edge leading.

Both of the three blade props started the soonest. The fan blade starts spinning with very little wind but is so inefficient the speed levels out very quickly, limiting the power output.

Great wind turbine Kathryn, I can tell you give most teachers a hard time. :-) Keep it up, it's those things YOU have an interest in that will lead you to your greatest potential.

Kevin

That is a very nice machine! The graph is very interesting  
to study, too. Now I see why fan blades are used on fans  
instead of propellers. I always wondered about that.

Thanks for teaching me something.

Keep at it!

Eric

Nice work. It looks better then my first "wind machine".

I was 9 years old and trying to bring a thin sheet of  
plywood panelling into the garage from the pickup bed.  
Suffice to say that it was a very windy day and I got  
thrown about 15 feet sideways off the tailgate! I marvelled  
at the power in that one gust.

Thus was born my fascination with tapping into nature's  
fury.

You might want to try making a savonius turbine for one of  
your experiments. The simplest way is to cut a 5 gallon  
plastic drum (kerosene containers from Walmart) right  
down the middle. For these small ones you can use some  
wood, bolts and thin steel rod without too much worry of it  
coming apart.

Stay on the path.

I agree -- congratulations on your project. And even more  
congratulations on your data acquisition and graphing!  
Looks very professional. I'd go for a 4 footer next!

By [Jon Miller](#), Section [Homebrewed Electricity](#)  
Posted on Sun Jan 4th, 2004 at 02:21:02 PM MST [Wind](#)  
how do I charge 12v batteries for inverter

i have a 12v SLA battery that is 7ah how much electricity ie amps and volts do i need to charege this battiry from dead to full in a day or so? + what sort of motor can i use to do this as i can not make coils?

[charging 12v batteries for inverter](#) | 2 comments (2 topical, 0 editorial)

Re: charging 12v batteries for inverter ([none / 0](#)) (#1)  
by [drdongle](#) on Sun Jan 4th, 2004 at 05:45:27 PM MST ([User Info](#))

General rule of thumb is no more than 1/10th of the rated power so 700 Ma maximum.  
A TDM generator would be a good choice but your never going to get much use out of a 7 AH battery.  
Dr.D

Re: charging 12v batteries for inverter ([none / 0](#)) (#2)  
by [RobD](#) on Mon Jan 5th, 2004 at 06:04:38 AM MST ([User Info](#))

SLA batteries charge in, what is called, a two step process. The first step charges them to a specific voltage usually around 14.7 volts for 12 v batts. The second step maintains a float voltage of around 14.1 volts only after the 14.7 volt limit has been reached. Your battery won't last long if it's dead now. It's not good to let batteries drop below 11.5 or min. 10.7 volts before recharging. RobD

## [New wind turbine on new tower!](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Sun Jan 4th, 2004 at 12:02:35 PM MST

[Wind](#)

Yeah! I finally got a new tower together this week and put my 14' machine on it.

It's been a fun (cold and snowy too) week. I pretty much finished up my 14' wind turbine and made minor repairs to it after it [fell off its stand](#) last week.

Pictured above I've got it back in my workshop. Main damage was to the tail, which I had to straighten. As it turns out, I think it may still need a bit of adjustment.

This alternator used to cog a bit, as the magnets were attracted to the 3 bolts which suspend the stator between them. This made balancing the blade pretty much impossible, so I took this opportunity to replace the 3 pieces of allthread and all the nuts with stainless. This not only eliminated the cogging issue, but also reduced drag on the alternator which was being caused by eddy currents in the steel. Since the magnetic field is no longer attracted to the hardware, the eddy currents are much less.

Forgive my bad pictures... I'll hopefully reshoot some of it if I make a webpage about this fun project. The base of

my new tower is in the same location as my last tower.

My [old tower](#) was actually pivoted in a notch in a tree stump which I'd cut with a chainsaw. It was wooden, and built up from trees and chains. It was 45' tall and worked OK, but looked a bit precarious in high winds with my [9' diameter wind turbine](#) on it.

The pivot for this new tower is a 3/8" round steel plate (just like the ones I made the new alternator for this 14' windturbine from) with a hinge welded up. The hinge is simply a piece of 2" pipe slipped over 1.5" pipe. Onto that I welded a 1.5" pipe about 1 foot long which the jin pole slips over, and a 2" pipe the same length which the tower itself slips over. This made assembly easy. The plate is lag bolted to the stump of the tree which I cut off flat and level. Come springtime Ill probably remove the tree stump and pour concrete.

The new tower is 60 feet tall, and has a 21' jin pole. The tower is made from 3" pipe at the bottom, and then at 21' 2.5" pipe, and 2" pipe for the top 20'. It's braced for 42' up to the top with 1" pipe. The top 7' of the tower has smaller sched. 80 pipe run down through it to stiffen it and a little stub of it sticking out for the windmill to sit on. I've also welded 3 7' lengths of 1" pipe to the top 7' to stiffen it. It's quite stiff, when on the ground and braced up in the middle I can jump on it and it only bends a little. It's supported by 8 guy wires of 3/16" steel cable.

I welded a foot on the tower about 20' from the top which assures that the windmill can not touch the ground when I lower it. This also seves as a good place to mount an anememometer. In the picture above Rich and I are assembling the machine at the end of the tower. The bed of my truck makes a nice platform to stand on since I cannot reach it from the ground.

A closer shot of Rich and I hooking things up. Actually, a very cold day...

Like my last tower, I pull this up with my truck. Yesterday when we did this we had about 7" of snow, I got it half way up and the truck started sliding and lost traction. So we had to shovel snow and put down some ashes under the tires...

And then it pulled up with no problem! It seems very easy and rigid while raising and lowering. Of course, once we got it up the wind stopped and we had no wind for the rest of the day. This morning we've had a bit and it's been fairly interesting. It starts spinning around 5mph (maybe a bit less) and is actually cutting it at around 5mph making over 5 amps at 7 mph, which I think is quite good, but above that it's underperforming. I'd hoped to see cutin at more like 7 mph. Basicly, the alternator is producing too much voltage at too low of rpm I think.

Today weve had 25mph winds. At 25mph Im getting around 700 watts it seems, and rpm is around 160 (too slow!! - the blade is stalling). Id like to see more like 250 rpm at that speed and more current. I experimented by disconnecting one of the 3 wires from the machine, and it sped up quite a bit and made a good bit more power except in the very low winds. Of course... my line loss was worse and its not right that way. Its furling nicely. It starts to furl at about 25 mph I think - but if the blade was running faster and more efficiently that would come down a lot, so I believe a slightly heavier tail would be appropriate.

Ive not tried to get real windspeed vs output data yet (I can tell its not so good) - but I did get some interesting data on the alternator itself when its hooked to my batteries. These numbers take into account the whole line and at 12 volts my line losses are significant.

At 80 rpm Im charging at 7 amps  
At 90 rpm, 12 amps.  
At 95 rpm, 15 amps  
At 110 rpm, 25 amps  
At 160 rpm, 55 amps

I think I have a few choices to fix this machine so it's working well...

Best, would be make a new stator with fewer windings and heavier wire which would increase cutin speed and reduce

losses in the alternator.

Second best would be to actually increase the airgap in the alternator as it is. This would have a similar affect I think, but do nothing for my wire losses in the alternator.

I could add resistance to the line. This would speed it up and although my line losses would be worse, the benefits of the prop running at a more efficient speed would most likely outweigh the additional line losses.

I could make a bigger/slower prop! - but thats a lot of work, and I think a larger prop may very well burn up my stator in higher winds. As it is, its safe and slow and quiet and although it's not making the sort of power I'd expect from a 14' machine, I am getting a bit more than I used to from my 9' machine so it's OK. Furthermore, I'm elated that it works, and the tower seems solid and no catastrophies happened! I was never too happy with the way the stator came out in the first place, so I'm happy to make a new one, it takes 1 days time.

Here are links to the previous postings about this project:

Re: New wind turbine on new tower! ([none / 0](#)) ([#1](#))  
by zubbly on Sun Jan 4th, 2004 at 04:58:30 PM MST  
([User Info](#))

Hi Dan.

Great job on that genny. Sorry to hear that it does not perform (yet) the way you would like to see, but i am sure you will make the changes you need to do so. The only thing i don't like about odd number of coils per phase (in your case 3) is that the other alternative is to make a 3Y connection with the stator you have now. This would increase cut in speed to 3 times of what it is now. Probably a little too high for what you want.

have fun-Zubbly

Re: New wind turbine on new tower! ([none / 0](#))  
([#6](#))  
by DanB on Mon Jan 5th, 2004 at 08:38:22 AM MST  
([User Info](#))

Hi Zubby - yes, i know what you mean about having 3 coils per phase.

But - I dont mind. I think it'd be different a bit if we had slotted laminates directing the magnetic field exactly where we need it, but with a air core design like this - or, with laminates only beneath the coils, there are always problems with hooking coils in parallel - no matter how well you wind them there will be current flowing between them it seems. In past machines I made, I'd usually wire parts of the stator in parallel, and have numbers of coils which were divisable by lots of numbers so that I could hook things in parallel or series or a combination of the two so that I could match the alternator to the blades. This worked out OK, but in every case I noticed drag on the alternator as soon as the parallel connection was made. Sometimes not bad - and often times I'd bring the single phase down on 3 wires and rectify the seriesed parts BEFORE I made the parallel connection - which solved the problem. In this case though, with 3 phase, that would be tricky. Best is just get it right I think, making a stator is not a big deal.

Im fairly sure the most efficient alternator will definitely NOT have any parallel connections in it and if its 3 phase it will be wired in Star. Like Ed suggested, I could quickly wire this into Delta (perhaps I should give that a try...) - but I think it would be a bit fast then and there are inefficiencies associated with the Delta connection. Perhaps Ill try that though... just for fun.

Yesterday I did add some resistance to the line and it helped quite a bit, although she still needs a better stator.

Dan

Great job as usual : )

I think you did you self a big favor reinforcing the pipe like you did.  
As there all ways is a bit of tweaking needed with home built machines at first .  
A more rigid structure make things a lot easier and safer when raising lowering .

And after all this should be a hobby an not an extreme sport : )

Old F

([User Info](#)) <http://www.windstuffnow.com/main>

You do some nice work Dan! Definately sounds like its stalling the wings. Once you work out the kinks your going to have lots of power! Would it take the cut in to high if you wired it in Delta? Might cure 2 problems with one wire...

You must be quite determined, I hate working outside in the snow and cold. It takes me about 2 hours to get motivated and dressed for it. Once the shop is warm its not a problem but first thing in the morning.... I hate winter can you tell?

Have Fun!

Ed

Re: New wind turbine on new tower! ([none / 0](#))  
([#5](#))  
by DanB on Mon Jan 5th, 2004 at 08:28:34 AM MST  
([User Info](#))

Hi Ed -  
I think Delta would bring cutin speed a bit high.  
Furthermore - after discussing it some with Hugh  
(and I think hes right on this...) - the Delta  
connection tends to be inefficient in low winds. Im  
also unhappy with the thickness of this stator, and...  
making stators is fun! So I'll just make a new one.

Yes, the cold is rough. As I sit here now, I think my  
shop is at about 5 below 0. Days like today - its  
impossible to heat my shop above about 40.

([User Info](#))

Hi DanB,

That's a nice looking tower!

I'd love to see what a stator wound up for 120 VAC or  
higher would do with those killer magnets!

Keep up the great work.

Ted.

[Alternators](#)

### SMALL AXIAL ALTERNATOR

I had told Zubbly and Mech last week that I would post some pics of a small axial alternator I had built. This is my first post, I hope the pictures turn out, if not, I included links to their current locations on the server.

It is downright primitive compared to some of the designs I've seen here, but I'm still pretty proud of it since I came up with it from scratch. This first prototype I built was simply 16 coils of magnet around bolts, mounted in a box, with 16 ceramic magnets mounted on a disk. I built it before I was aware of this site, it has losses from eddy currents, I'm sure, and it cogs significantly, but it works.

Currently, all coils are wired in series, this way, it generates a useful voltage (13V) at under 60 rpm, although not much current. I had tried 4 sets of 4 coils in parallel and two sets of 8 coils in parallel, and although they appeared to put out more current, they required much higher rpm's. In low winds, which I suspect are the most common, there would be no productivity.

I rigged it up for a temporary installation by mounting it

on a small tower made of rebar and an inch and a quarter galvanized coupling. I used double sealed bearings around a threaded tube for the joint.

I fit those within an inch and a quarter copper coupling. It didn't fit perfectly, so I put a couple of layers of electrical tape around the outside of the bearings to snug them up.

I used a piece of inch and a quarter tube to hold the bearings in the fitting, holding it in place with screws drilled through the fitting and tube so that the wind couldn't pull the machine off of the tower. I checked on the turbine recently and found that there was a little play at the bearing where it mounts to the tower. I'll have to find something a little better for future designs.

I weighted this on a two story roof, added a small metal turbine modeled after an ornamental windmill, and tied it in with a pre-existing 12 volt solar system. This connects to a Trace C-12 Load controller.

This charges a 12V. Deep Cycle Battery,

which keeps a couple of white led lights on in my laundry room and a small utility closet. Excess power generated is wasted right now. At present, I leave these lights on all of the time. This fixture has 70 or so leds, I think, I would have to open it up and count them as I can't remember - its been up there more than a couple of years now. They are mounted on a pcb, three in series with a 120 ohm resistor. Probably not as efficient as a flourescent, but they are maintenance free.

I'm currently working on a smaller design built with more durable components that I can fit into a smaller tube rather than a box. I was shooting for a two inch diameter tube, and a 48 volt system, but have had difficulty generating the voltage and power at lower rpm's. I may try and design something to fit into a 4 inch pvc tube. I have a 4 story building in Chicago that I can mount them on, but they would have to be not so obtrusive,hence, several small machines vs. one larger one. Below is a picture of an experimental 3 phase stator that I have been working on for a dual rotor axial type machine. I will have to greatly increase the number of turns of wire for this design to work.

This gives you a rough Idea what I'm up to, so any advice, suggestions, criticism is appreciated.

Just trying to have fun. Rich

Re: SMALL AXIAL ALTERNATOR ([none / 0](#)) ([#1](#))  
by zubby on Sun Jan 4th, 2004 at 07:25:01 PM MST  
([User Info](#))

hello Rich.

Thanks for making the post. That is a nice job for using such common materials. I would be proud of it myself. looks like you are definately on the right track. Also like the idea of you designing and building to suit your own needs.

I noticed your last picture. looks like you are a fan of using wave windings. keep at that area, as it is a simple and very good way to make easy multiple poles from one coil. I will also be using that technique in my next genny. But with a different twist lets say.

great job!  
keep having fun-Zubby

Re: SMALL AXIAL ALTERNATOR ([none / 0](#)) ([#2](#))  
by Harry Luubovv on Sun Jan 4th, 2004 at 11:47:08 PM MST  
([User Info](#))

Hi Rich,

I like what you did and do. It is always nice to see innovatively thinking persons.

Now my criticism if you don't mind. The wave winding is good to the point that it saves wires (And so saves weight) and also saves resistance counts. However, we have to be very careful as to phasing. Because, it is a wave winding so all the coils are wound as one giant coil spread all over the outer perimeter of the stator backing disc. And so all the magnet poles will have to pass the coils in a more precisely synchronized way. Meaning, you will have to have the same amount of coils against same amount of magnets and spacing would have to be

same between magnet poles and coils--more cogging. If these rules not observed, you will lose out pretty large due to waveform cancelling one another between coils obviously. In worst of cases, you might end up having zero volt ! If one pole happens to be North cutting while another pole happens to be south cutting at the same instant, both the peak and valley waveform will cancel out one another--Zero output !

And then, a complete closed-loop of a coil is more in efficiency than a half open coil.

It is known that multi phases are better for battery life than a single phase charging. Just imagine, the wave technique would entail longer wires again even though you can still employ the wave technique, just imagine the picture, I need to say no more because you simply would need to have running wires to bridge between coils of same phases.

This is all the negatives I can give you, now you can pleasantly see that I am that devil to ya :-

-No love loss-  
Luubovv.

Request for hydro info

I have a seasonal creek running an average of 5-6 months per year. The head is 4 feet with a flow varying from about 25 gal/min to a full 3 foot culvert. Can anyone here advise me on the best way to investigate the economics and practicality of installing a micro-hydro plant? Thanks

be a good idea to do a little research instead of posting every ? that pops into your head. try reading the re faq. [http://www.fieldlines.com/faq/re\\_faq](http://www.fieldlines.com/faq/re_faq)

and then read the links at the bottem of the <http://www.otherpower.com/> page. then try doing a search using <http://www.google.com/> then come here and post an intelligent informed question.

by [kell](#) on Sun Jan 4th, 2004 at 07:11:50 PM MST  
([User Info](#))

Most important: how much head? That is, how far does the water drop. If you can get a meter or two you might be able to work up a pretty good system (just guessing; I actually have no practical experience). Somewhere on the otherpower.com site there is a picture of a super simple setup a guy made with some kind of ventilator fan driving a generator with a belt. It is basically just plunked down in a creek where the water runs over a log.

### [motor bike battery charger](#)

By [Jon Miller](#), Section [Homebrewed Electricity](#)  
Posted on Sun Jan 4th, 2004 at 02:34:29 PM MST [Alternators](#)  
how much can my bike charge?

I have just got a bike, 50cc. that puts out about 4 amps of power which goes through a regulator and then to a bulb 25w and a 5ah 6v battery. My question is there any spare amps to charge another 5ah 6v battery with the light on?

"OHM's Law" ([none / 0](#)) ([#1](#))  
by [wdyasq](#) on Sun Jan 4th, 2004 at 04:59:11 PM MST  
([User Info](#))

Jon, If you find the formula for 'Ohms Law' it states the relationship between Volts and Amps. It will also show you have not given some important data anyone would need to answer your question. Good luck, ROn

Re: motor bike battery charger ([none / 0](#)) ([#2](#))  
by [drdongle](#) on Sun Jan 4th, 2004 at 05:52:57 PM MST  
([User Info](#))

Actually "Ohm's law" is the relationship between Voltage, Amps and Resistance. What he needs is the Power formula which is  $P \text{ (watts)} = A \text{ (Amps)} \times V \text{ (Volts)}$ . John needs to know the load the lamps provide and then he can calculate if he has any reserve available.

Dr.D

Your lamp burns up 25 watts of power. You have a six volt system. Since watts=amps x volts, the amps drawn by the lamp would amount to 25 divided by 6, or at least 4 amps. Actually, the way these things work, the voltage regulator probably holds the system voltage at about 7 volts, so the lamp's draw would probably come to 25 divided by 7 or about three and a half amps. At the risk of confusing you, the wattage of your lamp can be expressed as a precise figure only for a precise voltage. Increase the voltage and the watts go up (lamp burns brighter), decrease it and the watts go down. The 25 watts figure on your lamp is approximate for the voltage on your bikes system. That voltage may drop at idle, for instance. Bottom line, your bike's charging system has to have some excess capacity above what the lamps and ignition draw, in order to be able to charge the battery. So yes you could put more battery capacity on there and still have it charge, but it might take a little longer to charge the extra battery capacity, since your charging system sounds like it doesn't have a hell of a lot of extra beef designed into it.

### [3 Phase ???](#)

By [Hank](#), Section [Homebrewed Electricity](#)

Posted on Sun Jan 4th, 2004 at 10:53:34 AM MST

[Wind](#)

Confused about 3 Phase benefits vs. Single Phase

I'm considering building another genny. My first one is a single phase which I'm pleased with. All the postings I've been reading suggest a 3 Phase is better so here I go with some lengthy questions (I apologise in advance for this long post).

First I want to make some assumptions to level the playing field in comparing a single to a 3 phase unit. Both will be single rotor, all coils are the same wire and # of windings. Voltage given is at some arbitrary rpm but the same for both

	Single	3 Phase
1. # of magnets	12	12
2. # of coils	12	18
3. Resistance/coil	.1	.1
4. Total resistance Series/Star	1.2	1.8
5. Total resistance parallel/delta	.6	.6
6. volts/coil	2	2
7. coils/phase	12	6
8. Total v(series)	24 (12*2)	10.39 (6*1.732)
9. Total v (par/del)	12	6

Am I missing something in my understanding of 3 Phase? Based on the above assumptions a Single phase would be the way to go. You get higher voltage in either combination (series/star or parallel/delta) using single phase. I'm assuming current will follow the voltage and resistance so I don't see any 3 phase advantage here either.

Any clarification will be greatly appreciated as I think (dangerous) I'm missing something.

Hank

Hank, The advantage of three phase the way it is usually done by people on this site is a smoother power flow, less vibration ect. However if you go 3 phase using the design shown in Electric Ed's recent drawing (thanks Ed) the huge advantage is putting copper inside of holes created by each coil, ie there is room for three times the copper by interleaving your coils, Yes, you have to have room on the inside and outside of the magnet ring for the coils to cross without increasing the air gap. If the magnets stand "proud" of the rotor disc the space is there. Ed of windstuffnow has done great work in this area using cast forms and slotted stators, I have not built any axial alternators only radial with iron cores where interleaving of phase coils is standard in "all" 3 phase machines. Hope this helps Make the wind fun!  
Victor

Re: 3 Phase ??? ([none / 0](#)) ([#2](#))  
by Hank on Sun Jan 4th, 2004 at 01:37:57 PM MST  
([User Info](#))

Thanks for the reply Victor.  
I understand the smoother operation aspect of a 3 phase and also being able to utilize the open space with more copper (coils).  
In the example I used above to compare the single and 3 phase units I did use more coils for the 3 phase unit (50% more, interleaved). Unfortunately when I do the math for power output somehow it does not add up for the 3 phase unit (even with more copper).  
I think, maybe, I'm missing something even though I read all the posts and links on 3 phase units.

To much time to think will get me into trouble!

Hank

Hello Hank,

It seems I'm the only one actually doing the "interleaved" coils on this site, although, Electric Ed may be using the same or similar technique.

The way I wind my 3 phase units... Think of the single phase you just made, 12 poles - 12 coils... add two more single phase coil sets offset slightly from the first. Now you have 3 single phase alternators in the same space.

Wire them in star or delta and your 3 phase is done. So in the above example... 2 volts per coil x 12 = 24 volts x 1.732 for star = 41.5 volts. For delta you'd end up with the 24 volts but you would divide the star wire by 3 for the ohms. ( in star as your example 1.2 ohms x 2 = 2.4 in star or 0.8 ohms in delta. Also by going this route you can lower your amount of turns

per coil to achieve the same output and lower the resistance in the wires thus increase output.

Also, you can change the configuration a bit and run it as 3 single phase units, each with its own rectifier. If you series them together you tripple the output voltage ( less phase offset ) or parallel them to tripple the amps ( again minus the phase offset). 3 single phase units run just as smooth as a 3phase unit ( basically the same thing ).

Take it a step farther, you can run 3 separate single phase units with different wire size and turns, having 3 cut in speeds ( like a low, medium and high gear). So many variations... so little time....

Lots of fun!  
Windstuff Ed

Re: 3 Phase ??? ([none / 0](#)) (#4)  
by Hank on Sun Jan 4th, 2004 at  
07:13:51 PM MST  
([User Info](#))

Thanks Ed I was hoping you would shed some light on this,

I guess the part that is stumping me or perhaps I don't understand is the total voltage.

In my example I used a single phase (the first column) and 3 phase (second column).

In the 3 phase example I assumed 18 coils for 12 magnets. These would be interleaved.

I used the info on your web-site as a teaching tool. Incidentally it is very good. If I understood it correctly, to find voltage you would measure any one phase then multiply it by square root of 3 (1.732). If that is the case, then there are only 6 coils (18/3) in any one phase and the resultant voltage (based on my assumption of 2 volts/coil) would yield 12 volts for that phase.

Therefore the total voltage for all three phases would be  $12 * 1.732 = 20.8$  volts. Is that correct?

wheras the single phase would produce 24 volts.

I did make a mistake in my voltage calculations in the first thread for 3 phase, star and delta!!! Sorry.

I can see the advantage in Delta as the resistance will be 1/3 as opposed to 1/2 for single phase in parallel with the same voltage.

You do bring out some interesting possibilities with 3 phase however. Getting the itch to build another one!

Hank

<http://www.windstuffnow.com/main>

Hi Hank,

I started using the 3 coils per pair of magnets a long time ago and your right the "alt from scratch" represents this. From experimenting I found I could basically increase the amount of wire in the stator by simply using 3 coils per magnet.

After building a couple that way it actually sunk in that I was making single phase alternators and wiring them into a 3 phase configuration.

It seemed almost too simple at the time. Since then I've been experimenting with different variations and found you can actually make a 1kw unit using small #20 wire, although, I wouldn't want to hold it there for extended periods of time. My downwind unit has 8 poles ( ceramic magnets) and 24 coils ( 3 sets of 8) on an 8" disc. Its topped out at around 60 amps in some gusty winds. After checking it, expecting to see some black coils they were all still bright and shinny.

It did quit working after that but It had burned out the relay on the star/delta switch. I replaced the relay and its still running!

I can only guess as to how many I've built using this method and almost all of them had smaller wire ( 20 - 18 - 15 gauge) all of them seem to work exceptionally well with the exception of my multi disc multi stator alternator which came in at about 1/2 of what I expected at a given rpm. I hadn't taken into consideration the magnets on both sides of the discs robbing flux from the silicon. A learning experience and it was fun.

If you can imagine 3 single phase units each producing only 20 amps at a given rpm... In paralell you have 60 amps approx. Easy to do with #20 wire. Use #18 wire in the same configuration and each phase will deliver 35 amps or 105 amps... now your welding... use #15 wire ... well you get the picture... more coils, less turns, less resistance more power.

([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

I think your coils need to be larger and your magnets need to be spaced farther apart because the coils won't fit.

## [generating electricity using Earth's magnetic field?](#)

By [dude8604](#), Section [Homebrewed Electricity](#) [Free Energy](#)  
Posted on Sat Jan 3rd, 2004 at 08:22:31 PM MST  
???

I'm working on a school science project and was wondering if any of you could help me. I'm doing a science fair project in which I will test the feasibility of using electromagnetic induction and the Earth's magnetic field to create electricity by moving a wire coil. Someone was telling me that if you take a wire coil and move it, power will be generated because of the Earth's magnetic field (because of electromagnetic induction. Does this actually work and how can I test this? I'm having trouble finding info on this. Anyone have any ideas of where to look or what to search for? I found out that there is a device called the Grove Earth Coil invented by an English scientist in 1900, but I can't find any more info on it. Thanks for any help!

[generating electricity using Earth's magnetic field?](#) | 2 comments (2 topical, 0 editorial)

using Earth's magnetic field? ([none / 0](#)) ([#1](#))  
by [drdongle](#) on Sat Jan 3rd, 2004 at 09:41:23 PM MST  
([User Info](#))

It works but the trick is the motion, that is finding a way to move the coil continuously through the natural magnet field and as that field is very weak producing enough power to be usefull.

Dr.D

It's easier to build a giant compass, with the pointer connected to a gearing system that drives a generator. You have a couple of "Wings" or "Fins" built to capture the wind so that each time the wind blows on the wings, it turns the compass body away from magnet north, the pointer moves southwards of course correspondingly, and so the gearing underneath registers the movement, converting the movement into generated power. Simple and straight ! Heck it, cancel that wings stuff, you just move the compass body by your own hands, it is just a science project anyway, we don't need wind in this case !

Love, not hate  
Luubovv.

[Alternators](#)

### 1 big coil vs multiple smaller coils

Hi,

I want to build a small wind generator that will output only a few Watts (5-10W) to charge a 12V battery (I know that buying a small solar panel would be simpler but I'm interested in building a wind generator). I want it to be able to charge the battery in very low winds (10 mph). I don't care about getting high power in high winds.

I think that winding more turns of wire around a coil raises it's voltage at low rpms. But my question is: Is it better to have a big coil with a lot of turns or many smaller coils in series? Example: If I have a 10 magnets rotor, is it better to have 1 coil with 500 turns or 10 coils in series with 50 turns each?

Should I go 3 phase in star configuration to get more voltage at low rpms?

And what kind/size of rotor would be appropriate?

Thanks in advance and sorry for my poor english...

Re: High voltage at very low rpm ([none / 0](#)) ([#1](#))  
by [Budgreen](#) on Sat Jan 3rd, 2004 at 08:29:54 PM MST  
([User Info](#))

for just 5-10W it seems like a lot of trouble to go through. I have a small stepper motor that puts out about 6-8W into a battery in low winds I think that you might have better luck with something like this, but it is your call

Re: High voltage at very low rpm ([none / 0](#)) ([#2](#))  
by [Norm](#) on Sat Jan 3rd, 2004 at 09:36:05 PM MST  
([User Info](#))

It will have to be a very small 12 volt battery...5amp/hr. Well anyway try <http://www.picoturbine.com/> their more advanced alternator 3phase should work you wouldn't necessarily have to hook it up to a vawt. Have Fun! Norm.

I signed up on this board with the same basic question. Looking for a "portable" wind generator to be set up and used when camping, which will mostly be in the Oct-Dec timeframe, and out in the woods. Not good for wind generation, but not good for solar in the northern part of the U.S. either. My homemade furnished camper will be heated via a tent stove, it will have LED for basic lighting (at least to prevent stubbing a toe!), and possibly a radio. So my electrical loads should stay small. However, I would like to experiment for the learning experience as much as anything, not to mention having multiple sources of power for flexibility. So, being in the woods (major wind blockage) and having to stay portable, I am severely limiting the available wind to be harvested. Therefore, I would like to build something that is maybe the size of a box fan or slightly larger, that will at least contribute to battery maintenance. This raises another question; if the batteries are somewhat low, will the increased load of a low battery stall a small wind generator in low winds? I have recently built a lawnmower engine-powered GM alternator to do bulk recharging of batteries, but would rather not even use it at all. As it is, I had to build a variable pulse width generator to reduce the motor load on the tired ole garbage-picked lawnmower engine when the battery is low, or it would stall. Perhaps this pulse width modulation could be used for a small wind generator when used on low batteries? I have read many posts on this board as well as some other sites, and it is very confusing. Number of poles, phases, number of windings, number of prop blades and design, stator diameter, etc. Very hard to figure out for a small capacity battery maintainer that I would like to build. Any suggestions would be appreciated.

Since your needs are very low, and you don't have access to either a good wind, or a source of good sunlight, you might want to use the possibility of using a bicycle connected to an alternator?

[http://www.otherpower.com/otherpower\\_experiments\\_bicycle.html](http://www.otherpower.com/otherpower_experiments_bicycle.html)

The owner of this site claims that he can get 60 watt without struggling, and 120 watt, when he is pedaling as fast as he can.

Your needs are very low, so if you could pedal while you are listening to the news or doing other things, and you would get an excess amount of power, - probably enough to power your lights and other things during the evening?

Look at the bicycles boat owners use - they are very compact. If you cut one of those apart, (remove everything you don't need, like the saddle and the wheels), and connect it to an alternator you would end up with a small human powered generator, which you can power while you are sitting in your chair.

/Steffen

Since your voltage is high and current needs low you might want to run single phase. RobD

([User Info](#))

Thank you for your advice. I know that building a wind generator is a complicated way to get 10W and will turn out to be more expensive than simply buying a solar cell, but I'm interested in building my own alternator and maybe it will be a prelude for a bigger one eventually. There's still one question unanswered: Is it better to have 1 coil with a lot of turns or 10 coils with 10 times less turns each in series. Thanks

Re: High voltage at very low rpm ([none / 0](#)) (#6)  
by Electric Ed on Sun Jan 4th, 2004 at 07:36:43 AM MST  
([User Info](#)) <http://www.electric-ed.com>

[quote]"Is it better to have 1 coil with a lot of turns or 10 coils with 10 times less turns each in series."

Yes. With your windings evenly distributed around the circumference of the machine, all of the available magnetic flux is acting on coils at all times.

I believe that the most efficient layout for an axial-flux machine is the twin-rotor three phase.

**Three Phase Winding - all coils identical**

Connect the coils of each phase in series for higher voltage, and parallel for higher current

"Edge-on" View from here shown below

**Magnet Spacing - Equal to the coil span**

After interchanging the center phase leads, connect the phases in wye for higher voltage, and delta for more current

**Voltage waveforms at the instant when magnets are at position illustrated above**

Note - At any instant, one phase is always opposite in polarity to the other two

**Twin Rotor Magnet Arrangement**

Electric Ed

Posted on Sat Jan 3rd, 2004 at 01:27:55 PM MST

I have noticed that most of the better postings are using what seems to be a same drawing program.

I would like to post a few things, however a picture or pictoral drawing usually gets the point across better. What is the drawing program that works best here? is it shareware? can I post PDF drawings here?  
I am going to try posting a couple pictures I took at the Searsburg Vermont Wind Farm (560KW per machine 40ish meter rotor)

I was working on the Wind Monitoring Tower there when I took this.  
I thought a few of you might like to see this.

I post a lot of drawings. I use the Wondoze Paint program and convert the file to a GIF Image so the file size will be real small.

Small file size is important, I suggest you use GIF images for drawings and JPG images for Photos. And try to keep the pic size under 650 pixels.

[Is 15.3 volts too high to leave my batteries charging?](#)

By [zmoz](#), Section [Homebrewed Electricity](#) [Batteries](#)

Posted on Sat Jan 3rd, 2004 at 01:15:14 PM MST

Is 15.3 volts too high for long term battery charging?

Sorry to keep bugging you guys about my batteries, but this is the first time I've actually had to store any. :) I have two automotive starting batteries that I am storing in the garage for the winter. One is brand new, the other is about 4 years old. Their voltage when charged is within .4v of eachother. I wired them in parallel and planned on leaving my 1 amp trickle charger on them for the winter. After the charger has been on for a few hours, however, the voltage is up to about 15.3, with about .3 amps going into each battery. Is this too high to leave them "floating" for the winter?

[Is 15.3 volts too high to leave my batteries charging?](#) | 2 comments

battery charging - ([none / 0](#)) (#1)  
by VermontMaple on Sat Jan 3rd, 2004 at 02:05:49 PM MST  
[\(User Info\)](#)

Zmoz

Charging batteies is a tricky business. And floating them for an extended period is even a harder. I have had a lot of experience over the past decade floating lead acid batteries. Most trickle style battery chargers have some minimum current always being fed to the battery . This is fine for a short time (1 week or so) however if you are not cycling your batteries...like most off the off-grid poeple do, you will boil out the acid in your battery. Many years ago I had a very useful conversation with a battery engineer at C&D corporation about proper charging and maintenance of lead acid batteries. His advice is as follows. Never allow the float voltage of the charging device exceed the natural float voltage of the battery. The natural float voltage of the battery can be found by initaly charging the battery very hard for enough time that you are satisfied it is fully charged..The battery will usually be warm/hot...for a standard car style battery charge it at about 10amps (about 1/10 to 1/3 of the amp hr rating of the unit 60-100 amp/hrs for car batteries = 6 to 10 amps)

And charge it for about 24 hours. The voltage of the unit should be well above 14 volts at the end of the charge cycle. Now let the battery rest for 15 minutes after removing the charger, then measure the voltage of the battery (to 2 decimal places if possible). This is the natural charged voltage of this particular battery. Set the voltage out on your charging unit not to exceed this voltage. If the battery is kept at this voltage it will not evaporate its electrolyte, and be always ready for use.

As for paralleling batteries, one will usually discharge the other until the lowest voltage unit is at its natural voltage. If the battery have the same natural voltage (or very close

+\_.1 volts) than they can be paralleled without a problem.

Stacking, paralleling batteries is a complex subject. Whenever possible stack/parallel batteries from the same lot if possible or at least the same capacity and age. There are tricks using fuses as swamping resistors (and safety devices) to help better stacking/paralleling...but I will save that for a future post if anybody is interested.

Re: battery charging - ([none / 0](#)) ([#2](#))

([User Info](#))

you could try draining the acid after you have fully charged them. never tried it but batteries will keep for years like this. just pour the acid back in in spring. no charging, no freezing, and you can just forget about them till you need them. do a google on battery maintenance, its all there somewhere.:-) bob

Alternator/motor

Can automotive alternators be modified to be used as motors?

[Automotive alternator used as motor](#) | 6 comments (6 topical, 0 editorial)

Re: Automotive alternator used as motor ([none / 0](#)) (#1)  
by [RobD](#) on Sat Jan 3rd, 2004 at 04:39:07 PM MST ([User Info](#))

Hi, Not easily or efficiently. Car alternators are designed with a narrow specific purpose and while they can be used in other applications they usually don't excel. RobD

Re: Automotive alternator used as motor ([none / 0](#)) (#2)  
by [rhud](#) on Sat Jan 3rd, 2004 at 07:10:28 PM MST ([User Info](#))

Hi, I seem to remember a pamphlet i received from linsay publishing telling how to easily turn an alternator into a motor, but there's a catch (there always is). you had to remove the diode pack and bring the three field winding wires outside the case. so now what you have is a three phase motor with slip ring feed to the rotor. (most of us dread a three phase motor) but in this case the idea was to also remove the diode pack from an alternator that was being used to produce power, there by turning it into a three phase generator that could feed the motor. i'll try to find the information, i'm too tired to think. but its a good tired, i just got back from North Carolina with my new GM-90 engine from Mike. I'm going to post the experience when i can think (better).

Interesting to think about... putting three-phase ac into the stator would set up a rotating magnetic field? Seems like you would still have to put direct current into the field. And what about the voltage regulator? Like to hear more.

Re: Automotive alternator used as motor ([none / 0](#)) (#4)  
by Harry Luubovv on Sat Jan 3rd, 2004 at 10:20:11 PM MST  
([User Info](#))

You can forget about the regulator, you just turn the alternator as fast/slow as you want, to generate the amount of voltage you want. But of course if you want a specific amount of current and be able to hold to a certain voltage, then you will need your own electronics regulator. But for simplicity, it is not necessary at all to have the regulator, just adjusting the RPM is enough. You can also rectify the AC output to feed the rotor current requirement. Or have Neo Mags fitted to it and forget about drawing unnecessary electricity from the output for the rotor all together !!!

I like something what I read in this board, so I'll repeat what other person said :  
"Put the bunny back in the box". Or was it supposed to be "Put the bus back in a cage !" ?? :- Gettin' old, cannot remember too well.

Ciao.  
Luubovv.

Re: Automotive alternator used as motor ([none / 0](#)) (#5)  
by Harry Luubovv on Sat Jan 3rd, 2004 at 10:32:55 PM MST  
([User Info](#))

See what I meant ? Gettin' old really .....  
because, I said to rectify the AC output to feed the rotor. I was still thinking to use the alternator as a generating source. But in true fact, you can rectify the same AC that feeds the alternator to supply the rotor need. Or you can try to have a separate small coil fitted to the rotor, and let this coil generate some current as the generator/motor turns, to feed the rotor. You will also need a couple of diodes here too. This contraption is rightfully called " Self excited circuitry" All of these are totally and entirely possible !!

Put the bus back in the page !  
"Page" or "Cage" ? ..... Couldn't rememebr too well again :-  
Luubovv.

The \$64,000 question: would it run as an induction motor or a synchronous motor? The rotor on an alternator is very different from the rotor of an induction motor. It could work, but probably very, very inefficient.

Theoretically you could make it run like a synchronous motor, but you would have to put in an alternating current to the rotor that's synchronized with the current going into the stator, and chances are the phasing you would need for that current would not be precisely in phase with any of the three phases going into the stator. Maybe if you use a capacitor to shift your rotor current 90 degrees from one of the phases of the stator, the magnetic fields of the stator and rotor would be close but just off enough to give you some torque. Otherwise you might have to do something like installing hall effect sensors to register angular position of the rotor and signal a controller to apply power of the necessary polarity to the rotor. In that case it would be running like a brushless dc motor and you might use dc in the stator... now I'm confusing myself. Ha ha.

But you see the problem. An alternator is just not designed like a backwards motor.

1/3 HP Sump pump Motor, HELP

[Wiring](#)

I need help, this will be my first attempt with an induction motor. Before I get started tearing everything apart (and making more work for myself than I have to) I thought I'd ask some questions.

First, Is it worth it? This pump fell over on the well and was not discovered for a few weeks. It turns freely but will not start, switches and contacts shot, windings seem to be in pretty good shape.

Second, specs: 1/3 HP, 1725 RPM, 115 volts, SFA 6.7( I assume amps), single phase

Observations: 36 segments on stator, 2 sets of windings one smaller wire one bigger wire (startup and run I would imagine) not sure of gauge size. Connections Blue wire one thin one thick winding wire, Red wire one thin winding wire, White wire one thick winding wire, 2 thin winding wires connected together. There seems to be 4 groups of each size wire around stator. Tried to get picture of the way it is wound, hope this helps.

Questions:

How is the best way to proceed (ie does this have to be completely rewound, how many poles, can I make use of both sets on windings (low and high speed) etc.

How much power and at what speed should I expect.

I haven't even considered blade design yet I figured I get these questions out of the way first.

Thanks for any guidance in advance

Wildbill

Wild bill, It is presently a four pole motor, to use more poles than this it would have to be rewound, twelve poles would be an obvious choice. Is it worth it? At low speeds this would yield a very low power unit. Most induction motor conversions start with a much larger motor. I think Jerry uses 3/4 or one horse motors for his garbogens which have only about 4' diameter blades. Make the wind fun! Victor

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi WildBill I have some wind test results from a very similar 6.7 amp, 1725 rpm, 1 ph., 120 volt garbage disposal motor. 10 mph 5 amps, 15 mph 8 amps, 20 mph 12 amps, 25 mph 23 amps, 30 mph 25 amps, 40 mph 40 amps, 45 mph 45 amps. This is using 3 of my plastic blades at 49 inches tip to tip. These same blades have done 1200 watts top end on the 1 hp. If you were using a 1 hp motor the out put above 15 mph would just about double. Your motor has 4 start and 4 run windings. The starts may be aluminum wire. Also it appears the starts have the typical coil sizes. That is 2 of the start coils are small and 2 are large. Reassigning the coil arrangements will yeald proper results for 12 volt charging. Tom W has a scimatic on his web page. My alt have been made with the old Wondermagnet #29 curved neos. They fit the lamination bore perfect. However the amature in this motor is to short for these magnets. I take the armature from a furnace blower motor. All these motors are free at your Heating and air conditioning shop or at your plumber or at motor rewind shop or at your garage door shop. And Harbor Freight has nice new unit 3/4 hp \$60. I'll post more latter I must go to work now but there is much more I'll share with you on this subject. JK TAS Jerry

Re: Help with Induction Motor ([none / 0](#)) ([#3](#))  
by wildbill hickup on Sat Jan 3rd, 2004 at 11:02:48 AM MST  
([User Info](#))

Thanks for the info Jerry. While I was sitting around this morning I decided to check windings. They are both aluminum. Large winding shows open circuit, connecting ohm meter between where small wires connected together and red wire shows open, same connection between small wire splice and blue wire is the only one shorted resistance reads.3 ohms. Correct me if I'm wrong but there should be continuity in all, yes? I guess it spent to much time under water. I might as well unwind, maybe I'll learn something. I have some difficulty picturing how these are wound. I'm still very interested in doing the induction motor conversion I guess I'll just have to find another test subject, this one seems to be shot.

Wildbill

P.S. In one of your postings(I think it was you)I read that it was getting hard to get those curved magnets. Are they still hard to get or was that just a temporary shortage?

Hi WildBill All Electronics has the cuved neo magnets for \$5.50 each. the problem is they woun't garranty N,S, pairs. If you ordered 4 magnets you may end up with any combination like 3 Ns 1 S or all S or all N or who knows what?. For a 4 pole motor you need 2 N and 2 S. It impressive to see just 4 little \$5.50 magnets do 1200 watts. And even more exsitting when powered by 3 \$10 blades. I have very clean 4 pole stators for \$10 each. These range from 5.6 amps to 7.6 amps. The diferance on the garbage disposal motor is an unusual large diameter bore. This is partly why they preform so well compaird to standard motors of the same HP rating. They are also very easy to reconect the coils for bettery operation as a wind genny. JK TAS Jerry

Hi Jerry,

Have you seen these guys?

<http://www.rare-earth-magnets.com/SearchResult.aspx?CategoryID=21&Keywords=Segment&All=True>

They list some arc shaped magnets and have separate part numbers for North and South magnets.

But I'm not sure if they are the right size for the induction motors or not?

Have a look and if they are I might try one of these too!

Ted.

That thing with All Electronics bums me out. To get the mags in pairs you would have to know somebody that lives in L.A. and willing to go to their store to pick the mags. I know it's doable that way because I talked to somebody in L.A. that went to the store and picked out mags by polarity. But really All Elec should just get a clue and put the mags in two big piles. I tried talking to them but they just won't listen.

Hello DR.D :) The bigger 3 meters is a 16 poles pmg and with 2.18/1 gearing i am using it for heating and that in a series resonant circuit with capaciteters it works perfekt.

And i am using a volt and amp meter as a power grid meter 172kwhours so far..But its a tricki to meter the watts, have sen 450 volt and 3.5 amp, max power i think is 700-800 watts ???

put it upp yesterday for testing...

For the small 2 meters i havet got so far with

[Alternators](#)

Something that is a bit vague on all experiment pages :)

Hi,

A few times I see mentioned that there should be another glue like layer on top of the laminates, because otherwise coils can short out the laminates. if 2 coils would do that, it would "ruin the alternator". Now, what is exactly what isn't allowed?

The copper of the coils touching the metal of the laminates?

Or:

Are coils not allowed to touch laminates at all (should there be a airgap between?)

I'm not sure, and I couldn't find it on this forum either. And I prefer to try to do this right the first time, :)

Regards,  
Sponge

by Electric Ed on Sat Jan 3rd, 2004 at 05:55:11 AM MST  
([User Info](#)) <http://www.electric-ed.com>

The sharp edges of the steel laminations could wear through the thin enamel insulation on the copper magnet wire, and short out the coils, so there must be insulation between the two. Motor rewinders use a material they call "fish-paper".

Here is a photo (thanks to zubbly), showing the slots insulated, and ready for the coils, for one of his induction motor conversions.

[http://www.otherpower.com/images/scimages/253/us\\_stator\\_insulated.jpg](http://www.otherpower.com/images/scimages/253/us_stator_insulated.jpg)

Re: Coils "Shorting out laminates" ([none / 0](#)) ([#3](#))  
by zubbly on Sat Jan 3rd, 2004 at 08:48:44 AM MST  
([User Info](#))

hello Sponge.

Magnet wire on its own does have an insulative coating. this coating is intended to only serve as electrical insulation between turns of the coil only. It should never be relied upon to insulate the coils from the laminates.

the material i use is DMD 180 degree celcius(dacron-mylar-dacron) which is intended for this purpose. thickness available ranges from .003-.025 inches. you should be able to obtain some from any electric motor rewind shop or another suitable material. if insulating stator slots, you just cut it to size. if insulating a flat laminate surface, i suggest using a thin coating of 5 minute epoxy on the laminates and applying the insulation in one thickness layer.

hope this helps

Zubbly

## [coil shape and size for pm axial field alternator using donut magnets](#)

By [Oliver](#), Section [Magnets & Magnetism](#)

Posted on Fri Jan 2nd, 2004 at 12:00:11 PM MST

[Alternators](#)

### coil shape and size for pm axial field alternator using donut magnets

Hi all, I'm planning on building an axial field type alternator using donut shaped permanent magnets. The magnets have a diameter of 5.5cm and a hole of 2cm and I am thinking of using 12 of these on the rotor. I know that the poles of these magnets are on the face's of theses magnets, but not sure of the field lines. What would be the best coil shape, size and design? I am only using one rotor, so I am thinking thin and flat - but not sure on the shape and size? Thanks for your help!

[coil shape and size for pm axial field alternator using donut magnets](#) | 7 comments (7 topical, 0 editorial)

Re: coil shape and size ([none / 0](#)) ([#1](#))

by Electric Ed on Fri Jan 2nd, 2004 at 04:44:35 PM MST

([User Info](#)) <http://www.electric-ed.com>

Some of the basic principles are illustrated below.

I believe "straight sided" coils, preferably a trapezoidal shape, so that the coil sides are aligned with the radius of the machine, will give good results.

To maximize the field flux density, I recommend that you use two mild steel rotor discs, even if the second one does not have magnets on it.

## Magnet / Coil Spacing

In order to connect coils in series or parallel, so that the voltages, (or currents in parallel) will add instead of cancelling, the voltages induced in the coils must be "in phase" with each other.

The only way to ensure that the coil voltages are in phase is by accurate magnet / coil spacing.

Magnet center-to-center spacing should equal the coil "span".

The objective is to have the leading edge of a NORTH pole reach one side of the coil - -

- - just as the leading edge of a SOUTH pole reaches the other side of the same coil.

## THINNER IS BETTER - - - -

Three cross-sectional views of

by Oliver on Sat Jan 3rd, 2004 at 03:11:47 AM MST  
([User Info](#))

Hi Electric Ed, Thanks for your reply, very nice diagrams! So should the inner diameter of the coil be the same as the outer diameter of the magnet? I was originally thinking of having the coils the same size of the magnets to get the most flux passing through them. Thanks for your help Oliver

Re: coil shape and size for pm axial field altern (none / 0) (#3)  
by Electric Ed on Sat Jan 3rd, 2004 at 06:05:59 AM MST  
([User Info](#)) <http://www.electric-ed.com>

That depends on the magnet and coil sizes.

Refer again to my diagram. The important part reads - "Magnet center-to-center spacing should equal the coil span"

Does that make sense?

## Magnet / Coil Spacing

In order to connect coils in series or parallel, so that the voltages, (or currents in parallel) will add instead of cancelling, the voltages induced in the coils must be "in phase" with each other.

The only way to ensure that the coil voltages are in phase is by accurate magnet / coil spacing.

Magnet center-to-center spacing should equal the coil "span".

The objective is to have the leading edge of a NORTH pole reach one side of the coil - -

-- just as the leading edge of a SOUTH pole reaches the other side of the same coil.

Re: coil shape and size for pm axial field altern ( [none / 0](#) ) ( #5 )  
by Oliver on Sun Jan 4th, 2004 at 04:48:18 AM MST  
( [User Info](#) )

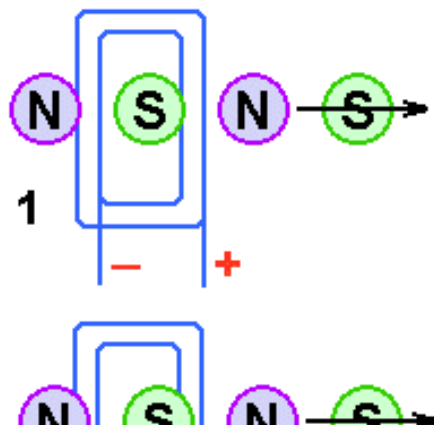

Electric Ed, when is the emf induced in the coils? - when the whole coil is over one pole e.g. N OR when one leg of the coil is over N and when one leg of the coil is over S? Thank you.

[ [Parent](#) ]

Re: coil shape and size for pm axial field altern ( [none / 0](#) ) ( #6 )  
by Electric Ed on Sun Jan 4th, 2004 at 06:50:02 AM MST  
( [User Info](#) ) <http://www.electric-ed.com>

Voltage is induced when one leg of the coil is over a North, and the other leg of the same coil is over a South.

Electric Ed

### Generation of an Alternating Voltage

Views 1 thru 7 represent the positions of the magnet poles as they move in relation to the stationary coils.

[ [Parent](#) ]

Re: coil shape and size for pm axial field altern ([none / 0](#)) (#7)  
by Oliver on Sun Jan 4th, 2004 at 11:34:46 AM MST  
([User Info](#))

Thanks for the clear reply Ed, I may have to re-think my coil design as at the moment it will do the following both legs of the coil will be over the same magnet (n-pole), then one leg over north pole - other leg over air (gap between magnets) one leg over north pole - other leg over south pole one leg over air (gap between magnets) - other leg over south pole both legs of coil over south pole on same magnet I assume this would cause a problem with the sine wave i.e a positive half cycle - a space until coils line up - then a negative half cycle and so on. My coils are already quite big due to the size of the magnets - might have to make the even bigger? Cheers Oliver

Use two magnets, a coil. light up 3-20 Leds without any batteries on your bike.

This bicycle safety flashing light system is based on a newly invented electrical generating system, NO battery needed, No friction on any parts of the bicycle. No drag. Very bright. Get the energy almost free (at least on bicycle). Standby light. Details: [www.freelights.co.uk](http://www.freelights.co.uk)

## [1.5 hp induction conversion](#)

By [zubbly](#), Section [Homebrewed Electricity](#)

Posted on Fri Jan 2nd, 2004 at 10:11:04 AM MST

[Alternators](#)

last one for a while

Hello everybody.  
This shall be my last induction conversion, at least for a while. This genny is made from a 1.5 hp US ELECTRIC, 4 pole, 575 volt, 1.77 amp, totally enclosed fan cooled motor. The test results shall be at the end of the posting. Sorry, but some of the pics are not the best quality.

The first pictures are of the rotor conversion. I used the same method as the previous ones. It does work well. I started with making the fibre glass cage which holds the mags in place and also serves as a mold to later fill with resin. On this one i filled it with fibre glass resin to see how it would turn out. It did work well but my preference is still epoxy resin, as it has much more strength and thermal conductive properties.

I used a piece of ABS drain pipe to make the mold. I first turned the pipe in a lathe to to the inner dimation that i want the cage to be. I then covered it with one layer of waxed paper so that i will be able to get it off the pipe. I built up multiple layers of fibre glass cloth and resin larger than the outside diamater that i want the cage to be. After it had hardened well, i turned it in the lathe to the outside dimation that i want. I then cut to length, marked out the spacing for mags with a skew of one stator slot, and drilled 48 3/4 inch holes with a hole saw. There are 48 neo mags, 3/4 inch wide by 3/8 inch long.

The next pictures are of the stator insulated for the new winding, insertion of the coils, connecting the winding, and of the finished winding ready to be dipped in electric motor varnish and baked.

I had before the permanent winding, wound by hand a complete test winding with only 5 turns of 1 #19 magnet wire to get my preliminary data with which i calculated the permanent winding.

The permanent winding has 12 poles, 3 phase consequent pole, 18 coils, 6 per phase, with 65 turns turns per coil. I used 1#22 and 1#23 magnet wires in parallel which is the same as using 1 #19 1/2 wire. The connection has 12 lead wires which give me the capability to connect either 1 Y, 2 Y, 1 Delta, or 2 Delta. This gives me a very broad range to connect for various driven speeds and voltage outputs.

**TEST VALUES: OPEN VOLTAGES AT VARIOUS CONNECTIONS AND SPEEDS. AC volts.**

All testing done in a lathe.

1. Y: @70 rpm-22.5 volt, @115 rpm-41.0 volt, @190 rpm-67.0 volt, @300 rpm-105.2 volt
2. Y: @70 rpm-10.1 volt, @115rpm-19.7 volt, @190 rpm-33.2 volt, @300 rpm-52.4 volt
1. D: @70 rpm-11.0 volt, @115 rpm-22.5 volt, @190rpm-37.5 volt, @300 rpm-59.1 volt
2. D: @70 rpm-3.0 volt, @115rpm-10.3 volt, @190rpm-18.4 volt, @300 rpm-29.3 volt

**TEST VALUES UNDER LOAD:**

The loaded tests were carried out using a lathe at various speeds, a 12 volt truck battery, 2 bridge rectifiers to make DC voltage, and amperage was based using a 1 foot length

of #10 lead wire in the positive output lead with millivolt readings taken at the 1 foot spacing. Each millivolt represents 1 amp. The voltage at the battery terminals was also taken at each test to determine the wattage output. Wattage output was determined by multiplying millivolts times the battery voltage. The values for each speed and connection will be given in wattage output, millivolts representing amperage, and battery voltage.

1. Y: @70 rpm-29-2.1-13.6, @115rpm-63-4.6-13.8, @190 rpm-132-8.2-16.15, @300 rpm-204-13-15.7
2. Y: @70 rpm-12-.9-13.01, @115 rpm-77-5.1-15, @190rpm-210-12.7-16.5, @300rpm-377-22.3-16.9
1. D: @70 rpm-17-1.3-13.44, @115rpm-85-5.8-14.7, @190rpm-203-12.5-16.25, @300rpm-351-21.4-16.4
2. D: @190 rpm-186-12-15.5, @300 rpm-492.6-29.5-16.7

The best output was achieved at 300 rpm, 2-DELTA, and 492.6 watts. I had hoped to get more output from this genny. Perhaps if i had used longer magnets I would have achieved more wattage. The benefit i have gained though is getting some watts at very low rpm's. In the long run, perhaps it will make up for the lack of output.

#### CONCLUSION:

I think induction motors are still a very good source for making gennys. I have gained many new friends on the IRC HOMEPOWER chat line, and after many discussions have come to the opinion that rewinds are not in the capability of everyone wanting to do it. This leaves me with the option of putting forth a little effort in instructing those interested on how to re-connect the existing winding for multiple Y-D connections. I think this would give many more possible outputs over a varied speed range. This I think is very possible using a numbering system which can be applied to most 3 phase motors. A littl feed back from those who would be interested in this would be most helpful.

I hope these efforts have been of interest and useful to you.

[1.5 hp induction conversion](#) | 3 comments (3 topical, 0 editorial)

Re: 1.5 hp induction conversion ([none / 0](#)) ([#1](#))  
by zubbly on Fri Jan 2nd, 2004 at 03:50:15 PM MST  
([User Info](#))

Hello again.

There is one important piece of information that I forgot to include with the posting concerning the multiple connections.

The winding was wound with 1#19 1/2 magnet wire. As you change connections, so does the number of magnet wire conductors to make up the connection. As you increase the number of circuits, the amount of copper handling the amperage also increases. Also, this makes it more versatile to match your battery voltage system. This is the added value of using multiple connections.

For this particular winding, here is how the magnet wire adds up.

1. Y-1 #19 1/2
2. Y-1 #16 1/2

1. D-1 #16 1/2
2. D-1 #13 1/2

Hope this makes it easier to understand my use of multiple connections.

Zubbly

## [Energy from sound?](#)

By [stop4stuff](#), Section [Homebrewed Electricity](#)

Posted on Fri Jan 2nd, 2004 at 05:52:37 AM MST

[Alternators](#)

a solution to urban green energy?

Happy New Year everyone.

My primary interest in whats happening on Fieldlines is to have a better understanding of motors,coils,generators,magnets and how they all work...  
...my goal is to build a micro 5-way electronic compressed air actuator that I can use in conjunction Lego Mindstorms and Lego Pneumatics to control air powered devices on my Lego robot J5 (see. <http://www.stop4stuff.com/lego/technic/mindstorms/new-j5/> for a build diary.)

Whilst browsing threads and absorbing input...  
No-one seems to be discussing the extraction of electrical energy from sound.  
...a microphone generates electricity.

Also I have read and understood the reasoning why linear alternators are inefficient...  
...isn't a microphone a linear alternator?

speculation over with... try this...

1. obtain a car stereo speaker, the bigger the better.
2. attach an LED across the speaker terminals.
3. gently, but quickly tap the speaker cone

you should see the LED flash intermitantly (if it doesn't, swap the LED connections over)

Tapping on a steel coffee tin placed open end over the speaker also makes the LED light up.

I haven't a clue what voltages or currents are involved... but the LED lights up.

Sound can be focused, in the same manner as sunlight, onto the collector by means of reflectors... like the old fashioned 'ear trumpets' often seen in old black & white slapstick comedies (Charlie Chaplin, Laurel & Hardy, etc).  
Nature can produce devices that mix sounds to a level of white noise... listen to a sea shell!

- [Also by stop4stuff](#)

the 'ear trumpet' is a spun shape, a large inverted cone with a smaller inner inverted cone.

I understand a little about electronics, however I think that there would be a whole load of different frequency sounds (and ac voltage frequencies generated)...

...could the sound coming in be split by physical filters to separate different frequency sound before it got to the collectors (microphones), or be used to create powerful harmonic frequencies?

...could the different frequency voltages be collected separately and then converted to an average frequency before final smoothing out and frequency reduction?

Why could electricity generated from sound be useful?

...wind generators are good for sparsely populated areas... more space to put them up.

...the noisiest places are often places where it would be impossible to put up a wind generator.

and no I've not forgotten about solar power...

could the underside of a motorway (freeway) bridge be covered with solar panels?

Generating electricity from sound could be an addition to other green energy solutions, who know's maybe one day we'll have fence panels that provide power to white LED street lighting.

About transformers and sound...

a transformer hums...

it makes a noise...

Can it be vibration that makes a transformer hum?

...a transformer has no moving parts to create the inertia to make it vibrate!

...so why does a transformer put out noise energy?

The trick with a sheet of aluminium and a neo magnet is cool... even near vertical the magnet creeps down the ali sheet.

sorry to go on.... first timer poster... fresh with enthusiam :)

p.s. love the hamster powered alternator on theotherpower.com... we tried something similar with Angel (my daughter's Syrian hamster) in a ball running on a Lego setup... friction vs hamster... friction won

[Energy from sound?](#) | 10 comments (10 topical, 0 editorial)

Re: Energy from sound? ([none / 0](#)) ([#1](#))

by Rich G on Fri Jan 2nd, 2004 at 07:23:50 AM MST

[\(User Info\)](#)

The ear is a very sensitive and broad range detector. I believe that the energy of the least sound detectable by the human ear is something like 10 to the minus 12th watts/meter squared. For those who are not comfortable with scientific notation that is .00000000001 watts spread over a one square meter area (if I got the zeros correct). That is, I think the reference level for sound Db comparison. At 100 Db hearing damage is a threat. This level of sound energy is still less than 1 watt/meter squared. You are absolutely right, of course, that sound can be converted to electrical energy. As you observed, microphones do just that. I suspect that the reason that ambient sound is not tapped as an energy source is the low energy density. I may have this all wrong. These days, I am not an expert in anything -- just check with my wife! The world is a fun place to explore! Rich

Re: Energy from sound? ([none / 0](#)) (#4)  
by stop4stuff on Fri Jan 2nd, 2004 at 09:01:41 AM MST  
([User Info](#)) <http://www.stop4stuff.com>

hey Rich,  
thanks for the input...  
my father (a V E R Y serious person) once tried explaining Db's...  
something like...  
for every 1Db increase the noise level increases by a factor of 10  
i also remember somewhere people melt at around 220 Db  
I hear what ur saying about the low energy density of sound...  
These days, appliances are smaller and use less energy.  
I once owned a Radiogramme... a beautiful piece of 1950's furniture  
that had a record deck and a LW/MW/SW radio built into it, 240v (UK)  
mains only and soaked up loads of juice.  
Now i have a mobile phone that can store+play 60+ mins of MP3 music  
and recieve FM radio... the phone does the same job on much less  
power (and can be hooked up to an amp in car or home.) + i can talk to  
ppl too!  
places like under motorway bridges get very loud, as well as airports...  
sound may be low density energy... tap it and it's free energy for low  
powered devices :)

Re: Energy from sound? ([none / 0](#)) (#2)  
by wooferhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Fri Jan 2nd, 2004 at  
08:03:35 AM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

Sound does not contain very much power. In order to get power from a speaker you must move it mechanically like you were doing when you were tapping the speaker cone. I never hooked an LED up to a speaker, but I find it hard to believe an LED would light just from sound. Even if you could light the LED with sound, That is not very much power and you will want to run it through a Bridge Rectifier in so you can store the power in a battery. the bridge rectifier will pull the power down by 1.2 volts and you won't have anything left coming out.

I messed around with trying to get power from a speaker

<http://www.fieldlines.com/story/2003/10/11/204029/79>

But I could never figure out how to get enough 1/2 inch motion to generate anything usable.

Re: Energy from sound? ([none / 0](#)) (#3)  
by Harry Luubovv on Fri Jan 2nd, 2004 at 08:50:13 AM MST  
([User Info](#))

Well now of course as you all know, that the day will come one day, that we could use sound as energy source. Just look back not very long ago, scientists got themselves killed trying to fly in the machines they built. Others laughed. Now everyone takes flying for a normal thing, noone says if it wis possible or not possible. Time is a funny thing ! Mankinds will advance in technologies until the world explodes oneday ! !

Happy New Year.

Luubovv.

by stop4stuff on Fri Jan 2nd, 2004 at 09:19:06 AM MST  
([User Info](#)) <http://www.stop4stuff.com>

i checked out ur item...  
i didn't find it b4  
I then shouthed AARRGH into my speaker (bought the wife running and got a sore throat)... the LED gave no response.  
I then tapped the speaker some and found ur right... it takes about 1/2 movement to light up the LED...  
The coffe can didn't work 2nd time round :(  
isn't learning fun!

[ [Parent](#) ]

About transformers and sound ([none / 0](#)) (#5)  
by Norm on Fri Jan 2nd, 2004 at 09:10:52 AM MST  
([User Info](#))

A transformer has moving parts....same as a guitar string, if something is humming its vibrating and if its vibrating ....whatever is vibrating is a moving part. Norm.

Re: About transformers and sound ([none / 0](#)) (#7)  
by stop4stuff on Fri Jan 2nd, 2004 at 09:37:46 AM MST  
([User Info](#)) <http://www.stop4stuff.com>

thanks Norm, good input!  
does that mean a transformer could be made much more efficient by stopping bits from moving and not lose energy through vibration?  
does a transformer vibrate as a complete unit or are there internal parts that disipate energy by banging against each other?  
so many questions have i...  
need more good input...

[ [Parent](#) ]

Re: About transformers and sound ([none / 0](#)) ([#8](#))  
by Electric Ed on Fri Jan 2nd, 2004 at 10:01:40 AM MST  
([User Info](#)) <http://www.electric-ed.com>

The sound is created by the core laminations vibrating. Transformers are given "sound ratings" by the manufacturers, and quieter models cost more. The laminations have to be clamped together more securely.

Electric Ed

[ [Parent](#) ]

Re: Energy from sound? ([none / 0](#)) ([#9](#))  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Fri Jan 2nd, 2004 at 12:40:19 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

Transformers buzz because the magnetic fields interact with the windings and the magnetic relationships between the wires that are next to each other in the winding. So the wires may all be attracting each other at one instant and then all repelling each other at another instant. And of course all of those magnetic forces are interacting with the iron core.

} = - W o o f - = {

Re: Energy from sound? ([none / 0](#)) ([#10](#))  
by E man on Fri Jan 2nd, 2004 at 11:17:57 PM MST  
([User Info](#))

Speaking of sound, check out this cool article:

<http://www.memagazine.org/backissues/march98/features/sound/sound.html>

MacroSonix Corp. (Tim Lucas) has built these oddly shaped vessels to concentrate sound energy to be used as compressors, particle seperators, and combustion [generator] devices. The devices don't "receive" energy from the ambient noise around us; instead, they are driven with a solenoid at about 400 - 500 cycles per second, and although they are only displaced about 100 microns the gas inside is accelerated to generate resonant sound waves that build into enormously powerful compression waves. The resulting compression waves can then be valved for various uses. These guys also ganged up with Los Alamos National Labs to do interesting work with Acoustic Stirlings, apparently lending a hand with a resonance chamber that could be used for liquifying gases particularly natural gas that would normally be tossed while drilling for oil.

Happy New Year Everyone!

I love this website just as much as the day I found it.

-Elliott Bell

[Rant](#)

Would you like to own one?

Chevy has a group of new models out this year, me being a chevy fan most of my life, and gave 30 years of my life in experimental as well as a service tech... I saw an ad on USA for their new models... Talk about disappointed !! But for all us gas mileage misers... guess what ??? GM is building a new model that gets super gas mileage! It has a 3cyl 800cc engine and tops out at around 120 mph. 60 mpg on the highway! Oh... I should mention... You CAN'T buy them in the US.

Have you ever tried to find out about different auto models of other countries? It's like some kind of military secret...

Anyway do a search for Chevrolet Spark.

No more S-10's the Colorado is replacing it, just another gas guzzler... Anything to keep us below 30mpg... I guess my Chevy days are over...

My Rant for the week  
Windstuff Ed

Yup!

It's true - they often hold back the best for other markets. Check this one out - it's from where I used to work. I had this thing doing 155 mph at least once a week, not really even breathing hard.

V8, rear wheel drive, all independant suspension - puts a lot of high performance offshore stuff to shame.

[http://www.gmarabia.com/content\\_data/LAAM/SA/en/GBPSA/chevrolet/models/lumina/lumina\\_coupe.htm](http://www.gmarabia.com/content_data/LAAM/SA/en/GBPSA/chevrolet/models/lumina/lumina_coupe.htm)

Oh well one can always hope!

Ted.

Yeah, 60mpg would be nice, but I certainly wouldn't be caught dead driving anything that looks like this.  
;) Why not just get an old honda and strap in a Briggs V twin? :)

60 mpg don't look so good when a blonde in a red Pontiac Firebird passes 2 other cars in a no passing zone, hits your corner bumper, as you're making a left turn (turn signals on and clearly visible)....spins you, your wife and the '70 olds that you are driving 180 degrees. (slew'd the back bumper over about 2 inches hardly a scratch on the chrome (good chrome back then) demolished the whole front end of her car) it was determined by the skid marks that she was doing about 70 in a 35 mph no passing zone (but thank goodness she was wearing her seat belt (her words)) She had been in an accident a month prior and had just got it back from the shop...worried about her insurance premiums...cops came she wasn't cited.

The Olds only got about 18mpg and gas cost about 75 cents a gallon back then. ....but we're still here. I don't know if we had been driving a 60mpg car like the above??? I think the better gas milage you get the more the gas is going to cost...they have to get x amount of dollars from us.....Norm.

Yeah, I had an accident recently and if I had been in a car like that I'd probably still be in the hospital, or dead. I completely smashed the front end of my jeep, but I wasn't hurt, just a little sore.

Re: 60 mpg Chevrolet ([none / 0](#)) (#10)  
by RobD on Sat Jan 3rd, 2004 at 06:01:18 AM MST  
([User Info](#))

It's not necessarily size that protects the driver. The Germans came up with crumple zones for a reason. They found that what damages the human body is G forces and the more you can reduce those forces by gradual body collapsing the better the individual's chances of survival are. Larger vehicles are no safer than small vehicles built safely. Small cars have better maneuverability and can avoid accidents better and the distance you travel upon impact in the cab of larger cars is greater also. This combined with the forward inertia of heavier vehicles ( $F=ma$ ) and their tendency to flip over from the higher center of gravity make them less safe in many accident conditions. Take a look at the safest cars and also look at the formula one racers that drivers walk away from after high speed accidents. The damage to the vehicle doesn't necessarily equate to the damage to the driver. The safest thing you can do is drive slower regardless of the car you are driving. Speed equals higher impact. RobD

Great point RobD, I thought I was the only one who thought this way. I don't believe we need 300 hp hauling a 5000 lb auto to go to the store. Manufacture's seem to dictate what they want us to buy and drive. I can remember when most cars and trucks were quite distinctive, Now they all pretty much look the same. Nissan seems to be quite daring with the inovative body styles the've come out with.. cool but costly.

I guess, to get what I really want, I'll have to build it myself....

Ed

## [Fun with trees and chains](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Sat Jun 7th, 2003 at 10:06:35 AM MST

[Wind](#)

Was getting bored and worried about my 35' tower...

---

I spent yesterday "upgrading" my old pivoting tree tower which used to be about 35' tall (barely enough to get the prop above most of the trees around here). In the last windstorm we saw 55 mph gusts and it obviously needed some work. So.... I ran up and got Ward to give me hand with it (we kind of have an agreement, that we always help each other with windmill projects).

My old tower (which is still part of my new one) pivots in the stump of a tree. It consisted of one lodgepole pine with a gin pole and I'd pull it up with the truck.

I looked for a taller tree near the road with no luck, so decided to go for the "modular" design...

Pictured above is my new tower arrangement, you can see how 3 trees are strapped together to make things stronger and taller. At the very top you can see a "T" made of pipe. This is a sort of "foot" so that when the tower comes down it comes to rest upon that so that the wind turbine never touches the ground. In the past I'd land my tower on a barrel... which worked so long as it came down in the right spot!

The trees are strapped together with short bits of chain. I wrapped the chain around the trees as tightly as I could by hand, and left about 4" between the ends which I took up as much as I could with 3/8" dia allthread. This really squeezed the gaps out between the trees and made things very tight! Once the chains were tight we pounded nails in the links and bent them over - so that should things ever get loose the chains (and hopefully the trees) would stay put. I should add, that this whole design amused my very skeptical neighbors greatly and seemed very much against the odds... it's a case of making due with what you've got (or being a cheap skate??) ... I've got about \$100 into this, and the whole cost is in guy wire and cable clamps.

Above you can see the gin pole setup (which is also of "modular" design so more trees can be added as necessary). The gin pole is attached very near the top of the tower with a very heavy (1/2" diameter roughly) cable, so that when raising and lowering all the force is pretty much on the cable and straight down on the poles into the pivot.

Here you can see the gin pole hooked to my truck, this is how I raise and lower it. This works well enough that I can easily hold the wind turbine 6 inches off the ground with the truck and lower it very gently. It's interesting to note... lots of folks will say that you must have level ground for a tilt up tower so that the side guy wires stay tight on the way down. I'm not even close to level here, one of the side guys is about 10' higher than the other. What happens, is that one set of guy wires stays tight on the way up and down - the other gets more and more slack as it gets closer to the ground. So when going down, the tower is held tight by only one set of wires, and it leans a good bit to the side. It looks funny - but it works fine.

Is it strong???... don't really know yet as I've not seen high winds on it yet. It is guyed at two places (8

guy wires total) and seems much more rigid going up and down than it used to. Furthermore... we did have one good test yesterday. Before putting the turbine on top, we raised it once to test it and everything looked good. Then I went to lower it. I unhooked the back guy wires and had the truck hooked to the gin pole - with just enough slack so that we could get it slightly tipped by pulling on the far guy wires (opposite the truck). It tipped nicely... but never stopped like it was supposed to! It crashed to the ground, pulling my truck into a tree and smashing out the pass. side headlight and slightly denting the front. Some quick forensic investigation of the disaster turned up the fact that I'd left my truck in neutral. Amazingly though... the tower took absolutely 0 damage, and we simply put the windmill on and raised her back up with no problems. This really looks rigid, compared both to my old tower, and Wards steel pipe tower. Nothing bends much - no creaks, no cracks...

When working on this sort of thing, we try to be careful and act as though everything could fall at any time. This policy pays off.. especially with a space cadet like myself! At least the dent in my truck has a fun story behind it...

Too much fun!

As usual I'm working with the front volvo wheel bearing and hub. This time I've got 2 disks, 14" diameter cut from 3/8" steel. I had these plasma cut by a shop in town, they cost \$20 ea.

I cut out the center hole 3" diameter with a hole saw. A good hole saw has no problem cutting through 2 disks at once so long as it runs slow enough and has enough oil on it. The holes for the studs are 1/2".

Pictured above the two disks are done, and they fit the hub pretty nicely.

The magnets for this machine are pretty large. 16 of them fit together to form a ring with 8" inner diameter and 14" outer diameter. They are wedge shaped. In this machine I'm using 12 per rotor so there is a bit of space between them (about 3/4"). I worked out what seems a reasonable coil shape/size and made the coil winder which is shown above.

I layed out where the magnets go and used a center punch to mark their locations. Placing them went pretty quickly. As each magnet went into it's place I used super glue to tack them there so they'd not be sliding around on me as I placed more.

I cast the magnets in resin as shown above, and mounted the back rotor to the wheel hub.

I drilled and tapped 3 holes in the front rotor so I could have 3 jacking screws to make lowering and raising this hopefully a safe and smooth operation. So far it seems to work nicely - takes a bit of time, but it goes very easily!

I got most of the metal work done on the main chassis here. It's about the same as the last ones... hope it's strong enough!

Another shot of the same thing...

The tail boom is 7' long right now. My goal here is a 14' prop, although once I start testing coils I may find that slightly smaller is more appropriate. My biggest concern right now are the forces on the tail pivot. It pivots on 1" shaft (instead of pipe like the last ones) and seems quite strong, but after seeing some bending/stress on my current 9' dia machine I'm wondering a bit. This will be a 12 volt machine, so I'll probably (hopefully!) be dealing with a lot of current. Well see what happens... it'll be fun no matter what!

Great job. I'm building one wind system myself and I'd like to know, when you finish this Generator, how much power is it outputing.  
Continue the magnifig work.  
Miguel

Hi DanB,

Nice One!

What are the details on those wedge-shaped magnets you're using on this one? Also I've been looking for some definitive info about how much temperature fiberglass resin will take in the stator before bad things start to happen.

I was able to find some info on the web about epoxy resin - there's instructions on the West systems site about how to remove epoxy/cloth - you can heat it to 200 F and it will start to soften. But I haven't been able to find anything about plain old polyester resin, the type I've been using in stator casting.

I've seen several mentions of adding talc to the mix, and one site that said this helps increase the resin's capabilities to withstand temperature. Have you had any experience with stator problems due to heat?

What wire guage will you be using in this stator - or have you decided yet?

Very interesting project, I think there might be a lot of mileage in the increased diameter units!

Ted.

Re: new wind turbine ([none / 0](#)) (#3)  
by DanB on Thu Dec 4th, 2003 at 07:49:16 AM MST  
([User Info](#))

Hi Ted -

like I said, the magnets are such that 16 will form a "ring" 8" ID and 14" OD, and they are 1/2" thick. It's interesting to note, that even the 3/8" steel is not quite thick enough... they are slightly magnetic on the back side. I've got 120 of these - they were (unfortunately) rather expensive.

REgarding the resin and heat - I think about this sometimes. Fortunately making a new stator is not too difficult!

But I believe it really boils down to keeping things within reason with the coils. I can wind it for whatever cutin speed I want, but the resistance must also be low enough so that too much heat is not generated while it's handling the power from whatever size prop I put on it. If resistance is too high, that'd mean I probably wound it for too low a cutin speed, put too big a prop on it - and at higher power outputs I'd expect it might melt! So it'll take me a bit of trial and error poking coils in there while the rotor is on the lathe to figure out what's appropriate. (I hope!!) Another issue of heat is obviously the furling system - to have it turn away from the wind in time. There is a lot of talk about stator cooling etc... Im really not sure if it's an issue or not yet to be honest. I've not seen any problems with it yet on past machines. My guess is folks have problems with it when resistance is too high. Im sure you could push the limits a bit more by cutting holes in the stator or some means to improve cooling, but my guess is that the "limits" are already well within reason so long as the coils are wound well, and the machine furls at the right time.

Time will tell...

Nice machine Dan! Just tossing some numbers around and the size of the magnet sections I believe a 7kw machine could easily be built with them. ( single rotor with silicon laminants ).

Using 12 of them as you have I calculate 2kw at 300 rpm and 4kw at 500 rpm. My numbers were using 36 slots and 8 turns of #12 wire per coil. If it went beyond 2kw for extended periods of time it may require some cooling but its all do-able. I take it your looking for 2kw+ from it?

Looks like fun to me!!!!

Ed

([User Info](#))

interesting numbers Ed... Im really not quite sure what to expect from the dual rotor, and I suspect Ill have less than perfect coil design. If it works out to be 14', and I think thats what Ill shoot for, then I suspect top speed will hopefully not be more than about 350 rpm.

I've messed with it a bit this morning trying to figure how to wind the stator up. It's fun after building a few one starts being able to make a "good guess" - and my good guess seems to be very nearly confirmed by actually testing a coil in it this morning on the lathe. I think what will fit (barely) and get a good cutin speed around 75 rpm is 32 windings made up of 3 strands of AWG 14 wire. (I think thats close to AWG 9 wire). And there'll be 3 coils/phase (total of 9 coils) and it'll be wired in star. Since AWG 9 wire would be pretty difficult to wind, I'll make it up from 3 strands of 14.

Should be fun, well see how today goes. If I'm ambitious perhaps I'll have the stator done by days end. Lots of fun ahead!

Hi DanB,

At the risk of sounding heretical - why not try a setup that produces some higher voltage AC for this unit? Like around 120...

If you were using a 3 phase stator, wound with 14 AWG, it should be able to handle 17 amps without excessive heating.  $17 \times 120 = 2,040$  watts  $\times$  3 phases = 6,120 watts.

Then transform, rectify, heat, or otherwise use the power at the source of the load. You could probably use a run or two of inexpensive 12 / 3 to convey the power from the pole to the load.

Just a thought!

ps. when I asked about details for those magnets - I was mainly interested in how much \$\$ and if you'd be putting them on wondermagnet.com for sale!

On cutting disks - I had the pair made for the alternator I built at a local machine shop, though by abrasive water cutting not plasma. The water cutting machine is pretty cool - it uses garnet (like on sand paper) fed into a high pressure water jet. The whole thing is run by computer so I had 4 pie-shaped holes cut into the 17" disks to lighten it somewhat, and the center hole and bolt holes done at the same time. It didn't cost any extra either.

I'm finishing up a set of foam-core epoxy / fiberglass blades also in 14' diameter right now. The cores are cut with a hot wire, then covered with epoxy and fiberglass cloth, then vacuum bagged. Sounds like a lot of trouble, but the whole process is actually quite easy and makes a very light and strong blade. Mine will have a 24" diameter "hole" in the middle to clear the alternator assembly. So the blades themselves are 6' long, and start 12" out from the center of the hub. This really is a lot of fun - good luck with this project and looking forward to your next posts!

Ted.

Hi Ted -

you asked... "At the risk of sounding heretical - why not try a setup that produces some higher voltage AC for this unit? Like around 120..."

If you were using a 3 phase stator, wound with 14 AWG, it should be able to handle 17 amps without excessive heating.  $17 \times 120 = 2,040$  watts x 3 phases = 6,120 watts.

Then transform, rectify, heat, or otherwise use the power at the source of the load. You could probably use a run or two of inexpensive 12 / 3 to convey the power from the pole to the load."

- I could, and it would make some sense for sure. Like everything I think doing that would have its pros and cons. The transformers would be expensive and have their own losses. I think most of my power is in the low winds, so probably 90% of that which comes in will be under 500 watts - here, 12 volts is reasonable. And, my tower is pretty close - only 100' from the house. But yes - should I ever build a large machine that is a greater distance away, I think seriously about playing with transformers. could be that I should be doing that now... hard to say.

You asked about the magnets - Ill list what I have (not many of them) on our shopping cart soon for \$20 ea. These are kinda expensive - special shapes cost more than normal disks or blocks, and I only got 120 of them so they are costly.,

DanB,

Why didn't you ask the plasma shop to cut the 3" hole and the 5 1/2" holes for you ? A friend of mine owns a sheet metal laser cut shop and it's seem to me that it doesn't take much more time or effort for them to cut additional holes. The most time consuming part is to set the sheet or plate on the X Y table. Its only a little more of info to put in the program, since its all computer driven. Maybe they are not using the same technology. Just wondering...

Keep the good work.

Barnac from the cold Montreal today. Winter is really knocking on the door. Go habs habs go :-)

hello DanB.

only one thing to say, Beautiful job. i hope it works great.  
i have one question and just one concern.

are those neo magnets? i just didn't see where or if it said.

my concern is those huge magnets. the size so large and the ATTRACTION to each other on opposite plate so powerful, i am wondering if the resin is sufficient in strength to keep them in place once the alternator peaks out on its temperature rise.

every genny is a step closer to a greener world-----zubbly

Re: new wind turbine ([none / 0](#)) ([#12](#))  
by DanB on Fri Dec 5th, 2003 at 04:29:02 PM MST  
([User Info](#))

Hi Zubbly -

the magnets are Neo's. I don't share your concerns here (perhaps I should!) for a couple reasons. first - they are neos and they are stuck down very tightly all by themselves! The resin surely helps. secondly - being a larger machine, it hopefully will run pretty slowly, 400 rpm would hopefully be very top speed, - hopefully a bit less actually. Lastly - the magnets, and the magnet rotors don't heat up much I shouldn't think. All the heat is in the stator and the magnet rotors are isolated from the stator by a layer of moving air, so I doubt they get very warm at all. Fun stuff.. time will tell.

by JW on Fri Dec 5th, 2003 at 09:24:40 AM MST  
([User Info](#))

Looking at windstuffnow's post and falls over in chair. Personally I would not doubt these numbers could be possible. Thinking about some of Electric Ed's post's, noticing the spacing of the magnets (with 12) on the rotors. Reminds me of this day along time ago, sitting in class, with a collage professor telling us "there is no way to improve the efficiency of an automotive alternator" then he went on with some mumbo jumbo about the superior waveform that the stator produces blb bla bla. then theres the non-clogging aspect of these dual rotor machines.

Considering DanB is using a star wiring pattern, AC could be the intended output. Great Job DanB, your work is very impressive...

-JW

should start charging between 6 and 7 mph I think with if it runs at a TSR of around 6. The lathe is great for this sort of thing, it makes it very easy to hold a single coil in exactly the right space and gives me a range of rpm to play with. I welded 4 nuts to the back of the back rotor so that I could get this thing in the 4 jaw chuck on my lathe... the rotors are 14" diameter, my lathe has a 14" swing.

I figured from my tests that, if it's wired in Star, which I was planning, that 32 windings per coil would be just right. As it turned out, 31 windings of 3 strand of AWG 14 wire worked out perfectly, so I went with that... close enough. Pictured above I've layed out the areas where the coils must fit on plywood. This will later become the bottom of the mould.

Above you can see the coil winder in the front, and in the back there is a stack of 3 spools of magnet wire from which I wound the coils. Doing it this way is much easier than trying to wind with really heavy gage wire. I also suspect that with very heavy wire, in a dual rotor machine like this - we might actually get eddy current losses within the thick copper wire. This should help. The other option would be to just wind my coils with 93 windings of 14 gage, and rather than wire my coils in series - I could've wired them in parallel. But - past experience has shown that wiring coils in parallel creates losses, because certain windings are slightly out of phase with others and this allows current to flow between the coils when they are wired in parallel. So I believe series is the best way to go - and at low voltage, the current becomes so much that I have to either use very heavy wire, or a bundle of finer wire. I've opted for the bundle...

## [Alternator finished](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Mon Dec 8th, 2003 at 08:20:54 AM MST

[Wind](#)

I got my alternator tested and almost finished

As per my [last posting](#) I'm trying to build a larger 14' diameter wind turbine.

Again, the steel rotors for the alternator are 14" diameter, and the magnets are such that 16 of them form a ring 14" outer diameter and 8" inner diameter, so the magnets are 3" tall, and about 2.5" wide at the top. I'm using 12 of them, so there is about a 3/4" gap between the magnets.

I wound up one coil with 120 windings of AWG 14 wire - I knew this wouldn't be right, but I figured that by poking this one coil between the magnet rotors on my lathe I could get a pretty good idea exactly how many windings I needed per coil to get an appropriate cutin speed, and once I knew that I could figure the thickest possible wire that could be used to fit that many windings in the limited space available. I figure for a 14' prop, it should start charging (cutin) at around 75 rpm if I'm running with a reasonably slow tip speed ratio. This

In this picture all 9 coils are wound and the mould is ready (in the background). I'm out of nice large pieces of fiberglass mat, so I've cut lots of little squares and strips to work with. This worked out fine.

Above is the stator. It actually came out OK, but not great. Kind of lumpy on the back side and a bit thicker than I'd hoped. The stator is about 5/8" thick. I was concerned that this extra thickness would compromise my airgap and raise the cutin speed above that which I'd hoped for... meaning I'd either have to make a new stator, or use a smaller prop. (or run with a 14' prop and a high TSR which is an option I would probably not feel comfortable with... too fast.)

Yesterday I got the whole thing together. My total airgap at this time is around 7/8", but cutin speed is right at 75 rpm... just about perfect I think! It was interesting assembling it. When I had only the back rotor on with the stator, it cogged pretty badly against the 3 bolts that hold the stator. This is typical - and usually goes away almost completely when the 2nd rotor is placed on. Of greater concern however was that not only did it cog - but it had a lot of drag on it! I was fairly certain at that point that there must've been currents flowing between the parallel strands of wire in each coil, in which case I'd have had to start over - probably build a higher voltage machine and use transformers or something. As it turned out, after the top rotor was placed on - all this drag, and all the cogging disappeared. So I figure the drag must've been due to eddy currents in the bolts that hold the stator. Kind of impressive at any rate, because the drag was very significant, I'd not have thought that 3 bolts could've been responsible for so much - but they must've been, because it's fine now. Lots of fun - tomorrow I'll hopefully find some nice boards in town to start carving on!

Looks very nice Dan! What was the ohm reading on your coils when completed? To bad the gap came out larger than you wanted, thats going to eat up some power but should still kick out some good power.

I'm designing an alternator to work with a slow turning VAWT. The idea is to have the unit start charging at low rpm's ( around 30 to 45) but produce full power with very small rpm changes. ( full output by 100 rpm's or so) It's been quite challenging and I'm still a bit off for the final product. I'll be using similar magnets ( my smaller segments - which are only 2" tall x 1.57 top ). I may steal your idea using strands of smaller guage wire as opposed to one heavy strand. This may help reduce copper losses by reducing the eddy currents and I believe, not sure yet, I may be able to get more copper in the magnetic path this way. Interesting idea anyway...

Keep us posted on your output data when its together!!!

Have Fun  
Ed

Re: Alternator finished ([none / 0](#)) ([#2](#))  
by DanB on Mon Dec 8th, 2003 at 10:59:12 AM MST  
([User Info](#))

Hi Ed - when I hook the meter to it it says .1 ohms (and beeps at me). So it must be somewhere between .1 and .2 ohms/ phase.

The airgap is kind of a bummer, but on the bright side, the cutin speed came out exactly where I wanted it and the stator is a bit stronger/less flexible - which is good I think because it's large enough - and the coils all pretty much touch each other, that weakness in the stator was a concern. It came out this way because I used a bit more fiberglass than normal on both sides, and I heated the resin up a bit much before I started (and mixed it a bit too hot) so that by the time I was putting the top on my mould it was already setting up. (I should've been more patient!).

Perhaps next time I'll have the resin go a bit more slowly and then perhaps I could get away with slightly thicker wire and a few less windings (maybe 4 strands of AWG 15 wire) so that resistance is a bit lower.

I wonder if, in your case there would be any advantage to using multiple strands (other than that they are a bit easier to handle). Would eddy currents in the copper be an issue with you, since you'd be burying the windings inside slotted steel laminations? It seems the laminates might take care of the eddy current losses in your case.

Hi Dan,

Just playing with numbers and what you've given in data. I've calculated between 1100 and 1400 watts in a 25mph wind not including any losses... let me know how close I came...

After calculating out the differences in wire sections it actually takes up more space using smaller wire to make up a larger equivalent. I thought it might come out a little more efficient since the air gaps between wires would be more filled in... Fun figuring it out though... back to the bar stock...

Have fun  
Ed

"After calculating out the differences in wire sections it actually takes up more space using smaller wire to make up a larger equivalent."

Hi Ed.. I have to say, Ive not calculated this - but if we ignore the thickness of the insulation, that doesnt make sense to me... it should be the same shouldn't it? Except that - really large thick wire is harder to wind tightly, so I actually tend to think the opposite, It seems I can squeeze in a bit more copper this way, but I could be wrong.

Hi DanB  
I asked this ? a while back. I thought i could get more copper in a coil of the same physical size if i used smaller gauge wire.

Then the group consensus was. Big wire , small wire the copper amount would be the same. I thought I could squeeze more wire in with the small stuff and parallel the coils rather than series?  
DA-NO?

I think it should be the same either way... except for the thickness of the extra insulation on the smaller wire. In this case - I had to do it, because the thought of winding a coil like this with something between AWG 9 and AWG 10 wire seems daunting - and I'm certain I'd have had some eddy current losses in the thick wire.

DanB,

Do you twist the 3 wires together to form a single cable as you wrap? Or do you just wrap the three somewhat side-by-side?

Seems like with the twist things might be tighter though a tougher job to do. But there may also be some danger of damaging the insulation as you twist and wrap the coils.

Pretty work! You said the magnets were expensive. Are you guys going to offer them on the Wondermagnets site? Would we need to float a loan to be able to afford them? You already have some magnets for \$45 each on there. A few folks might be willing to go for \$80-\$100 magnets, especially those who are completely off the grid.

Bach On

- I'm just as happy as if I had good sense! -

Looks very nice Dan! What was the ohm reading on your coils when completed? To bad the gap came out larger than you wanted, thats going to eat up some power but should still kick out some good power.

I'm designing an alternator to work with a slow turning VAWT. The idea is to have the unit start charging at low rpm's ( around 30 to 45) but produce full power with very small rpm changes. ( full output by 100 rpm's or so) It's been quite challenging and I'm still a bit off for the final product. I'll be using similar magnets ( my smaller segments - which are only 2" tall x 1.57 top ). I may steal your idea using strands of smaller guage wire as opposed to one heavy strand. This may help reduce copper losses by reducing the eddy currents and I believe, not sure yet, I may be able to get more copper in the magnetic path this way. Interesting idea anyway...

Keep us posted on your output data when its together!!!

Have Fun  
 Ed

Hi Ed - when I hook the meter to it is says .1 ohms (and beeps at me). So it must be somewhere between .1 and .2 ohms/ phase.

The airgap is kind of a bummer, but on the bright side, the cutin speed came out exactly where I wanted it and the stator is a bit stronger/less flexible - which is good I think because it's large enough - and the coils all pretty much touch each other, that weakness in the stator was a concern. It came out this way because I used a bit more fiberglass than normal on both sides, and I heated the resin up a bit much before I started (and mixed it a bit too hot) so that by the time I was putting the top on my mould it was allready setting up. (I should've been more patient!).

Perhaps next time I'll have the resin go a bit more slowly and then perhaps I could get away with slightly thicker wire and a few less windings (maybe 4 strands of AWG 15 wire) so that resistance is a bit lower.

I wonder if, in your case there would be any advantage to using multiple strands (other than that they are a bit

Hi Dan,

Just playing with numbers and what you've given in data. I've calculated between 1100 and 1400 watts in a 25mph wind not including any losses... let me know how close I came...

After calculating out the differences in wire sections it actually takes up more space using smaller wire to make up a larger equivalent. I thought it might come out a little more efficient since the air gaps between wires would be more filled in... Fun figuring it out though... back to the bar stock...

Have fun  
Ed

"After calculating out the differences in wire sections it actually takes up more space using smaller wire to make up a larger equivalent."

Hi Ed.. I have to say, I've not calculated this - but if we ignore the thickness of the insulation, that doesn't make sense to me... it should be the same shouldn't it? Except that - really large thick wire is harder to wind tightly, so I actually tend to think the opposite, it seems I can squeeze in a bit more copper this way, but I could be wrong.

Hi DanB

I asked this ? a while back. I thought i could get more copper in a coil of the same phizical size it i used smaller ga. wire.

Then the group consencis was. Big wire , small wire the copper amount would be the same. I thought I could squeez more wire in with the small stuf and perelell the coils rather than sories?  
DA-NO?

I think it should be the same either way... except for the thickness of the xtra insulation on the smaller wire. In this case - I had to do it, because the thought of winding a coil like this with something between AWG 9 and AWG 10 wire seems daunting - and Im certain Id have had some eddy current losses in the thick wire.

Hi DanB  
I asked this ? a while back. I thought i could get more copper in a coil of the same phizical size it i used smaller ga. wire.

Then the group consencis was. Big wire , small wire the copper amount would be the same. I thought I could squeez more wire in with the small stuf and perelell the coils rather than saries? DA-NO?

I think it should be the same either way... except for the thickness of the xtra insulation on the smaller wire. In this case - I had to do it, because the thought of winding a coil like this with something between AWG 9 and AWG 10 wire seems daunting - and Im certain Id have had some eddy current losses in the thick wire.

DanB,

Do you twist the 3 wires together to form a single cable as you wrap? Or do you just wrap the three somewhat side-by-side?

Seems like with the twist things might be tighter though a tougher job to do. But there may also be some danger of damaging the insulation as you twist and wrap the coils.

Pretty work! You said the magnets were expensive. Are you guys going to offer them on the Wondermagnets site? Would we need to float a loan to be able to afford them? You already have some magnets for \$45 each on there. A few folks might be willing to go for \$80-\$100 magnets, especially those who are completely off the grid.

## [New wind turbine fun!](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Fri Dec 19th, 2003 at 10:04:06 PM MST

[Wind](#)

Almost finished my 14' machine today.

I wish I'd got better pictures, but here today I pretty much finished my 14' wind turbine which was started on Thanksgiving day. The start of the project can be seen [here](#), and some details about the alternator are [here](#).

This picture shows how the back rotor of the alternator fits on the spindle.

Above is shown the stator. In this alternator, the back rotor is mounted well behind the hub, so that the wheel hub is actually centered in the stator. The studs between the two rotors are very short, and strong (I hope!).

### Poll

Whats going to happen?

I think the tail will fall off.

I think the blades will explode.

I think the stator will melt.

I think all of the above will happen!

I think it will work fine!

Votes: 3

Here the whole alternator is assembled. It's quite heavy - I'd guess this assembly here weighs close to 100 pounds. I figure close to 25 pounds of magnets (maybe even a bit more), and somewhere around 10-12 pounds of copper - not to mention the steel.

My shop is a 10 X 50 mobile home with a small hole in one side where I made an addition (for my lathe). A 14' diameter prop is quite a tight fit! Of course, it cannot be turned over, brought outside, or hardly moved at all without being disassembled. This prop is similar to others I made. The width at the tips is 3.25", at the root it's 9.5". The pitch at the tip is 3 deg, it's 6 deg half way out and tapers down to whatever the thickness of the board allows at the root. The prop is made from almost perfect, vertical grain knot free fur. The board was a 2X10 (so 1.5" X 9.5" after being planed).

Above I've put all the pieces together to make sure it fits OK, before painting it. It's looking rather large and daunting to me now... the tower project concerns me a bit - as do the forces that a machine this large will have to endure!

Here I've painted it up and slathered the blades in lots of linseed oil. Picture doesn't show too well (perhaps Ill get my better camera out tomorrow)... it's green with a red alternator (holiday spirit!) and the hub and tail is painted black. In the background you can see the 10' 48 volt machine we're just finishing up for my neighbor.

Theres another shot from the back. I may change the tail (it may be a bit too small Im thinking...). Otherwise it's done though, and I can clean my shop and think about a tower. Yesterday I had lots of pipe delivered, so at least I've got the materials.

Nice Job Dan! I'm anxious to see some data on your 14' machine. Looks like your definately haveing a good time!

Wow...looks great. You will need a substantial tower with heavy guys and anchors to handle this beast. Can't wait for the results.

Looking good Dan!

As for a tower . I just mite have a Christmas present for you : )

Things are falling in to place and hopefully in a few days. I will have the first 10 foot section built and will have some pics.

It is based on the Wind works plans an is a octahedron. It will be a guyed tower using ten foot sections that bolt together.

This makes things a lot simpler than the free standing tower in the plans.

My gut is telling me that I could meet my design goal of a tilt up tower that is ridged enough to support its own weight plus 200 pounds of wind generator when raising or lowing.

The guy wires will act as safeties and not a important part of the structure during the lift as in a pipe tower.

When the tower is up the guys would be tighten and supply the bulk of the wind load strength.

The very best of the holidays to you and yours

Old F

[Wind](#)

**we've been chipping away at a 48 volt Machine**

Over the last week our neighbor Adam has been coming up to build a 48 volt machine for his cabin which is a couple miles down the canyon. This machine is nearly identical to the last [few wind turbines](#) we made recently with a couple changes which will hopefully be improvements.

Pictured above Adam is wiring up the stator. Being a 48 volt machine this stator is a bit different. The coil form is the same one we used on [Moe, Curly, and Larry](#). Those machines were 12 volt, and we wired each coil with 65 turns of AWG 14 wire, each phase consisted of 3 coils in series and the stator was wired up in Delta. Some discussion with [Hugh Piggott](#) helped me to understand that wiring the stator in star (which changes how we'd wind the coils) would make things a bit more efficient, especially at lower output levels (low winds). So this machine (Adam named it Moby) is wired in Star, and each coil is made up of 140 windings of AWG 17 wire. The magnets are identical as the last machines we made, 12 2" diameter X 1/2" thick disks on each rotor. The rotors on this machine are slightly larger, these measure out about 11 3/8" which is also a slight improvement.

After some thought about vibration, and watching how quickly shorting the alternator stops it (and seeing how the stator bracket gets slightly twisted), I decided to beef up the stator bracket a bit over the last machines. This arrangement is much stronger. There have been no failures in past machines over this yet, but I feel more comfortable with a stronger bracket. The picture above shows to some degree how this has been strengthened.

Above we have it almost painted. Adam liked the idea of a whale for a tail, (which is only in primer right now but will be painted white) hence the name Moby! The only other improvement on this machine over past ones is that we welded part of the hub puller into the center of the front magnet rotor to make pulling (and lowering back down) the magnet rotor a bit smoother. This works really nicely this way... much safer I think. As it is I think we can still take almost 1/8" of airgap up by adjusting the front rotor. Cutin speed (measured as DC through rectifiers) is 140 rpm right now, so I think it will run nicely with a 10' diameter prop which hopefully we'll start on today!

## [Fun with meters and graph paper](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Thu Nov 6th, 2003 at 10:06:49 AM MST

[Wind](#)

I spent a while yesterday watching meters on my windmill.

I started out yesterday by dropping my [single rotor brake disk windmill](#) again. I had it down a couple days ago for [repairs](#), and found that the bolts holding the prop on were not so tight anymore, so I really tightened them a bunch.

The airgap was pretty tight on one side, because when I was building it I clamped the lid tightly on the mould, and the mould broke while the resin was setting up... making for a somewhat less than flat stator. So the airgap is tigher on one side than the other. Tightening the prop evidently squeezed just a touch out of the airgap, because it started clunking up on the tower and was having a bit of difficulty starting. Normally this machine seems to startup easily below 5mph. Once down, it was clear that the magnets were lightly rubbing a high spot on the stator. So I took it all apart, and widened the airgap by a little more than 1/16" and stuck it back together.

One interesting thing to note, which I'd not really payed attention to when I built it (and it's not been apart since), this machine has removable laminates that stick to the back side of the stator by the attraction of the magnets only. The airgap (distance from the magnets to the laminates) is pretty wide, about 5/8". This is made up for somewhat by the fact that I used rediculously large/thick magnets. But - it was interesting to note how easily the alternator spins when the laminates are off, and what significant drag they added to the alternator when I put them back on. This is the good stuff.. really thin silicon steel laminates, and still the drag on the alternator is very noticable. In this case, it doesn't seem to be a problem, because the machine does startup just fine, but you can sure feel the iron losses when you spin it by hand.

It was only two days ago that I hooked up the [Vortex anemometer](#), so yesterday was really the first time since I built this machine in May that I've had opportunity to watch output vs windspeed. I don't know how accurate it all is since I cannot verify that the anemometer is accurate. At our elevation (8200'), I suspect that changes things a little bit.

Pictured above you can see my primitive power system and the meters I love to watch! Top one is an old Weston voltmeter. It's in full agreement with the voltage readings I get off my Trace inverter, it amazes me how accurate many of these very old meters still are. The bottom analog meter is my ammeter, it shows 0-80 amps - it also is quite accurate, pretty much in full agreement with my Fluke clamp on. Top and left is the readout for the anemometer (A bike speedometer). The yellow meter hanging off the wires to the left is my Fluke 377 clamp on meter which does a great job of reading frequency on my windmill so I can now get pretty accurate rpm readings.

I'd always been of the impression that this wind turbine ran a bit too fast. It's quite fast compared to the dual rotor machines I've built since. Working it all out - after watching frequency, and windspeed on the anemometer for quite a while and writing down lots of figures/taking averages - this windmill is running at a TSR (tip speed ratio) of 6.3, in a 15 mph wind, and... also, exactly 6.3 in a 20 mph wind. So, I guess it's not too fast... it seems quite within reason.

Yesterday was a good breezy day, with winds from the West and SW, so the anemometer on my tower was in a good place. The max windspeed I ever saw was 26mph. Average was around 10. The machine starts to furl right around 25 mph it seems. I wish we'd have had more wind (we will... if I'm patient!) so that I could see this power curve reflect that. I've seen this machine peg my 80 amp meter on occasion - my guess is that happens when a violent gust hits it briefly from a weird direction, because the furling system shouldn't really allow that. I basically watched the ammeter and the windspeed indicator and put dots on my graph, the red line is an approx average. A few readings were very consistant throughout the day and I would've put gobs of dots in the same spots. 2.5 amps @ 7mph, 8 amps at 10mph, 20 amps at 16 mph, 30 at 20mph. Didn't ever see lots of wind much above 20, but it seems to be in the 40-45 amp range at 25mph.

Hard to say how accurate all this really is, but I doub't the anemometer is reading high, simply because it's hard to believe my machine would be running at a TSR much below 6.3 (it seems to spin pretty fast!) An optimistic reading on the anemometer would mean that I was running at a lower TSR, which is hard to believe. So.. I kind of feel lucky - this machine seems to be running a little bit better than I actually thought it was, slightly better than my truck tests indicated.

The anemometer is fun... I'm dying for a REALLY windy day now!

## [Windmill Repairs](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Sun Nov 2nd, 2003 at 10:43:18 AM MST

Yesterday I lowered my windmill for repairs and inspection....

[Wind](#)

I lowered my wind turbine yesterday for repairs. It's been up for about 6 months now, and as per my last posting - we had very high winds over the last week. One guy wire had broken, and I could hear the weight rattling up on the tower.

Pictured above is shown how the weight (a bunch o' washers) was bolted to the front of the prop and it had come loose. Actually, even though they were very tight when I raised it, and locktightened, all 5 of the nuts holding the prop on were surprisingly loose. Even if the weight had stay'd put, I think the prop would've started rattling soon. This time I put lock washers in, re-tightened it and used locktight. I also put a couple wood screws in to help hold the weight in its proper position. Hopefully this will last till spring! (at which time I'll hopefully build a better tower and replace the machine with another one)

This picture shows the tail pivot, and the notch which sets the stops for both unfurled, and furled position. I'd taken care when I built the machine to reinforce this notch around the sides and the top with additional metal. Still not strong enough, the pipe has flared out at the bottom some. I didn't do anything to fix this for now, I think it'll last through winter, but perhaps next time we'll use even more reinforcement or larger pipe for the pivots, or both...

We fixed the broken guy wire, and added a Vortex anememometer which was sent to us as a sample for testing. So... it'll be fun to get some sort of windspeed data here at my house! As it looks now.. obviously the anememometer is running in the wake of the blade... it's very unusual for us to get winds from the East, but at the time of taking this picture that was the case. Most wind is from the west, and the anememometer is about 3.5' in front of the prop in that situation. Still, far from ideal... but it should give some kind of rough idea! Fun stuff... it's interesting to see how these hold up. Had I not lowered this machine (or had I not been home on Wed morning) I suspect it would've completely failed soon. We'll see how the tail pivot holes up! For now, it looks happy... new grease, new linseed oil on the blade. At this time (after only 6 months) the blade looked pretty much like new with no signs of wear or warping.

wood crushing? ([none / 0](#)) ([#1](#))  
by wdyasq on Sun Nov 2nd, 2003 at 10:53:21 AM MST  
([User Info](#))

Dan,

Could the loose bolts be the result of the wood crushing? I have had that happen on some wooden tooling I have built.

It is always amazing what Mother Nature can do to somethingone thinks of as -bullet proof-

Thanks for the update,

Ron

Hi Dan,

Thanks for the close up views.

I would say that the blades probably expanded and contracted with moisture. When they expanded (in wet weather) the wood was crushed, and when they contracted they came loose. That's why you should not leave the axe out in the rain. (the handle gets loose)

I was surprised by the state of the low end stop. There is not usually much stress on that. Either there has been some heavy turbulence, causing the tail to slam down on its stop, or there has been some heavy vibration perhaps.

I wonder is that a single phase machine? Vibration from the alternator could also work things loose.

I am surprised you can get away with such thin pipe between the guys and the windmill.

The anemometer position is a constant problem. Too far below the machine and it as less wind. Too close and it is influenced by the windmill. You will find that the relationship between windspeed and power depends a lot on wind direction.

The best place for the anemometer is on a separate tower upwind. Easier said than done though.

Hugh Piggott <http://www.scoraigwind.co.uk>

Re: Windmill Repairs ([none / 0](#)) ([#3](#))  
by kww on Mon Nov 3rd, 2003 at 06:59:51 AM MST  
([User Info](#))

Hi Hugh,

About the thin pipe, it seems like to me if the turbine turns out of the wind early/with low rotor thrust a much smaller pipe would work. Dan's turbine appears to prove this, since that's how he makes them I've read. I like the idea of such a design since it seems like to me you can get a lot more out of a small setup, except for the rotor, since a large rotor will make a significant amount of power for a small alternator in LOW winds. And, it's not really much harder, time consuming, or expensive to make a 10 footer as opposed to a 6. I'm just hoping my design can hold up to the high winds using smaller pipe, guy lines, etc. like Dan's does. Btw, great book (Windpower Workshop), thanks for writing it as it's come in very handy. Now you just need to write one for us electrically challenged. ;-)

Kevin

Re: Windmill Repairs ([none / 0](#)) ([#4](#))  
by DanB on Mon Nov 3rd, 2003 at 07:16:35 AM MST  
([User Info](#))

Hi Hugh - yes, I have no doubt it's due to moisture that the prop nuts are coming loose. The wood is definitely crushing beneath them... the nut's have not turned, they were still locktightened in their original position. I expect this will be something to watch for on all the machines we put up this summer. I've noticed we don't have this problem on Wards (the old one I made a couple years ago for him) because we made a solid steel plate to cover the front of the prop that went between the nuts and the wood. Everytime we check that it's still good and tight. I thought washers would be good enough (perhaps they are)... making the plate takes a bit of extra time, although I think in the future it may be worth the extra trouble.

The tail pivot... it would not be hard to make it stronger. I think part of the problem is that the notch was not landing in full contact with the stop... it was making contact at the very bottom first so all the forces used to be at one point. I think it has "worn in" so to speak and suspect it may not get much worse. Time will tell...  
It is a 3 phase alternator, this is the machine I made in May, with a single magnetic rotor and laminates, so I don't think alternator vibration is a significant issue. It is however a very turbulent place. The tower is 45' high... I think even 100' would not get me out of the turbulence here too well. We have hills fairly close on both the North, and the South sides and lots of tall trees. It's fairly mountainous and the wind rarely comes from one direction for very long. I believe this is the main problem... to get out of this turbulent situation on our property would probably be impossible, but surely a taller tower would help.

Regarding the small pipe above the guy wires. I agree... it's very much pushing the limit. I never see it flexing, but it still makes me nervous. It is however stronger than it looks. The pipe is fairly thick walled stainless steel, which is much stiffer than

common steel water pipe. There is also tight fitting steel pipe, the next size down - pounded down inside it all the way, and there is a 1" steel pipe (which you cannot see in the picture) welded to the back side.

(kind of a conglomeration of junk...). I have no doubt that a single piece of steel water pipe this size would bend over immediately, I know this just from testing machines on my truck! (I've bent a few pipes over on my truck while testing!) Hopefully next spring I'll have the time/resources to build a stronger, taller tower - I'd not feel comfortable putting any larger machine than this on my current tower.

Re: Windmill Repairs ([none / 0](#)) ([#5](#))  
by veewee77 on Mon Nov 3rd, 2003 at 01:37:24 PM MST  
([User Info](#))

Here is a thought on how to fiux the anemometer/downwind thing. . .

Put the anemometer on a swiveling arm and put a tail out the other direction a foot or two more than the anemometer. The tail will keep the anemometer upwind of the genny at all times.

just my \$.02 and worth!

Doug

## [Wind turbine update!](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Thu Oct 30th, 2003 at 09:26:16 AM MST

[Wind](#)

We've had the first real good windy week of the season up here!

---

Its the first chance we've seen good high winds on all the machines we made since spring. Lots of days in a row with winds 20-40mph and gusts as high as 80!

The machine I made for myself in May: <http://www.otherpower.com/bdwm53.html>  
Has done fairly well. It starts up easily and produces well and the furling system works smoothly. The winds started to subside yesterday, but I took a couple pictures of it from right below the tower to show a bit of how it's furling.

In this picture we're having reasonably strong winds, probably about 30mph and you can see the alternator/prop is starting to turn away from the wind. Again, with this system.. the tail is always with the wind, the prop and the alternator pivots away and the tail gets raised.

This machine, on it's primitive [tree and chain](#) tower looks a bit precarious in high winds, but it's held up OK through the 80mph gusts. On windy days it seems to produce a pretty constant 200-500 watts with peaks well over 1KW (my meter shows 80 amps and I've seen it pegged often). I think the prop on this one runs a bit fast... a bit faster than I'd like. After this week of strong winds, I've had two minor failures... either of which could've been major! (I got lucky...). Yesterday morn the tower was moving around a lot, and one of the top guy wires had broken at the turnbuckle. Why??... when I put the tower up I ran out of good cable, so I doubled up some stuff that was too thin and it snapped. The other failure is that the weight which I used to balance the prop is bolted to one of the studs that holds the prop on. Evidently it's coming loose, because I hear it rattling up there. For now the machine is shorted out (shut down) and hopefully today I'll find the time to lower the tower and fix it. Considering how the tower is made... that in and of itself could be an adventure!

This machine we put up a couple months ago... one of the [triplets!](#) It's been looking very solid and safe and slow all week. It's doing very well in the lower winds, but it's hard to say in higher winds because we only had a 25 amp meter when we installed it, which is often pegged. Yesterday (as the winds were dying down) I brought up my new DC clamp on meter and watched it for a while. The machine basically runs too slow to get the sort of output we'd expect from a 10' prop. Part of the reason is how close the tower is to the batteries (8' away!)... so the line loss is almost 0. Yesterday I cut about 25' of AWG 14 extension cord and added it to the line. The result was impressive, it sped the machine up significantly and it was much quicker to produce higher currents. In seemingly mild winds we were seeing 25-30 amps with peaks of 45, but at the time we were no longer having strong winds. Before adding resistance to the line, it took a huge gust to make this machine furl because the prop was turning too slow to really catch the wind as it should. After adding some resistance, it started furling much sooner. It was a fun experiment, but in the end we removed the resistance, because the machine was already producing more power than Tom could use and we figured that with that in mind, there was no sense in running it

any faster than necessary. Should Tom figure out how to use the extra power, we can improve output significantly by putting the resistance back in the line... or... making a larger prop, or widening the airgap in the alternator a bit so it doesn't load the prop up so much!

[Wards wind turbine](#) has been hanging tough through it all. He does shut it down sometimes on windy days when he's gone, but hes getting a bit less careful about it now that we kind of feel it's obsolete. This is the 1st brake disk windmill we ever made. It's a bit slow to start, it takes a constant 10mph for a few seconds to get it spinning up, but once running it does pretty well. He actually mounted an [anemometer](#) to his tower recently, so it's been fun to get some data on it. Seems like he's seeing around 5 amps in 10mph winds from it, and since it has no furling system he occasionally sees peaks around 120 amps in very strong winds. Knowing what I know now... I'm kind of surprised how reliable this machine has been and that it's actually still standing!

[The Caboose](#) windmill has seemed very solid so far. It's another case of too much power... Dave really can't use it all. He's got 1 solar panel, between that and the wind turbine his batteries are always full and it seems his windmill is shut down more than half the time. His machine is also 12 volts, and the line between the windmill and the batteries is about 400' long! We've got 4 strands of 10-3 romex running from it to the batteries (for a total of 12 strands of AWG 10 wire) and should be adding more, but as it is it doesn't seem to overspeed and has no problem getting 500 watts (sometimes more) down to his batteries.

It's been a fun and interesting week to see how all these hold up! I think the only failures are at my house and thankfully I shut the machine down before disaster struck. I was rather afraid I'd wake up yesterday morning and find a few windmills down after the 70-80mph gusts we had, I'm glad that was not the case.

Dan,

There is something in your post that I don't get. My poor brain can't figure it.

Usually we say that a windmill will overspeed in strong wind if not loaded (free wheeling). When loaded a windmill will slow down right ?

What I don't get is that you stated in your post that one of the reason your mill was running slow was lack of line lost and that by adding line lost your mill speeded up ? (In my perspective, lower line lost imply less load while higher line lost imply more load) What is that I don't get ? Can someone enlighten me ?

Regards Barnac

I am neither for, nor against, but quite to the contrary ;-)

Re: Wind turbine update! ([none / 0](#)) ([#2](#))  
by DanB on Thu Oct 30th, 2003 at 11:17:57 AM MST  
([User Info](#))

By line loss... we mean resistance in the line.

Imagine if we short the line out... then the resistance in the circuit (except for that in the alternator) is 0 for all practical purposes... and it loads up the machine hugely causing it to turn very slowly. When it's turning this slowly.... the blade is basically forced to go much more slowly than it would like to, or need to in order to produce good power from the wind. (it's stalling...)

Instead of shorting it... we could unhook it completely for any load which would be pretty much infinite resistance and it would free spin, running dangerously fast and probably making lots of noise and not being very efficient.

The batteries are a load, but in our case the load was too much - it took too much. Just a small increase in rpm at the alternator resulted in a big increase in current and that curve didn't match up well with the power available from the prop over a range of windspeeds. By adding resistance it can increase in rpm some (to keep with the prop) and not have such an immediate increase in current, so the prop is able to maintain at a higher, and more efficient speed over a range of windspeeds.

On the downside, were losing more power in the line. Basicly we've sacrificed a small bit of efficiency in the electrical end of things to allow the prop to run much more efficiently... in the end we come out way ahead on the deal. Our added line loss doesn't hurt us hardly at all in the low winds (7-10mph) where were getting 10 amps or less anyhow, but we do lose a lot of power when current gets higher. At 12 volts, when we see 40 amps current flowing (480 watts into the batteries), we are losing about 400 watts into heat just in the xtra line I added.... (not very efficient) - but were still gaining in the end. I actually think I will change the line and instead of 25', go to about 15', because that added line really allowed the windmill to speed up a bit too much I think.

Somewhere is the perfect balance! Again though... in the end we don't use it that way, because the machine does well anyhow in low windspeeds and if Tom cant use the extra power anyhow, there is little point in running it faster than necessary. It was a fun week watching/playing with these things...

Re: Wind turbine update! ([none / 0](#)) (#7)  
by Dave B on Thu Oct 30th, 2003 at 10:08:09 PM MST  
([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Dan,

Knowing what you know now I'm looking for some advice. I'm the one who has built the Volvo alternator for pre-heating water. Can you tell me the width of your blades at the root of your 10' rotor ? Also an approx. TSR ? I notice that for ease of carving I'm sure that not too many people carve the root area and "drop" to the specs. given in the Excel blade program for most any given TSR & length. I understand that once the blade is turning the root area may not have much affect on performance but ONLY if the load is such that the added torque is not needed. This could be the case more times than not for charging batteries. In my application (and testing proves this out) I will want, and need all the torque and speed I can get at any speed as I will be adjusting the load to "crank" the power. I would rather see my mill turning slower with the torque needed than to have it stall or be hard starting. Can you guess or do you know the rpm range of your 10' rotor for various wind speeds unloaded ? I'd like to hit 400-425 rpm in 25-30 mph furling say after 30 mph. Do you think the Volvo design is capable of spinning a 12' prop at these speeds or should I stick with whats been tested say the 10' and carve that root to spec. to get that torque I need ? Great information and thank you for sharing your thoughts based on your experience. Dave B.

[ [Parent](#) ]

Re: Wind turbine update! ([none / 0](#)) (#10)  
by DanB on Mon Nov 3rd, 2003 at 07:52:22 AM MST  
([User Info](#))

Hi Dave -

The width at the root depends sometimes on what lumber I find available. Usually about 8" wide, and I prefer to find wood 2" thick, but usually its 1.5" thick. At the tips, I've been making them about 2.5" wide and about 3/8" thick, and on all mine the thickness has tapered to full board thickness at the root, and that taper has been a straight line. (not really proper at all... \*) At the root the pitch is as much as the board will allow. About half way between the root and the tip it's about 5 or 6 deg. So far... my blades have not been very scientific!

I've not done good measurments of rpm, but I'm guessing that my 9' machine (single rotor alternator) is probably running with a TSR of around 10. I believe the 10' dual rotor machines are running with a TSR between 5, and 7 in low winds (each one is different and the TSR changes depending on line loss and the nature of the battery bank). The 10' machines are stalling, probably around 15 - 20mph I think, so as windspeed increases the TSR gets less and less... and the blades become less and less efficient. Adding resistance to the line, having a wider airgap, using smaller magnets next time, putting on a larger prop OR rewinding the coils for higher cutin speed... any of these things would change that and allow the blades to run at a more efficient speed.

So I think really... we try to make blades that \*like to run at a certain TSR when loaded by the alternator, but in the end it's the loading of the alternator that will determine what TSR they actually run at. My 9' machine runs a bit on the fast side, and the 10' machines are running a bit on the slow side, and changes in the line - and/or the alternator would bring them into more efficient operation. Actually - I think my 9' machine is running with reasonable efficiency over the range of windspeeds, and slowing it down would make it safer - but may cost me a bit of power. None of these machines make much noise - probably the only one I hear any sound from the prop on is Daves (the one at the caboose) - where we had a 4, or 5 deg (cant remember) pitch at the tips. Hugh advised me to try a bit less - and they became almost totally silent. Even the caboose windmill is very quiet, but you do always hear a slight whooshing sound when its running.

When I make blades generally... I tend to work from blades I've made in the past that worked OK, - and I look at other peoples blades. I have a nice set here that Ed made which I use for "inspiration"... although I believe I make some compromises for strength. Mine are a bit wider and thicker at the tips than perhaps they should be... but I get nervous with wood when it gets too thin. I also keep my old windcharger in mind when I make blades, it had a straight pitch from root to tip, the thickness remained the same, from root to tip - and you couldve made the whole blade from a 1 X 4. (it was 6' in diameter if I recall). Bergy blades also have constant thickness and constant pitch from root, to tip - and they are quite efficient.

I could be wrong... but I think that blades are quite forgiving if you're not looking for absolute maximum efficiency... I think anything in the "ballpark" can be reasonably efficient. If you are usin the spreadsheet - I'd just design the prop for a reasonable TSR (like 7), and tune your alternator and your load untill it runs best. Since your not charging batteries here, I should think you have a lot of flexibility by changing the load to get things matched up nicely.

[ [Parent](#) ]

Re: Wind turbine update! ([none / 0](#)) (#11)  
by Dave B on Mon Nov 3rd, 2003 at 10:48:43 AM MST  
([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Dan,

Thank you for your response on the blade info. Like you say, I will have quite a bit of flexibility with adjusting my load(s), cut in speed etc. as I will be designing a variable load controller circuit using solid state relays. I really will need the torque to keep things turning most efficiently in higher winds with my load adjusted properly. Hopefully through basement testing with my 2 hp electric motor set up running the alternator I can design an efficient auto load circuit depending on rpm. This is fun stuff. I think I may take it a step up to a 12' rotor after reading your comments or possibly a 10' with TSR 7 and carve it to spec. including the "extra" drop needed at the root for torque and startup. Thank you again for sharing your info. and photos. You guys have got me hooked. Dave B.

by kww on Thu Oct 30th, 2003 at 08:42:27 PM MST  
([User Info](#))

That's quite a tower Dan, looks like something I'd make myself. :- ) I've got giant timber bamboo(4" diam., 50 foot tall) planted, when that gets big enough I'll trade you a load for some magnets. ;- )  
Anyway, I was wondering what size pole you use at the top to mount your 10 foot turbines too and kind, thin conduit, thick water, steam, or gas pipe? Also, you wouldn't happen to have any idea of the force needed on your 10 foot turbines to get them to furl?  
Kevin

Re: Wind turbine update! ([none / 0](#)) (#8)  
by DanB on Fri Oct 31st, 2003 at 07:49:38 AM MST  
([User Info](#))

Hi Kevin -

At the top there's 2" pipe going all the way to the top (almost) with 1.5" pipe inside that, and the very top stub is 1.25" pipe which is dropped down inside the whole thing, but sticks up about 10" and the wind turbine sits on that. All the pipe is shed 40 water pipe except the 2" which is stainless. (junk I had on hand...)

Then, on the outside of the whole thing, there is a length of 1" pipe which is welded to the side, and drops below all the pipe by about 4' and its chained to the tree...

It doesn't seem to flex much... but a little. When I drop this next time (didnt get to it yesterday) I'll be strengthening things.

[ [Parent](#) ]

Re: Wind turbine update! ([none / 0](#)) ([#9](#))  
by kww on Fri Oct 31st, 2003 at 04:31:56 PM MST  
([User Info](#))

Hi Dan,

Sounds like if it's going to break it'll be at the top, right where the 1.25" goes into the rest. That seems really small, based on Hugh's book and the hint of power available I saw in my own turbine, but if it furls easily (with little trust on the rotor), it seems ok. Especially since you've already had it in 80mph winds. :-). The reason I'm so interested is that I'm going with a 1.75" pole at the top 7 or so feet, then 2" the rest of the way down. I'm using 4 1/8" galvanized steel guy wires. I figure this is way more than enough to support the tower since it only takes around 70 lbs of thrust to completely furl the rotor, we'll see. :-). Thanks.  
Kevin

## [Motor generator Grid tie?](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Sat Oct 11th, 2003 at 09:29:13 AM MST

[Wind](#)

Wonding if a motor-generator might be a reasonable option.

I've been thinking about how to grid tie a wind turbine which charges a 12 volt system. Nobody currently (that I know of) is making a grid tie inverter for 12 volt systems.

It's got me wondering if we couldnt simply drive an induction motor with either a 12 volt DC motor, or a 120AC motor through an inverter to "dump" power into the grid. Of course we'd need a cutoff switch to make it all safe/legal etc... bt it seems a reasonable option. I used to run my power tools off an old 1500 watt 12VDC - 120AC honeywell motor generator (back when inverters were expensive) - it seems like under full load it was reasonably efficient, like 70% or something. To grid tie a system, it seems like a fairly small motor generator could be turned on when battery voltage got over a certain point, and turned off... below a certain point, and it might make for a reasonable system.

I've not yet messed with using induction motors as generators. I wonder how much faster than the rated speed we'd need to run an induction motor in order to have most efficient output - and how all this would work out.

([User Info](#))

Hi Dan,

Your idea will certainly work, whether it is worth the trouble or not depends on the fun factor of, spinnin the meter backwards.

An induction motor behaves as a generator when connected to the line and spun above its synchronous speed, ie a four pole motor typically rated at 1725 rpm on 60 hz, will start looking like a generator above 1800 rpm and reach full or rated power at approxamatly 1875 rpm ,or the same % slip above synchronous speed as it had below it as a motor. Note the slip is a function of load, the 1725 motor will run slightly under 1800 rpm with no load. All above speeds are for 60 hz power on 50hz sync speed would be 1500 for a four pole motor

To impliment the motor generator I would think torque, not speed, as the induction generator will hit a wall of torque at its rated slip. It is possible to push past this speed with enough horsepower , at which time the generator will become unstable, hoever if your pime mover has limited torque this is not an issue.

As far as safety goes, although the utility will insist on UL

listed safety cut out relays, in the real world it would be nearly impossible to generate into a dead line with an induction machine as the machine requires lagging current for excitation but can only produce leading current. A capacitive line ( rare) could supply the lagging current but the electrical load would have to be very low to keep from damping out the whole process. Normally a utility failure would present a very high load. In any case a line failure would lose freq and voltage regulation within a few cycles( this is what trips the safety relays) .

Make the wind fun!  
Victor

Re: Motor generator Grid tie? ([none / 0](#)) (#2)  
by monte350c on Sat Oct 11th, 2003 at 07:27:53 PM MST  
([User Info](#))

Hi DanB,

Seems like a pretty good idea, a fairly straightforward circuit could be designed to set the on/off points for the motor generator. A while back I found a pretty good book (free!) online - <http://www.eece.ksu.edu/~gjohnson/> there's some info and ideas especially in chapters 5, 6, 7. The whole book is a good read with detailed calculations on a wide variety of wind topics, but it reads well not at all like a dry tech book. Keep us posted on your progress with this one. I have been thinking about trying an induction generator with a small gas engine to charge batteries. There's a site somewhere where a fella uses capacitors parallel with the motor. If I find it I'll post again.

([User Info](#))

DanB,

I have looked into doing this with engine powered generators for sometime. Once I contacted an engineer at tech support for ELLOT MAGNETEC. I was auditioning as a perspective buyer of a 155kw generator element. I asked the guy how do I connect to the grid with this thing? He then asked me what do you intend to drive the the gen-element with? I replied a 400hp V8 engine. He replied that the engine might be kind of underpowered for the application, but said I could do it, and the engine might wear out in a year or less.

I was told a "VAR POWER CONTROLLER" would keep the freq in phase. He said it will actually throttle or govern the engine based on the freq in the main line.

There is also another way to do it with an inverter, but its much more experimental, you must use a Isolation Transformer thats rated for the "KVA" of what you expect the power company to buy. And apparently the the "VAR" reads the incoming modified sinewave and reads the output sinewave to the grid and interups the voltages to

keep everthing "in phase"

to do this your output must be in the "neighborhood" and the isolation transformer helps in both cases. but I believe the "VAR" makes sure all the power you want to go "upstream" goes out to the grid correctly and in phase.

My best advice would be to find someone who "cogenerates power" with a diesel gen-set. And ask some questions about how they get "all" there output up into the grid. I have run across several people who have done this. but they are moving big power, over 50 to 500kw. They say they can just break even, between the cost of fuel and there needs in there factory, assuming they dont pay taxes on the power they use for themselves.

By the way I happen to have a 500kva isolation transformer just laying around, and will probnably be thrown out pretty soon. what I think is neat about these Isolation transformers is that they will put 3kw into the grid, or 400kw just as easily. depending what the control electronics tell it to do providing you have that much output. and the disconnects are inbetween to Isolation transformer and the grid.

If you want the Isolation transformer I have let me know you can have it, but it weighs about 1000lbs, and is in a nice indoor type cabinet with a control screen.

-JW

I found a bunch of information concerning VAR's and other items specific to phase matching from this manufacturer:

<http://www.basler.com/html/rscacc.htm>

This might help you with understanding how the pro's do it!

I'm thinking of doing something along these same lines with a diesel motor running on veggie oil and grid-tie the output! I might just break down and buy a whole diesel genset from ebay.

-Beui

[Wind](#)

It's almost done!

I finally got the page made for otherpower.com about the dual rotor machines we've been playing around with. It takes time... when you start out with about 200 pictures.

It's fairly redundant - about the same as the caboose windmill, but hopefully a bit more detailed. Hopefully I didn't make anything too awful confusing or get my math all wrong or something. There are still a few spelling errors at this time, and we're actually scanning all my "dancad" pictures so they can be seen more easily! (instead of shooting them with my antique Sony Mavica).

Some of that should be fixed by tomorrow. Of course... just like I am about my windmill blades, I don't worry too much about the little things.

<http://www.otherpower.com/trips1.html>

Building the windmills is the fun part! Making the webpage takes just as long it.. well, it's pretty fun too!

Now I can knock a couple items off my "honey dew" list and get back to bigger and hopefully better windmills!

Nice job

I was wondering about the shape of the coils in relation to those 2 inch magnets as I have been curious as how to wind a coil for that magnet.

Another thought/question

After seeing your 3 stators in a pic for the three machines it got me thinking.

If you were building a three phase machine could you build 3 single phase stators then adhere them together to get you 3 phase stator. this would definitely make it easier, also each phase could be check prior to assembly and could be seperated if one phase ever needed changing.

Just a thought

Very,very, very interesting but myself can only take so much in from books or reading web pages and probably like yourself need that hands on class room enviroment to ask those questions which i need answers to. But i got to give it to you, you put the work in and got the output from that work and they look good...wish i could have something with big prop but not where i live (Damn!!!!). Theres mainly two things i dont grasp and thats the building of the props and how the furling system works, hey maybe i need to attend a course by Hugh!!! It has crossed my mind more than once and one day it might just become realality. I dont know how big your community is up there at otherpower but have you ever wonder of building a wind farm and having your own grid? Keep building them gennys cos i will for sure, even though mine look like toys in comparison they still have a purpose and that is to charge batteries. Love the site and the things you guys make.....sean

Just out of curiosity how much current does one of those produce at say 120 rpm? Well actually how fast would it have to spin to light something like a 40 watt CF? Norm.

Re: New Webpage about the triplets. ([none / 0](#))  
(#6)  
by DanB on Sat Sep 27th, 2003 at 10:54:50 AM MST  
([User Info](#))

Sorry Norm - I've not tested for that yet... I don't have a powerful enough test setup to test current over a range of rpm yet. A 40 watt CF though... wouldn't take much. I suspect probably you'd do that easily at 110 rpm or so, right after it hits 12 volts.

It seems that a very small increase in rpm = quite a current increase into the batteries. I don't think I've seen these ever exceed much over 400 rpm before furling out, just judging from the sound of the alternator. You can hear the alternator start humming shortly after cutin. I've sat/listened even on windy days, and I've heard it on occasion cover about 1 octave (the faster it goes the higher pitch hum).

My digital multimeter, which can measure frequency, doesn't seem to do well at very low frequencies.. the readings I get are chaotic, so Im unable to determine rpm that way when it's up on the tower.

I really need to make a good test setup where I can drive these with a gas engine or something to get some good data.

Excellent job! Excellent web page too. I only have one question. Exactly how much air gap do you have between each of the rotors and the stator?

Re: New Webpage about the triplets. ([none / 0](#))  
([#9](#))  
by DanB on Mon Sep 29th, 2003 at 08:49:59 AM  
MST  
([User Info](#))

generally about 1/16" on each side, a bit less perhaps.... so the total airgap from magnet to magnet is about 5/8.

We actually made one machine with a smaller tail and a smaller 8' diameter prop. On that one we had to have a higher cut-in rpm, and allow the alternator to spin up faster. So on that one we opened it up quite a bit - almost 1/4" on each side! This brought "cut in" rpm to about 165 and allows the alternator to run faster without generating so much current, basically an attempt to "match" the alternator to a smaller prop.

Not very good use of magnets though - if I was going to build an 8' machine I'd use smaller, or fewer magnets. We did it this way thinking that someday we'd probably want to upgrade the machine to a larger prop once DanF builds a stronger/bigger tower.

by dconn on Tue Sep 30th, 2003 at 03:59:28  
AM MST  
([User Info](#))

Hi DanB,

On the smaller prop do you think you would get away with only one disk of magnets and have, say, the front disk with no magnets at all instead of the bigger air gap? I'm thinking this because the magnets are probably the biggest expense and they could be added later with a new prop as an upgrade.

All the best,

Derek

## [Disk Magnet spacing in axial flux alternators](#)

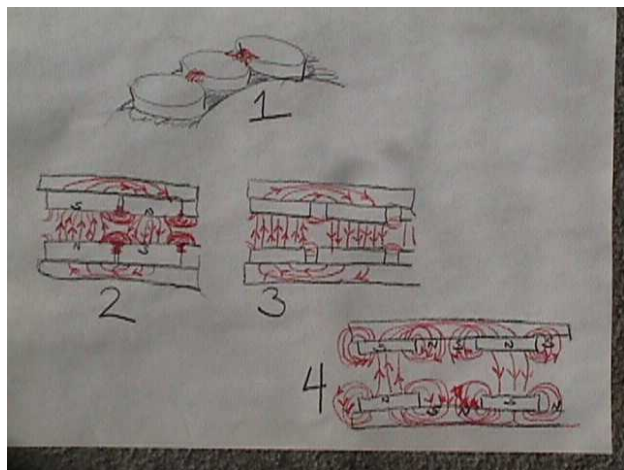

By [DanB](#), Section [Homebrewed Electricity](#)

[Alternators](#)

Posted on Tue Sep 16th, 2003 at 10:39:08 AM MST

Reno's last posting made me think about this...

There is some speculation here, I wonder if others have opinions about it.

Picture #1 shows disk magnets in close proximity.

Anytime magnets are very close there will be leakage from pole to pole (lines of force which are not going through the coils but rather from magnet to magnet). This becomes more of an issue the wider the airgap gets. In a laminate machine, with the coils down in slots, the airgap can be very thin (like 1/16" or less) and leakage is minimized. In a laminate machine with coils on top of the laminates, or a dual rotor machine - the airgap gets wide and leakage becomes more of an issue. To avoid leakage, and make better use of the magnets, we might want to put some space between the magnets. With disk magnets I think it's less of an issue because most of the leakage will be at the point where the magnets are closest - as shown in picture #1.

Picture #2 shows about the same thing - leakage between magnets which are practically touching. I think this arrangement might compromise coil shape a bit too, hard to say.

Picture #3 is basically a compromise - there is some space between the magnets, but much less than their diameter.

I think this is a good compromise and allows for nicely shaped coils.

Picture #4 shows what I think might happen if you space the magnets too far apart! You could get leakage from the top of the magnet to the bottom, actually creating more poles than you planned on and causing some problems.

Kind of speculating about this, but it makes some sense - if your airgap is a bit over 1/2" in a dual rotor machine, and you have lots of space between the magnets, it seems like some flux will not go through the airgap, and go

straight to the pole on the back side of the magnet. This is not ideal...

I think (speculation) that ideally, in a machine with a wide airgap - that disk magnets should be spaced not touching, but not as far apart as they are in diameter. In practice, there are nice numbers of magnets to use in a 3 phase alternator, like 8, 12, 16...etc. If using disk magnets, I would choose ones that have reasonable diameter, and choose a number that allows for some space, but not too much space between them. Just speculating as usual! Opinions?

It seems to me that pic #4 would only be the case if the steel backing that actually was used for the rotor was too thin and allowed to saturate with flux. If the steel disc was thick enough, it should neutralize the flux path throughout the entire steel rotor. Isn't this what you want, ... enough strength in the magnet to hold itself to the rotor and not slide around. You want to focus the flux path very sharply between rotors. You do not want the magnets flying off of the rotors so that's why it is important to use a steel rotor that is thick enough to allow for the flux path from the back side of adjacent magnets to complete the 'outside' circuit'. When I say outside circuit, I mean the side of the magnet touching the rotor and not the side facing the stator. But your right Dan, this would only be a problem if the air gap was allowed to get too large. RoyR

Re: Disk Magnet spacing in axial flux alternators ([none / 0](#)) ([#4](#))  
by DanB on Tue Sep 16th, 2003 at 04:23:23 PM MST  
([User Info](#))

Well - I should just test it...  
but I think, no matter how thick the steel, some magnetic field would leak back around the side of the magnet to the back side.. or to the steel surrounding the magnet. The lines of force should look for the shortest path "back home" - if the airgap is wide, right around to the back side of the same magnet might be the shortest path. It would be moreso the wider the airgap, or the further apart the magnets I think. Just guessing :-).. I need to get out some iron and test it I guess.

by DanB on Tue Sep 16th, 2003 at 07:05:53 PM MST  
([User Info](#))

that would surely work, except I think it would be a bit large to poke in between the two rotors. It also doesn't give a real good idea of the "strength" of the pole. It would definitely give some idea on a single rotor though.

The Gaussmeter works a lot like a compass, but has a very small probe. It tells polarity though, and field density.

Re: Disk Magnet spacing in axial flux alternators ([none / 0](#)) (#8)  
by hvirtane on Wed Sep 17th, 2003 at 08:01:40 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I think that your pictures are qualitatively correct.

But I'm wondering about the picture 4. if there really is that kind of flux much with thick plates.

I'm more concerned about the empty space between the magnets in that sense that there is no flux at all in that area to hit the coils.

It means that you need higher speeds, when the gaps between magnets are bigger?

I think that there isn't any perfect layout, which is always the best and only good measurements will tell, what is the best configuration using different kinds of magnets.

With every layout there are some compromises to be made?

- Hannu

Re: Disk Magnet spacing in axial flux alternators ([none / 0](#)) (#9)  
by DanB on Wed Sep 17th, 2003 at 08:45:28 AM MST  
([User Info](#))

I would agree - no matter what you do, especially if were having a wide airgap... then some compromises are being made. Every move has its pros and cons.

[ [Parent](#) ]

Re: Disk Magnet spacing in axial flux alternators ([none / 0](#)) (#10)  
by troy on Wed Sep 17th, 2003 at 11:47:03 AM MST  
([User Info](#))

Yet another interesting discussion. I would point out that a dual rotor alternator is allowed to have TWICE the "air gap" from magnet face to magnet face (compared to a single rotor, from magnet face to lams) with no degradation in performance or flux loss to adjacent magnets. In a dual rotor setup, each facing magnet of a pair contributes to the transmission of the flux. Think of it as the one magnet pushing the flux and the opposing magnet pulling the flux. But if you have a single rotor, the lams can't produce any "pull", but only contribute a better conduit for the push of the single magnet.

I don't have a gaussmeter, but it would be fun if the Dans could do a quicky experiment to confirm the flux readings between to neos 1/2" appart vs one neo (same size, etc) 1/4" space from lams. You would need a small hole in the lams to measure the flux at the face of the laminations.

Anyway, keep up the excellent work,

troy

I dont have a good enough 9V battery for my Gaussmeter! Tried....  
Maybe after my next trip to town.

[ [Parent](#) ]

9V battery woes ([none / 0](#)) (#12)  
by TomW on Wed Sep 17th, 2003 at 01:32:21 PM MST  
([User Info](#))  
<http://oneota.net/~earthsourcepowr/>

DanB;

I dont have a good enough 9V battery for my Gaussmeter!

When I started messing with data logging with an RS232 meter to the PC I almost immediately dug out a 9 volt DC wall wart and a battery clip from the junkbox. Since the PC runs off AC I simply plug the wall wart into the power strip the PC runs off of. When the PC is powered up the meter is automagically on too.

Seems like in your case you generally would be using the meter in an area where AC is available so this may help. If you use a 9 V battery clip you can always pop a battery in there if you need to go roam with it. Those 9 volt batteries seem to go bad at the worst times. Just my \$0.02. Be aware that the polarity is "backwards" from how the clip may be marked when you use it this way! Mine had red for + and black for - which is good when it will hook to a battery but opposite when you use it as the battery.

Cheers.

TomW

Re: Disk Magnet spacing in axial flux alternators ([none / 0](#)) (#13)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Sep 17th, 2003 at 02:31:21 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I've run some similar tests using my magnets for a dual rotor system. The magnets alone show 3200 gauss, on steel show 4500 gauss. Between two rotors and a 1/2 " gap I'm getting about 6800 gauss.

The same set up using 1/2" thick coils over a lamination I get about 4800 at the lamination.

Another setup with a slotted stator and the air gap is .02" reads 9800 gauss in the air gap. Doubling the magnets over the slotted stator jumps to 1.3 Tesla in the gap.

The dual rotor system is much better than the coil over iron system but still falls behind in the overall power you can achieve with a slotted stator. There are advantages and disadvantages to both systems but for the simplicity in building, coil over lams is the simplest, the dual rotor comes in second and of course the slotted stator last. Power wise and efficiency the order is reversed.

I've been contemplating a way to decrease the gap between the two rotors by using the overlapped coils 3phase wiring. I think that has bothered me most about the design. The inline 3phase version has to create all the voltage in fewer coils which makes the amount of turns high and the gap between the rotors larger. By spreading the coils out you need fewer

turns thus keeping the magnets closer to the flux.

I haven't built one as yet but my idea was cut out a ring in plastic. Drill the holes around the outer diameter that would represent the slots in the stator and saw through the top layer of each hole just wide enough to get the wire through. Once wired you would have a very thin stator. From there you would make a mold to make the mounting tabs and pour over the wire in those areas. Still working out some details on the idea but you get the picture. Another idea was to build 2 rings with hooks and wire it to the hooks, It would look like spokes in a bike but the wires would be allowed to spread out a bit that way so the later is still prime in my mind.

Have Fun  
Ed

Re: Disk Magnet spacing in axial flux alternators ([none / 0](#)) ([#14](#))  
by troy on Thu Sep 18th, 2003 at 10:08:36 AM MST  
([User Info](#))

Hey thanks Ed, excellent food for thought. A slick easy cool strong overlapped thin three phase stator seems to be a very elusive beastie. But I keep thinking about it...

Also, if I embed a 3/8" copper tube for cooling around the outside edge of the stator next to the coils, will the flow of electricity in the coils induce eddy current in the cooling pipe?

Best regards,

troy

more fun with DanCad!

In the last couple windmills I made I took lots of pictures but never made things very clear about exactly how they are wired up.

In response to Paulpics posting, and lots of email about how to wire up the 3phase stator where we have 12 magnets, and 9 coils I made these drawings.

Each coil is numbered - and colored, according to which phase it's in. Each coil has a "start" - which is the inside, and an "end" which is the outside. The "starts" are labeled A, B, and C, and the "ends" X, Y, and Z.

So we have the choice to wire the stator into Delta, for lower voltage and lower resistance... and higher current, or Star for the opposite. The windturbines I made recently are all wired in Delta and the picture above shows the connections. Then we can either use 6 diodes, or 2 bridge rectifiers to rectify the 3 phase alternating current into direct current which we hook to batteries for charging. In practice - I actually use 4, or 6 35 amp bridge rectifiers -

3 new wind turbines to test!

---

We finally finished up 3 machines yesterday. The first couple days of construction are here:

<http://www.fieldlines.com/story/2003/7/31/23486/2284>

Hopefully Friday we'll find time to test them all. These are all very similar to the Caboose windmill we made earlier this year: <http://www.otherpower.com/davesmill.html>

The only real difference being slightly shorter coils and slightly lower resistance. The stators all have 9 coils, each 65 windings of AWG 14 wire. They are dual rotor alternators, so each half of the alternator has 12 magnets 2" diameter X 1/2" thick for a total of 24 per machine. DanF named them early in their construction, Curly, Moe, and Larry :-).

Curly is a 10' diameter machine. The alternator cuts in at 110 rpm. This was the first machine to be finished, and all along the way it kept 1 step ahead of the other two. This machine will actually get installed down near town. We're looking into the possibility of grid tying it... just for fun! I wonder if anybody has any good advice about the best, and most cost effective way to do this.

Moe is also a 10' diameter machine almost identical to Curly! This will go up at TomH's house and hopefully help out his batteries some, 'cause they need it especially in the winter time.

Larry is basically the same as the other two, but due to his tower situation... and for fun, we made this one smaller. It's got an 8' diameter prop on it and the tail is shorter (4' long boom) and smaller. In an effort to better match the alternator to the 8' prop, we actually widened the airgap about 1/4" which increased the cut in speed to 160 rpm. This will go on a tower which DanF is building on the side of his house... it's a small lattice tower suspended in the center of tires which he's got bolted to the house. It'll be interesting to see how that works... find out how much noise it makes inside!

Friday we'll do some truck testing to get rough output figures and make sure they run reasonably square to the wind and furl at reasonable windspeeds before we put them up. Next week we'll start on some towers!

([User Info](#)) <http://homepage.ntlworld.com/s.amesbury/homepage.htm>

Wow looks like a production line you going there, the way you Dans are going you could have your own community wind farm up with power supplied to all the houses up there. Of course that depend on the distance between houses and could get costly in cable.....sean

Great to see those 3 reaching completion. Looking frward to hearing about them cranking out the power.

As for grid intertie, the simplest solution is probably a Trace SW or a 'power station'. That would do a god job of turning the DC into grid AC. I am not sure if Outback have a product to do that for you yet. Hugh Piggott <http://www.scoraigwind.co.uk>

## [Too much fun! 3 windmills...](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Thu Jul 31st, 2003 at 11:48:06 PM MST

[Wind](#)

Lots of pictures...Hope you have broadband!!

We set out this week to build 3 wind turbines along the lines of the [Caboose Windmill](#) which we made last month. TomH, who is scraping by with about 250 watts worth of solar panels, and DanF, who is doing somewhat better but needs a lot more power year round, each get one, and there will be one extra. So mostly DanF and TomH worked with me on this, although other neighbors dropped by and helped out some too. Two of these machines will have 10' diameter props, and DanF's will be somewhat smaller due to the nature of his tower. We're building all the machines identical, except DanF's will have a shorter tail, and we'll probably wind up making the airgap extra wide so that it allows a smaller prop to spin up to a reasonable speed.

We started out with lots of pipe, allthread, and iron bar. Each windmill takes about 5 1/2' of 3/4" steel pipe, 7" of 1" steel pipe, and 70" of 1/2 - 13 allthread. Each machines also requires 42 1/2-13 nuts.

For each machine we'll need 24 magnets 2" in diameter and 1/2" thick. Each one will have 9 coils of AWG 14 magnet wire, 65 turns each. This comes out to almost exactly 5 pounds of wire.

Of course, each machine requires some Volvo parts. I like to look for the 11" brake rotors off more modern cars... they will replace the 10" rotors which come with the struts we'll use to make the machines from. Since these are dual rotor alternators, we'll need 2 11" brake rotors for each machine.

Pictured above you can see the set of plans we started with!... these will be almost identical to the caboose windmill, although I'm making slight modifications to the coils and taking notes along the way.

I picked up 6 strut assemblies in town, we'll only need 3 of them now. We'll have to completely strip all the parts off these. One must be careful taking these apart, the spring is under great tension! Best is to have a spring compressor for the job, but if not... be very careful! I undid these with a pipe wrench and aimed them out my door. Some of the springs flew over 20'!

DanF is turning the rotors down flat, and leaving a slight lip on the outside edge to help hold the magnets in. Half these rotors will have to have the center hole turned out to about 3" diameter, since the back rotor has to fit over the back side of the wheel hub, and the hole is too small. .

Pictured above Tom is cutting up allthread for the studs, and making the brackets for the stator. We'll also have to cut the strut assemblies, and several pieces of pipe for the tail assembly

Above is shown the studs which hold the alternator together, and the brackets for holding the stator on. The small wedge shaped piece sets the angle for and holds on the tail pivot.

We cut the strut so that the spindle could be welded to the side and offset from the tower about 5". Pictured above Tom is welding all this together.

Pictured above we have 3 main windmill frames welded up. You can see how the tail pivot is angled at about 20 deg.

DanF and Tom are working on the mold. It's basically a 3/4" piece of plywood 18" square, and on top of that we have 1/2" material with a hole 14" in diameter in it. In the center of the mold there is an island (Aslo of 1/2" material) 5.5" diameter. I think next time we'll reduce that to 5", as it would fit around the studs and make the coils fit a bit better. This worked fine though. The lid for the mold is simply a disk of 3/4" plywood 14" in diameter.

I drilled through all 9 stator bracket pieces at one time. The stator bracket is made up of 3 parts, each of 2" X 3/16" steel bar cut 7" long with a 120 deg angle so they fit together nicely. A half inch hole is drilled in each one at 6.25" from the center of the bracket. Once the bracket is assembled and tack welded together, we drill a hole in the center 1 7/8" diameter with a hole saw. This allows it to fit right over the wheel spindle. Once that's on, we'll weld it on there.... you'll see in the following pictures.

Pictured above is the finished stator mold. You can see where we drew lines to help locate the coils properly. We caulked all the seams between the wood, and before we actually use the mold we'll grease it carefully with axel grease.

Pictured above are all the brake disks which DanF turned down on the lathe. Doing this leaves the nice lip to hold the magnets in, and also leaves a nice rough surface to help glue the magnets in with. I think it's important, especially with used brake disks which often get worn down to a smooth, hard - shiny surface... not good for gluing to, and magnets would slide all over it. After we turn them it's quite rough - lots of friction, yet flat. We clean them carefully with gasoline or laquer thinner before we glue the magnets on.

Pictured above you can see the assembled stator brackets. We've only drilled the center hole (1 7/8") in one and layed it on there, the other two still need finishing.

I'm starting to wind coils for the 1st machine in the picture above. The spool of wire is laying on a bolt which is held in the vise, and I'm keeping fairly tight tension on the wire with one hand while I crank with the other. Again, each coil is 65 turns of AWG14 wire. This goes quickly, each coil takes about 1 minute to wind. Once wound up, we use thin viscosity super glue to hold it together, with accelerator to dry it quickly. Once the glue is dry the coils lift right off the form. It's important to wind every coil the same, and keep them tight. It's wise to leave the leads on each coil about 12" long.. since this a 3 phase machine, each coil is hooking to another coil which is 120 deg around the stator from it, so there is some distance to be covered!

Here you can see the coil winder. It's heavily waxed with crayola crayons... this keeps the super glue from sticking to the wood and helps the coils come off easily.

DanF is spacing out the magnets on the back rotors. We do the back ones first, and then we can pretty much assemble the alternator with only 1 rotor. We then will put the 2nd rotor on without any magnets, and mark out where the magnets must go. This is important, because wherever there is a magnet on the back rotor, there must be a magnet with the opposite pole on the front rotor facing it. We pretty much lay out the 12 magnets on each back rotor by eye, there's about 3/8" between them. We then take playing cards (as shims) and go around making sure that the space between each magnet is the same... our tolerance here is the thickness of 1 playing card!

Tom is wrapping tape around the outside of the magnet rotors. This serves as a sort of mold, so that when we pour resin in it won't leak out the sides! Not real pretty, but it seems to work out OK.

DanF is using the mold to trace the size of the ring he'll have to cut out of the fiberglass fabric which we'll use to reinforce the stator on both sides of the coils. The ring he's cutting is 14" outer diameter and 5 1/2" inner diameter so it fits exactly the size of the stator.

Pictured above I'm gluing up the inner part of the mold for the magnet rotors, made of a tinker toy can and playing cards. This holds the resin from leaking to the inside.

Here we're greasing up all the molds with ordinary axel grease.

We're getting ready to cast one stator and 3 of the back rotors.

We've poured the resin, and the stator mold cover is on, with lots of weight on top of it!

After a couple hours we removed the stator from the mold. It came out easily and looked just fine!

This brought us to about the end of our first day. We got 3 of the struts completely welded up and ready to go with stator brackets and everything.

We also finished molding all 3 stators on the 1st day. They all turned out OK, and it was a bit surprising to me that we never scrapped any parts.

We started the 2nd day with some coffee, and got right to pounding the studs out of the wheel hubs.

The studs are replaced with 10" pieces of 1/2" - 13 allthread.

I'm holding down the wheel hub while Tom carefully lowers the magnet rotor

onto the back of it. This can be a bit tricky, since the powerful magnets are attracting it to the sides. Two folks makes it somewhat easier, although it can be a 1 person job with some patience and focus.

Above is pictured how the back rotor fits over the back of the hub. Now it is easy to see why we had to turn the center of the brake disk out some... before it would not fit on in this way, the hub was larger than the hole.

We clamped the stators to the stator brackets, and got them centered. After that we drill through the 1/2" holes in the steel bracket into the stator so that the mounting holes line up perfectly. It's important while clamping to make sure that the holes will go through resin only and not hit the copper coils! Once these are drilled out, we mark them so they always go back on the same

way.

Above we have the back rotor and the stator on one machine. At this point, with 1 rotor on, the alternator can be wired up and tested to some degree. It won't work nearly as well as it would if it had both magnet rotors on, but it works well enough to test.

A great way to strip magnet wire is with a propane torch... the enamel burns off quickly and light brushing with sandpaper leaves nice shiny copper ends.

In the picture above we have the stator completely wired in Delta, with the leads coming out to 3 brass screws (1/4-20). It's a 3 phase alternator. Each phase consists of 3 coils wired in series.

This picture shows the tail pivot with the notch which sets the stops. These will pivot over the stubs on the machine, and the tail is welded to them.

When the studs are tightened (very tight) to the hub, they bend a bit. Since they are 10" long, they never wind up fitting through the holes of the 2nd magnet rotor by themselves. Pictured above Im using an inverted (Im putting in on backwards to avoid the attraction of the magnets) brake rotor to determine how badly the studs will fit the holes! In the end we'll have to adjust them all... which is sort of a trial and error process of putting the rotor up, seeing which ones need bent, and bending them best we can.

Here I'm bending the studs with a long pipe. This actually goes pretty quickly.

Once the studs are straight, I drop a blank (its got no magnets on it) rotor onto the alternator, and carefully mark where the magnets need to go and what the polarity should be. Again, if there is a North pole on the back rotor pointing out, then there must be a South pole on the front rotor facing in towards it. We carefully mark for this, and then we mark 1 stud, and 1 hole - so that from now on it must always go together the same way.

After all the front rotors are marked and the magnets placed, we glue them in same as we did the back rotors. Tom and Rich are doing this in the picture above.

We snapped the front rotors on, and here Tom and Rich are testing the first alternator. We didn't check rpm, but this seems to be about the same as the last caboose windmill we made... generating 12 volts at around 100 rpm or so. They all seem very similar and very effective at slow speeds.

That's pretty much where the end of the 3rd day got us! Mostly it's been 3 people working for 3 days on this and we pretty much have 3 machines done except for paint, props, and tails. We're having too much fun!

Very nice Dan and thanks for the cobalt mags. :- ) Im currently working on that machine. I just wanted to say that there is another way to make sure the faces of the mags match up on both rotors. What I do in assemble the dual rotor machine so that it has the rear rotor in place and then the stator just like you do. I then do all the common tests. When it comes time to match up the mags before gluing the second rotor, I mount the front rotor on backwards so that the magnet side is facing out (except of course there is no mags glued yet). I then take a paint pen and mark the two rotors so they only will go on in one direction only. I then take a "T" square and hold it perpendicular to the two rotors (edge wise). I hold the inside of the square to the rear side of the rear rotor so that I can follow and trace a center line to the front rotor. I do this all the way around the front rotor so that I have perfect increments around the side of the front rotor that line up with the mags on the rear rotor. I then remove the front rotor and lay the square across the face of the front rotor and follow my trace in to the center. This will allow you to see where the center of each mag should go on the face of the front rotor. You just have to make sure that you follow the poles over and write on the rotor "N" or "S" depending on which pole should face in (it will be obvious with the square when you follow across to the second rotor). You then should place your mags and space them with the shims and thats it (well, glue and resin of course :- ) ). Wish I had

a pic of how I did it. Hope you can visualize. Sounds like your having fun!!!  
RoyR

([User Info](#))

Hi Fred.

The machines are all dual rotors, meaning that there are magnets in the front and back of each set of coils. No laminates are needed for such a set up since the magnets of the rotor in front are being attracted to the magnets of the rotor on the other side of the coils.

Aren't you working on a double rotor machine yourself? Same principle.

Xeroid.

Howdy Dan. I take it these magnets arent as thick as the first one the caboose you built a few weeks ago. what is the approximate thickness of the goop you put over the top of the actual magnets themselves once you put the tape around the rotor. This should be a good comparison on the magnet strength. Looking forward to the results and the finish wiring . Thanks JB Dayton Nevada

My mistake there Dan. The magnets are the same. Im getting a clearer picture on this now. the bearings and everything on the back driving the front hub through the long all thread studs.i like it. I was wondering i got some delrin here or some kind of plastic about 3/4 inches thick. i was wondering if i might drill some big holes in the put the coils in the center and cover both sides with some thin aluminum. i guess the stator could be square and you could use 4 studs also. One thing I forgot is how much is one magnet supposed to cover in coil area. a coil and a third? i guess that is what it works out to be. 9 magnets 12 coils is that right. Getting late . Time to stop thinking. Later on. JB

by DanB on Sat Aug 2nd, 2003 at 10:16:12 AM MST  
([User Info](#))

Hi JB -  
you could probably make the stator from delrin, insert the coils, and glue them in there, that would work fine.  
Aluminum covers would be a bad idea though... you'd have serious eddy current problems! You might be surprised when the alternator barely wants to turn at all.

Making the mold from plywood is really easy, and we simply place the coils in the right spots (or try) and then bring all the wires out. When we mold the stator, we first grease the mold, then put down some polyester resin (I get it from Autozone in 1 gallon cans for about \$20), then we put down some fiberglass fabric to reinforce it, then we put in the coils over the top of the fabric. Then we mix up new resin and mix it with talcom powder and pour that over the coils so it pretty much fills up the mold. Then we put down more fiberglass fabric, and pour resin over that - and put the lid on the mold.  
It's real easy, probably a lot less work than messing with delrin and I think a bit stronger and less flexible.

You don't want any metal other than your copper coils in the stator...

Thanks Dan. Got ya covered on the stator . Ill make it all resin and fiberglass. another ??? Im not real hot on the wiring yet, in fact im a little slow on it. lets Call any of the nine coils #1. do we start off with one wire of 1 coil at a copper lug and then it is serised thru number 4 coil 120 degrees away then seriesed thru #7 coil 120 degrees from #4 coil then finished of with the remaining wire of #1 coil at the same copper lug we started with. Is this correct???????? and you do the same for coils # 2 -5 and 8 and 3 -6 and 9 taking them coils to their respective lugs for the total you got on this one of 3 lugs. If this is correct where do you go from here and where do you pick up the ground wire. I noticed on the papoose windmill you had 6 lugs but i dont want to confuse myself more on this. can you clue me in. JB

[Wind](#)

Broke out my CAD program and am attempting to explain this again!

---

I was reading the post below about it, and I've also recieved some email so I thought I'd try my best to explain how it works. It's a bit of a balancing act between offset, tail boom length, prop diameter, tail weight... A good idea would be to buy Hughs plans or check out Ed's software unless you enjoy lots of trial and error (like I do!).

Pictured above is a very simple furling system that uses a spring. The tail ALWAYS stays with the wind, but when the wind gets too strong, the prop, and the alternator pivot on the mast and turn away from the wind. In this case, the force of the wind against the prop has to overcome the tension on the spring. You can see the tail is slightly offset to one side to compensate for the fact that the alternator and prop are offset to the other side. The length of the tail boom, and the size of the tail, and the angle at which the tail is slightly offset must be proper in order to compensate for the offset of the alternator and the diameter of the prop. The tail is mounted on a vertical pivot (so the pivot for the tail is parallel to the tower). So the picture on the top left is of the machine during normal operation, and the lower picture shows how it would be if it was furling out of a high wind.

Above is another CAD drawing of a very similar system, this is pretty much what Hugh Piggott has perfected.

Just like the spring system above, the tail is mounted on a pivot. In this case however, the pivot is offset to one side, and it is at an angle (about 20 deg usually) to the tower. The tail is always in the wind, and in order for the rest of the machine to turn away from the wind, the tail is raised because it is pivoted at an angle. So this works exactly like the spring system, except that instead of the force of wind on the prop having to stretch a spring in order to furl, in this case it must overcome the weight of the tail in order to furl. The system is easily adjustable by changing the weight, or length of the tail. It's nice because it is simple, and reliable. Springs make noise, rust... wear out, and break... gravity will never let you down!

There's a bad... but kind of fun picture of my machine in a violent storm. You can barely see... the tail is up high (and with the wind) and the rest of the machine is turned almost completely out of the wind, yet still spinning nicely and producing reasonable amounts of power. It all works very quietly, reliably and smoothly.

Great drawings Dan! This must be the notorious DANCAD software that everyone needs to have. I like it!

I've tried alot of different ways to furl these systems. Side furling, tilt, spring and a few stupid ideas of my own. The spring system works but has a built in problem... as the spring stretches it progressively adds more tention which means higher winds to achieve a reasonable furling. I must say that hugh's gravity system is the best I've seen (and used - with several under my belt). The simplicity and functionality of the unit makes it about the best choice for home building.

Have Fun!

Ed

Re: Furling system ([none / 0](#)) (#8)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Jul 23rd, 2003 at 12:18:48 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I built one out of wood , "U" bolts , and hinge that worked out quite well. It was a small machine with a 6 ft prop. Used an Amtek motor U bolted to plywood with a 1.25" water pipe U bolted to the same plywood. The hinge was bolted on at a 20 degree angle and the tail bolted to the hinge. A steel tail stop was bolted to the top. A quick and fun project. Kind of a "windmill in a day" project.

Too much fun...

Ed

Re: Furling system ([none / 0](#)) (#4)  
by DanB on Wed Jul 23rd, 2003 at 10:01:47 AM MST  
([User Info](#))

yes, I do like that system very much. I tend to wonder what the "upper limit" is for prop diameter used with this system. Undoubtably there are strange forces on the blades while it's furling, and while it's furlled... I suspect that in very large machines it might not work so well.

Hopefully... we'll never find that limit!

DanB,

BOINNNNNG!!! I think I finally see the crucial piece of information that I've been missing!

Dan wrote:

"the tail is mounted on a pivot. In this case however, the pivot is offset to one side, AND IT IS AT AN ANGLE (about 20 deg usually) TO THE TOWER."

I had understood that the tail was not mounted perpendicular to the plane of the blades. I had assumed that was the 20 degree angle. But that is really what you are calling "offset to one side." THERE ARE ACTUALLY TWO ANGLES INVOLVED.

Viewed from the top - the tail is offset from the plane of the blades by some number of degrees. But the hinge is also mounted at an angle from the straight up of the tower. So the tail doesn't go straight up and down like a see saw. It's leaning.

This means that the tail vane may not really be exactly perpendicular to the ground. It may actually lean to one side at 20 degrees (in your example). So wind can exert force that gets under the vane to push it up.

What had totally flumoxed me was that I couldn't understand where the lift was coming from? I had missed the fact that the tail doesn't move up and down exactly perpendicular to the ground.

Sorry to waste so much bandwidth on this, but I just wasn't grasping the situation accurately. I'd missed the second angle.

Thanks Dan. You're my hero - (just not an anonymous one.) ;-)

Bach On

I think he's got it ! ([none / 0](#)) ([#6](#))  
by Chuck on Wed Jul 23rd, 2003 at 12:01:10 PM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

yes, I think you have it now.

For a little further illustration, or to confuse things more, depending... I show below my wind generator viewed from below during a calm. You can see some of the angles involved. Note that I didn't bother to make the tail perpendicular to the tower and it serves to highlight the furling angle.

Also, since someone asked, there is no welding on this particular machine's furling system. In fact there's no welding on this machine at all. I used a couple cheap pillow blocks and a 12"x1/2" bolt to hold the tail.

Chuck

Re: Furling system ([none / 0](#)) ([#7](#))  
by DanB on Wed Jul 23rd, 2003 at 12:15:44 PM MST  
([User Info](#))

Ideally the tail could, and probably should (but it doesn't really matter) be perpendicular to the ground in normal operation. The angle of the tail doesn't give it any lift... or at least, it's not necessary for that to happen. The tail is lifted only by the force against the prop.

Actually Dan, I think it does matter. Angled the way it's shown in the picture the tail does provide lift itself, which is not desirable. My experience has been that this machine furls too soon and part of that I blame on the tail surface being at that angle. This is one of things I'm fixing this week.

Chuck

Re: Furling system ([none / 0](#)) ([#14](#))  
by DanB on Wed Jul 23rd, 2003 at 05:24:32 PM MST  
([User Info](#))

Yes... I guess mainly I meant.. that if the tail is not square with the tower it doesnt matter too much, it means that it's probably got less surface area since it should be with the wind all the time, so if the tail is not vertical it has to be a bit larger. If in its resting position it's both not vertical and tipping down (or up I suppose) then it could get some lift from the wind which would not be ideal. So.. it should be vertical...

Itll be fun to see yours after that's fixed... it would benifit in both performance and appearance! I'm dying to see your next one too!

Hi Bach on

I actually never built myself one of these furling system.

I guess you have a grab on it now, but the fact that the tail vane rise is not caused by the wind exerting a force that gets under the vane to push it up, but simply because It's mounted on a pivot at angle relative to horizontal axis (22 deg relative to the tower or 68 deg relative to the ground).

In the spring system the pivot on wich the tail vane is monted is not on an anle relative to the vertical plane. It's parrallel to the tower and vertical to the ground (0 deg to the tower; vertical plane, 90 deg to the ground; horizontal plane) so when the system is furling the tail vane rotate around the vertical axis, staying in the same plane relative to the ground (horizontal).

Like a garden gate does when you open it. It's rotating around the vertical axis staying in the same plane relative to the ground (horizontal plane). Now imagine that the stupid snow plower strucked the gate post and bented it 22 degree from the vertical axis (the tower)and the edge of the gate is now barely touching the ground when close. Now what happens when you try to open the gate, the edge of the gate will rise relative to the ground... wright? The more you open it the more it rises relative to the ground. Cause now the gate rotate around an axis who is no longer vertical to the ground so the edge of the gate doesn't move in the horizontal plane anymore but keep going away from it the more you open it. Now what happens if you let go ? the door will close by itsel (well helped a bit by gravity ;-)).It's the same thing with the fridge's door when the fridge is not level i.e. on an angle relative to the vertical plane.

Now in the second furling system when the force of the wind against the prop rotate it away from the wind and as the tail vane always stays with the wind, the tail vane as no choice but to rotate around that 22deg of vertical axis and the edge of the tail rise relative to the ground.

Anyway, it's only my perception of the thing and I may be totally wrong...

P.s.: please furling guru if I'am wrong tell me :-)

Re: Furling system ([none / 0](#)) (#10)  
by hvirtane on Wed Jul 23rd, 2003 at 01:06:47 PM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Basically this gravity system of furling is the same as used with Marlec small wind chargers for example.

With Marlec the hinge is on the far end of the tail boom.

My friends here are complaining that the system is not really good, when water goes in between the tubes in the hinge and so during the winter there is ice.

I'm still not sure, if the gravity system is better or worse than the old German system with another tail on the same plane as the prop.

I made small drawing of that system during an earlier discussion.

- Hannu

Re: Furling system ([none / 0](#)) ([#12](#))  
by [scoraigwind](#) ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Wed Jul 23rd, 2003 at 03:54:06 PM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

Thanks for such a clear explanation, DanB. So many people ask me about how that works.

There are problems with getting the best angle for the hinge. Each setting has some side angle and some back angle. I usually set it so the side and back angles of the hinge are almost equal so that the power output stays about the same over a range of winds. But the output peaks a little in the middle where the tail is climbing most steeply.

So when I get really fussy I use a different type of hinge with a cam at the top. The tail hangs off a belt or chain, that wraps around the cam, so that the axis of the hinge changes. That allows full control over the tail furling forces.

The Marlec version with only the vane hinged works after a fashion for a while until the force of the wind on the boom alone is enough to pull the rotor back into the wind.

The system with the side vane is great for a type of pump that needs the crank shaft over the well, but has no other advantages compared to the offset rotor systems. The side vane is unstable in operation and ugly.

My perspectives :-)

Hugh Piggott <http://www.scoraigwind.co.uk>

Re: Furling system ([none / 0](#)) ([#17](#))

by Smithson on Thu Jul 24th, 2003 at 04:06:02 PM MST

([User Info](#))

The fact that the lowest setting for the tail is actually [according to Hugh's plans] 100 degrees from the rotation of the blades is what puzzles me. Or 80 degrees [10 degrees off perpendicular]. In other words if the blades were 3 o'clock and 9 o'clock then the tail would be sitting at 11 o'clock not 12 o'clock with no wind. I read some where else that as the wind first hits the machine it settles it tail in the 12 o'clock position with the blades at 3 and 9 o'clock.

What I'm wondering is if you can actually use this to start the machine turning more easily? Let say that the root of the blade is 27 degrees. With the tail at 100 degrees [11 o'clock] would this actually for that time as the wind first hits the blades make the root of the blades 37 degrees and help with starting thr blades in light winds? Now I haven't fully figured this out but off the top of my head it would seem that you would have to have a counterclockwise rotation, but would that help?

My Yard is getting filled with JUNK! I thought I'd post a bit of it here and help keep our classifieds section rolling some. Some of this stuff is going to be pretty much the price of shipping, other stuff a bit more. Keep your eyes peeled in the near future, as we'll surely be coming up with more JUNK in the next few weeks as we clean up a bit!

First come first serve on this stuff! - and I'd rather one person didn't take it all. One item per person... Just send me an email: [danb@starband.net](mailto:danb@starband.net), and make the subject of the email "Garbage Sale" (so I don't accidently erase it along with gobs of spam!) I don't want send any of this out of the US.

Lot #1: There's been lots of discussion in the past about playing with ceiling fans! If any fan has potential, this may be the one! It's very large, and heavy, with nice looking castings of iron. Might make a neat wind turbine... or slow hydro alternator. The rotor runs on a bushing, which probably wouldn't hold up long to high rpm. The inner diameter of the stator is almost 9", and the rotor is slightly smaller. I suspect one could make a pretty interesting alternator with this. It may need re-wound, or it's possible that the coils could be wired together differently and used as they are with proper magnet placement. A fun project, but one of those things I'll never get to. I'll send it to the first interested party for the price of UPS shipping... about \$15 in the US.

Lot #2: Here's an old servo motor with something on the back (maybe a tach?). The motor itself is 4" diameter and about 7" long. It might make a good small windmill, but I'm not sure - there are not voltage or rpm ratings anywhere on it. It appears to be a fairly typical PM DC motor with brushes and a commutator. I think we could ship this out for \$12.00 within the US. I've not tested it - don't know if it works or anything!

Lot #3: Bargain Alternator Kit! These are some old Samarium Cobalt magnets from old hard drives. The Samarium Cobalts are not quite as strong as the NdFeB, but fairly close. These could make a nice alternator. They are about 1" wide, 1.5" tall and 3/8" thick. I've got 15 arranged here in a partial circle (About 10.5" diameter) and there are 20 more in the assemblies which need to be taken apart (Phillips screwdriver) to get the magnets out. You could build one tight ring (and have a few magnets left over) with all the magnets touching, or... put some space between the magnets and have enough for a dual rotor machine. I'll also throw in an old, dirty 5 pound roll of AWG 16 magnet wire! \$40 includes shipping.

Lot #4: Too lazy to build your own windmill? Here is a SW windpower Air 403. It's complete... the rubber gasket might need replaced. Here is the thing... I helped a neighbor fix his up last year, and SW windpower got confused (when they fixed his) and put the wrong stator in! So we swapped stators around a bunch and found that his machine worked better with my stator in it! And.. mine has his stator in it. His stator is for an Air 303 - so this doesn't work right. But... I did get a brand new Air 403 stator for it from SW windpower, and all it needs is to be installed which is pretty easy. You'll need allen wrenches and a bit of mechanical talent, but not much... all the parts are here, it's a 5-10 min fix. There is a small chip out of the nose cone near one of the blades that shouldn't affect anything. \$250 includes shipping, and I'll let the buyer return this if not satisfied for a refund.

Lot #5: This a "converted" 2hp single phase induction motor, same one I used in one of my old windmills: [http://otherpower.com/danb\\_windmill.html](http://otherpower.com/danb_windmill.html)

It still works fine. It cogs a bit, and the steel hub (a gear) is welded on the shaft, so you'd have to grind that off if you need to replace the front bearing. Pretty heavy, I think it'll be about \$20 to ship - so, \$20 includes shipping.

So.. if you want any of this \*junk\* send me an email, or just reply to the posting letting me (And everyone else know) which LOT # is "sold" and as soon as we get payment (or we can do COD for an extra \$5) we'll ship it out!

### [Anonymous postings](#)

By [DanB](#), Section [Site News](#)

Posted on Tue Jul 8th, 2003 at 11:07:06 AM MST

[Scoop](#)

All users will have to sign up an account.

Due to some problems we've had recently, and the fact that this board is getting more use lately, we've decided to require that all folks posting on the board sign up for a user account.

We've had to delete a couple of REALLY bad spam and postings lately - fortunately we caught them quickly before too many folks saw them! It's kind of unfortunate, but it will have it's benefits.

Anybody with a user account can easily upload pictures onto our server and use them in their postings. Folks who have been regularly posting without an account may not be aware of this.

Getting an account is easy.

- Use the 'create new account' link in the login box on the right side to start. You just need to enter your desired username and a valid Email address. This REAL email address will never be posted to the board unless you do it yourself...on your User Preferences page you can enter an email address that will be displayed. Many people use Hotmail or Yahoo addresses for this.

- In a couple minutes you'll receive an Email from Otherpower.com containing your username and a cumbersome (but strong) random password. Log in and you'll see whole bunch more menu choices available to you.
- You can change your password with the 'user preferences' link in the menu. Be sure to check out 'display preferences' and 'comment preferences' too -- there's some powerful features in there.

Sorry we had to do this, and I hope folks realize ... were not trying to drive anyone out here! Requiring a bit of accountability for postings should hopefully drive away some of our troubles, and make things a little easier for us in the end. We like to take days away from the computer everynow and then, but lately that has not been possible as we've had to keep on top of this board, and Anon postings are pretty much the problem.

If anybody has problems setting up an account, or simply wants us to do it for them - just send us an email: [admin@otherpower.com](mailto:admin@otherpower.com) - we'd be happy to setup your account, and email you your password. (sometimes it might take us a day or two, but we'll get to it!)

No more cloak and dagger users. Cool. All too often anonymity is used by those who don't wish to be accountable for what they say or do.

It is unfortunated for those users who just don't have a great deal of computer saavy, but in the end, I think this is the right move.

Well done guys.

Xeroid

I think that is a great move also. Even though I had trouble in the beginning of this new board, I feel all the worthwhile people will figure it out and join us. Thats what this is all about anyway, right?? figuring things out?? This board is too valuable to all of us to allow spammers, solicitors and instigators to intervene. Good move!!

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

While this move is maybe the only thing you can do at the moment, it probably will affect the quality of the board as well.

It is quite certain that there are many such people, who for different reasons don't want to give to you any valid email address, but anyway wanted to be involved in these discussions.

But it might as well create counterattacks. It is quite easy to obtain all the time new email addresses, create an account and to make even worse spams?

It anyway creates harm to such people, who don't want you to know their address and who anyway enjoy the company somehow to change their email addresses regularly.

- Hannu

Hi Dan, I didn't see a place on the new board for profiles like the old board. Did I just miss it? I like the new board, by the way. RobD

Re: Anonymous postings ([none / 0](#)) (#8)  
by TomW on Wed Jul 9th, 2003 at 08:46:47 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

RobD;

I know you addressed the question to Dan but I'll take a shot at answering it.

I think the closest thing to "profiles" would be either "user info" or the Diaries Section with the Diary being the only thing a user can really edit.

So if you want to share your personal info like general location, contact info, etc thats the best option I can think of.

Personally I have found that my info from the old board has been used to sign me up to spam lists and everything from the gun-owners action committee, Republican national committee list to the Libertarian Party Newsletter. Not to mention several emails threatening everything from legal action and computer attacks to personal injury.

I leave it to you to figure out who might be doing it. I certainly wouldn't want to be in his, er, pants when the authorities investigate the source of said email threats.

Just noting a valid reason for not posting too much personal info online.

Cheers.

TomW

-----

Yes, these are some of the things, why some  
people wanted to stay 'anonymous heroes' and  
anyway develop these technologies further.

It is quite easy to see that a kind of fight between fossil  
oil industries and renewable energy industries is among  
the most important issues of our time concerning  
the world politics, not only usa inner politics.

(For example: It is quite common in Europe to have an  
opinion that the main reason or even the only one  
for mr bush and his allies  
to attack iraq was just the oil available there.)

Please explain ([none / 0](#)) (#11)  
by TomW on Thu Jul 10th, 2003 at 06:50:32 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Hannu;

Damn, I know we have a bit of a language barrier but just what  
the hell does that have to do with my comment? You can easily be  
a registered user without other users knowing your info. I openly  
posted my information and it was used as a weapon against me.  
This has absolutely nothing to do with internal or external US  
politics it has to do with a person with bad manners and a worse  
education acting like a spoiled child.

Since you seem to be his only active supporter perhaps its time  
you started a board for him to misbehave on or just let it drop.

I sure hope you and Kevin enjoy your relationship but I think he  
will NOT be missed here.

Cheers.

TomW

Hello,

it is unavoidable that there always are some disagreements, which kind of technology to develop and how to develop it.

I'm myself a kind of anarchist, who thinks that it is not so good idea to make very many people dependent on big companies' rule, who again themselves are dependent on the people, who are forged to pay them. You see that this is the case with power companies, oil companies, weapons industries, etc.

The maybe most cited example of anarchist literature concerning power companies worry about self made energy comes from France in older times, in the age of windmills. Windmills were banned, because they give to some people a possibility to make energy themselves.

Please see somehow the other side of the coin as well, JCP and the other defenders of the anonymity have got their point, too.

Re: Please explain ([none / 0](#)) (#13)  
by hvirtane on Thu Jul 10th, 2003 at 09:05:34 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I'm generally getting quite a lot of garbage mail.  
I just tried to guess, why you got it.

I started years ago to get a lot of  
garbage mail, when made some notes  
concerning some world politics issues.

My message had nothing to do with Kevin.  
Just trying to find out, why  
you got all that garbage mail.

There are different reasons for different people  
to want to stay anonymous.  
There is no way to secure this kind of board from  
experienced hackers to find out your email address  
if it is given to the board admins.

This is the reason I think that it is not so good  
to stop anonymity here.

But for me it means quite little.  
I'm already used to garbage mail.

Lately is has been increasing quite a lot.  
I'm quite sure that it has very little to do  
with anyone posting here, maybe something  
to do with some people  
reading this board, however.

## [More tower fun!](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Fri Jun 20th, 2003 at 10:43:41 AM MST

[Wind](#)

The caboose windmill is up!

We spent the better part of last week building a new [10 foot diameter wind turbine](#) for my neighbor Dave, to help power his [caboose](#) and his future building site.

It's about 200 feet, straight up a steep hill and a wonderful site for a wind turbine. To the east, there is no obstruction... you can see parts of town over 20 miles away, and to the west he's clear for at least a half mile. Tricky thing here though, there is no flat ground at all. I don't care to climb trees and we couldn't afford a crane, so a tilt up tower seemed the only way to go.

After careful thought about location, we decided to try putting a strong, and wide pivot between these rocks, so that it would tip down to the east and he could pull it up either with a winch or his truck down his driveway to the west. The pivot is about 2.5 feet wide and made up of 1 piece of 1.5" pipe inside of another piece of 2" pipe. The tower will be welded to the 2.5" outer pipe, which will pivot over the smaller pipe. It needs to be strong! Since there is no flat ground here, we cannot count on guy wires to hold things up while raising and lowering the tower. It will need to be free standing while it goes up and down.

Here DanF is cutting bits of pipe and rebar that we'll need with the torch.

We cut the rebar at about 10 inches long, and used a hammer drill to make 6" deep holes in the rock. We covered the rebar with epoxy and hammered it in.

Rich beat on the bars with a hammer so that we could get the pivot in level.

Once a couple were spot welded, we hammered the other bars, and the pivot so that everything could be perfectly level and we'd have reasonably tight joints for welding.

Pictured above I'm welding up the pivot to the rocks as best I can with my little 120VAC mig welder!

Dave is jumping on the pivot to see if it moves at all. Of course, it didn't. In the end, we'll do some concrete work under the pivot and around the rebar.

Our neighbor Tom came by and helped do some very professional welding with the torch! (and gave us some pointers)

Above I'm arc welding on the gin pole and assembling the tower. The tower is 30' tall. The 1st section (15feet) is 2.5 inch ID schedule 40 steel pipe. The 2nd section slides in and is made of 2" pipe, it's about 13 feet long. Then it tapers down to 1.75" pipe and a little stub of 1.5" pipe which the wind turbine fits over. The gin pole is 2" pipe, and its attached at the pivot, and connected to the top of the tower via steel cable.

Pictured above the tower is pretty much done. I did not catch our guy wire mounts in pictures. At the top of the mast, I simply welded chain around the pipe and hooked 3/16" guy wire to that on 4 sides. At the bottom, we found

bedrock for 3 of the locations, and one is attached to a chain around a big tree! (this is a temporary measure - Dave is going to make a more permanent anchor for that one). To go into the bedrock, we did the same as for the pivot. We drilled 1/2 inch holes down 6 inches deep into the rock, and hammered rebar (coated with epoxy) down in. We welded chain to the rebar so that the guy wires could be easily attached.

At this point we test raised the tower with no guy wires attached. It went up smoothly, and we then could attach the guy wires and tighten them up. Once that was done we unhooked the guy wires and lowered it. (it seemed that some of the guy wires might tighten on the way down). After it was down, we checked the length of the wires and found that one gets pretty loose, and another one to the south was just about perfect! So, as it turns out, we can safely raise this tower with the guy wires attached! This was a bit of a load off my mind.

Dave assembled the wind turbine on the end of the tower. Notice how we hold it off the ground with a barrel. This will protect the blades and the tail when it's lowered. We ran the power cord for the wind turbine right down the inside of the tower, so that it can yaw easily. There is a big 3 prong plug at the bottom so that it can be occasionally unplugged and untwisted should it be necessary.

We then pulled it up with the truck and everything went smoothly. The machine started turning in the first breeze and was making power immediately. We figure the cost of this tower... about 2 folks worked 2 days on it. (half the work was just moving a ton of tools from My house to the top of the hill and back again!) We spent about \$125 on pipe, and about \$100 for guy wire - we used fairly expensive steel cable for that. Time will tell how it holds up!

01:26:35 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

Thanks for the story, Dan.

It's fun to see you finding the same solutions - I have also used pipe within pipe for a tower base hinge, and I have put rebar into rock with epoxy. I wonder how it worked out with welding so close to the epoxy resin. I would normally do the welding first and the epoxy after, but that is not an option for your pivot pipe anchoring.

Where possible I like to drop the tower uphill. That means it has less far to go, and the side guys have a better chance of being on a level. You could then use a pulley to redirect the lift vehicle rope, or better still get yourselves a griphoist. Much more relaxing.

I also find it helps to use cheap polypropylene rope (blue rope) as temporary guys during the first lift. I can fiddle about with them more easily, and they stretch if necessary. I can then adjust the permanent guys once it is erected.

I'd hate to try erecting it without any guys (too scary).

Hugh Piggott <http://www.scoraigwind.co.uk>

Re: More tower fun! ([none / 0](#)) ([#5](#))  
by DanB on Mon Jun 23rd, 2003 at 09:04:11 AM MST  
([User Info](#))

Thankyou for the comments Hugh! Unfortunately we didn't have many options for tower placement, and as it worked out, it sits on top of about a 10' tall rock outcropping! So there was no possible way to tilt it uphill on this site! (trick is making sure the machine doesn't fall off the end when we lower it!) The rope guy wire idea is a good one, I think I'll get some of that for next time! Something with a bit of stretch would be good. Fortunately - due to lucky placement of the wires here, we can keep the side ones on while raising and lowering which eases my mind greatly. Regarding welding and epoxy... yes, it kinda worried me a bit too! I guess time will tell! We'll be putting concrete around it too, and under it so it will pivot in a concrete "bearing" soon... In the end, we'll probably add another 5-10' to this tower. Right now there are a couple trees to the west which are a problem, and the choice is either killing them, or adding some to the tower. I think adding to the tower is the best solution here.

Caboose  
Beautiful Mountains  
Windmill

You all ran away at age 12 to live in a Story Book. I sure wish I had done the same.

Awesome Life!

Re: More tower fun! ([none / 0](#)) ([#4](#))  
by Gary D on Sun Jun 22nd, 2003 at 08:47:02 PM MST  
([User Info](#))

Dang it, in Southern Pa. no one seems to know anything about tilt ups. Wish I could see and help raise a few to understand it. Would seem to me you would need to run your gin pole wire to a pully on the ground then up to the truck bumper. Otherwise when the gin pole gets closer to the ground, you would be putting sideways stress instead of down pressure. I guess I'm dense or something here. Dan has all the fun!! :-)  
Looks great tho... Have to do one and then maybe then I'll understand it. Beautifull views!! Gary D.

Re: More tower fun! ([none / 0](#)) ([#6](#))  
by DanB on Mon Jun 23rd, 2003 at 09:13:05 AM MST  
([User Info](#))

Hi Gary - you're absolutely right, a pully on the ground where the gin pole comes down would probably be a good idea. In this case (and with other tiltups I've done)... there is some side pulling force on things when it gets near the ground, but not so bad as you'd think. Once the tower is near vertical, the weight of the gin pole does the work and it will simply fall into place without any pulling from the truck. As it approaches that "balance" point - the pulling force required is very light... so for these reasons a pully is not necessary... (but it would be ideal!) A winch is better too. I find it very easy with my tower to raise and lower the tower, it is a big old F250 with 4wd, very low gears and a fairly small 6 cyl engine. Dave has a somewhat newer truck without such low gears, and a big V8 engine with a real grabby clutch! He had no problem raising it... but in our test run, he scared the heck out of me lowering it! So... Ill either do the driving next time, or we'll get him a winch of some kind.

([User Info](#))

Good Post and very usefull information. I do need some prof. advice on towers. I am ready to construct a 40 ft. tower and raise a Volvo type genny with an 8 ft. rotor. My first stab at a tower was to use 20 ft. Of 3" sched. 40 into which I'd insert 20 ft. of 2.5" pipe and top it off with 2" (all sched. 40) and welded. Reading your post I'm wondering if this will not be an over-kill. The genny will have a furling system for high wind protection. With this set up I was also thinking of using only 4 1/4" cable guys set at about 35 ft and extending out about 100 ft. As you have one whole hell of a lot more experience with towers I'd be very gratefull for any advice. ( I realize that the stronger the better, but there is such a thing as over-kill and that's \$\$\$\$). Also, if you have any pointers on welding these sections together I'd like to hear that as well. Do you use any sleeves for re-enforcment? or do you just run a bead where the pipes are inserted? Thanks, Hank

Re: More tower fun! ([none / 0](#)) ([#8](#))  
by DanB on Tue Jun 24th, 2003 at 01:02:41 PM MST  
([User Info](#))

Hi Hank...

please know... I'm not a professional!! (see my fun with logs and chains posting...)

I've put a few homebrew machines up with resources that were available. Most of them stayed up.

But - specifically to answer your questions about what Ive done....

(1) I think using the 3" pipe is probably wise. I think were pushing it with this one.

(2) I slide the pipes together, and I didn't do a bead all the way around, just in spots. The reason... you weld all around the pipe and I think you'd weaken it!

(3) I think the 1/4" is probably OK, but I think with a 40' pipe tower, Id have two sets of guy wires. The lower set could probably be thinner stuff... but the pipe towers are really flexible! Then... I wouldnt guy it at equal lengths! We did Wards at even 15' increments, and it vibrates because the middle guy wires were midpoint between the ground, and the upper ones,... it was a harmonic point! WE had to move the lower set up a bit. On Wards, we've got the lower set up at 20', the top set up at about 32, and the machine sits up at about 37'. At first it was at 15, and 30, and it was much less stable.

For a 40' tower, to go out 100' from the base is too much I think. I think you'd be safe to go our about 30' - 40', but there is nothing to be gained (I dont think) by going out further from the mast than the guy wire is tall!

Re: More tower fun! ([none / 0](#)) ([#9](#))  
by Hank on Tue Jun 24th, 2003 at 08:19:15 PM MST  
([User Info](#))

Thanks DanB, You have been really helpfull. I realize none of us are pro's on this subject but there is a lot to say for experience ( I've modeled most of all of my genny on your design). I guess using mid guys will be the way I'll go and I never considered the harmonics. Good point!! The reason I was thinking of going out 100 feet or so was to reduce the tension on the cable (under load) and the anchoring system. Will have to run the math again if I will use mid guys (the longer the guys the less tension they are subjected to). Also didn't realize that pipe towers were so flexible. Thanks again, Hank

[Alternators](#)

I just put up some bargains for alternator builders.

To help keep some of these wind turbine projects affordable, I've listed some of our larger magnets in lots of 12 and 24 on our shopping cart at the lowest possible price. I'm listing these only in our electricity/components and electricity/renewable energy categories! (you won't find them under magnets).

[http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user\\_action=list&category=Electricity%3BComponents](http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user_action=list&category=Electricity%3BComponents)

by Gary D on Fri Jun 20th, 2003 at 06:24:02 AM MST  
([User Info](#))

Gee, wish you could do a deal on the 1 inch by 3/8 magnets too. Can fit more of them in a 10 inch disc. Would love to try several duel disc's with the inchers. Have low windspeeds in Pa. here and more magnets should mean lower startup. If only I could decipher windstuff's great prop- wire sizing program, I'd feel better ordering it too. Realize you have to make a profit, so if not, I'll still be ordering some anyway. Thanks Gary D.

Re: Good deals on BIG magnets ([none / 0](#)) ([#6](#))  
by DanB on Sat Jun 21st, 2003 at 07:37:24 AM MST  
([User Info](#))

Gary - hard to say. More poles doesn't necessarily mean higher voltage if you are compromising surface area.

We are actually way overstocked on that size right now and I probably will do some kind of qty discount deal on them soon.... but - I think you might do well to go slightly larger than 1" in diameter, depending on your goals!

I wouldn't get too intimidated by the prop! (working out the stations with Ed's software or Hughs book is not difficult, you would also do fine to just run a straight pitch from root to tip - or some compromise between the two.)

I just assembled a webpage about the caboose windmill...

It's basicly the same as my postings from the last week, all put together in one nice long page.

<http://www.otherpower.com/davesmill.html>

Tomorrow we're going to build a tilt up pipe tower for it in a super location at the very top of a high hill! It should be a blast...

## [Caboose windmill, Day 4.](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Sat Jun 14th, 2003 at 07:10:56 PM MST

[Wind](#)

Today we got some rough numbers anyhow...

That's pretty much where we left off on the 3rd day of work on this project. It was basically together, and done - but the blade needed balancing, the front rotor on the alternator wobbled a bit, the airgap needed adjustment... etc. We spent a few hours making these adjustments, and repeatedly putting it together and taking it apart so that it got easy and we felt confident that it would go back together the same way every time.

I also spent some time carefully measuring the resistance of the stator (or trying to) with batteries, a volt meter, and an ammeter. I was kind of worried that it might be on the high side, and the shape of the coils bugged me a bit (they are a bit too tall and not quite as wide as they could be). Testing a single phase of the alternator consistently came in around .8 ohms it seemed. This wasn't quite as bad as I'd thought - and although it could surely be improved, it should work fine for this machine since we were really worried about getting good output in 10-20mph winds.

I also checked it with a voltmeter and a tachometer - I thought it was cutting in below 100 rpm, but as it turns out it seems to be hitting 12 Volts AC right around 115 rpm which seems reasonable for the 10 foot diameter prop we made. So, I decided not to make a new stator!.... maybe someday we'll make a better one.

Here Dave is soldering up 6 bridge rectifiers we'll need in order to convert the 3 phase AC current into DC current useful for charging batteries.

We made a short tower that fits the front of my truck. In the end, this short tower will go on top of Daves (probably wooden) tower down at the caboose. The machine weighs too much to lift it up this high, so we had to disassemble it, and reassemble it on the truck for testing.

It was a pretty good calm day for this sort of testing today, although the more I do it the more I'm starting to take this sort of data with a "grain of salt". We get pretty consistant readings at higher speeds, but lower speeds (like 10mph) come in all over the place. When testing like this, I have a 12 volt battery on the floor of the truck, a volt meter, a frequency meter, and a DC ammeter.

The frequency meter always gives numbers that bounce around and I don't trust it fully, but the numbers did seem to make some sense this time, so I'll write down the rpm as we got it and it may.... or may not be right! This battery was about half charged - and we ran the power to it with about 20' of AWG 14 extension cord (I figured this kind of simulates a longer line from the windmill to the battery made of better wire, plus... it was handy). When we do this, we always run one way down the road at a certain speed, turn around and go the other way at the same speed - so that we can kind of average the numbers out. Even the lightest breeze will cause it to do much better one way than the other.

So here's what we come up with roughly in the truck test...

Our neighbor Tom is in the Volvo pacing us (his speedometer works... mine doesn't) with his flashers on to warn oncoming traffic.

Remember, it starts charging at around 110-120 rpm and the frequency meter in the truck was in agreement with the tachometer I used on my workbench.

At 10mph we were getting readings ranging between 5 - 20 amps, 10 amps seemed a pretty close average, so a little over 100 watts. At 10 mph the frequency meter didn't seem to be working so we got no rpm readings. (we later found it a wire had come loose)

At 15 mph it was producing about 15 - 20 amps consistantly both directions. At 20 mph 25-30 amps, and it was just starting to furl. At 20 amps output it seems to be running right around 400 rpm. At 30 amps output it's running right at 500 rpm.

At 25 mph we seemed to be getting around 30 - 35 amps and it was furled out some all the time.

At 30 mph we got consistant readings of 37-40 amps and it was quite furled out by this time (I'd say it was at about 45 deg to the wind). At 37 amps output we recorded around 550 rpm.

I've certainly seen higher numbers from past machines which did not furl

before - but I don't think I've ever done so well at very low windspeeds, which is what's important. Output could be increased I think by adding weight to the tail (so it furls a bit later) and making a better stator. I think it's fine as is though. It runs square with the wind - the tail seems of fairly reasonable size and overall it runs pretty well. I like the double rotor design, it's a bit more work than others I've made, but it has 0 load on the bearings, and 0 losses in the laminates. I can give this alternator a good spin by hand, and then walk across my shop and give one of my old laminate alternators a good spin. The old ones will rotate once or twice and then stop... this one will keep turning for 10 or 20 seconds. Time will tell how it holds up! Sure was fun though.

We've got 4 days into it now since we started with the front strut assembly off a Volvo and all that's left to do is get it into the air down at the caboose.

Looking really good. What a treat to see the progress step-by-step!

One thing I did wonder about:

Are you going to leave the stator and rotor exposed? Or do you intend to make some type of cover for them? Seems like up your way that snow and ice getting in there could be a problem.

Bach On

- I'm just as happy as if I had good sense! -

[caboose windmill, Day 3!](#)

By [DanB](#), Section [Homebrewed Electricity](#)

Posted on Fri Jun 13th, 2003 at 11:46:56 AM MST

[Wind](#)

we're almost ready to strap it on my truck!

Here's what we did yesterday on Daves new wind turbine project! Again, the alternator on this is a dual rotor 3 phase machine designed for the 12 volt system in his caboose. We started this project on Tues June 10th, and this posting reflects what we did on Thurs June 12. By Wed night we had the alternator pretty much together, the chassis for the machine welded together, the tail made and the blades were cut out and the front side roughed out with the draw knife.

[Click Here](#) to see progress on the 1st day.

[Click Here](#) to see progress on the 2nd day!.

Here we are finishing up the front of the blades with a power planer. We did most of the work with the draw knife, but the power planer does nicely to finish things up quickly.

While Dave was planing on the blades I made up a cable with lugs on it and wired the alternator in Delta. For more details on Star, or Delta wiring and 3 phase alternators, checkout Ed's 3 phase basics [here](#).

Here Dave we are roughing out the back side of the blade (making an airfoil) with the draw knife.

Same as above, working over the back side of the blades with a draw knife, but here you can really see things coming together! This blade is nearly done.

Once the blades were carved and sanded fairly smooth, we put them together - measuring from tip to tip to make sure the distance between tips is equal. Then we used 10 inch diameter plywood disks, one half inch thick, and screwed one on each side of the blades with a ton of wood screws to hold them together.

This is a simple tool I made to go with the machine. Notice my beautiful welds... (I have one of those cheap 120 AC mig welders which barely work on good power. Up here I have to run it off my generator which stalls quickly when I start welding. Welding here is very frustrating...)

Once you get two magnet rotors like these made up, and close to each other, it become impossible to pull one off without a tool. This makes the job easy. It should also be said... one of these rotors is a very powerful and dangerous thing! Two is twice as bad... anything that gets between them gets smashed. This tool does a nice job of removing the front rotor, but it's not so useful for putting it on gracefully! On this machine we've simply been lining it up and letting it snap into place which works fine as long as you keep your fingers clear! (I did get my thumb in there yesterday and my thumbnail is turning black today) Better would be for me to weld a nut right in the center of the front rotor and then we could use this same setup for smoothly lowering the front magnet rotor onto the alternator. I may do this today.

Here is a picture of the wheel puller in action. It doesn't pull it quite straight, but it does a good enough job to make it very easy to pull the rotor off by hand once it's a few inches back.

We pulled the whole thing apart in preparation for painting. Here you can see all the alternator parts on my workbench.

Here Dave is putting primer on the machine. First we ground off some of the uglier welds and then cleaned it carefully with gasoline to remove any oil.

That's pretty much where we wound up at the end of day 3! We used wood stain on the hub and tips of the prop, and on the tail. The rest is good old Avacado green epoxy appliance enamel just like on my last machine. Today we'll work on getting the wobble out of the front rotor, balancing the blade - and hopefully doing some tests on the alternator. Just turning it by hand, I'm thinking it's probably hitting cut in voltage around 80 rpm or so - which may be a bit too slow, and the resistance in the stator seems a bit high, but I've not measured it properly yet. At this time, I'm very tempted to re do the stator. The coils are a bit taller than necessary (meaning extra resistance) and since the cut in speed seems pretty slow, I'm thinking that fewer windings

of heavier wire might be appropriate here. But it would probably work OK as is and we'll probably drive it around on the truck as is and find out! (Maybe later today or tomorrow).

[caboose windmill, Day 3!](#) | 2 comments (2 topical, 0 editorial)

Re: caboose windmill, Day 3! ([none / 0](#)) ([#1](#))  
by troy on Fri Jun 13th, 2003 at 03:35:25 PM MST  
([User Info](#))

In addition to the nice mill, you have a lovely Volvo in the background. Don't steal the spindles off that one.

Best Regards,

troy

PS, if you want a treat for welding, get the portable DC ReadyWelder. Runs off 12-36 volts and has a 100% duty cycle. Makes the cheapie welders look like rubbing two sticks together for fire. They say it can do aluminum too, but haven't tried that yet. A little pricey but this is an industrial quality tool. Only takes the small spools, so that's something of a drawback, but man does it weld. I'm not that good as a welder since I don't practice much, and it makes me look good.

tr

Re: caboose windmill, Day 3! ([none / 0](#)) ([#2](#))

([User Info](#))

Fantastic machine!

You might also look into a converting Delco alternator for use as a welder. They're seriously cheap of course, and although mine didn't weld wonderfully, it was quite passable; the trick was in setting welding amps with engine speed. I couldn't find a big enough engine to power it though, I wound up using two cheapy 3.5 hp engines belted together, with pulleys off of A.I.R. pumps on the engines.

Demetri  
Always be the lead dog.

Here we were putting allthread and nuts into the stator bracket to hold the stator on. The allthread is 1/3" diameter.

Pictured above you can see the notch in the tail hinge which determines the angle of the blade during normal operation and when it's furling in higher winds. We reinforced the pipe around the notch to make things stronger, my guess is it might crack eventually if we didn't.

Here Dave is putting the stator on over the first magnet rotor. It's interesting to note here... with one magnet rotor on the machine, and the 3 long pieces of steel allthread which hold the stator on, that the magnets are somewhat attracted to the allthread and at this point the machine cogs a bit. When we attended [Hugh Piggot's seminar in Guemes Island](#) in April, we used stainless bolts for this, so the magnets would not be attracted to it. I kind of wondered if this cogging would get worse with the 2nd magnet rotor on (since there'd be twice the magnets and the top rotor might be getting attracted to the nuts on the front of the stator)... or better, since the magnetic circuit would be completed and the lines of flux would be concentrated between the magnets. As it turned out, when we did put the 2nd magnet rotor on the front of the stator this cogging disappeared completely. I was planning to replace this steel allthread with stainless, but as it turns out I think it is not necessary.

Here we're gluing magnets on the 2nd rotor. It is very important that the 2nd rotor line up perfectly with the 1st one. In other words, wherever we have a North pole facing out on the 1st rotor, we must have a South pole facing it on the 2nd rotor. Keeping in mind that there are 5 studs which hold the 2nd rotor on, we have to take care to position the magnets exactly. What we did, is put the 2nd rotor on without any magnets, and made some marks around it noting the position and polarity of the magnets on the 1st rotor. We then positioned the magnets on the 2nd rotor accordingly. This worked out well.

Here we basically have the whole alternator together. At this point we could spin the alternator by hand. We're getting about twice the voltage at any given rpm now with two rotors than we were with only one before. We didn't have a tach, or even a clock with a second hand.... so no real numbers yet.

But it seems to be hitting cut in voltage (12 Volts) perhaps a bit below 100 rpm.

We soldered all the connections on the stator and made 6 lugs (2 for each phase) from brass screws and brass nuts.

Here the alternator is pretty much done, and the tail is finished! (If you look real close at the ammeter on the wall, you can see that my [last wind turbine](#) is putting out about 40 amps. It was a breezy day!)

I drew up and cut out the profile for one blade, and Dave is tracing it onto blank boards in preparation for making the other two. The wood here is 6/4 (an inch and a half thick) Eastern White pine. It's pretty lightweight, but fairly dense and strong. We have a couple knots to work around here, but not too bad.

Here Dave is cutting out the blades on the bandsaw.

Since the blades get very thin (in this case about 3/8") at the tips, it saves time to remove some of the thickness of the board with the bandsaw.

Pictured above we are roughing out the front of the blades with the draw knife.

At the end of the 2nd day we had the front side of the blades roughed out. Each blade is 5 feet long, for a total diameter of 10'. The pitch at the tips is 5 deg, and it gets steeper to about 6 deg in the middle of the blade, at which point it gets steeper quickly towards the root (near the hub) until we pretty much take up the whole thickness of the board. No real scientific blade design here, just going with what feels good and what's worked fairly well in the past! I'm a day behind now... we put our 3rd day in yesterday and I'll get those pictures up soon!

Very cool!! Wow, twice the voltage with two discs?? Cant wait to see it finished. Im currently working on a dual rotor also. Ill post it when Im finished. Im just curious what kind of spacer you made up to hold the discs the right distance apart or did you just use nuts on the allthread adjusted to the same height? Do you notice any wobble in the discs when the stator is loaded down? Im wondering if using just nuts on the allthread would be stable enough to keep the vibrations down at high rpm as opposed to a solid aluminum or stainless machined spacer?? Have fun!! RoyR

Re: Dual Rotor Brake Disk Windmill, Day 2! ([none / 0](#)) ([#2](#))  
by [DanB](#) on Fri Jun 13th, 2003 at 09:03:56 AM MST  
([User Info](#))

were just using nuts and half inch allthread.

Time will tell! I think it'll be fine, but if we must make a space then that's what we'll do. At this point, there is a bit of wobble in the front disk - although it is running flat so we could take it out with a weight.

We'll be playing with that today I think.

A weight should work as long as its running flat. Let us know what happens :) Oh, and one more question. In the post you show a pic with your ammeter in the background and your new turbine is putting out 40A. At what windspeed do you think it was doing 40A? just curious. Have Fun! RoyR

by [troy](#) on Fri Jun 13th, 2003 at 10:38:03 AM MST  
([User Info](#))

This is a very similar design to what I am currently working on, so I am obviously anxious to see what she'll do.

The biggest difference is that you have those enormous huge 1/2" thick magnets, while I am using the recycled big hard drive mags (39's I think).

So much fun, so little time.

troy

By our rough estimate, I'd say it's doing 40 amps at 30 mph and above (thanks the furling system). We've built a couple of Bike Speedometer anemometers, but there are a couple bugs in the design we are working out. Ward is coming up this weekend with his (that broke) and we hope to finalize the design. One of them is slated to mount on DanB's windmill tower, so we'll have better data soon! DANF

[Wind](#)

Were having too much fun this week!

Yesterday my freind and neighbor Dave came up to start building a wind turbine for his small power system. Currently he's got 2 105 watt solar panels setup which do OK, but his site is not excellent for sun. He does have a pretty good wind site up the hill from his caboose. His system is 12 volts, so were building the machine for that.

As usual, we started with some Volvo parts (just have too many around...). We're using the front strut assembly off a Volvo 240, and two 11" diameter brake disks which fit the wheel hub. This machine will be very much like the last one I made. [Click here](#) for more details about that. The main change we're making here, is that this will be a dual rotor machine. The tail will also be slightly larger and longer. It should be slightly more powerful at lower rpm than mine was, we're using slightly more magnet and exactly the same 3 phase stator design as I did last time.

To make the furling tail assembly, I cut the strut about 6" from the wheel spindle. We want the spindle (and therefore the alternator and the prop) to be offset from the tower about 5" to the side.

I ground it out so its a good fit for welding. It will be welded on at an angle to provide more contact between the two pieces making the joint stronger. I also like to weld it on so that the spindle (and therefor the alternator and the prop) is pointed up about 2 deg to help keep the tips of the blade away from the tower.

Pictured above you can see what I described a bit better. You can also see the wedge I was setting up on the back side to hold the tail pivot out at about 20 deg.

I like to cut the brake rotors down so that there is a slight lip (about 1/16 inch) to hold the magnets in. This helps a bunch too in spacing the magnets out evenly later. Pictured above Dave is doing this on the lathe.

Here Dave is learning to run the lathe and his freind Fred is cutting up various metal pieces which we'll need.

This is how the brake rotors look after cutting them down to make a lip on the outside which holds things together. I don't think this step is necessary - but it's easy and provides some insurance against magnets flying loose. It also makes a nice clean flat surface to put the magnets down onto.

You'll notice that the rotor on the right side has a larger hole in the middle than the one on the left. We turned it out a bit so that this rotor could actually fit on the back side of the wheel hub! (where I put the stator on past machines...). This way the back rotor sits behind the wheel hub with its magnets pointing forward towards the stator.

Here Dave is struggling with strong magnets trying to lay them down with about a quarter inch between each one. They kept sliding together - he was

getting a bit frustrated! These magnets are 2" diameter X 1/2" thick. They go down with alternating poles up. Were using 12 of these on each rotor. Once they get placed down and approximately evenly spaced, we used playing cards as shims to make sure the space between each magnet was exactly the same. Its kind of trial and error, but it goes very quickly. Once they are right - a few spots of super glue on each magnet holds them in place untill we pour polyester resin around them.

Since this is a dual rotor machine, the stator will not be able to bolt on in place of the backing plate like I've done in the past. The stator will have to be in between two rotors, and held on by a bracket which ties into the outside of the stator. These are the pieces I made up for this bracket. The bracket will actually bolt on in place of the backing plate (to the strut assy behind the wheel spindle). These 3 pieces are cut from 3/16" thick X 3" wide steel, and they are 7" long.

Above you can see how those go together. After this we drilled holes in the center to bolt it down, and a large 1.75" dia hole in the center for the wheel spindle to pass through. We also need to drill holes out at the ends to accept allthread so we can mount the stator to it.

Pictured above Dave is winding up some coils. Just like my last one, each coil occupies the space of about 1 and 1/3 magnets (so 3 coils take up space occupied by 4 magnets, so there are 9 coils in the stator). Its 3 phase, so each phase consists of 3 coils in series. The coils are made up of 65 windings of AWG 14 wire.

Here Dave is putting duct tape around the inner and outer diameters of the magnet rotor. This simply serves as a "quck and dirty" sort of mold, so that we can pour the resin around the magnets and it hopefully wont run out the sides!

Pictured above is the mold we made for the stator, and we're putting some fiberglass fabric in the bottom to strengthen it.

We first poured a bit of resin in the bottom of the mold (got the fabric saturated) and then placed the 9 coils in. Then we cover the coils with more fabric, and pour resin over those and put the lid on the mold.

Here we are pouring resin (mixed with talcom powder) into the magnet rotor. We'll have to make 2 magnet rotors, but for now we're just doing one. It is possible the alternator will work OK with only one magnet rotor and the other rotor simply serving to conduct the field of these magnets (like laminates except it'll be rotating) - so we're not doing the 2nd rotor until we test the alternator. We may even decide to use different magnets on the 2nd one.

Pictured above the main chassis of the wind turbine is pretty much together. You can see now how the stator bracket bolts on.

Here you can see the magnet rotor, and the stator mold while the resin sets up. The battery serves as a weight to hold the top of the mold down tightly.

After about 2 hours we opened the mold and took the stator out.

Above you can see how we replaced the studs in the wheel hub with long (10 inches) pieces of allthread. The allthread will serve to hold the magnet rotors, and the prop securely to the wheel hub.

That's where we were at after 1 day (About 8 hours of work). You can see things starting to come together! My guess is we'll have this done in another day or two. It should be said, this machine is very similar to the one we built at the [SEI Wind turbine workshop on Guemes Island](#) in April. It's very much along the lines of Hugh's [Axial Flux Windmill Plans](#). If I really wanted a guaranteed good machine, I'd probably follow them to the letter, but I like to play with junk I have on hand and experiment a bit. I should also say - again, we have about 8 hours into this so far, and I believe we'll have it completely finished in about 20 hours. But it might come out a bit cleaner, prettier - and possibly a lot better if we took a little more time on certain steps. Time will tell! It's fun though, and since I have limited time to put towards this sort of thing, and Dave only has a few free days available, we're trying to move things along quickly.

I love it.

I especially like the simple stator mounting bracket.

You could make the magnet positioning easier by whittling some pieces of stick to fit between them as you put them in. You can start removing the sticks once you have got some way into it because the magnets do not wander so eagerly once they have partners on each side.

I think some cars have flat disks that would be much esier to mount because you don't have to allow for the deep offset when you come to mount the disks apart.

Get some rpm data for the machine this time :-)

can't wait for the next instalment.....

Hugh Piggott <http://www.scoraigwind.co.uk>

It's a modern 1 hp Mike Brown steam engine. When I got it the bolt that held the crank to the crank shaft had sheered off. Took a couple hours to disassemble it, easy-out the bolt and fortunately I had the right part in my bolt bucket.

Lots of cleaning, it was almost stuck due to very hardened grease in the packing glands and the crosshead. But now it runs great on 80 pounds of compressed air and it's surprisingly powerful and runs for a surprisingly long time off my small air tank.

Now I get to learn about boilers and all the good stuff in between! I've been wanting to do this all my life, so it should be fun. Fortunately the engine came with a couple videos and the book which came with it when new. These Mike Brown engines seem really well made, with good bearings everywhere and tight tolerances. New they cost around \$1000, a bit out of my league for a "toy" - but in xchange

for a solar panel I couldn't turn it down. Although I don't really need the power - I'm dying to see it spin and generate some power off a wood fire!

Mike Brown seems an interesting fellow judging from his website!

Dan;

Pretty neat. I would love to make power from wood as we have a lot of renewables in the timber resource here.

If I wasn't scared to death of steam explosions I might try one.

This picture is from behind the machine, you can see how the alternator rotates 'round so the blades become more parallel with the tail.

Pretty bad picture... it was raining on me and really windy, but you can see how she was really getting nailed by the wind here...

After watching this, it was clear my tower needs a bit of work if it's going to support this 9' diameter machine. Shortly after taking these pictures I ran in and shorted out the machine to shut it down and protect the tower. It was producing about 40 amps when I shorted the 3 leads, and it stopped very quickly and never turned more than a couple rpm after that even in very high gusts. I made a couple changes and added some fun pictures of testing this machine on the truck last week to the page: <http://otherpower.com/bdwm53.html>

Furling tail ([none / 0](#)) (#1)

by Gary D on Mon Jun 2nd, 2003 at 08:22:49 PM MST

([User Info](#))

Hi Dan, the pic's show the furling great! Never understood the "lifting" effect explained and shown like this before. Very understandable (at least to me). Was looking at your furling setup pic. and wondered if a washer was used as a stop to keep the tail from coming around into the blades? Is this design in Hugh's Book?

Also wondered if you are going to get any more 1 inch by 3/8 disc's in or are they history?

Thanks and great workmanship as usual Gary D.

1" disks... ([none / 0](#)) (#3)

and the washers... ([none / 0](#)) (#4)

by DanB on Mon Jun 2nd, 2003 at 09:50:19 PM MST

([User Info](#))

the washers serve both as a stop for the tail and to reinforce the tail pivot. It's exactly Hughs design except he used a somewhat tidier piece of steel which was cut at the 20 deg angle and served the same purpose. I just didnt have the patience to find and cut the steel - the washers were handy and reasonably thick, so it is strong.

[ [Parent](#) ]

looks good ([none / 0](#)) (#2)

by billf on Mon Jun 2nd, 2003 at 09:29:00 PM MST

([User Info](#))

Great job on the mill and it looks good! I'm glad you have added furling and Hugh's design seems to work well for us homebrewers. I can't over emphasize the importance of having some sort of self limiting system designed into each mill. After a year I think I've hit on a good combination of tail size and weight to control output on mine and limit the lateral loading on the tower. It's still hairy though watching the tower sway and the mill furl in a strong thunderstorm.

billf

very dynamic pics ([none / 0](#)) (#5)

by Chuck on Tue Jun 3rd, 2003 at 09:36:46 AM MST

([User Info](#)) <http://www.greeleynet.com/~cmorrison>

Dan,

Boy, you really get a sense of the violence in the wind from your shots. And yes, that was some storm. When it came through here it just about flattened some of our small trees. Just for reference, Here are some shots of my test mill unfurled and furled on a much more pleasant day.

This is sitting at rest without any wind.

Here in about a 20mph wind the tail is partly furled.

the T Arm... ([none / 0](#)) ([#7](#))

by DanB on Wed Jun 4th, 2003 at 06:48:22 PM MST

([User Info](#))

I should make a page about my tower so everyone could have a good laugh...

The "T Arm" is actually a foot - so the tower comes to rest on it so I dont smash the machine when it comes down.

in the past, with "non-furling" wind turbines, I always made them tail heavy so they'd come down on the tail. (lots easier to fix a tail than the prop!)

I actually plan to stick an anemometer up on there probably tomorrow (on the foot).

[ [Parent](#) ]

Re: Furling tail ([none / 0](#)) ([#8](#))

by labinnah on Tue Jun 17th, 2003 at 08:45:43 PM MST

([User Info](#))

DanB when you shut your windmill down because of the high winds you stated that you shorted the 3 leads, causing the blade to not turn anymore. Could you please elaborate on this on why that works that way. I am looking to design a windmill that will have to live in hurricane area and am curious as to what design features I can add that would help it's survivability. Any other comments on high wind conditions would be welcome as well, for I am a novice in these matters. Thanks

This is the machine I made last week after making all those coils tests. Thankyou Ed for the laminates, and Hugh for lots of ideas!

This machine doesn't represent a huge increase in power over the last one I made with a 9' prop... it's probably about the same. But it turns much more freely and is very quick to respond to very light breezes. Very rarely do I catch it not turning, even on seemingly still nights. In 7mph it's definitely turning and making an amp or two and about 8 - 10 amps at 10mph.

There are more details about it here: <http://otherpower.com/bdwm53.html>

It took the better part of a week (5 days) to put this together, probably about 30 - 40 hours.... and it was a fun week! I got it on my tower and erected at 1am thursday morning.

([User Info](#)) <http://www.scoraigwind.co.uk>

what a lovely job, Dan

I wonder why you made the blades turn counter-clockwise?

Also - what grade are the magnet blocks? They are huge! I guess they would be expensive?

I wonder how you get mph data? Is this from the truck test? Is it flat acm or how do you prevent background windspeeds influencing the data?

I have put a link to that diary on my homebrew windpower page. I have just been updating the page anyway.

Thanks for the lovely pictures. If they get dim I just tilt the screen on my laptop a little. I could probably also adjust the brightness in a control panel. Or download the picture and adjust it in a graphics package.

Hugh Piggott <http://www.scoraigwind.co.uk>

Counterclockwise?? ([none / 0](#)) ([#7](#))  
by DanB on Sun Jun 1st, 2003 at 08:20:26 AM MST  
([User Info](#))

I don't know Hugh - I never really think much about that actually. I suppose the only reason to go one way or another would be the nature of the wood in the prop.. if one was avoiding some blemishes it could determine clockwise or counter.

Yes, I tested this on the nose of my truck. Kind of rough data, but I've tested them all this way so it's kind of becoming a good comparison now! My guess, is on the truck, although there is little to interfere with wind coming at the machine (its up about 15 feet and 8' roughly above the hood) and located in the very front) I suspect air could pile up against the cab some and affect it - probably for the worse but it's hard to say.

Yes, the magnets are huge, and would be kind of expensive. I guess, overall they have about the same overall mass as the magnet you're using in your dual rotor machine - although I believe your alternator is more effective because I know that using magnets half as thick on each side gives much better results over an airgap like this than using full thickness on one side and laminates on the other. I tested that...

Overall I'm happy with it. A couple hours I could change it to be a dual rotor machine (the stator was made with that possibility in mind), but as it is it's performing reasonably well in very low speeds which is what I want.

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I looked at your pictures and texts.

I'm sharing the comment that your pictures are really dark.

You've made most of the improvements, which were there waiting for your earlier machines.

I think that the furling system is really important.

The work you've done testing different coils is very valuable for others as well.

For the area, where I'm living we need machines, which will generate good power even under 5 m/s wind. That might be possible to achieve by changing the design by adding more blades and moving the laminates nearer the coils...?

- Hannu

Sorry about the dark pictures... ([none / 0](#)) (#8)  
by DanB on Sun Jun 1st, 2003 at 09:22:27 AM MST  
([User Info](#))

Lots of my pictures were taken at night... it gets tricky :)

Yes, I think the furling is system is wonderful. Truly I've not had real problems up here with machines breaking down due to a lack of it, but we rarely see high and sustained winds. For me, in this environment - the furling system allows a much larger machine on a smaller tower. In the setups I've made which do not furl, the tower is the scary part in high gusts.

Regarding generation in low windspeeds... I'm not sure, but this one does seem to do well I think. A bit over 100 watts at 10mph it seems, and it starts up and spins freely well below that. Although there is a bit more power there to be had... I don't think there is much. Tweaking the blades a bit might get more - I don't think more blades would be the answer as it has no problem spinning up quickly and cutting in below 10mph. Slightly faster blades might help, but I tend to doubt that because I see it start up in the slightest breeze and it comes right to cut in voltage and sits there most of the time, making a little bit of power as it becomes available from the wind.

Too much fun - I can spend hours listening to the breezes and watching the meters! We've pretty much gone into summer and the windy season is over so I'm getting a good feel for how this one runs in very light breezes.

[Alternators](#)

What is the best one can hope for...

What is the best one can hope for in a wind turbine that uses a permanent magnet alternator at say... 30 mph, assuming the machine "cuts in" (12 V) at a reasonable speed, say 10mph? Seems like if open voltage on the alternator at 10mph is 12 volts, then it should be around 36V at 30 mph - assuming the machine has a fixed prop that runs at a fairly constant tip speed ratio. So by nature it seems like the alternator that produces efficiently at 10 mph must be fairly inefficient at 30 if it has enough resistance to allow the prop to run where it wants to. Seems like the only way to avoid this would be the use of some electronics to change the wiring configuration of the alternator... Or possibly a 4th diode in the center of the star in a multiphase setup like I posted earlier?

PMA efficiency ([none / 0](#)) (#1)

by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue May 27th, 2003 at 08:26:53 AM MST

([User Info](#)) <http://www.windstuffnow.com/main>

Are you talking about overall efficiency or simply alternator efficiency? The best unit I've ever seen was an axial flux unit making an efficiency of 96%. This was a motor/alternator combination. Extremely low resistance and very little heat was created while the alternator was in operation. The best I've achieved to date is 90%, this was an axial flux unit with silicon slotted stator, low resistance and N35 neo's. Air gap of .025". Conventional wiring. The only reason, I can see, that the efficiency drops is because of heat losses. Once the unit starts heating up the efficiency drops progressively as heat increases. The resistance in the wires provide a perfect place for the heat to build up. On the other end of it, the stator itself will build heat to a certain degree. The thinner the steel strips in the stator the less heat will be created. The stators built with standard sheet steel used .030 created a considerable amount of heat under load, I switched to .019 silicon and the heat was considerably lower. I'm now using .014 silicon and the heat problem is just short of going away. Most of the heat now is in the wires. I'm building a multi disc, multi stator axial flux unit now, which I hope to have completed by this coming weekend barring any interruptions. Basically 4 alternators in series. A 3 phase unit. It's proven quite challenging to this point in design.

On your "4th diode", I'm not sure what your suggesting here. In a star configuration the ends are tied together the starts are the output. In delta the starts and ends are together and the ends of each are outputs. Basically two different wiring schemes. I've used relays to run both on a mill which works out very nice, at least on a small scale.

This is the configuration on my small downwind using RobD's star/delta switch control. You'll have to explain the "4th" diode idea in greater detail or post a drawing... much better for me to understand a drawing than it is picturing words. Delta wiring also has its drawbacks for efficiency because it has a tendency of back cycling current through one phase while in operation but still offers benefits, especially on higher resistance units.

Another fun subject... Lets hear more on this... Lets get lots of opinions going

Thanks Ed... ([none / 0](#)) (#2)  
by DanB on Tue May 27th, 2003 at 08:53:33 AM MST  
([User Info](#))

Thankyou for the reply. I guess what I'm saying... relates to matching the alternator to the load.

If the load is a battery, and the alternator is well matched to the battery at a low rpm (like 10mph) - where it is probably most efficient. Wouldn't you agree that they must be most efficient at low outputs?

If the prop has a fixed TSR of say... 7, then the alternator must run at 3X the rpm @ 30mph than it does at 10mph, and in order to allow the prop to do that, there must be some resistance in the alternator (if there was 0 resistance then it would take an infinite amount of energy to speed it up past cut in right?) - so either the alternator must allow the prop to speed up and be... fairly inefficient since the battery voltage doesn't change - or the prop would speed up very little at higher speeds and become inefficient (or go into stall).

So if we have an alternator which is producing 15 volts open in a 10mph (a good match for charging a 12V battery), then in must be producing 45 volts open at 30mph and it must have enough resistance in it to allow the prop to run at that speed, so therefor it must be fairly inefficientt at 30mph.

Regarding the 4th diode.... In a star connection, the terminals - like you said, are at the starts of each phase, and the phases are basicly in series. What if we added the 4th rectifier in the center of the star connection (this would be at the "end" of each phase where all 3 phases are connected). It would be lower voltage (like Delta) so the machine would cut in early due to the star connection, but then when rpm got up a bit you'd have available current between the center of the star and each leg. Does this make sense? - it would have to come down on 4 wires. Something like this:

So the output off the legs which we normally get would be higher voltage and "cut in" early - but current would start to flow from the center at higher rpm and be very low resistance. Does this make sense at all? (I'm showing off my lack of understanding here....)

[ [Parent](#) ]

4th dimension... ([none / 0](#)) (#3)

by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue May 27th, 2003 at 10:20:47 AM MST

([User Info](#)) <http://www.windstuffnow.com/main>

I see what your doing... Just looking at the drawing, wouldn't you need 3 rectifiers? All going from center connection to end connectors...? This would allow the ends of the star to produce voltage then you'd have to switch to the output of the 3 rectifiers at speed. Thus reducing the resistance by 2. In Delta configuration you basically reduce resistance by 3 or 1/3 of star so your gains would be higher.

It seems to me... and this is just a theory at this point... that the wind coming through the prop is cubed and the alternators are linear. With less resistance in the wires and slower turning props we can just about match the cubed input. Since say a TSR of 1 on an 8ft prop changes the rpm very little as the wind increases and low resistance reaps large gains with minor rpm changes there would be a simple match. On the other end of it, we don't necessarily need speed to generate power we need torque. The speed change would only be relevant when torque is needed (power increase). ( Thus the Free wing idea). As an example... say we have an alternator with extremely low resistance, A large prop turning very slowly and the increased wind would only change the prop speed by say 1 or 2 rpm but the power coming through the prop is cubed so the change in speed is absorbed as torque into the alternator.

Even though the alternator only changed 1 or 2 rpm the increase in power is significant. Its hard to envision from words but when you work out the numbers in an extremely low ohm alternator the change is quite significant. For instance lets say we build an alternator that makes 12V at 30 rpm and has a wire resistance of .1 ohm. So its making 2.5 rpm per volt. At 35 rpm (only 5 rpm difference) its making 20 amps... when it jumps to 40 rpm its making 40 amps and so on... Since windspeed and rpm are linear through the prop we can make an alternator that produces cubed output in relation to input power. Its an interesting subject and I've been trying to work out some details about the relationship for years. My Freewing design utilizes pitch change instead of speed to overcome the linear speed relationship to the cubed power input. This offsets the low resistance problem and torque needed to get the speed. But I'm not convinced its actually needed with the right fixed pitch prop and alternator configuration.

More Food for thought... Don't ya just love working through complex problems? Its easy to build a complex machine but its more difficult to build a simple machine.

Still having fun!

Ed

Star/delta switch ([none / 0](#)) (#4)  
by Gary D on Tue May 27th, 2003 at 09:50:15 PM MST  
([User Info](#))

can the star/delta switch be used in a single phase machine? On the website, it's stated it is for 3 phase machines. As for Dan's thought of increased resistance, if you had say 20 coils in sections of 5, all starting in series. at a set voltage couldn't you split it to 2 sets of ten, then at another voltage setpoint cut it to 4 sets of 5 coils? Wouldn't that help keep the heat away a certain ammount from the coils? Match the coils to the blade rpm, so to speak? Just rambling here, no hands on yet. Gary D.

[ [Parent](#) ]

efficiency and speed cahange ([none / 0](#)) (#5)

by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Wed May 28th, 2003 at 01:12:22 AM MST

([User Info](#)) <http://www.scoraigwind.co.uk>

Dan, you have put your finger on the big design challenge. It is not hard to design an alternator to cut in at the right speed. and the speed will increase as you put a load on and thtorque and current go up. But an efficient alternator will only need a little extra open circuit voltage to push plenty of current out so it will only increase in speed by a small amount.

Very efficient alternators work at near constant speed and this presents a probelm for the blades. Blade performance is best if the speed varies in proportion to windspeed. We do want the speed to rise to about 3 times the cut in speed before we get full power.

There are several possibilities.

Settle for a less efficient alternator (easy to do in the days of ferrites and still very possiblle if you make a small one and cool it well.) We'd like to do better, though.

Or you can switch star/delta. I have done this but neither of the two is very well matched and I always seem to like the star connection better. Delta goes rather too fast when the wind dips.

Using a DC-DC converter like Bergey windpower and some others is probably the ideal solution but you need to know your power electronics pretty well. then you can let the speed rise and the voltage rise at the alternator and convert the extra volts into extra amps with electronics.

Or you can try to make the blades work better at varying tip speed ratio. This solution appeals to me becuase it is nice and quiet if you hold the speed down. It also has a better chance of working well if the wind keeps changing.

Finally on the question of the rectifier, it is fine the way you have drawn it but it can cause some confusion where people think that only two AC wires are usable because they are on a single phase bridge. A better way to draw it is to show that each AC wire has a diode to the positive and a diode to the negative. so you can get circuits between any two AC wires and the battery. The physical layout of the diodes may be as shown but in fact the AC wires are all connected in the same way and so Ed need not worry.

Hugh Piggott <http://www.scoraigwind.co.uk>

My two cents' worth is only water ([none / 0](#)) (#6)

by hvirtane on Wed May 28th, 2003 at 03:51:47 AM MST

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

While I'm thinking that Ed's comment is quite much on the right track and waiting impatiently for results of his new projects (multiple disc alternator and the 'free wing' design) I wanted to ask for your comments on my old idea as a solution for the problem.

a) Controlling the speed of the windwheel makes it not efficient on broad ranges of wind speeds.

So it is maybe best to change the speed of the windwheel according to the speed of wind. (Fixed TSR)  
(Ed's 'free wing' might have a solution to this problem.)

b) Varying the RPM of a generator with the speed of the windwheel creates another problem. Generators are efficient only at narrow band of RPM.

-----

So why not to use water as 'a transmission gearbox'?

If the windwheel is running a pump to pump up water in reservoir and the power is taken out by a water turbine, when the water is running down:

1)

a) Water turbines can be made more than 90% efficient.

b) The water wheel (maybe pelton) can run at a fixed speed so that the generator can run at its best efficiency speed. (We can collect water in the reservoir, when we get it more from the windpump than we use in the waterwheel to generate electricity.)

2)

a) I think that pumps are even more efficient than water turbines, but are they efficient at different speeds?

b) If they are we can let the windwheel to change its speed according to the speed of the wind so that it is reasonable efficient at different wind speeds.

- Hannu

Gravity issue ([none / 0](#)) (#7)

by Bach On on Wed May 28th, 2003 at 07:00:16 AM MST

([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

That's an interesting concept.

But isn't there some theoretical or practical limit on how high a standard pump can raise water? Seems like it was 32 feet. Modern pumps overcome this for deep well systems, but they do it at a cost - substantial \$\$\$.

Is this going to be practical for a wind ginny?

Bach On

- I'm just as happy as if I had good sense! -

[ [Parent](#) ]

practicalities ([none / 0](#)) (#8)

by wpowokal on Wed May 28th, 2003 at 08:34:15 AM MST

([User Info](#))

Yes 32' in theory at sea level, decreases with altitude.

I'm not sure if the discussion is around pumping water with electric pumps or the classic windmill to reciprocating pump.

Having had experience with windmills I suspect that is not an option, and if electric pumps are to be used then we are still talking about a wind generator.

Water storage could have applications in "low" of batteries, power utilities that have hydro systems use this principal. They pump water up overnight while system load is low and generate with the stored water during peaks in power demand.

So yes the idea has merits in my humble opinion, but not for all, the additional infrastructure would negate the benefits for many.

regards Allan

[ [Parent](#) ]

Water lift VS, water push ([none / 0](#)) (#10)

by Gary D on Thu May 29th, 2003 at 07:16:55 AM MST

([User Info](#))

I think you are comparing lift (suction) versus push. A pump can much more easily push water than suction it. It doesn't take a strong submerged pump to push water uphill. Likewise even a jet pump with a foot valve can push water much further but not as effeciently. Just a thought. The Dan's and anyone associated with fire equipumnt or plumbing can back me up if they wish. We always put the portable pumps as close vertically to the water supply for this reason. just my 2 cents take it or leave it sit . Gary D.

[ [Parent](#) ]

lift vs suction ([none / 0](#)) ([#12](#))  
by troy on Thu May 29th, 2003 at 11:44:44 AM MST  
([User Info](#))

You are fully correct. Lift (vacuum driven) is limited to ~32' at sea level, less at altitude. But pushing water (pressurized) is a whole different matter. Pressure can go up forever, albeit at higher cost eventually. You can pump water up a thousand feet in a skyscraper. Positive displacement pumps tend to be more efficient than rotary/centrifical pumps, but have more moving/wearing parts.

The general idea of using water for energy storage is a sound one, as some utilities use big resevoirs for exactly that purpose, using the stored water to drive generators during peak demand, then pumping the water back uphill during low demand (overnight).

The Achilles heel with this system is the size of the water storage needed to generate any significant amount of electricity. Plus, any time you use a multistep approach, each little conversion in the system costs you some efficiency. So we have added pipe friction and pump friction and eventually we still have to spin an alternator, which has its own losses.

Again, not that it won't work, just that it adds a certain complexity and some loss of overall efficiency.

Best Regards,

troy

[ [Parent](#) ]

Efficiency? ([none / 0](#)) ([#13](#))  
by hvirtane on Thu May 29th, 2003 at 05:31:24 PM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

First:

It is true that suction pumps have got a limit how high they can pump. It is as well true that pressurized pumps don't suffer from that limit.

It is of course certain that this kind of system with water reservoirs can be built.

-----  
The question is  
if it is more practical, more  
efficient and/or simpler and/or cheaper  
than for example running  
a generator directly by the windwheel  
charging batteries.  
This is the question I'm rising.  
-----

My proposition was that  
a) generators are efficient only on  
a narrow band of RPM and  
b) windheels are efficient  
only if we let them run much faster  
at higher windspeeds.  
c) These two things don't match.

But :  
1) if we run with the windwheel a pump directly, we can run  
the windwheel efficiently all the time?  
2) if we run the water down with constant speed  
through the waterturbine as well the generator is  
running all the time efficiently.  
3) So water is not only a reservoir,  
but it adds the efficiency of the system?

"The Achilles heel with this system  
is the size of the water storage needed  
to generate any significant amount of electricity."

Yes we need some amount of water.  
 $P(\text{kW}) = 10QH$   
where P is Power in kW , Q is the flow of the water  
in cubic meters per second  
and H is the height of the water in metres vertically

From this you can easily see that in practice for a  
small system, which uses less than 1 kW power  
the amount of water is not that big, if you have got  
a place, where the height, H can be made reasonable big.

The system can of course be made

as a closed circuit system.

"Plus, any time you use a multistep approach, each little conversion in the system costs you some efficiency.

So we have added pipe friction and pump friction and eventually we still have to spin an alternator, which has its own losses."

As said before the efficiency problem is the main problem, which I'm trying to solve by using this water system.

Generators can be made more than 90% efficient if run with constant speed. If their speed varies a lot,, they are not so efficient.

On the other hand

to make windwheels even reasonable efficient

it is necessary to vary their speed a lot?

And pumps can run efficiently on a broad range of RPM?

"Again, not that it won't work, just that it adds a certain complexity and some loss of overall efficiency."

My proposition is that it adds overall efficiency.

It certainly adds some complexity because man must build the water reservoir, pipes and the waterwheel, but it as well lessens some complexity, because generators running with constant speed can be made simpler than generators varying their speed. And batteries are not needed.

At present the only practicable and economically viable way to store electrical energy in very large quantities is to use it to pump water up to mountain.  
(Renewable Energy,  
Oxford University Press 1998, p. 219)

Maybe the only practicable way to store wind energy is to do the same?

- Hannu

Stand alone water generator ([none / 0](#)) (#14)  
by Gary D on Thu May 29th, 2003 at 09:36:14 PM MST  
([User Info](#))

Hannu, as I understand it the main problem with stand alone A.C. generators is the frequencies change as more or less load is applied. Homepower.com has a good article of someone who has been using this exact setup for years. The best way I see to overcome this obstacle would be to produce D.C. into a battery bank, then run everything needing A.C. from an inverter. That way you keep the hertz or frequency at 50 cycles per second. Forgive me if it's 60, not sure what your country's system is set up for. The battery bank would stay mostly charged and be there for evening out the fluctuations. Sorry for the long post, but this is a simplified answer. Someone else may have a better explanation. always enjoy your posts. Gary D.

I've seen the article ([none / 0](#)) ([#17](#))

by [hvirtane](#) on Mon Jun 2nd, 2003 at 06:25:22 AM MST

([User Info](#))

<http://www.cc.jyu.fi/~hvirtane/cooker/>

Hi,

the address worked perfectly and I've read the article.

Thank you a lot for the address of the article.

However this article is only about waterwheels. Their water wheel is running constantly with the full power.

I've got a friend here with the technology (self made) with a waterheel so that it automaticly adds the power when more load is applied. His technology is very advanced, however with a Kaplan turbine etc.

There is an old pond in his place, it was some tens of years before powering a watermill.

I think that it would be easier to build a quite simple crossflow (Francis) turbine with a simple automatic adjustment for the waterport.

In addition:

Probably the easiest method would be to use a battery

in between so that the water generator would automatically charge the battery when needed.

So that the battery would be almost fully charged all the time. The battery could be quite small ( 100 Ah - 200 Ah).

And the power for the appliances would be taken from the battery. So that the system would work a quite similar way as normal car electronics, but instead of the car alternator powered by the car engine there would be the hydrogenerator.

The friend of mine mentioned above is planning to use his big wind turbine later to pump up water (besides directly heating the house) to his pond to use the pond as 'the energy battery'.

([User Info](#))

You need 6 diodes (three pairs) for conversion of all three phases to DC. Note that using those bridges gives you 2 diodes in series which will cost you another .5-.7 volts drop & hurt your efficiency. I know the bridges are cheaper & easier to find than 3 phase bridges or high amperage individual diodes. But a half a volt can add a lot of amperage at 12 volts. My 30 amp charger is just about that much higher under load (low battery, charging at around 12v) than my 10 amp charger.

The alternator's efficiency should be relatively constant for 1/2 to full output in amps (or better, watts). Output voltage shouldn't affect it much except as it relates to the amperage output (and it does - I'm just not sure how). Of course your overall charging efficiency will go down if there is a big mismatch in alternator vs. charging voltage, which you have in your example. But at 3 times the speed (30 vs. 10 mph) you could generate 9 times the power. (it's a cube function). I don't think anyone is getting all of that power out, anyway.

So what you want to know is how to best get rid of the voltage mismatch & maximize the power you can use. Probably the best way is to use a switching power supply as a DC to DC converter. It's relatively easy to input from 15-60v and get out a regulated voltage for charging your batteries. You could do that with a linear supply, also, but there are some advantages to the switching supply. These are cheaper to buy than build (computer power supplies) although it may be difficult to determine just what the safe maximum input voltage is.

Switching from star to delta to get a better match is a good, inexpensive way to get better efficiency, with practicaly no additional losses. Using the DC to DC converter (85% eff.?) or an autotransformer (85-90% eff.?) might be worthwhile in certain situations.

.014 lams ([none / 0](#)) ([#11](#))  
by Gary D on Thu May 29th, 2003 at 07:32:17 AM MST  
([User Info](#))

Hey Ed, doing a few very rough calculations using .014 steel for lams, with .003 for the insulator (tape or whatever) on an 11" disc, it would come out to about 75 to 80 feet of 1/2 inch steel. That is on a 1 inch diameter lam. thickness. Twenty five to thirty wraps. Am I in the ballpark? or have you found a thinner insulator? This is very interesting. Was hoping (wistfully that 3 wraps of 1/8 cold rolled would work) but you very easily shut that thought out of my head. Thanks for the great info. Maybe this will help me get a good first genny off the ground finally. Gary D.

Re: Solar Stirling opinions wanted ([none / 0](#)) ([#3](#))  
by charged on Fri Dec 26th, 2003 at 02:23:41 PM MST  
([User Info](#))

First, don't get thrown by this. It works. It will be worth your time to learn it and make use of it.

Use electrostatic power transmission and you can use thin lines with nearly zero loss.

There's been much confusion in the engineering world about exactly WHAT constitutes an "electrostatic" charge. Simply put, it's a pure potential with little or no electron current involved.

Any inductor can generate a massless emf pulse and transmit what amounts to an RF transient spike. Those spikes only manifest as current once they "land" in a capacitor. A 400v EMF spike and a 400v step-up transformer are NOT the same thing. EMF is electrostatic in nature. That's why it has advantages over using standard issue inverter systems.

Here's what you do.

Rewind a power transformer so that it's 1:1. Just get two spools of #23 wire and wrap about 400 turns in a bifilar fashion. This means they're both wound at the same time.

Make your windings of a suitable gauge wire to handle whatever the maximum power output of the generator is.

Since this is a 1:1, matched impedance transformer, any AC you put into the primary will be duplicated, out of phase in the secondary, same:same. But, we're not using AC. It's inefficient.

If you put a full-wave bridge on the secondary (made from 1kv diodes) and you pulse DC into the primary, you'll see two things coming out of the secondary side. First, you'll see your input DC voltage pulse. THEN you'll see an emf "spike" immediately after.

If you place a high voltage capacitor, like a photoflash type after the rectifier, you'll see it's voltage rise with each input pulse on the primary. If you keep pulsing, the cap will keep rising in voltage WAY beyond the input voltage. Everything ABOVE the input voltage is an electrostatic pulse. It's something like RF. Tesla called these longitudinal pulse waves. They are electrostatic, not "transformed" in a conventional sense.

Here's how you drive the transformer for high efficiency.

You need a pulse-width modulator. This can be something as simple as a 555 timer with it's output driving an optocoupler. The optocoupler is connected between the collector and base of a large power transistor/MOSFET/IGBT/etc...

Your generator output should charge a large capacitor at low voltage, right AT the generator site.

The capacitor positive goes to one lead of the transformer primary. The other transformer lead goes to the transistor collector. The transistor emitter goes to the capacitor negative.

The PWM must be set so that the "ON" pulse to the transistor only allows the transformer field to build to about 1/3 strength, then shut's off. This very efficiently produces an emf spike from the secondary winding that goes through the 1kv rectifier bridge.

The positive and negative outputs of the rectifier bridge connect to the power-leads to the house.

INSIDE the house, you place about 1000uf of 400v photoflash capacitors RIGHT AT the point where the wires come in. Then you run lead from those HV capacitors down to a larger, lower voltage capacitor bank.

You'll need a scope to set the transformer pulse-width correctly. For the next calibration, hook your indoor capacitor leads directly across your batteries. This will hold the emf spikes low and the capacitor collection will widen the emf pulse a bit. Turn up the pulse frequency until you just have a VERY small gap between the end of the emf pulse and the beginning of the next input pulse.

There, you're all set. The 555 pulse circuit will draw minimal amounts of power and the power transistor and optocoupler are a common current path avalanche arrangement. Very efficient since all the current used to control both of them ALSO goes through the transformer primary.

So I don't repeat anything more, read my posts in this other thread for the description of HOW to use the power once you've transmitted it to the house.

([User Info](#))

The greatest power is equal to the greatest temperature differential from the center of your dome (I'm assuming your using this as the focal point of your heat for the engine). So if you can get the center of the dome up to cooking temp you will be generating usable power even with the losses of the Stirling. I've thought about the idea myself but you need a large engine and it's all moving parts that wear out.  
RobD

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Hi,

a really interesting project.

The simplest stirling I've found in the Net:  
<http://www.emachineshop.com/engine/>

Another way to start is to use Ed Lenz's drawings, which are very good. (<http://www.windstuffnow.com>)

For the tracking I would use a pole at the same angle as the axle of the earth. The mirror could run round the the axle at the same speed as the earth rotates. You could make the seasonal adjustment of the axle by hand or make even automatic using a clock mechanism...

We had some discussions about tracking systems here:  
<http://www.fieldlines.com/story/2003/6/26/10248/0825>

Instead of making the stirling hot area to be in the focus point of your mirror you might as well heat with the mirror hot water or hot oil and circulate that fluid on the hot part of the stirling. The advantages would be that you would

have no need to move the engine and the engine could work even if there are some clouds on the sky... My concept to heat fluid using the sun:

<http://www.cc.jyu.fi/~hvirtane/through.jpg>

You might as well make the mirror of flat mirrors, something similar as the 'teton' concept:

<http://www.ida.net/users/tetonsl/solar/solarhom.htm>

A high voltage transmission using electric pulses (charged) and condensators sounds really interesting.

Hannu

Re: Solar Stirling opinions wanted ([none / 0](#)) ([#7](#))  
by [qwerty172](#) on Sun Jan 4th, 2004 at 09:33:05 AM MST  
([User Info](#))

Look at the sun power patents for stirling engines. They produced the best designs in the early eighties and still hold the record for conversion of solar energy to electricity (38% efficiency). They did it using a differential stirling engine based on Senft design I believe.

Also look at free piston stirling engines hooked up to a linear alternator. Its the simplest design possible for a generator, and it can be seaaled completely allowing for high pressure engines.

[Propellers, what is the max number of blades?](#) | 3 comments (3 topical, 0 editorial)

Re: Propellers, what is the max number of blades?  
([none / 0](#)) (#3)  
by DanB on Thu Dec 25th, 2003 at 07:12:28 AM MST  
([User Info](#))

Hii -  
"Everything I see uses three blades."

There is a reason for that. Typically fewer blades run faster and more efficiently. Two blades runs (as a general rule) a bit faster - and even more efficiently in many cases than three but the drawback is vibration. (they shake when they yaw). Sometimes the shaking can be overcome with weights - or sometimes it may seem un noticable, but any time you have two heavy spots a wheel and turn it (like a windmill yaws) its going to shake.

More blades generally have a bit mroe surface area and start more easily. 3 blades is a good compromise, probably the best compromise.

"I will be building an alternator that will need a twelve foot three bladed prop. Can I use, say (just for discussion) a six bladed 6 foot prop? "

No. Your 3 blade 12 footer would run at a reasonable speed and probably have lots of power. Your 6 blade 6' would probably have too many blades - a bit mroe torque - but it would be inefficient - even for a 6' prop. Power is related to the square of the diameter (the area). Your 12' blade covers a bit over 100 square feet. Your 6' prop covers about 30. The 12' prop (done well) should make 3 X the power of a good 6' prop. A 6 bladed 6' prop will have lots of xtra drag, so itd be even less powerful I suspect.

the 6 bladed 6' prop might have a bit of xtra torque to get your big alternator turning, but it will not have the power to spin it up to the sorts of speeds itll need to go to make power as it would if it had a 6' blade.

Hope that makes sense... (havent had any coffee yet this morning, its dangerous for me to do, or write anything before coffee!)

## [Propellers, what is the max number of blades?](#)

By [South Dakota Farmer](#), Section [Homebrewed Electricity](#) [Wind](#)

Posted on Wed Dec 24th, 2003 at 06:10:10 PM MST

I am trying to find out if a smaller diameter multiblade (6 blade) prop will work on an alternator that would be spec'ed with a three blade 12 footer?

Everything I see uses three blades. I will be building an alternator that will need a twelve foot three bladed prop. Can I use, say (just for discussion) a six bladed 6 foot prop? Am I going to end up dealing with twice the tip speed? thus a lot more noise? Or am I going to raise the starting wind speed to a point that it isn't worth it? or, or, or? Obviously I don't know squat about the physics of props and wind, but I have a lot of it! The other night on the ridge we had sustained wind speeds of 86 mph... and that is not unusual. Ripped a \$400 door off of one of the tractors! and those doors are designed for this type of thing. I don't expect to have this kind of wind all the time, but am wondering if anyone has a handle on or can point me in the right direction on propeller design or the pitfalls of experimentation. I am planning on building a few Axial flux alternators. Thanks for the help

[Propellers, what is the max number of blades?](#) | 3 comments (3 topical, 0 editorial)

Re: Propellers, what is the max number of blades? ([none / 0](#)) (#1)

by Kevin L on Wed Dec 24th, 2003 at 09:44:58 PM MST ([User Info](#))

Three blades are used because as you increase the number of blades you increase the leading edge and blade tip resistance. At half the diameter you wil reduce the tip speed by half. The power output will be much lower at 6 ft because the increase in power exponentially increases with diameter. A 6 X 6 ft blade will produce much less power then a three bladed 12 footer. Use caution if you are dealing with 86 mph winds. I don't have enough high wind speed experiance to say weather it should or shouldn't be done, but you certainly would want the system a safe distance from the house, as lossing a blade in 86 mph winds could send that blade very far. Use caution expecially if the house is downwind! You will also want a very good furling system. Good Luck

You have located the place where art and science mix. I believe there is a point where blade number controls the rpm but I don't know where this is (1000 blades?). 100000? Currently I run 6 blade and 3 blade mills. Thin high aspect blades with optimal helical pitch turn very fast in 6' diameter mills (probably near 2000 rpm in 35 mph breeze (the permanent magnet alternators characteristics matter too). Great fun to experiment with! Mostly, I deal with 20 to 50 mph here in the canyon. Two of my mills tilt back beginning at 30 mph or so and are able to take 60 mph (they look and sound like monsters at these higher wind speeds. The other two use 6 blades and do not tilt back and I am experimenting with them above 40 mph. One of these mills was on a 1 1/2 " pipe threaded into a 2" union with a 5' lever arm to the guy point. It broke through the threads at about 45 mph. I never found two of the blades! The present lever arm is 2 feet with 1 1/2" pipe and I think it will hold to 50 mph and more. 80 mph is a big difference from 50 so take it slow and make it strong :- ) I've resigned myself to furling/feathering/tip back or swing out of the wind mechanisms for these higher speeds but I don't like wasting those winds. If I can be of help

I think you have to make a judgment (gamble?)... totally knot free is rare and hard to find. Knots are acceptable depending on how they run through the board - how large they are, where they are etc....

The 10' machine we recently finished is from Eastern White pine and has a few knots in the wood - one of them worries me a bit, but I think itll be fine. The fir Im using on the 14' experiment is totally knotless... but also quite expensive.

Gary,

Good wood is where you find it. The last vertical grain, clear Doug Fir I bought was from an architectural supply company. It came in 20 foot lengths. I paid ~\$4 a board foot.

Almost any straight grained wood will make a good prop. Selecting pieces of wood has more to do with it than species. The species that are 'aircraft aproved' grow in long straight lengths and tend to be light for their strength. Beyond that, there is growth ring orientation, ring count per inch and runout. There are also some other quailits spar material must possess.

Spar grade material is not necessary for windturbine propellers. It is pretty from a working standpoint.

Proper moisture exclusion is something else that will keep wooden things 'stable.'

Ron

Not an answer to your question, and not from Dan B....

Have you considered building up a blade from scarfed sections of wood, or even laminated sections of veneer or very thin plywood? I used to laminate kayak paddle blades this way and had good success with them, particularly in not having them warp or twist with long term exposure (immersion) to moisture. I know that propellor makers sometimes use this technique to build props. One advantage of the lamination process is that the waste is minimized: as a corollary it is less difficult to find the large sized stock that is necessary to produce a propellor from a single piece of wood. By stacking the laminates in a progressive fashion, as in a spiral staircase, the "dead" area that has to be cut away to achieve a wing shape is reduced.

Traditional kayak paddles (the "Eskimo" kind -- not the kind that looks like two canoe paddle blades stuck together by a handle) are shaped much like a windmill blade, and function in the same manner as a wing. Because they are a symmetrical foil, however, it is the angle of attack at which the blade is pulled through the water is what generates lift. The leading edge presented to the water changes depending on how you happen to pick up the paddle, so having a regular leading edge shape just on one edge would be impractical. With a traditional kayak paddle, you kind of fly the blade in the water. Hard to explain, but intuitive once you get past thinking that you have to struggle to pull a blade through water to move forward.

Regular polyester resin is a good glue, providing both waterproofing and high resistance to delamination due to applied stresses (the glue joint will have a greater tensile strength than the wood itself.) If you were to construct the wing out of 1/16" veneer thoroughly impregnated with resin, you could probably overcome all the problems associated with changing humidity.

General suggestions based on kayak paddle building experience:

Prepare a jig to hold the laminate sections in place.

Cut the laminate sections to final dimensions (i.e. before shaping..."rough" dimensions.)

Sand the laminate sections with a medium grit paper, and blow them clean -- the idea being to create an open pored surface into which the resin will soak.

Coat all sections with a coat of resin...BUT...don't mix the resin very hot (use less catalyst than normal.) This will give you time to handle the sections. Use plenty of resin so that it soaks into the laminate sections. Allow the resin to set to the "tacky" stage.

Coat the mating surfaces of the laminate sections with a layer of regular resin and place them into place in the jig.

Clamp them firmly using clamps and cauls (clamping boards used to spread pressure evenly) covered in wax paper or Saran wrap (won't stick to resin.) Clamp firmly

enough so that the resin begins to squeeze from between the laminate sections, but not so firmly as to drive the resin out of the joint. Unlike regular glue, resin works better with a thicker (than wood glue) joint.

Wipe excess resin from the surfaces before it hardens.

Once the wing is set and has cured for a day or two, you can shape it. A rasp, Sureform, and spokeshave are handy tools to use.

Cut a piece of 6 ounce fiberglass cloth to the rough shape of the wing, plus 2" (50mm) extra around the edge.

When you have the shape you desire, finish sand the wing and coat ONE SURFACE with a layer of resin.

Drape the pre-cut 6 ounce fiberglass over the resin-wet surface of the wing. Wet out the glass until the depth of the weave is 1/2 filled with resin.

Be sure to wet out the 2" (50mm) extra fiberglass around the edge. The weight of the wet cloth will help to keep the fabric in contact with the edges of the wing (leading and trailing.)

When the surface has set to the "tacky" or "firm green" stage, use a razor knife to trim away the extra 2" all around. Then add additional coats of resin to the glass fabric until the weave is filled, waiting for the resin to reach the "tacky" stage between coats.

Once one side is finished, turn the wing and do the other side the same way.

On a paddle, the fabric does not wrap around the edges of the blade, but simply lies flat along the trailing/leading surface. On a propellor, where the leading edge is rounded, I think I would apply fiberglass to the upper layer first, so that the extra cloth would drape down enough to wrap around the leading edge to the bottom of the wing.

Then the lower surface's layer of cloth could simply be laid so that it reached from the trailing edge (after trimming the edges, and filling the weave) to the point where it just overlapped the wrapped portion of the upper layer at the bottom of the leading edge. The lap-joint could be sanded smooth once the glass had cured.

If you wanted to, you could take a length of fiberglass or graphite tape (or nylon webbing -- the thinnest you could find), soak that in resin, and apply it to the leading edge of the wing to add abrasion resistance.

I used to use small diameter nylon rope soaked in resin and laid along the edge of the rounded end of the paddle blade as an extension for abrasion protection. I would put it on before the fiberglass cloth, so that the cloth would lie across the upper and lower edges of the rope.

A very good description of how to cover paddles with fiberglass in a book called "Building a Strip Canoe", by Gil Gilpatrick. You can probably find other similar instructions in other canoe building books.

JUST FALSE ([none / 0](#)) (#5)

by wdyasq on Mon Dec 22nd, 2003 at 07:58:51 PM  
MST

[\(User Info\)](#)

-Regular polyester resin is a good glue, providing both waterproofing and high resistance to delamination due to applied stresses-

This is just a false statement. There are resins, epoxy, that are good glues. Polyester will allow water to pass if left in immersion. So will epoxy - but, most epoxy formulations have been modified to resist this.

You can get away with a lot for things in temporary use. But if a polyester/wood lamination is left in water, strange, not so good things, start to happen.

If one values their labor at all, they will opt for the proper materials to built a windturbine. I'm not going to live long enough to be able to repair things I made with the wrong goo. And I hate to do things twice because I got the wrong information.

Ron

([User Info](#))

Well, it is certainly a matter of degree....

Polyester resin will allow water to pass if left immersed constantly, as in boat hulls that are left in the water. There is a process called blistering that takes place wherein water gets through the resin and into the laminate creating blisters. This takes a long time with constant immersion. You don't see it on trailer sailers that spend most of their time out of the water. Blistering is the bane of folks who bought fiberglass boats built in the ~ = first half of that industry's history. For something like a paddle, where "immersion" is frequent and continuous, but not constant, polyester's disadvantages don't outweigh its advantages: it's cheap, it's easy to work with (again, relative), and it comes in gallon cans at Wal-Mart.

I forgot to mention, that I would also paint a windmill blade that was covered with polyester resin. It is not 100% resistant to UV by any means. And if you want to pick an expensive material that the sun will destroy after a couple or three years or 5 years, by all means, go with unprotected Kevlar -- I have an old Kevlar racing canoe that you can almost poke a finger through. It only weighed 30 pounds (partly because it had no coloring in the epoxy), and was fast as the dickens, but 10 years seems to be well past the lifespan of Kevlar subjected to a lot of UV. Fortunately, I got it used -- it was getting about as much damage from using it as a guide boat as the sun was dishing out.

The epoxys available are certainly good, but cheap, they ain't, and they don't come in gallon cans at Wal-Mart.

([User Info](#))

I haven't seen epoxy resin sold at Wal-Mart. The only thing I have seen there is polyester resin. I could have missed it, though, so it might be there. I think the kits of resin and fabric that you get in the auto repair section (which is where I used to get stuff to make paddles) have polyester resin in them.

Bondo is one of the brands that market such kits, IIRC. They should have big gallon cans of it, too, and little tubes of MEK (methyl-ethyl-ketone) catalyst that is used with polyester resin. MEK is a very toxic substance, by the way, so working with polyester resin does raise issues of personal safety. Epoxy resins also raise safety issues -- some people have had allergic reactions to them.

Be sure to read the MSD (material safety data) sheets that come with any chemical products you use.

Wow - 30 feet! (love to see/hear more about that one!)

I got mine from a local yard that sells nice tools and wood mostly for fine wood working - interior finishing and cabinet making folks. You can spend about however much money you want there. Mine was not cheap - for the prop I spent about \$160 for the wood. The eastern white pine they normally carry is about 1/4 the price and is often just as good in my opinion - it just happened they didnt have any that was knot free at the time so I went for the fur.

Good luck! - Thirty feet seems... quite daunting! I hope I have that much courage some day!

Re: Help, DanB ([none / 0](#)) ([#10](#))

In looking for lumber for blade use (and I've been looking at construction grade lumber for the most part), I haven't found anything that is "knot free". When you guys with experience say that you're using knot free wood, is it really completely knot free, or are the smaller knots (1/4" to 1/2") alright? I've been able to find material that doesn't have the large obviously not good knots, but there is always a multitude of the small ones. Acceptable or not?

Thanks,  
Matt

I think you have to make a judgment (gamble?)... totally knot free is rare and hard to find. Knots are acceptable depending on how they run through the board - how large they are, where they are etc....

The 10' machine we recently finished is from Eastern White pine and has a few knots in the wood - one of them worries me a bit, but I think itll be fine. The fir Im using on the 14' experiment is totally knotless... but also quite expensive.

DanB, Thanks for the info. At those prices my prop would be in the 1200- 1500 dollar range. I built a deck in Crested Butte in the early eighties for a friend and the lumber we used was beautiful and cheap. I guess those days are gone. I am trying to get some pictures of my new project in its current stage. I will be needing a bucket of neos to convert a one of the 15HP motors to PM alternator. The other one will feed the grid directly.  
Garry

I'm building an 11ft, one piece, two blade prop for an old Wincharger 32v 1000 watt that I'm restoring. I got four 2"X6"X12' boards at Home Depot and cut them in strips to get rid of the knots then alternated the grains when I glued them together. I'm going to paint the prop and put those airplane epoxy strips on the leading edges of the blades to protect them. There is a guy that sells the copper strips like were used on the original Wincharger prop, but it's too much bother to nail them on.

"WIND's KID - 5" from Lithuania | 3 comments (3 topical, editorial)

Re: "WIND's KID - 5" from Lithuania ([none / 0](#)) ([#1](#))  
by DanB on Tue Dec 23rd, 2003 at 07:48:00 AM MST  
([User Info](#))

Pretty neat! It seems like quite a large machine to mount to a roof top. Does it vibrate the house?

What is the blade diameter? Is this the one you said was using helicopter blades? - what is the hub/planetary gear setup from?

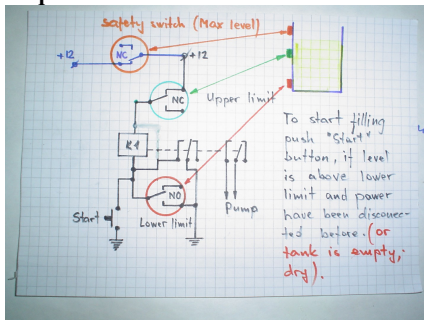

The furling system is interesting - you said its like the whisper? It seems as though lifting only 20 deg might not protect the machine enough in higher winds. I think the whisper actually tips up, and to the side.

It's fun to see so many approaches to windpower. Sounds like quite a neat group of kids.

Hi DanB,

the "WK-5" isn't noisy and it doesn't vibrate too much. Blades are balanced statically and dynamically very carefully. The blade diameter is 3.35 meter. The weight of each one is 1.870 kg. Total weight of prop with spindle - 6.420 kg. Blades are made of wood and laminated with fiber glass. For hub / planetary gear we used an old boring machine gear. Blades aren't helicopter blades. The windmill with helicopter blades is located about 200 km away from my city. I hope to tell about this monster A.S.A.P.

The picture above explains our furling system of "WK-5".

## ["WIND's KID - 5" from Lithuania](#)

By [Virgis](#), Section [Homebrewed Electricity](#) [Free Energy](#)

Posted on Tue Dec 23rd, 2003 at 05:23:03 AM MST

A story about our windmill "WIND's KID - 5", made by members of pupil's club from Naujoji Akmene.

Hi all,  
I have promised to tell about the last our project translated into reality. Now I have a free time to do it. Our turbine have been a little damaged (blades) during the last storm, we lowered our windmill and I have a chance to show our windmill in detailes much more better.

Below is shown general view of "WK-5".

Lowered "WK-5"

Above is shown alternator with simply furling system. It is similar to WISHPER furling system. Turbine lift up 20 deg.

Above is prop 3.35 m diameter.

To excitate alternator we use control unit with anemometer. Excitation starts at 5.0 m/s wind speed. The value of excitation current depend on wind speed.

Picture below shows alternator. It is 3ph 160 VAC rewinded tractors 850 W 24 V alternator.

3 ph AC / 160 V DC rectifier is shown below.

Gear box ( ratio 1:6)

Here is showh assembled brush and sliding ring system.

This picture shows hoisting unit.  
In the older wind turbines we made there was no system  
by which turbine could turn away from high winds. Now  
we are going to modify our "WK-5" and to make furling tail

like it is done by DanB.

Best regards  
Merry Christmas for all!  
Virgis

[Really thin coils.](#) | 5 comments (5 topical, editorial)

Re: Really thin coils. ([none / 0](#)) ([#1](#))  
by DanB on Mon Dec 22nd, 2003 at 11:05:30 PM MST  
([User Info](#))

Im not quite sure I follow you.... but heres my thoughts.

"Imagine a sandwich - plexiglass on the outsides, with a 1/4 inch thick wood core."

Im not sure why you'd want plexi in there.... it would serve as an alternative to casting things perhaps, but in the end... that plexi is taking up extra thickness or.. space where you could have copper!

"The wood core is thin enough that the thickness can't get but so large. After winding, I'd seal it with some form of epoxy, or maybe use resin."

That kind of almost describes the coil winder that I use. its a sandwich - plexi on the outside and wood on the back and a wooden form in the middle. Before I loosen the nut on the end, and take the coil off - I put glue (super glue) into the coil which sticks it together and makes it hard so that when I take it out it doesn't get any thicker. There are other ways to do this too - making the form so that you can tie, or tape the coils tightly before you remove them.

Hard for me to say - and perhaps Im misunderstanding, but It shouldn't be difficult to wind good thin coils, and inch is quite a lot! But I don't often hear of this being a problem. I think your idea of plexi would surely work - but Im doubtful that it would make things easier and in the end I think you'd wind up with possibly an even larger airgap - because the plexi occupies space where you could have copper wire.

Dan,

Thanks for the response. I've tried 1 by wood as the core for my coils. I've also tried dowels. The quarter inch thick wood seems a better thickness. I might even try to plane that down to something like 3/16 of an inch.

I suspect my post was not clear. I'm talking about two different steps. First, using the plexiglass as a mold for the nine individual coils.

After molding and setting the coils in whatever glue/resin to hold them together, that plexi and wood would be removed and probably discarded. Pure copper would remain.

Then there would be one thickness of plexiglass to which my nine coils would be glued. This should leave me with a stator in the range of 3/8 to 7/16 inches thick.

A difficulty I always seem to have is that my fiberglass molded stators often vary in thickness. This often forces me to have a wider gap to accomodate the less than "plumb" and uniformly level surfaces. I just haven't found the right process to end up with a level molded surface. The plexiglass should be uniformly level, while adding minimally to the thickness.

The plexiglass I have is about an 1/8 of an inch thick.

Bach On

[Really thin coils.](#)

By [Bach On](#), Section [Homebrewed Electricity](#)  
Posted on Mon Dec 22nd, 2003 at 10:35:57 PM MST [Alternators](#)  
Speculation:

I've now tried different techniques for winding coils. Most end up being an inch thick by the time they are set in Fiberglass resin. Even with dual magnet disks, that's quite a gap.

I've been toying with an idea. I'd appreciate any feedback. First, the goal is 9 coils with 12 pairs of 1 inch by 2 inch by 1/4 inch thick magnets. I'm anticipating a 16 inch diameter set of magnet rotors.

My wire is 18 gauge. I got it from a motor rewinding shop. Here's the idea:

Imagine a sandwich - plexiglass on the outsides, with a 1/4 inch thick wood core. I might also include fiberglass cloth in the sandwich. The coils would be 50 - 60 turns of wire. The wood core is thin enough that the thickness can't get but so large. After winding, I'd seal it with some form of epoxy, or maybe use resin. My stator would be made of plexiglass. Each of these nine sandwiched coils would be glued to this plexiglass stator. Providing there are few screw holes to produce stress fractures, do you think this might hold up?

Yes, plexiglass can get brittle. But by keeping things as thin as possible, my hope would be to keep the gap between my magnets relatively thin.

Suggestions and comments would be appreciated.

Im not quite sure I follow you.... but heres my thoughts.

"Imagine a sandwich - plexiglass on the outsides, with a 1/4 inch thick wood core."

Im not sure why youd want plexi in there.... it would serve as an alternative to casting things perhaps, but in the end... that plexi is taking up xtra thickness or.. space where you could have copper!

"The wood core is thin enough that the thickness can't get but so large. After winding, I'd seal it with some form of epoxy, or maybe use resin."

That kind of almost describes the coil winder that I use. its a sandwich - plexi on the outside and wood on the back and a wooden form in the middle. Before I loosen the nut on the end, and take the coil off - I put glue (super glue)

into the coil which sticks it together and makes it hard so that when I take it out it doesn't get any thicker. There are other ways to do this too - making the form so that you can tie, or tape the coils tightly before you remove them.

Hard for me to say - and perhaps I'm misunderstanding, but it shouldn't be difficult to wind good thin coils, and an inch is quite a lot! But I don't often hear of this being a problem. I think your idea of plexi would surely work - but I'm doubtful that it would make things easier and in the end I think you'd wind up with possibly an even larger airgap - because the plexi occupies space where you could have copper wire.

Dan,

Thanks for the response. I've tried 1 by wood as the core for my coils. I've also tried dowels. The quarter inch thick wood seems a better thickness. I might even try to plane that down to something like 3/16 of an inch.

I suspect my post was not clear. I'm talking about two different steps. First, using the plexiglass as a mold for the nine individual coils.

After molding and setting the coils in whatever glue/resin to hold them together, that plexi and wood would be removed and probably discarded. Pure copper would remain.

Then there would be one thickness of plexiglass to which my nine coils would be glued. This should leave me with a stator in the range of 3/8 to 7/16 inches thick.

A difficulty I always seem to have is that my fiberglass molded stators often vary in thickness. This often forces me to have a wider gap to accommodate the less than "plumb" and uniformly level surfaces. I just haven't found the right process to end up with a level molded surface. The plexiglass should be uniformly level, while adding minimally to the thickness.

The plexiglass I have is about an 1/8 of an inch thick.

Bach On,

If I were trying to build the thinnest and strongest stator for the thickness, I would make the front and back plates of high-tensile epoxy resin and 'S-glass' or carbon-fiber cloth first. These thin laminates would be made on a piece of waxed plate glass and made with as little resin as it took to soak the cloth. All excess would be pulled off or I might vacuum bag it with 'peal-ply'.

I would then make my coils and sandwich them between the two skins I had just made. Spacer blocks would keep the skins at a constant thickness and squeeze out the excess resin.

The resulting product would have the structural material as separated as possible. The 'skins' would likely be less than .030 inches each.

But, there is an old saying -Go ahead, it's not my cow.-

Why dont you try to explain what you are trying to do, I mean, the final product; it may be better, this way, for someone to understand what you are trying to do, this way you may get a lot of more practical help.

Hi guys,

Don't forget, it is important to use clamping-down method while epoxying the sandwich. This will keep the stator thinner and the clamps can be adjusted to get an even thickness ALL AROUND the stator disc as you can squeeze the coils down (Unless you already have the coils wound in high density, which is not so easy to do in homemade situations). That too, you won't even have to fabricate spaces. Using 4 or even 6 clamps around the disc can get must precise height adjustments than using the "Lazy" 3 clamps. With 3 clamps, sometimes you might think you got it under control but when the resin or epoxy is dried and you opened the clamps, you would find the uneven thickness still. (Sorry for the outburst "Lazy", did not mean to contradict others. Just wanted to update ideas. Get the drift ? :-)

Smile,  
Harry Luubovv.

Wow - 30 feet! (love to see/hear more about that one!)

I got mine from a local yard that sells nice tools and wood mostly for fine wood working - interior finishing and cabinet making folks. You can spend about however much money you want there. Mine was not cheap - for the prop I spent about \$160 for the wood. The eastern white pine they normally carry is about 1/4 the price and is often just as good in my opinion - it just happened they didnt have any that was knot free at the time so I went for the fur.

Good luck! - Thirty feet seems... quite daunting! I hope I have that much courage some day!

In looking for lumber for blade use (and I've been looking at construction grade lumber for the most part), I haven't found anything that is "knot free". When you guys with experience say that you're using knot free wood, is it really completely knot free, or are the smaller knots (1/4" to 1/2") alright? I've been able to find material that doesn't have the large obviously not good knots, but there is always a multitude of the small ones. Acceptable or not?

Thanks,  
Matt

I think you have to make a judgment (gamble?)... totally knot free is rare and hard to find. Knots are acceptable depending on how they run through the board - how large they are, where they are etc....

The 10' machine we recently finished is from Eastern White pine and has a few knots in the wood - one of them worries me a bit, but I think itll be fine. The fir Im using on the 14' experiment is totally knotless... but also quite expensive.

DanB, Thanks for the info. At those prices my prop would be in the 1200- 1500 dollar range. I built a deck in Crested Butte in the early eighties for a friend and the lumber we used was beautiful and cheap. I guess those days are gone. I am trying to get some pictures of my new project in its current stage. I will be needing a bucket of neos to convert a one of the 15HP motors to PM alternator. The other one will feed the grid directly.

I'm building an 11ft, one piece, two blade prop for an old Wincharger 32v 1000 watt that I'm restoring. I got four 2"X6"X12' boards at Home Depot and cut them in strips to get rid of the knots then alternated the grains when I glued them together. I'm going to paint the prop and put those airplane epoxy strips on the leading edges of the blades to protect them. There is a guy that sells the copper strips like were used on the original Wincharger prop, but it's too much bother to nail them on.

I think thats close... the best bet is experiment I suppose. Id try the coils slightly larger. If it were me, If you're not going to break the magnets, then Id try to run them close together so the poles are as equally spaced as possible.

[Alternators](#)

I think collecting hard drive magnets is a labor of love.

Well,

I'm building this windmill and I'm tryng to use mostly recycled parts. I've found an old strut and brake rotor from a junk yard; however, I have only one rotor. The strut was not attatched to a car and as I do not have the make and model number of the car I've had difficulty finding another matching rotor. It seems then the best thing to do is to build a single rotor machine.

I've been collecting hard drive magnets for the magnet part of things. They are of different shapes and apparently strengths. What if I were to use two different or even three different sizes or shapes of magnets on the same rotor? As long as they were still balanced would it make a meaningful difference?

I also have a hard time both understanding and locating matereial for laminates. I am really attracted to the dual rotor mills; however, I lack a second rotor. Could I use a peice of plywood or perhaps some plate of steel for a second rotor and use different magnets than I used for the first rotor or weaker magnets than the first rotor? I would be doing this more to not have to deal with the whole laminates end of things ,not really to produce more power. It also gives me another way to divide up all these different shaped magnets.

I really would appreciate any comments on these questions,

Jeremy tnhach@yahoo.com

Hi Jeremy,

Thing to be carefull with "hard drive" magnets is that a lot of them have the N and S pole on the same face. I don't think you can use these effectivly for an alternator. Look for magnets that have a N pole on one face the S pole on the other.

If you want to make a dual rotor take the disc you have to a junk yard or scrap metal yard and match it to some other one.

As this has not worked for you then a plate of steel would be the way to go, plywood is out.

I suspect you can mismatch magnets (not an ideal way to go) the outcome may be that some of your coils will produce more voltage/power then the others. In a series system I don't believe it will matter. In parallel it may, I really don't know.

As far as laminates go (for a single rotor) you would want very low carbon steel strip or special laminate steel (Silicon). A good way to check if a piece of steel is suitable for laminates is to put a magnet on a piece of this steel then remove it. Now check if there is any residual magnetism in the steel by trying to pick up a pin or small nail with it. The less residual magnetism the better. For reference try this with a hack saw blade, it will have a high residual magnetism and are not good for laminate material.

I ended buying a 4'x8'x .060 1008 steel sheet. It only cost me \$20. It cost me \$40 to have it sliced to the width I needed at the tin smith.

Have fun,

Hank

by [Sponge](#) on Sun Dec 21st, 2003 at 02:27:44 AM MST  
([User Info](#))

Im working myself on a harddisk magnet rotor, this week I'm going to try my test setup for it.

As you might have noticed.. magnets come in all sorts and sizes.. liek this picture demonstrates. I took it yesterday night, bit unsharp:

(clickable)

My current amount of proper magnets:

(clickable)

I have not yet made laminates. I can't find any decent info about it. The only metal I can find overhere is 10mm wide, 1mm in height and 1m long. (or a 16mm wide version). I'm not sure if that is bad, good, or semi good. The only strips I can find are aluminium...

Oh, I forgot: Does anyone think the material from a "cookie box" (like where my magnets are on, at the top picture) would be a nice amination material? :) It's thin.. :)

Also, right here:

<http://www.fieldlines.com/story/2003/10/15/102538/69>

Someone is telling about his HD magnet windmill (somewhere in center of the page), but the guy doesn't have a nemail adres unfortunatly.

Regards,  
Almar

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#4](#))  
by [Jeremy](#) on Sun Dec 21st, 2003 at 09:09:34 AM MST  
([User Info](#))

Thanks for the advice,

The part I find confusing about laminates is firstly, what kind of metal to use (which I think I understand more about from your comment) and secondly, are the strips wound in a coil or are they concentric rings insulated completely from eachother? I would also love an example of a product or thing in everyday life that is made of this metal. I suppose I'm ignorrant to what low-carbon or silcon steel is. It sounds so specialized, but perhaps it is an everyday metal I come across all the time. Thanks again for the insight.

Jeremy

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#6](#))  
by Hank on Sun Dec 21st, 2003 at 09:43:02 AM MST  
([User Info](#))

Jeremy,

Low carbon steel is probably the cheapest steel. Probably used in making cars. You may also find it in a Auto Body supply shop. It's soft and easy to work. You can also call a steel supply shop and ask about it. Key here is "low carbon" and that's what I would recommend as being the most cost effective.

The strips are concentric rings insulated from each other. I used masking tape on one side for the insulation.

The pic here shows my stator. If you look carefully behind the coils in the center you will see the laminates. The width of all the laminates should be at least the size of your magnets and they serve the purpose of focusing and completing the magnetic circuit.

This greatly enhances the power capabilities of the genny.

Have fun,  
Hank

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#7](#))  
by Sponge on Sun Dec 21st, 2003 at 10:30:10 AM MST  
([User Info](#))

btw, staying on topic, I have tried various coils today..and right now, the power output of one coil - currently without laminates - is still a bit disappointing I think. I get about 0.3v with one coil (circular, and wide), spinning my mill as fast as I can. So I'm wondering a bit if I could improve my coil:

Note: Right now you see various magnets. This was just quickly for testing if it was a magnet problem for the low output. For my "real" setup, check out picture above!

Since this is my first windmill, I have no idea how those coils exactly work, even after reading all sites I could find :)

All my magnets look like:

Anyone can tell me what the best size would be? :)

Regards,  
Sponge

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#10](#))  
by DanB on Sun Dec 21st, 2003 at 11:59:23 AM MST  
([User Info](#))

Yes, I would try what Electric Ed suggests below. I think your coil is way too large... at most, it should be the size of a single magnet there, so that the OD of the coil is not larger than two poles (1 magnet).

Id also try to keep the coil pretty thin - if you use laminates, i believe there becomes a point of diminishing return when the airgap is thicker than thne magnets. So if you can stack your magnets up to say... 1/4" thick - try to keep the airgap (distance from magnet to laminates) not much more than that...

It sounds a bit funny - but I think perhaps youd get better results if you could break those hard drive magnets in half so that there was a bit of seperation between the poles.

[ [Parent](#) ]

by [Sponge](#) on Sun Dec 21st, 2003 at 01:20:01 PM MST  
([User Info](#))

Thanks, a bit like this?

I don't like breaking the magnets in two, actually :)

Regards,  
Sponge

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#12](#))  
by Hank on Sun Dec 21st, 2003 at 02:14:13 PM MST  
([User Info](#))

You may want to make your coils look more like Ed showed, sort of rectangular. You want the magnets crossing the wire at a right angles (90 deg.) not parallel. So the hole in the center should be larger than your magnets are wide and the magnets should just cross the legs of the coil.

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#13](#))  
by [Sponge](#) on Sun Dec 21st, 2003 at 02:45:13 PM MST  
([User Info](#))

Yeah, I tried rectangular before, but somehow the circular one gave more output :). But I guess it was my first "flat" coil. So, if I understand correctly, it should be like this? (or more like the bottom coil?).

With one magnet per pole, it's easier to be sure than with these HD magnets :)  
So.. just checking :) (And I think there are more people looking for answers like these in the future too :- ) !)

Regards,  
Almar

Yes that's more like it. NOT like the bottom one it's too large. Also I think you might want to make the legs a bit longer so the whole magnet can be seen thru the hole in the center of the coil.

Magnets passing parallel with the coil windings don't produce power. This is a waste of potential power.

The coils don't have to be perfectly rectangular, you may want to make them a bit trapezoidal to sort of fit to the shape of your magnets. Perhaps similar to the pic I have above in an earlier thread.

I think that's close... the best bet is experiment I suppose. I'd try the coils slightly larger. If it were me, if you're not going to break the magnets, then I'd try to run them close together so the poles are as equally spaced as possible.

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#15](#))  
by kell on Sun Dec 21st, 2003 at 07:43:29 PM MST  
([User Info](#))

Consider the moment the coils pass between magnets. Flux lines extend from the north pole of one magnet to the south pole of the adjacent one just as they extend from the north pole of a single magnet to its own south pole. The coil will see that. So doesn't it make sense that the north and south poles of two adjacent magnets should measure the same distance apart as the north and south poles of a single magnet, in order to optimize the functioning of your generator?

Try dangling a needle on a thread to find the exact point a pole is located at. Measure the distance between the north and south poles of one of your magnets. That should be the distance, center to center, for you to mount the magnets. You may have to adjust the distance from the center of rotation of your ring of magnets in order to make it all come out even because, in this case, you are dealing with a fixed magnet spacing. That may be why some people succeeded with HD mags and some didn't -- it might be kind of a crapshoot whether the poles are spaced evenly even if the magnets themselves are spaced evenly. Another reason all your magnets should be the same.

by [Sponge](#) on Mon Dec 22nd, 2003 at 02:55:01 PM MST  
([User Info](#))

Thank you guys!

I'll try it tommorow when I have a bit more time to do some testing. The "needle and a wire" trick seems to work to find the exact "pole centerpoints".

I think haddisk-magnet alternators are nice for a first windmill experiment. I think this entire thread might be usefull to other people as well :) (Although the only "bad" thing of this board is that this thread will probably be down 2 pages if I post my results and no one might see it, except for searchers :-))

Regards,  
Sponge

Yes, I would try what Electric Ed suggests below. I think your coil is way too large... at most, it should be the size of a single magnet there, so that the OD of the coil is not larger than two poles (1 magnet).

Id also try to keep the coil pretty thin - if you use laminates, i believe there becomes a point of diminishing return when the airgap is thicker than thne magnets. So if you can stack your magnets up to say... 1/4" thick - try to keep the airgap (distance from magnet to laminates) not much more than that...

It sounds a bit funny - but I think perhaps youd get better results if you could break those hard drive magnets in half so that there was a bit of seperation between the poles.

You may want to make your coils look more like Ed showed, sort of rectangular. You want the magnets crossing the wire at a right angles (90 deg.) not parallel. So the hole in the center should be larger than your magnets are wide and the magnets should just cross the legs of the coil.

[ [Parent](#) ]

Yeah, I tried rectangular before, but somehow the circular one gave more output :). But I guess it was my first "flat" coil. So, if I understand correctly, it should be like this? (or more like the bottom coil?).

With one magnet per pole, it's easier to be sure than with these HD magnets :) So.. just checking :) (And I think there are more people looking for answers like these in the future too :-) !)

[Laminated Copper Coils?](#) | 8 comments (8 topical, editorial)

Re: Laminated Copper Coils? ([none / 0](#)) ([#5](#))  
by DanB on Wed Dec 17th, 2003 at 10:41:40 PM MST  
([User Info](#))

I think what he had in mind is not wider wire... but picture winding your coils with tape. You can get magnet wire in square, and rectangular shapes -and it would save a lot of space and definitely allow for significantly more wire in a smaller space. I wish I had a good selection of such wire - I think it would be great. I suspect winding nice clean tight coils might be tricky with really thick stuff, but if you had the resources and the patience the coils would come out really nice.

I've used bar stock to make some extremely powerful alternators as well as copper sheet. It is, however, very difficult to work with and you have to do some advanced planning on winding them and setting them into place. One I experimented with was made from copper sheet, punched out the coils and soldered together to form a "slinky" style coil.

You can get almost double the turns of an equivalent size but it will take a couple days on each coil. The outcome, of mine, wasn't real rewarding for the amount of work I put into it and the idea was scrapped. I believe the limit was 30 to 1 which is to say the width of the sheet can't exceed 30 times the thickness of the metal. Ribbon wire would be much better and easier to work with. I used a thin plastic sheet for insulating between the copper and I'm sure I was getting a "capacitor" or "skin" effect from the unit.

Another idea was to use a circuit board to form the coils, simply etching the coils from a copper clad board and laying them in place. This worked well but didn't make any real power, but... I believe it could be done with a thicker copper using less turns and more magnets. Yet another attempt to solder straight wires between circuit boards to create coils.

The idea here was to use thicker return lines to reduce the wasted resistance on the upper and lower portion of the coil thus reducing the over all resistance of the phase. This also worked fairly well if you have the patience. If they were made on an assembly line put together by robots would have great potential... doing it by hand, and making all the wires and parts... well it took me a month to make

Re: Laminated Copper Coils? ([none / 0](#))

([#7](#))

by [cevonk\(atsignhere\)aol.com](#) on Thu Dec 18th, 2003 at 11:33:37 AM MST ([User Info](#))

That is the general idea that I had in mind.

Here is a (hopefully small) picture of what I had in mind. I'm guessing (literally) that the eddy currents would be as bad with laminations as they would be with solid stock. I think that the same situation would exist with regard to eddy currents as exists with laminated stators, or thinner versus thicker wires. The thinness of the laminations would hopefully reduce the problem of "skin" conduction as it exists in very thick conductors (which sounds like a different kind of "skin" conduction than the capacitance induction that you mention in using the film as an insulator between the coil layers in your experiment.

The thought is that the coil segments could be struck from copper sheet on some kind of die, or that they could be cut in a stack on a scroll saw. Having been shaped, they could be coated with a thin film of insulation (polyester resin?) Then they could be soldered together at the top. An adhesive would be placed between the insulated layers where the magnet passes over them, and they would be compressed until the adhesive cured. The end sections of the coil would not be glued to each other so that they could be bent into the fan shape at the top of the coil to provide surface area for cooling the coil.

## Laminated Copper Coils?

By [cevonk](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 16th, 2003 at 09:56:38 AM MST [Magnetism](#)

Instead of using wire, how about using laminated copper sheet in coils?

I was looking at pictures of the coils that were recently displayed in the discussion about thin coils, and then I was reading another post about using contact cement as the insulator between laminates in a laminated stator. I got to wondering.

How about using laminated copper instead of copper wire in the coils? The area of a cross section of #10AWG (0.1019" diameter bare wire, 0.1039" insulated) copper wire is 0.00816 square inches, or 5,26 square mm. A 1/4 inch, or 6.35 mm, wide strip of 1/32", or .79 mm, thick copper sheet has a cross section of 0.0078 square inches, or 5.04 square mm. If one has 1", or 25.4 mm, wide magnets, a copper lamination of 1/32" thickness of equivalent width would have a cross section of 0.03125 square inches, or 20.07 square mm. This would be the equivalent of 3.83 wraps of #10AWG copper wire.

One (theoretical) advantage to using a copper laminate would be that the copper could be more densely packed -- the thickness of the insulation separating the copper wires is reduced quite a bit, existing between the laminate sections (a reduction of nearly 75%) and at the two edges, the edge insulation representing a significant reduction dependent on the number of wraps used. Assuming of course that a thickness of insulation could be applied by the amatuer that is comparable to the thickness used on commercial magnet wire.

If an insulation thickness of 0.001 inches, or 0.0254 mm, were applied between the laminates, a coil equivalent to 46 wraps of #10AWG magnet wire could be constructed with a 12 laminate sections having a thickness of 0.388 inches, or 9.85 mm.

A coil having 46 wraps of #10AWG magnet wire configured in a 5 wrap width by a 9 wrap depth would have a width of 0.5195 inches, or 13.2 mm, and a depth of of 0.9351 inches, or 23.75 mm.

The wire coil would be thicker by 0.1315 inches, or 3.34 mm. As we saw from the calculator example elsewhere, 1/8" of difference in the field airgap represents a significant difference in field strength.

Maintaing the same thickness, the laminated coil could contain an additional 4 laminates, equalling roughly 16 more wraps of wire, or an increase of 34% in the amount of copper between the magnets.

Since the wire coil would also be slightly narrower than the copper laminate coil by 0.0649 inches, or 1.65 mm, and thus narrower than the width of the magnets, for a given rpm, the wire coil would spend 1/16 less time in the influence of the magnets' field. Simply by using the

laminates, there would be a 6.5% effective increase of rpm.

Where the coil laminates extended above the magnets and across to the other side of the coil, the laminates could be "fanned" or spread open to increase the thermal losses of the coil over the laminate surface.

Does this make sense?

The numbers of it all. ([none / 0](#)) ([#1](#))  
by BryanA on Tue Dec 16th, 2003 at 03:11:18 PM MST  
([User Info](#))

Okay, that's totally mindblowing for me who has little experience but lots of desire. It sounds like you're in a perfect mind set to test this with a practical model where nominal results would reveal themselves.

But as a theory, how far away from the status quo is this concept? Perhaps it's done the way it's done because that's the way it works best? A possible 6% improvement does warrant a little research I would think.

Re: The numbers of it all. ([none / 0](#)) ([#3](#))  
by cevonk ([cevonk\(at\)signhere\(aol.com\)](mailto:cevonk(at)signhere(aol.com))) on Tue Dec 16th, 2003 at 09:50:26 PM MST  
([User Info](#))

I wish I had the ability to approach showing nominal results, but for various reasons right now I'm stuck in theory. :-)

I'm not sure that it is that far away from the status quo. It's just a re-organization of the commonly used material not a departure from the standards.

One thing I can see is that it using a flat section of coil that has X times the cross sectional area of a piece of wire is that the voltage would drop and the amperage would rise (unless I have that backwards.)

If a amperage or voltage were desired, the either the width of the laminate could be adjusted or the voltage could be manipulated after the electricity leaves the stator (which would cause a loss in efficiency.)

([User Info](#))

Apologies if I have not fully followed you but,

Are you proposing the same number of turns?

I believe the flat copper you discuss would be commercially available, I still have some coils out of starter motors that are wound exactly this way.

The fanning of the "wire" would add some resistance to the total coil, but the cooling effect may more than compensate for this.

Oh and big commercial generators use copper bars, your proposal would cetrinally allow for a neat coil.

regards Allan

those have batteries in them.

They are basicly just "fun" motors to watch - and they use very little power, but they use some.

["Perpetual Motion" Experiment.....](#)

By [Andy1807](#), Section [Magnets & Magnetism](#)  
Posted on Tue Dec 16th, 2003 at 10:18:40 PM MST

[Magnetism](#)

I am wanting to build a little perpetual motion device for my mantel, and I'm having trouble finding plans for anything similar on the internet.

I figured there would be a ton of experiments out here, but after looking for about 3 hours, I can't find anything. I'm looking for something pretty simple, using magnets. Any ideas? I'm also trying to learn more about magnetism, so if you have any other resources for me (other experiments, or interesting projects to build) I'd love some input.

thanks.

Andy

Hi Andy -  
Perpetual motion is a sort of "Holy grail" thing. Im quite sure it's never been achieved, although some disagree. Our "policy" when discussing it with customers/potential customers... is to try to explain that it's impossible and probably a waste of time. (unless you have a good time building something which may not work in which case you've spent your time better than lots of folks who are probably watching television or something!). There are patents for "magnetic motors" - which... Im quite confident never worked and never could work. (it does not necessarily have to work to get a patent! - it just has to be difficult to prove that it couldn't work). Here is our brief FAQ on that topic:  
<http://www.wondermagnet.com/magfaq.html#q17>

You could build come close.... building machines which use very little energy (kind of like desk toys you see which actually have batteries in them, but run for quite a long time!).

[www.keelynet.com/bedmot/bedmot.htm](http://www.keelynet.com/bedmot/bedmot.htm)

There is no such thing as "perpetual motion". But, there are many machines that gather ambient energy and concentrate it for your consumption.

Build one of these. You won't be sorry.

Enjoy!

Re: "Perpetual Motion" Experiment..... (none / 0) (#4)  
by Andy1807 on Wed Dec 17th, 2003 at 07:42:42 PM MST  
([User Info](#))

Maybe I shouldn't have called it perpetual motion. What I had in mind was something like you used to be able to find in mall shops 10 years ago. They had a black base and then had some type of chrome moving parts with magnets.

The idea was that the magnets repel each other, and then gravity bring them back together where they repel each other again. It was more of a curiosity than a "machine". Any leads as to where to find plans for something like this?

([User Info](#)) <http://www.windstuffnow.com/main>

Andy,

Those are driven by a small kicker circuit and are quite simple. The basic circuit was used in the "adams" and "bedini" motors. Another site that has a very simple circuit for doing just what you described is here....

<http://home.earthlink.net/~lenyr/magkick.htm>

That should get you going...

Have fun  
Windstuff Ed

A short story about homebrewed electricity enthusiast from small Lithuania town Naujoji Akmene.

---

I will try to tell a short story about my acquaintance Zigmas and his Windflower.

I thanks all who helped me to post this story. English isn't my native language, but I hope images will help me to do it.

### General technical data:

Theoretical power: 10kW at 15m/s wind speed  
Turbine diameter: 9.4 m  
Blades: (adjustable + removable) 12 big + 12 smaller  
Weight of one big blade: 24 kg  
Weight of one smaller blade: 14 kg  
Alternator: 10 kW 3 ph 380 VAC sinchrouas motor  
Total wieght on tower: 900 kg  
Furling system: Yes (remote controlled)  
Brake system: Yes (hydraulic)  
Tower height: 14 m

Thanks for stopping in and sharing.

This shows you can get lots of power from a low rpm high torque blade set.  
Very interesting in deed.

Old F

PS

Don't worry to much about your English . A lot of American have a hard time with it my self included and its are only language : )

Have Fun

[Twin Rotor Question??](#) | 5 comments (5 topical, editorial)

Re: Twin Rotor Question?? ([none / 0](#)) ([#5](#))  
by DanB on Wed Dec 17th, 2003 at 08:42:10 AM MST  
([User Info](#))

I'd agree with Ed to a large degree.. it boils down to available resources, and personal preference I suppose.

Regarding alternator built purely from scratch - there seems to be about 3 popular ways of doing things right now.

We can have a single rotor machine, with stationary flat laminates which have the coils glued over the top of the laminates.

- this may (or may not... hard to say) the easiest way to go. It works out fine, and the advantages would be the simplicity of it. It still required a bit of a wide airgap, and I think in the end you need about as much magnet overall as you would if you had a dual rotor machine. (in other words the magnets would be just as well, or better used in a dual rotor machine)

We can slot the laminates and bury the coils down in them (like any normal "storebought" generator) - or like Ed prefers to do. I think this must be absolutely the way to get the most bang from your buck in magnets and the best way to squeeze the most power at any given rpm from a given sized machine. (it can probably be smaller and weigh less) One drawback might be cogging - depending on how many phases there are and the layout of the stator.

The drawbacks of either of these laminate machines in my opinion are these...

there is a lot of force between the magnets and the laminates, so the bearing is under more stress. This may or may not be an issue - I think if you use a good tapered wheel bearing it probably doesn't matter too much. It may make it slightly stiffer to turn.

If you dont use very good, thin laminate material (silicon steel) - then the losses due to both hystoresis and eddy currents will make it stiff to turn, so it will not start as well in low winds and may be less efficient - especially in low winds.

I built a laminate machine in May (which is currently running at my house). It has 12 magnets, 1.8" diameter, and 1" thick. (very large magnets!). The stator has 9 coils each 65 windings of AWG 14 wire. Cutin speed is around 150 and it's got a 9' prop on it. The laminates are behind the coils (almost 5/8" back away from the magnets). It runs pretty well and I think the output is good, however it is noticably stiffer to turn than a dual rotor machine even though I've used very good laminate material. For example.. if I give it a good spin by hand... it won't go around more than a couple times (unloaded). In this case - it still starts up in 5mph or so.. so it is not a problem - but it's interesting.

5 minute interval.

Note: You may cloak yourself from appearing here in your Display Preferences.

The dual rotor machines Ive been making have two rotors - each rotor has 12 magnets 2" dia X 1/2" thick. (slightly more, but not much more magnet) and the stators are identical (65 turns of AWG 14 wire). They cutin around 110 rpm. There is 0 loading on the bearing, and 0 iron losses (because there are no laminates) and if you spin it by hand it turns for a long time before bearing friction finally stops it. The diff. in how freely they turn between the laminate machine and the dual rotor machines I've made this year is very noticable.

In other laminate machines Ive made - Ive had problems sometimes with the airgap chagnig - the magnets pulling the laminates out... etc, all of which can be solved by better construction. In the dual rotor machine though its a non-issue.

So, I definitely prefer a dual rotor machine to a laminate machine which has the coils over the tops of the laminates - it uses about the same amount of magnets to get the same output, and it turns more easily (starts turning in lower winds) and is probably a bit more efficient.

Ive not experimented yet with slotting my laminates and burying the coils in there... I think that would be the way to get the most power with the smallest alternator and the least magnets, but there will still be the drawbacks of ... a bit more precision work, cogging, and loading on the bearing to some degree I suspect.

There is 0 loading on the bearing, and 0 iron losses (because there are no laminates) and if you spin it by hand it turns for a long time before bearing friction finally stops it. The diff. in how freely they turn between the laminate machine and the dual rotor machines I've made this year is very noticable.

In other laminate machines Ive made - Ive had problems sometimes with the airgap chagnig - the magnets pulling the laminates out... etc, all of which can be solved by better construction. In the dual rotor machine though its a non-issue.

So, I definitely prefer a dual rotor machine to a laminate machine which has the coils over the tops of the laminates - it uses about the same amount of magnets to get the same output, and it turns more easily (starts turning in lower winds) and is probably a bit more efficient.

Ive not experimented yet with slotting my laminates and burying the coils in there... I think that would be the way to get the most power with the smallest alternator and the least magnets, but there will still be the drawbacks of ... a bit more precision work, cogging, and loading on the bearing to some degree I suspect.

## [Twin Rotor Question??](#)

By [Hank](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 16th, 2003 at 12:27:13 PM MST

[Wind](#)

What are the real advantages of a twin rotor?

Seems like twin rotors are in vogue now. Besides not needing laminates and reducing/eliminating cogging is there a real advantage that would justify the increase # of magnets and associated cost?

[Twin Rotor Question??](#) | 5 comments (5 topical, 0 editorial)

Re: Twin Rotor Question?? ([none / 0](#)) ([#1](#))  
by [windstuffnow](#) ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Dec 16th, 2003 at 01:21:36 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Hi Hank,

I believe this is another "personal preference" type answer as well as skill and tools available. There are advantages and disadvantages to both. I prefer building them with laminants. I think there is more bang for the bux, but... there is alot more work involved in slotting the laminants and its not something that's easily accomplished without the right tools. The dual rotor system compensates for the missing laminant by using the magnets to concentrate the field through the coils but is fairly expensive depending on the magnets you choose.

Cogging is only a problem when the magnets are lined up with the slots on the laminants this is easily overcome.

Cogging, due to current folowing through the coils is still a consideration in either system. Single phase systems tend to hum or vibrate, the 3phase systems still have the hum but its far less distinctive. So its basically back to the personal preference, skill and tools again... decisions... decisions....

Have Fun  
Windstuff Ed

by [JB](#) on Tue Dec 16th, 2003 at 05:43:37 PM MST  
([User Info](#))

Hey Ya Ed. Can you get into a little more detail how the cogging issue is easily overcome on the single rotor with laminates. Is it the laminates on the backside like the one that Dan did here the magnets actually the laminates on the backside. Thanks JB

Hi JB,

In the past I've used an equal number of magnets to coils on the slotted stators. The drawback to this is the slots line up with the poles causing a cogging as the magnetic field changes polarity from one slot to another. If you think of the coil arrangement used in the dual rotor machines the cogging issue is solved. I've designed a progressive 3phase machine that should prove interesting... It's definately been a challenge in designing. 16 magnets over 36 slots.

Anyway if you think of a disc with say 8 magnets and wire the coils in the stator slots the same way as the dual rotor disc your done... no cogging. I have a stator that I made up a long time ago but the slots were screwed up and I did a test using 16 poles over the stator. Ran smooth as silk. The stator was set up for 12 poles and had 36 slots. This got me to thinking ( dangerous -)... a few pads of paper and some scorched brain cells I found a way to use all 36 slots and use a 16 pole disc.

The current induced cogging should be reduced to a minimum also. I'll post the beast when its done. Should make for some interesting conversation... if it works

Have Fun  
windstuff Ed

Re: Twin Rotor Question?? ([none / 0](#)) (#4)  
by [Hank](#) on Tue Dec 16th, 2003 at 07:09:13 PM MST  
([User Info](#))

If I can chime in,

The single rotor unit I built had no static cogging. The main difference is that I did not have slotted laminates in the stator. It was very similar to the ones Dan built. I think slotted laminates will probably always have some cogging (just physics).

Cogging when producing power I think will always be there, it's the nature of the beast. Besides, it's a good sound when it's humming away. It's power into the batteries and you know it's working.

Having a blast,  
Hank

Re: Twin Rotor Question?? ([none / 0](#)) ([#5](#))  
by DanB on Wed Dec 17th, 2003 at 08:42:10 AM MST  
([User Info](#))

I'd agree with Ed to a large degree.. it boils down to available resources, and personal preference I suppose.

Regarding alternator built purely from scratch - there seems to be about 3 popular ways of doing things right now.

We can have a single rotor machine, with stationary flat laminates which have the coils glued over the top of the laminates.

- this may (or may not... hard to say) be the easiest way to go. It works out fine, and the advantages would be the simplicity of it. It still required a bit of a wide airgap, and I think in the end you need about as much magnet overall as you would if you had a dual rotor machine. (in other words the magnets would be just as well, or better used in a dual rotor machine)

We can slot the laminates and bury the coils down in them (like any normal "storebought" generator) - or like Ed prefers to do. I think this must be absolutely the way to get the most bang from your buck in magnets and the best way to squeeze the most power at any given rpm from a given sized machine. (it can probably be smaller and weigh less) One drawback might be cogging - depending on how many phases there are and the layout of the stator.

The drawbacks of either of these laminate machines in my opinion are these...

there is a lot of force between the magnets and the laminates, so the bearing is under more stress. This may or may not be an issue - I think if you use a good tapered wheel bearing it probably doesn't matter too much. It may make it slightly stiffer to turn.

If you don't use very good, thin laminate material (silicon steel) - then the losses due to both hysteresis and eddy currents will make it stiff to turn, so it will not start as well in low winds and may be less efficient - especially in low winds.

I built a laminate machine in May (which is currently running at my house). It has 12 magnets, 1.8" diameter, and 1" thick. (very large magnets!). The stator has 9 coils each 65 windings of AWG 14 wire. Cutin speed is around 150 and it's got a 9' prop on it. The laminates are behind the coils (almost 5/8" back away from the magnets). It runs pretty well and I think the output is good, however it is noticeably stiffer to turn than a dual rotor machine even though I've used very good laminate material. For example.. if I give it a good spin by hand... it won't go around more than a couple times (unloaded). In this case - it still starts up in 5mph or so.. so it is not a problem - but it's interesting.

The dual rotor machines I've been making have two rotors - each rotor has 12 magnets 2" dia X 1/2" thick. (slightly more, but not much more magnet) and the stators are identical (65 turns of AWG 14 wire). They cutin around 110 rpm. There is 0 loading on the bearing, and 0 iron losses (because there are no laminates) and if you spin it by hand it turns for a long time before bearing friction finally stops it. The diff. in how freely they turn between the laminate machine and the dual rotor machines I've made this year is very noticeable.

In other laminate machines Ive made - Ive had problems sometimes with the airgap changing - the magnets pulling the laminates out... etc, all of which can be solved by better construction. In the dual rotor machine though its a non-issue.

So, I definitely prefer a dual rotor machine to a laminate machine which has the coils over the tops of the laminates - it uses about the same amount of magnets to get the same output, and it turns more easily (starts turning in lower winds) and is probably a bit more efficient.

Ive not experimented yet with slotting my laminates and burying the coils in there... I think that would be the way to get the most power with the smallest alternator and the least magnets, but there will still be the drawbacks of ... a bit more precision work, cogging, and loading on the bearing to some degree I suspect.

Re: searl disk model ([none / 0](#)) ([#1](#))  
by DanB on Tue Dec 16th, 2003 at 07:54:35 AM MST  
([User Info](#))

I think if your goal is to just build a simple levitating disk - this would work, so long as it's teathered with a stick through the middle or something.

If you want to make a spinning/levitating top (like the levitron) - I think you might look to using a larger solid ring magnet. And it could work, but getting everything balanced and weighted properly is tricky. And then you'd either have to spin it by hand, or make some kind of drive circuit that would spin it from the base. (look up levitron on google)

In either case, you'll require a base with magnet in it.

If you really want to build a "Searl" disk... well, im a bit skeptical. I have serious doubts about Searl and his claims. I also have a problem with the related websites which offer impressive pictures (most of them kind of blurry) -and make claims, yet won't give you any "real" details untill you pay them \$50... which is what I've usually run into when I've researched "Searl".

## [searl disk model](#)

By [Redbone](#), Section [Magnets & Magnetism](#)

Posted on Mon Dec 15th, 2003 at 05:44:56 PM MST [Magnetism](#)

Hello, i'm fairly new to the board. I was looking to make a searl disk model. Here's my plan of action.

I have a weak background in science. My talent is in woodworking. I was going to make my disk out of wood, (red oak) with my magnets inlayed. I was thinking of utilizing the little button magnets that I can get at radio shack. Experimentation will determine the number of magnets needed on disk and on base. But i have a few questions.

1st, will properly inlayed magnets properly placed keep the disk centered and stable or will it just slide off. Spindle through the axis could solve this but I don't know if it will be necessary or not. Also the circle or elliptical inlay of magnets might be the simple and initial presumption of the pattern, but what if I layed the pattern in a spiral or coil pattern starting at center. Kinda like a crop circle pattern? Has anyone already tried this? If so what happened? I'm sure i'll have alot more questions as i go. I'll keep yall posted.

([User Info](#))

I think - if you were using Aluminum or something - then you would have a valid concern. But you should use steel - and the magnets will stick more tightly to that than anything else. Even if they were not glued down at all - you could build a dual rotor machine with good steel rotors and run the magnets so that they were almost touching - and they would stay in place.

Of course - in a dual rotor machine we need a certain thickness of stator just to fit wire and be strong enough not to warp. So I doubt you can get that close. if you bury your wires in slotted laminates, then you could run a very tight airgap - even then you should be fine without needing to bolt the magnets down.

### [Alt rotor Questions : magnets](#)

By [jimpep](#), Section [Magnets & Magnetism](#)

Posted on Thu Dec 11th, 2003 at 03:09:17 PM MST

[Wind](#)

I have visted Internet Fred's site and other postings here which are very good but I have a few more magnet questions that haven't been answered lately anyway.

Would 2 neo rings poled up the same be about the same as a bar ? It seems it would be a nightmare to fix a 1" by 2" by 1/2" neo as one previously posted. We are using fences, clamps and superglue or epoxy to do this ? With rings you could predrill holes and tap for a non magnetic fastner making installation easier ? What about magnet spacing. When does an adjacent oppositely poled magnet affect the other...it seems to me that neo magnets 3/8" apart would cause more lines of flux to be induced ..hence making the voltage greater than say ...2 neos at 5/8". Or is there a trade off distance where the opposing fields cause a decrease in induced voltage. What about laminations ? Can we pre-pot metal strips between magnet positions. What types of metal are best for laminations ?

[Alt rotor Questions : magnets](#) | 11 comments (11 topical, 0 editorial)

Re: Alt rotor Questions : magnets ([none / 0](#)) (#1)  
by [5kw](#) on Thu Dec 11th, 2003 at 04:02:22 PM MST  
([User Info](#))

Hi Jim,

"Would 2 neo rings poled up the same be about the same as a bar ? "

I was going to attempt this and decided it was a bad idea. Not only would it be difficult and probably a little dangerous, but those magnets would be constantly trying to flip just waiting for a weakness in the epoxy

"What about magnet spacing. When does an adjacent oppositely poled magnet affect the other...it seems to me that neo magnets 3/8" apart would cause more lines of flux to be induced ..hence making the voltage greater than say ...2 neos at 5/8".

I believe that for a given number of magnets you will get more power if they are spaced, but for a given amount of space you will get more power with the magnets touching.

"Can we pre-pot metal strips between magnet positions."

Any iron between the magnets is a bad idea. All it would do is shunt flux away from your windings.

Make the wind fun!

Victor

Would 2 neo rings poled up the same be about the same as a bar ?

--> Yes, You can make a single bar magnet using 2 or more magnets that are lined up. Example; you have 2 magnets with poles facing same direction.

It seems it would be a nightmare to fix a 1" by 2" by 1/2" neo as one previously posted. We are using fences, clamps and superglue or epoxy to do this ?

--> No need, your problem is in the fact that when the magnets are placed side by side they tend to want to separate.. let them. The proper distance is the amount they separate by. In other words, a separation is ok. I have tested this and it shows the field to be one contiguous field across the section.

With rings you could predrill holes and tap for a non magnetic fastner making installation easier ? What about magnet spacing. When does an adjacent oppositely poled magnet affect the other...

--> Don't fight the magnetic force, it's a loosing battle. Simple glue them as straight as you can and space them as equally as you can as the magnetic force allows you to.

it seems to me that neo magnets 3/8" apart would cause more lines of flux to be induced ..hence making the voltage greater than say ...2 neos at 5/8". Or is there a trade off distance where the opposing fields cause a decrease in induced voltage.

--> If there is I have not yet detected it. Perferably a single magnet is more ideal then two, but if all you have is smaller magnets, you can make up for it in quantity and strength... almost..

What about laminations ? Can we pre-pot metal strips between magnet positions. What types of metal are best for laminations ?

--> The thinner the lamination the better .014 to start or .012 is better. I am not sure what you mean by "pre-pot between positions" ?

Re: Alt rotor Questions : magnets ([none / 0](#)) (#3)  
by DanB on Thu Dec 11th, 2003 at 10:34:20 PM MST  
([User Info](#))

I'd disagree some Fred, thought I've not carefully tested it.

I think if you have two like poles, the more you force them together the more it will "push" the flux where it should be (in the coils). Space between two like poles is not a good thing - you could actually wind up with the opposite pole inbetween.

Ring magnets with a screw holding them down seems like a good strong way to go - but the screw (and the hole in the ring) could actually be an opposite pole, and the flux would be directed in less than ideal places.

I think 1 pole of an alternator should be a solid

magnet - anything else would be costing you. (you'd windup needing more magnet). Best would be a solid pole, 1 magnet, next would be smaller magnet forced together so they are touching. Worst would be lots of small magnets with gaps between them.

This is just my impression, I could be wrong here - I've played with this sort of thing but never really tested it.

Re: Alt rotor Questions : magnets ([none / 0](#)) (#4)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on  
Fri Dec 12th, 2003 at 08:53:09 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Dan is correct, pushing the magnets as close as possible will get you a better more concentrated field. If you press 2 opposing poles together the field is extended and actually creates a larger field. This is similar to how laminants work. Each laminant becomes opposing to the one next to it and extends the field. If you take several small sheets of steel or laminant material and place them on a magnet you can see the effect when you release the metal. All the sections will try to repel each other. If you force them together and take a gauss reading you'll find the strength greater than the magnet. This is why laminants work so well.

Another little known fact... If you put two magnets together each attracting and force two more together opposing each other and drop them off a tall building... the opposing pair will fall slower than the attracting pair. Wow magnetic wings!

Lots of fun  
Ed

Ed, Dan, and others;

Thanks for clearing that up. Didn't want to argue it but could not get my mind around ifreds reasoning on it.

Cheers.

TomW

By laying them out the way iFred explained works well also but the field doesn't extend out as far as pushing them together. By allowing them to spread apart will match the field of the magnet. In turn open up the area of the field. On a dual rotor system with a fairly large gap it would be better to butt them together. Where'as a laminated stator may better use the area of the magnetic field as opposed to the concentration. It all works well in the right places.

iFred tends to think outside the normal, this is usually where new things are found. I for one like unusual and creative thinking... the stranger the better! I'd like to say I think in similar terms but there are so many rules that are in the back of my head that sometimes makes it difficult. Like a cup overflowing... there is no more room to add more... sometimes we need to empty our cup in order to get more.

More fun than my cup will hold!

Ed

([User Info](#))

It is not difficult to place large magnets around the steel disk. There are a few good ways I think.

In Hughs plans (and at his seminar) he suggests you lay out a template on thin plywood or masonite, and simply cut out the spaces where the magnets would go. This makes it quite easy - you drop the template over the steel rotor, and drop the magnets in their holes. Take the template off - then glue them down (or cast the whole thing in resin).

In my current project, the magnets are much larger - 3" tall, about 2.5" wide and there are 12 around the 14" diameter rotor. I was concerned that placing them would be difficult, but it was quite easy really. (you always need to be very careful handling these sorts of things). I layed it out on paper, and layed the paper over the steel rotor, and simply transferred the corner locations where the magnets went with a center punch. Actually - I just did 2 of the corners on the same side. This way I could lay the magnet down, and slide it till the center punch holes pretty much stopped the magnet from sliding easily and it came out fine. (And quickly) With large magnets, especially blocks - you can tap them around easily with a non-ferrous mallet - or a piece of wooden dowel and a hammer. I think this is much easier - and in the end more economical than making up your poles from smaller magnets forced together. There is enough work in the whole project that I think you would not want to make compromises here.

Thanks for all your comments guys. Do any of you see 1/4" aluminum plating for the rotor base as a problem ? Also when set up your template you set glue in and then clamp your magnets into the glue ? Also say...if you had cheap neo rings ...fasteners made of non ferrious metals would not disturbe the field ? Maybe reduntantly asked : DanB : what about the seperate pole set up in a ring neo. Your saying a steel fastener will create a pole of its own ? How would this affect the output voltage waveform ? As harmonics or as more of a saw tooth waveform or a crappy waveform ? What about SS, Brass, Alum fasteners ETC...? Does the hole in the ring make it an inferior flux generator ? How much reduction in your estimation ? Lots of Questions .  
Thanks again Jim

([User Info](#))

Hi Jim -

"Do any of you see 1/4" aluminum plating for the rotor base as a problem ?"

Yes... actually - the rotor base must be steel, and 1/4" would be minimal thickness if your using magnets 1/2" thick. The steel plays an important part of the magnetic circuit. If you used Aluminum - it would work, but the field would be almost 1/2 as strong through the coils as it would be if you used steel. It's also convenient that the magnets stick tightly to the steel! Otherwise you'd be completely relying on the glue to hold things together.

"Also when set up your template you set glue in and then clamp your magnets into the glue ?"

When we took Hughs seminar- we first put polyester resin on the rotor, then set the template in there, and put the magnets in. (so there was glue under the magnets). There is no need to clamp them - they clamp themselves pretty well to the steel rotor.

I don't usually put glue under the magnets (perhaps I should)... usually when I do it, I place one magnet at a time (I don't normally use a template but perhaps I should). When a magnet is placed properly - I tack it there with just a bit of super glue (to prevent it from sliding around while I'm placing other magnets). Once all the magnets are placed, I pour resin around them.

"what about the separate pole set up in a ring neo. Your saying a steel fastener will create a pole of its own ?"

Steel conducts a magnetic field much better than air. Steel conducts a magnetic field in a similar way to how copper conducts electricity.

If you put a steel bolt through a ring magnet, you've created a short path from one pole to the other - so much of the flux will go through that bolt instead of through the coils. Even just the hole... (or a hole with a non-ferrous bolt through it) creates an unnecessary path from one pole to another. I'm sure they would work out OK - but I can't really think of a good reason to use ring magnets here.

"Does the hole in the ring make it an inferior flux generator ? How much reduction in your estimation ?"

Yes, I should think it would. How much would depend on a few things - like the thickness of the magnet, and the size of the hole. I suspect a 2" diameter X 1/2" thick disk magnet with a 1/4" hole in the middle would only be slightly (undetectably) compromised. A 3/4" dia X 1/4" thick with an inner diameter of 1/2" would probably be severely compromised. I've not really messed with ring magnets, so it is hard to say - but again, I can think of no good reason to go with ring magnets unless you happen to have a bunch on hand or something.

Have fun!

Thanks for the tip on the alum. I assume iron is the best ?As far as the rings are concerned I was trying to think of a way to get the magnets as close as possible to each other without flipping things and or having installation problems. I want to maximize the amount of flux generation ( amount of magnets) on the rotor. This forces me to place magnets closer than would normally be if left to the natural magnet forces. Thanks Jim

I think - if you were using Aluminum or something - then you would have a valid concern. But you should use steel - and the magnets will stick more tightly to that than anything else. Even if they were not glued down at all - you could build a dual rotor machine with good steel rotors and run the magnets so that they were almost touching - and they would stay in place.

Of course - in a dual rotor machine we need a certain thickness of stator just to fit wire and be strong enough not to warp. So I doubt you can get that close. if you bury your wires in slotted laminates, then you could run a very tight airgap - even then you should be fine without needing to bolt the magnets down.

Id agree Mike that some pressure on the glass would probably damp vibration some... if you do use magnets, be sure to pad them on the glass side, and you might put a bit of steel plate on the outside of the magnets to concentrate the flux where you need it and to help stop the magnetic field from going out and grabbing peoples keys... cassette tapes, wrenches, hammers - etc...

Id try something like this:  
[http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user\\_action=detail&catalogno=0076](http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user_action=detail&catalogno=0076)

([User Info](#))

Id agree Mike that some pressure on the glass would probably damp vibration some... if you do use magnets, be sure to pad them on the glass side, and you might put a bit of steel plate on the outside of the magnets to concentrate the flux where you need it and to help stop the magnetic field from going out and grabbing peoples keys... cassette tapes, wrenches, hammers - etc...

Id try something like this:

[http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user\\_action=detail&catalogno=0076](http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user_action=detail&catalogno=0076)

## Will magnets work for this?

By [mchimes](#), Section [Magnets & Magnetism](#)

Posted on Thu Dec 11th, 2003 at 06:54:55 AM MST

[Magnetism](#)

I guess I need to put something here to proceed

I just built a 2 room sound studio in my basement. I would like to tame sliding glass door resonance I've discovered. These doors are modified exterior sliding glass doors- so they are double paned with a sealed airspace in between the glass panes. I think several strong magnetic disks, the size of a glass coaster, could be afixed to the doors to dampen resonance. The trick would be to find magnets strong enough to bond to each other through 2 panes of glass and a 1/4" airspace (and dampen the resonance), but not strong enough to compromise the strength of the panes.

What do you think I would need?

Thanks,  
Mike

([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

Just cut some carpet padding into strips about 2 or 3 inches wide. Then glue them onto the glass around the outside edges. If your working in sound studios, then you will recognize this trick, many drummers do this to thier Bass (kick) drum heads do prevent them from resonating too long.

I do not think that magnets on each side of the glass would work. Magnets would probably just Lower the resonate frequency by adding mass to the glass. It would not be magnetic damping.

I'd tend to agree.

I think that putting magnets on both sides of the glass might damp things a bit - but it'd be kind of risky too... if they are to hold tightly, then the slightest accident (putting them on so they snap, or walking by with a wrench in your hand) might result in disaster.

([User Info](#))

Thanks for the suggestions. While agree the carpet pad idea would work, I'm looking for a more integrated, aesthetically appealing solution. Good points in the other post about the "snapping."

What if I put a felt buffer in between the magnets and the glass?

My second best option involves installing a cross bar across the glass from frame to frame and then wedging something in between the cross bar and pane. But isn't as slick and requires some work because of the moving panel.

Thanks,  
Mike

Just glue the felt to the glass and leave the magnets off. Why do you think putting magnets on each side of the pains will dampen the vibration? it will essentially put pressure inward on the glass. This will do nothing to dampen out the vibration.

I think the magnets will work better because they will apply pressure to the glass. I noticed if I place my hand in the center of the pane with some pressure it significantly reduces the over-ring.

Let's say you were experimenting with damping a snare drum, you might start with a felt disk the size of a half dollar placed about 2" in from the rim. That would help eliminate resonance. Now let's say you put a heavy wallet (which drummers will sometimes do) on the drum. Would the wallet method not be more effective at killing resonance?

Similarly, would a trampoline be more "bouncy" with a 50lb. child on the edge or a 200lb. man in the center while one was jumping on it?

I think this principle would follow with the magnets too with the glass panes. Am I in left field on this one : )?

Thanks,  
Mike

The vibration was damped by your soft had touching the glass. You will find that the vibrations will damp when you put your hand on the glass, the amount of pressure you apply will have little to do with the vibration reduction. Adding hard magnets will add mass and apply pressure between the panes, but you want something that will absorb the vibrations, anything soft will do: Felt, Foam Rubber, Your Hand, Carpet, Close curtains. In fact, curtains would be better anyway. You wouldnt want a large area of glass or mirror to be around the area your mixing in. Almost 100% reflectivity to sound.

([User Info](#))

I think the idea was missed sorry. What he is saying all the time is, that the glass pane is a large one, so the material in the middle of this glass become "Soft" sonic wise, one just has to apply some limited pressure onto the surface of this vibratiing material (The glass), then that be it, problem can be resolved.

Having soft materials attached to this glass is not the solution I think. Soft materials works good to kill sonic "Reflection" bounced off a suface and not doing good to control the surface vibrations of a piece of resonating material itself. And yes, a differnt case, when a drum skin is vibrating excessively, many bands use this method. But again, soft materials could not control vibrations from a hard or glazy surface, we do need some kinds of vertual real "Side forces" of touches to "Stiffen" the vibrating materials.

I could be wrong again, sorry.

Luubovv.

[Alt rotor Questions : magnets](#) | 11 comments (11 topical, editorial)

Re: Alt rotor Questions : magnets ([none / 0](#)) (#3)  
by DanB on Thu Dec 11th, 2003 at 10:34:20 PM MST  
([User Info](#))

I'd disagree some Fred, thought I've not carefully tested it.

I think if you have two like poles, the more you force them together the more it will "push" the flux where it should be (in the coils). Space between two like poles is not a good thing - you could actually wind up with the opposite pole inbetween.

Ring magnets with a screw holding them down seems like a good strong way to go - but the screw (and the hole in the ring) could actually be an opposite pole, and the flux would be directed in less than ideal places.

I think 1 pole of an alternator should be a solid magnet - anything else would be costing you. (you'd windup needing more magnet). Best would be a solid pole, 1 magnet, next would be smaller magnet forced together so they are touching. Worst would be lots of small magnets with gaps between them.

This is just my impression, I could be wrong here - I've played with this sort of thing but never really tested it.

Dan is correct, pushing the magnets as close as possible will get you a better more concentrated field. If you press 2 opposing poles together the field is extended and actually creates a larger field. This is similar to how laminants work. Each laminant becomes opposing to the one next to it and extends the field. If you take several small sheets of steel or laminant material and place them on a magnet you can see the effect when you release the metal. All the sections will try to repel each other. If you force them together and take a gauss reading you'll find the strength greater than the magnet. This is why laminants work so well.

Another little known fact... If you put two magnets together each attracting and force two more together opposing each other and drop them off a tall building... the opposing pair will fall slower than the attracting pair. Wow magnetic wings!

By laying them out the way iFred explained works well also but the field doesn't extend out as far as pushing them together. By allowing them to spread apart will match the field of the magnet. In turn open up the area of the field. On a dual rotor system with a fairly large gap it would be better to butt them together. Where'as a laminated stator may better use the area of the magnetic field as opposed to the concentration. It all works well in the right places.

iFred tends to think outside the normal, this is usually where new things are found. I for one like unusual and creative thinking... the stranger the better! I'd like to say I think in similar terms but there are so many rules that are in the back of my head that sometimes makes it difficult. Like a cup overflowing... there is no more room to add more... sometimes we need to empty our cup in order to get more.

More fun than my cup will hold!  
Ed

([User Info](#))

actually - Chuck suggested in an earlier posting that the 13 amp 24 volt motor works alright. I think if I tried it, I'd use kind of a large (7' or 8'?) 3 blade prop like Chuck did, and be sure it furls out early because its 13amp rating suggests that it may not handle the power of a prop that large in very high winds.

Here is Chucks discussion about that motor:  
<http://www.fieldlines.com/story/2003/10/13/155010/22>

Thats not a simple question to answer  
What battery voltage do you plan to use?  
What sort of appliances do you plan to use?  
Is this for a home, hunting/vacation cabin, business?  
I'm sure that the others will think of more questions

Dr.D

I was thinking about a 12volt system but do not know the advantage-disadvantages of it. So would a 24VDC 194RPM 13 Amp  
or 130VDC 3200RPM 15.3 Amp  
or 20VDC 550RPM .47 Amp  
be best. Thanks

by DanB on Thu Dec 11th, 2003 at 11:19:37 AM MST  
([User Info](#))

the advantage of a 12 volts system is that there are lots of lightbulbs/appliances which will run directly off 12 volts.

You'll find inexpensive power inverters which run on 12 volts as well. So if it's a small system, 12 volts is the way to go I think.

If it's a larger system, 24 or 48 volts has a lot of advantages in that you'll be needing to handle lots less current, and line losses will be less. (the whole system will be more efficient).

Problem is, 24 volt and 48 volt appliances are rare - so you'd probably be running everything off your power inverter. 24 and 48 volt inverters tend to be expensive.

I think if you have a 24 volt system, the 13.5 amp 194 rpm motor would be the way to go for sure. It would probably be good for up to 150 watts - and you'd see occasional peaks of much more, but like Chuck said in the "Hornet" posting - if it runs much over 13 amps it will probably fail.

For the 12 volt system, I'm not sure if any of those motors you listed would be ideal. The 24 volt motor would produce 12 volts probably at fairly low rpm (like 100 or something)... (chuck has one I think he might know exactly). Since the machine is only good for 150 watts or so, you need a fairly small blade and the small blade will probably want to run much faster than your 24 volt motor would in a 12 volt system.

The 130 volt motor would probably do 12 volts somewhere around 320 rpm - which is on the fast side.

(I assume that the motors will produce close to their rated voltage at their rated rpm when used as generators. This usually seems to be the case - but I wouldn't take it for granted) But it does have a reasonable current rating - 15 amps is not bad. I think perhaps with a very fast 2 blade prop 4 or 5' diameter, it might work. It would be fast though...

Air 403's have a 4' prop and they start charging at 400 rpm - so the 130 volt motor is a possibility I think.

The 20 volt motor would also be a bit fast, but rated at only half an amp you'd not get much power from it.

I run a 12 volt system, and I have found that a 90v dc PM motor to be the best bet as long as it is rated for 1200rpm or less, I have 2 windmills, and a hydro built out of such motors, and they do the job nicely. 12v is a nice way to go, because if you can find a old camper, you can get plenty of 12 volt stuff cheap.

Re: What PMA motor to use ([none / 0](#)) ([#7](#))  
by Dave Lochhaas on Tue Dec 16th, 2003 at 11:00:10 PM MST  
([User Info](#))

Hi MoMoose,

I'm in Boone County, Missouri, and I think I am facing some of the same challenges. I am just beginning to experiment with a Black and Decker electric lawn mower motor(mfg. unknown) and also an Ametek tape drive motor. With our Missouri intermittent low winds and occasional high winds and a lot of gusty and seasonal winds the key seems to be in a blade design that is very efficient at low wind speeds, 5-10 mph, and doesn't freak out with the winter and March gales that sometimes occur. I picture a mini wind farm of 100 watt generators all working together but my thoughts charge ahead and run amok while my free time lags behind.

I would like to meet with other Missouri folk of similar interests.

the advantage of a 12 volts system is that there are lots of lightbulbs/appliances which will run directly off 12 volts. You'll find inexpensive power inverters which run on 12 volts as well. So if it's a small system, 12 volts is the way to go I think.

If it's a larger system, 24 or 48 volts has a lot of advantages in that you'll be needing to handle lots less current, and line losses will be less. (the whole system will be more efficient). Problem is, 24 volt and 48 volt appliances are rare - so you'd probably be running everything off your power inverter. 24 and 48 volt inverters tend to be expensive.

I think if you have a 24 volt system, the 13.5 amp 194 rpm motor would be the way to go for sure. It would probably be good for up to 150 watts - and you'd see occasional peaks of much more, but like Chuck said in the "Hornet" posting - if it runs much over 13 amps it will probably fail.

For the 12 volt system, I'm not sure if any of those motors you listed would be ideal. The 24 volt motor would produce 12 volts probably at fairly low rpm (like 100 or something)... (chuck has one I think he might know exactly). Since the machine is only good for 150 watts or so, you need a fairly small blade and the small blade will probably want to run much faster than your 24 volt motor would in a 12 volt system.

The 130 volt motor would probably do 12 volts somewhere around 320 rpm - which is on the fast side. (I assume that the motors will produce close to their rated voltage at their rated rpm when used as generators. This usually seems to be the case - but I wouldn't take it for granted) But it does have a reasonable current rating - 15 amps is not bad. I think perhaps with a very fast 2 blade prop 4 or 5' diameter, it might work. It would be fast though...

Air 403's have a 4' prop and they start charging at 400 rpm - so the 130 volt motor is a possibility I think.

The 20 volt motor would also be a bit fast, but rated at only half an amp you'd not get much power from it.

actually - Chuck suggested in an earlier posting that the 13 amp 24 volt motor works allright. I think if I tried it, I'd use kind of a large (7' or 8'?) 3 blade prop like Chuck did, and be sure it furls out early because its 13amp rating suggests that it may not handle the power of a prop that large in very high winds.

Here is Chucks discussion about that motor:

[Getting rid of the cog - re-post](#) | 14 comments (14 topical, editorial)

Re: Getting rid of the cog - re-post ([none / 0](#)) (#11)  
by DanB on Thu Dec 11th, 2003 at 08:52:02 AM MST  
([User Info](#))

I've taken a couple Air 403's apart, and I've seen two diff. magnet rotors in them. Sometimes you'll find the magnets layed in straight - when they did that, the tops were arched (probably to reduce cogging a bit). In others (I think newer models) they use pretty normal bar magnets, but they are slightly skewed.

by RobD on Wed Dec 10th, 2003 at 04:58:42 PM MST  
([User Info](#))

I took apart an Air 403 and I found that the magnets on the armature had one section with a greater gap then the other. I think this does the same thing as they get very little cogging.  
RobD

Re: Getting rid of the cog - re-post ([none / 0](#)) ([#4](#))  
by dconn on Wed Dec 10th, 2003 at 05:49:33 PM MST  
([User Info](#))

Hi RobD,

I also wondered over that gap in the AIR403 magnet rotor. I think there are maybe 12 smallish neo magnets? I cant remember if the gap is a whole magnet width (The gap just wouldn't matter then?) but the stator is three phase (although there are different wire sizes on each phase - to allow for low RPM generation?) so you'd think that the poly-phase layout that iFred suggests wouldn't work so easily? iFred's layout a phase per coil.

Of course the gap in the AIR403 is very handy for that metal band to be screwed down with.

Actually the AIR403 rotor/stator layout is very nice - but its just too small and I wonder if it is better to have the magnets on the outside like Hugh Piggots brake drum plans (seemingly scrapped now in this new age of radial designs).

All the best - Derek

([User Info](#)) <http://www.windstuffnow.com/main>

iFred,

Thats darn'd close to what I'm comtemplating as my next low speed alternator. I've worked out the details on a progressive winding 3phase. 16 magnets over 36 slots. 3 complete 3phase units in one. It should handle low, medium and high speed operation while holding constant load on the machine. This has been one of my hold ups on the "Lenz" turbine because of the lower speed of operation.

The air 403 uses a similar concept as rob metioned. They've set their spacing back a bit and the phase difference is small so it still works. I think the unit suffers from the offset though with a little bit of canceling. It does allow it to start up sooner.

Have Fun!  
Ed

Re: Getting rid of the cog - re-post ([none / 0](#)) (#5)  
by Jerry on Wed Dec 10th, 2003 at 08:25:49 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Ed

The 403 needs all the sooner start help it can get. I wish you guys could see just how much time the 403 on my roof sets idel while the homebrew gennies are spinning.

I think the only reason SW put the space in the 403 was to have room for the screw that holds the band down to the amature. It dose make a cogging sound.

When I fist got the 403 I made the second mistake by mounting it to my metal shop. At low rpm it makes a growelling thats very anoing. Not to mention the blade noise.

How dose that poly phase thing work with N, S, N, S and the last north right next to the first N? Looks like there would be a bit of a lump or bump or a goofy wave form when this odd couple came around while the rest are normal nsns?

JK TAS Jerry

([User Info](#)) <http://www.internetfred.com>

interesting what this air 403 is doing. I have never seen one before, so I can't say but it sounds like it. Are there lots of diodes by any chance in any of the circuits?

Thanks!

Re: Getting rid of the cog - re-post ([none / 0](#)) (#8)  
by Jerry on Wed Dec 10th, 2003 at 09:02:49 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Ifred

I was having trouble with my 403. I sent it back to the factory twice for the same problem. The little brain inside would put a small load on my batteries during no wind days and drain power down a little.

I called the teck the third time and he told me to just take the little brain out. I did and it actually improved its overall performance a little. I would say its performance went from crap all the way up to suck. A small change but noticeable.

Again this is just my personal observation of my own 403. Others may not share my thoughts.

JK TAS Jerry

Re: Getting rid of the cog - re-post ([none / 0](#)) (#9)  
by RobD on Wed Dec 10th, 2003 at 11:06:38 PM MST  
([User Info](#))

Sorry you don't like your 403 Jerry. It does need some wind to go. I put a scope on the output and the wave is very good with no cancellation that I can see. The gap is less than one magnet width. I haven't played with the brain but the new 'x' is supposed to be an improvement on it that makes it start sooner. So maybe some people complained. They get a very good wave out of it with a sine wave that spends a lot of time high up. The magnet placement helps this from what I can see. I'm using the same band on my magnets they use. I bought some thin stainless sheets from my supplier and I cut them into bands. I tried using CV joint bands but they weren't as good. I use the bands with epoxy. (JB weld or liquid steel) The alternator I built for my exercise bike cogs badly so I may change the magnet placement on it. I'm also thinking of using several magnets in a staggered row around an armature to cut down on the cogging. I haven't tried it yet. I also thought of using a system to shift the armature out of the field to start my machines sooner but I'm against using too many mechanical things that can fail. Hugh has the right idea about using the largest diameter you can get. you pick up power with diameter that translates directly to armature speed.

How are the ends of the bands you cut held together?

[ [Parent](#) ]

Re: Getting rid of the cog - re-post ([none / 0](#)) ([#13](#))  
by RobD on Thu Dec 11th, 2003 at 01:57:41 PM MST  
([User Info](#))

I buy sheets of SS shim stock. (non magnetic .012" -6"x 24"). I cut the stock from 3/4" to 1/4" width depending on my mags. I drill and tap a hole in the gap, place the band and measure to the hole. I then clamp it together and drill a hole in the band and attach it with a SS screw. I make the band about 1/16" short so the screw doesn't bottom but holds the band very tight. I use a long dry epoxy so it sets overnight. The epoxy holds the mags from shifing and in place the band adds security in case the epoxy ever fails. I lose a few thousands in air gap but it works well and I don't have to overload the armature with epoxy which makes removing the magnets easier if I decide to change the design. (I hate gopping up my expensive mags with epoxy!)

So I took it outside hardly a bit of wind just a light breeze that you can just barely feel on your face...not even enough to turn the little pinwheel(which gives me another idea for a wind speed thing).Well anyway this foam cup thing is turning about 30 rpm even in this light breeze.

So I'm wondering ...what's the lightest wind anyone out there has ever had that makes some power, even if it takes a slight gust of wind to get it over the cogging. Curious and seriously...would like to hear your stories about success in light winds....as there are a few of us, is mostly all we've got. Jerry gave me an inkling of some success in light winds...anyone else? ( :>) Norm.

about 3miles an hour from a very small about 12 inch prop

Re: A very light breeze ([none / 0](#)) (#2)  
by Norm on Mon Jan 5th, 2004 at 07:47:13 AM MST  
([User Info](#))

Jon: A little more detail than that ...please your thoughts about where you think windspeed is a lost cause...is this 12 inch prop in use? is it hooked up to a generator...alternator. I was thinking this test of mine I probably had about a 3 mph breeze also, down on the ground, even 14 ft up on the peak of my shed might have been about 6mph up there, which would produce 8 times the power. Must do some further test and research. I think it would have to be a very sensitive system to even orient itself into the direction of the wind at anything under 5mph. OK Jon....Your turn..some of your thoughts. Havin Fun in NE Ohio. ( :>) Norm.

### Rebuilding an old Wincharger

I bought this Wincharger 32 Volt 1000 watt that had taken a bad fall. There's some broken parts and the prop is missing.

The airbrake was badly bent.

The tail casting and prop hub were broken.

The generator was complete except for missing through bolts. They are 9 1/2" long. I'll have to make new ones from 5/16" rod and thread the ends.

I bought a junk gearbox for twenty dollars that had a good tail casting and the pulley arm that I was missing. The shaft was frozen and one of the other castings was broken.

I installed new bearings and gaskets in the gearbox and painted all the pieces Rustoleum Sunrise Yellow. The original Wincharger color is a mustard yellow brown color. I couldn't paint it that color. It reminded me of something in a baby's diaper.

I removed the rivets and started straightening the airbrake last weekend but I ran out of oxygen for my torch. I should get it finished this weekend. The rivets are unavailable. I'm going to have to make some.

Looked through a whole bunch of two by sixes at Home Depot to get some that I could cut up to remove the knots. I alternated the grain on the pieces when I glued them together to prevent warping.

Here's the assembly a little further along. I've installed the tail casting with the new pin that I made and the pulley arm has a new pin and stainless pulley.

The turntable has a broken weld on the lower three point mount. It's also missing the top mount castings. They are impossible to find so I'm going to have to make some. The sliprings and brushes are in excellent shape.

([User Info](#))

Old F,  
Thanks. It's a Wincharger Model 3229 rated at 32 volts and 1000 watts. The rated cut in speed is supposed to be around 7-10 mph. The gearbox has about a 10 to 1 ratio. I'm going to use it to charge 24 volts instead of the rated 32 volts. These are noisy high maintenance antiques. But, it's a lot of fun searching for the parts and fixing them.

Straightening Sheet Metal ([none / 0](#)) (#3)  
by wdyasq on Sat Jan 3rd, 2004 at 06:37:57 PM MST  
([User Info](#))

Don, Most sheet metal can be straightened without heat. Any stretching that occurs can be 'spot shrunk' by heating a small area- it will 'rise'- the area that raised - while still hot, can be hammered flat with light blows on a dolly. When it cools it will shrink pulling a little more of the stretched area in. Good luck, Ron

A 30 foot octahedron tower

---

I am in the process of building a 30 foot guyed tower using Octahedron modules.

It is based on the 70s Wind Works plans for a free standing tower.

I decided to cut my teeth on a simpler guyed tower be for building a free standing.

Things are panning out nicely I have the first 10 foot section done. The vertical struts are 3/4 inch emt conduit and the horizontal triangles are inch and 1/2 angle iron 1/8 inch thick. With 2inch long an inch and a 1/2 wide 3/16 thick tab welded to the corners .

The thing that gets me is how strong this thing is and a ten foot section is held together with only nine 5/16 bolts. And weighs in at 41 pounds.

It's a odd looking beast and at certain angles it looks crooked as a dogs hine leg. Even tho its straight.

- [Old F's Diary](#)

A ten foot section consist two five foot modules and each module contains six vertical struts.

The conduit is flatted at each end an inch and a 1/2 back .  
I put the press together with odds an ends in the shop an a two ton bottle jack. It has a depth stop so I don't have to measure every flat just slide it in till it hit the stop an go. The flats are off set at 60o so they will line up with the tabs on the triangles.

The struts are done in three pairs. With a strut pair you will have one left hand and one right strut. You flatted one end of the conduit then turn it around.  
In the photo you will see the angle gage I use to do this the V is 120o angle so for a right hand strut you place the flat on the right hand side of the V this set the angle at 60o the other end is set in the press to the depth stop and flatted . For a left hand strut you put the flat on the left hand side of the V.  
Don't try to eye ball this been there done that and wasted conduit the gage make it easy.

The photo shows a left and right hand strut in the press I only flatten one at a time as the depth stop is only wide enough for one at time .

This photo show the guide to mark the bolt holes on the flats.  
It's a tab for the triangles its 2 inches long and a inch and 1/2 wide.

I measured back an inch an 1/2 And marked the center of inch an a1/2 square.  
Then drilled a hole I used this to mark the holes for the tabs and the flats.

Here is the angle gage

A horizontal triangle.

Here is where I am at for now next is the tower top section that will taper to a six inch triangle at the top.

Have so much fun it should be illegal

[hornet blades got about 800 watts 35 mph](#)

By [Geek](#), Section [Diaries](#)

Posted on Fri Nov 28th, 2003 at 03:41:27 PM MST

[Geek's Diary](#)

its working now :)

Will since a recent wind storm caused the tail to slip and then come off completely I order a new set of hornet blades with a 6 blade hub these are a much better match for my alt than the jerry blades were I maxed out at 100 watts now with the new blades I got a high of around 800 watts I did louse some lowend start it takes 10 mph to get it started where the jreeys would start around 6. at one point we were runing a shop vac stright off the alt it raan real nice it was a 7 amp motor I am not sure if it was quite flat out but it was in the 90s volatage wise. just goes to show the guys the are always saying match your alt to your blades. I should have it up on the tower next week this was all on hte road test.  
Geek

[hornet blades got about 800 watts 35 mph](#) | 10 comments (10 topical, 0 editorial)

Re: hornet blades got about 800 watts 35 mph ([none / 0](#)) (#1) by Jerry on Fri Nov 28th, 2003 at 09:37:50 PM MST ([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Geek Bravo good job. Let me ask a few questions.

You said you maxed out at 100 watts with the Jerry blades.

What are you using as your alt? How many Jerry blades? What diameter prop tip to tip. Are the jerry blades pitched at 23 degrees at the root?

Here is an entry in my wind test log book. This is from the S-10 wind test truck.

4-24-03, 8:00 pm, 50 degrees cloudy, 3/4 hp 6 pole furnace blower motor with 6 # 29 neo magnets, 6 starts windings perelell, 6 run windings perelell, 2 bridge diodes,

Prop 3 jerry blades with Mike mods, 23 degrees root, 49 inches, 35 mph, 50 amps 15.1 volts = 755 watts.

This is alittle behind the Hornets but low speed start up and total power colected at low wind was greter than the Hornets. The noise of the Hornets was also not acceptable.

The most I've seen from the Hornets is 80 amps The most I've seen from the Jerry blades so far is 80 amps.

I think there are more low wind days than high wind days. If you watch the gennys on my shop roof most days the Jerry blades are spinning and the Hornets are not.

Here is another test Nov. 24, 03

1 hp Garbogen 12 volt test. 3 Jerry/Mike mod blades 6  
Hornet blades

5 mph	3 amps	0 amps
10 mph	8 amps	2 amps
15 mph	15 amps	5 amps

I'll agree the Hornets have higher output at the higher wind speeds but not by much. The Hornets did 80 amps at 40 mph but the Jerry blades did 80 amps at 45 mph not far behind but in either case it was storm type wind speed and not the normal every day 5 to 15 mph wind. I own and use Hornets but in average normal every day wind these do not collect as much power.

So as you can see I'm very curious about how your Jerry blades are configured?

Thanks for some specs and info on your system.

JK TAS Jerry

Re: hornet blades got about 800 watts 35 mph ([none / 0](#)) (#2)  
by Geek on Sat Nov 29th, 2003 at 09:23:31 PM MST  
([User Info](#))

I had the jerry's in a four blade turbine unmodified (no mike modes)  
they were piched so the tips of the blades were near flat  
the hub had about about a 12 in dim.  
I thnk the problen was with my alt it really dosent start making  
good power till it is spinning real fast about 800 rpm (just a  
guess I don't have a tach)  
I really do like the Jerry's but the high speed of the hornets  
agreed with my alt much better.  
The allt way made by putting 8 #29 mags in a 1 HP 3 phase  
motor with the 3 phases wired in series (I still trying to sort  
the wiring because even with out a scope I can tell I'm not  
getting a very smooth output) I have tried to use the Y or delta  
that every one has talked about but I can't seem to make it  
work.  
this was my first real atempt so I'm pretty happy but I think  
there is still room to squee a few more watts out of this one.  
I really didn't hear much noise from the hornets at 35 or 40 I  
only wish I had a tach hooked up so I could be more helpful.  
Geek

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Geek

Like you I am RPM chalagned. Its just a mater of time though. Eventually i will have some rpm data on the plastic blades.

I do know the Mike mods make a drastic diferance in rpm. I won't fly the plastic blades without Mike mods.

The closest thing to an rpm gestamate I have is from a small dc motor I'm fling as a genny.

With this pm motor chucked up in the lathe 50 volts is reached at 500 rpm no load.

We recently had a storm and were seeing winds in the up to 35 to 40 mph range. I was seeing 125 to 150 volts from this motor no load. This motor is a 115 volt motor. It rated 1800 rpm.

I would guess the rpm to be around 1500 or so? Of course this was no load but the blades have developed 80 amps at 15 volts for 1200 watts wich is about 1.5 hp?

I was thinking of using a car type tachometer on the 80 amp GARBOGEN to get an rpm reading in the wind loaded.

Time will tell. JK TAS Jerry

Re: hornet blades got about 800 watts 35 mph ([none / 0](#)) ([#4](#))  
by desertratjack on Mon Dec 8th, 2003 at 12:14:01 PM MST  
([User Info](#))

I'm using hornet 6 blade setups. How to stop the NOISE? Guess I'll have to furl them with "tip-backs" just when they are really getting going. Windseeker 503 (3 blade- rated at 500w) generally outperforms the hornets until just about the point that the hornets make noise. Very sad as the hornets cost about 1/4 of the windseeker.

Re: hornet blades got about 800 watts 35 mph ([none / 0](#)) ([#5](#))  
by Geek on Mon Dec 8th, 2003 at 03:34:25 PM MST  
([User Info](#))

I think it is a matter of how hight the rpm are. I think my alt is a lower rpm than yours. I think that is why I'm not getting much noise out of these blades. You could try and round the tips I think that might make some difference but then again it may just muck things up too.

Sorry I can't help you more.

Geek

Always have a dream. Those with out dreams are just waiting to die.

([User Info](#))

I have the 6V and 12V hornet windmills. They both create the same noise around the same windspeed. I bought the 6V one because I thought it would drag the prop down below the noise speed. No luck. I wet sand the 6 blade hornet blades to 400 grit. Maybe the hornet blade tips deform at higher loads to make noise?

Please let me know is you notice any hints on how this noise problem.

Jack

Hi Jack

I sent you an e-mail this morning to the address you said to use but AOL said it didn't go through. Do you have an e-mail address that works?

Swami;

Must be a language barrier here. Can you explain just what you mean by aerial bunch cable??

It is a totally unfamiliar term to me.

Cheers.

TomW

Re: aerial bunch cable ([none / 0](#)) (#2)  
by BruceDownunder on Thu Dec 4th, 2003 at 07:21:58 PM MST  
([User Info](#))

Aerial Bunched cable is mains distribution cable suspended between poles . It is less dangerous to people in so far as it's insulated and therefore can be strung where yachties raise masts , hang gliders land and also it's less obstrusive compared with "open-wire" It still has the three phases and neutral in the "bunch' and is self supporting . In Australia ,after the bush fires burnt down many open-wire poles , they quickly restored service by rolling out bunched cable -quick to erect and tap into--it can be tapped into mid-span.

Bruce.

my first attempt

Hi all.

I've been following this board since Jan. this year and I have to admit it's been a very addicting experience.

I built a genni in the spring and spent the summer designing, cutting, drilling and bolting a tower together to mount my first generator on. A much bigger task than the genni was.

It's 98' self standing tower with a brake drum windmill.

Had to get above the 60' trees.

I hope to start getting involved with this board while building a bigger & better unit. This place seems to bring out the creativity in us. A real brain tease.

Here's a pic of the tower and hope to swap thoughts with some of you later.

ps; (isn't this stuff fun!)

That's quite a tower. What did you build it from and how did you stand it up?

Re: Up and running! (way up) ([none / 0](#)) ([#2](#))  
by marv ([windtamer@hotmail.com](mailto:windtamer@hotmail.com)) on Sun Nov 9th, 2003 at 02:49:32 PM MST  
([User Info](#))

Hi Rob  
the corner pieces are 3 1/2" x 1/4" angle iron (galvanized). The rest is mostly 3" & 2 1/2" angle + 1/2" grade #5 bolts. It weigh's 11,000 lbs. so I needed a 70 ton crane. (what a adrenilane rush)

marv.

All I can say is WOW!

Dr.D

Re: Up and running! (way up) ([none / 0](#)) ([#4](#))  
by Budgreen on Tue Nov 11th, 2003 at 07:19:55 AM MST  
([User Info](#))

just out of curiosiry, why grade #5 bolts instead of #8?

WHY grade 8? ([none / 0](#)) ([#5](#))  
by wdyasq on Sat Nov 22nd, 2003 at 06:14:44 AM MST  
([User Info](#))

Budgreen,

I'd guess (and take a sizeable bet on this one) grade 5 bolts are higher tensile strength than the metal they bolt together. Why spend the money?

It is an impressive tower.

Ron

[ [Parent](#) ]

Re: Up and running! (way up) ([none / 0](#)) ([#6](#))  
by marv ([windtamer@hotmail.com](mailto:windtamer@hotmail.com)) on Sat Nov 22nd,  
2003 at 04:09:31 PM MST  
([User Info](#))

Thanks Dr.D, Ron  
Thats right Ron. Plus thats what Ontario Hydro uses for  
bolts here.  
So if it's good enough for theirs, it's good enough for mine.

marv

Re: Up and running! (way up) ([none / 0](#)) ([#7](#))  
by troy on Wed Nov 26th, 2003 at 02:32:57 PM MST  
([User Info](#))

Holy angle iron Batman, THAT'S a TOWER!

I can only say that I am smitten with tower envy. Did you  
get a deal on the angle iron (2nd hand?) or pay full price.  
In any case, it's a beautiful tower.

Best regards,

troy

[kurt's Diary](#)

look here for answers to your RE questions

When new people find fieldlines.com they inevitably ask pretty much the same questions so this is an attempt to provide links to those questions in one easily found place

The most often asked question is probably "can I use a car alternator, induction motor, ect. For an alternator for a wind turbine. The link below should cover your questions on this matter quite well.

[http://www.otherpower.com/otherpower\\_wind\\_alternators.html](http://www.otherpower.com/otherpower_wind_alternators.html)

The second most asked question is probably about controlling voltages to the batteries in a wind system for example "how do I keep my 30v tape drive motor from frying my 12v battery bank." The batteries will pull the generator voltage down to their charging voltage until they are full then the power needs to be diverted somewhere else. That is the job of a diversion charge controller.

<http://www.bioelectrifier.com/charge.htm>

<http://www.homepower.com/files/shuntregulator18.pdf>

<http://www.xantrex.com/products/supercat.asp?did=333>

Number three most asked is probably what kind of batteries should I use or some variation of the same.

[http://www.otherpower.com/otherpower\\_battery.html](http://www.otherpower.com/otherpower_battery.html)

Probably not one of the most asked about subjects but should be is Efficient Lighting.

[http://www.otherpower.com/otherpower\\_lighting.html](http://www.otherpower.com/otherpower_lighting.html)

You can get good information on solar here.

[http://www.otherpower.com/otherpower\\_solar.html](http://www.otherpower.com/otherpower_solar.html)

Here are some good links on hydro

[http://www.otherpower.com/otherpower\\_hydro.html](http://www.otherpower.com/otherpower_hydro.html)

Beede meters

One of the things we all love are meters. Over the years, I have bought some used or surplus meters here, and some there, some are given to me, and others I find on ebay.

My latest find was on ebay, some Surplus new in box 1975 Beede 100 mv full scale meters, each costing about 4 bucks..

Using a freeware program, called meter.exe and a HP-GL capable laser printer, I can make a meter face for just about any size and shape meter one can think of.

The one I made today was for a PV application where I needed 20 amps full scale, and using a shunt out of 12 guage copper wire that I calibrated to drop 5 mv per amp.

These Beede meters are very easy to open and access the original blank face plate, and using the meter.exe program, designed exactly what I wanted. I then cut out the face I made, sprayed on some 3m adhesive, and reassembled.

Here is the result:

I have made several 11 to 15 volt expanded scale voltmeters, small amp meters, large amp meters etc, using proper scaling resistors and shunts.

More to come on meters.

JimU

hey jimU. beautiful job on the meter. just a suggestion. i guess what makes us all happy is when you see the needle riding the higher end of the scale. how about incorporating a sad face from the bottom end just under the numbers to the happiest face possible under the 20 amp scale. he he, call it a jimU meter. just crazy zub talkin, but it would be neat!

my two cents worth-----zubbly

[Propellers, what is the max number of blades?](#) | 3 comments (3 topical, editorial)

Re: Propellers, what is the max number of blades?  
([none / 0](#)) (#3)  
by DanB on Thu Dec 25th, 2003 at 07:12:28 AM MST  
([User Info](#))

Hii -  
"Everything I see uses three blades."

There is a reason for that. Typically fewer blades run faster and more efficiently. Two blades runs (as a general rule) a bit faster - and even more efficiently in many cases than three but the drawback is vibration. (they shake when they yaw). Sometimes the shaking can be overcome with weights - or sometimes it may seem un noticable, but any time you have two heavy spots a wheel and turn it (like a windmill yaws) its going to shake.

More blades generally have a bit mroe surface area and start more easily. 3 blades is a good compromise, probably the best compromise.

"I will be building an alternator that will need a twelve foot three bladed prop. Can I use, say (just for discussion) a six bladed 6 foot prop? "

No. Your 3 blade 12 footer would run at a reasonable speed and probably have lots of power. Your 6 blade 6' would probably have too many blades - a bit mroe torque - but it would be inefficient - even for a 6' prop. Power is related to the square of the diameter (the area). Your 12' blade covers a bit over 100 square feet. Your 6' prop covers about 30. The 12' prop (done well) should make 3 X the power of a good 6' prop. A 6 bladed 6' prop will have lots of xtra drag, so itd be even less powerful I suspect.

the 6 bladed 6' prop might have a bit of xtra torque to get your big alternator turning, but it will not have the power to spin it up to the sorts of speeds itll need to go to make power as it would if it had a 6' blade.

Hope that makes sense... (havent had any coffee yet this morning, its dangerous for me to do, or write anything before coffee!)

## [My Mini Geni isn't working very good](#)

By [wooferhound](#), Section [Homebrewed Electricity](#)  
Posted on Tue Dec 30th, 2003 at 02:35:48 PM MST  
finally wound some coils for testing

[Alternators](#)

I have been working on a Miniture Generator made by converting a Window Fan motor for use with permanent magnets.

I finished the rotor yesterday. Today i wound a coupla coils to test and see what I get before I wind the 12 coils that I'll need to complete the unit. But things don't look so good. I'm getting 25 millivolts at 1200rpm with a single coil. I'm spinning the rotor with it chucked into a hand drill rated at 1200rpm. The voltage is being measured after going through a bridge rectifer with a 4700mfd cap across the output. I was puzzled and wound another coil that I thought would give me better output. However the 2nd coil was just measurably better than the first.

The magnets are quite small and are probably the problem. They are 1/4 x 1/4 Disk Neodymium and are rated N38. They are grouped in sets of three with epoxy glue & tie wraps, the

same polarity pointing out in each set. 12 groups are glued around the rotor alternating North-South all the way around.

The 1st coil I made was 36 turns of 19ga wire. The 2nd coils was 40 turns and wound to the size of a group of magnets better.

I wanted to see the voltage loss through my rectifiers so I hooked a 9volt battery to it and measured the difference between the battery and the output. I was getting a 1.2 volt loss, so now I'm wondering if the little coils may possibly be putting out as much as 1.2 volts and then getting promptly absorbed by going through the Bridge rectifier . . .

[My Mini Geni isn't working very good](#) | 18 comments (18 topical, 0 editorial)

Re: My Mini Geni isn't working very good ([none / 0](#)) ([#1](#))  
by Electric Ed on Tue Dec 30th, 2003 at 03:14:02 PM MST  
([User Info](#)) <http://www.electric-ed.com>

From the photos, the coil "span" appears to be somewhat less than the magnet pole center-to-center distance. I suspect that there may be some voltage cancelling happening.

Also, there appears that there is no stator iron, which would create a very inefficient magnetic circuit.

Electric Ed

Re: My Mini Geni isn't working very good ([none / 0](#)) ([#6](#))  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Tue Dec 30th, 2003 at 06:33:57 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

When I was testing, I was only using 1 coil at a time. For the picture I just stuck those two coils in there so folks could see how I planned to place them. There will be 12 coils and 12 magnets and they will line up to each other 1 to 1.

The ring around the outside is the laminate material from the original fan motor. I was sure that would work for the stator iron.

([User Info](#))

Very interesting project! Getting things to work on a small scale is sometimes harder than on a large scale. If the magnets are 1/4" in diameter and 1/4" thick, it looks as if the field airgap between the magnets and the outside stator is about 3/4". With larger magnets, say 1/2" thick, that would work out to an airgap of 1 1/2", which would probably be a serious drawback.

It's neat to see the ideas that you are working on!

Re: My Mini Geni isn't working very good ([none / 0](#)) (#7)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Tue Dec 30th, 2003 at 06:39:35 PM MST  
([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

It's hard to tell the scale from the photos, but the airgap from the end of the magnet to the laminates is slightly over 1/2 inch. was planning on making coils at 3/8 inch thick.

Its so obvious I think you are joking?? ([none / 0](#)) (#3)  
by TomW on Tue Dec 30th, 2003 at 03:41:39 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Woofers;

You said:

The magnets are quite small and are probably the problem. They are 1/4 x 1/4 Disk Neodymium and are rated N38. They are grouped in sets of three with epoxy glue & tie wraps, the **same polarity pointing out in each set.**

Way back in alternators 101 we learned that the poles need to alternate N S N S N S etc.

That and the other drawbacks noted will produce a poor alternator.

Cheers.

TomW

([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

Thanks TomW

let me quote what you quoted and add the rest of the paragraph...

--Quote-----

They are grouped in sets of three with epoxy glue & tie wraps, the same polarity pointing out in each set. 12 groups are glued around the rotor alternating North-South all the way around.

-----

Perhaps I could have described this more clearly. As they say "A picture is worth a 1000 words" so here's a pic

The mags are grouped in sets of 3. Each set has all North or all South pointing out. putting the magnets together this way is very difficult as the mags are trying to run away from each other and flip around and stuff. Then these Sets are glued to the stator in alternating groups.  
set of 3 Norths  
set of 3 Souths  
set of 3 Norths  
set of 3 Souths  
etc.

([User Info](#))

What happens if you just run the output of one coil thru one small 1 amp diode? or even try measuring the ac voltage? ,, , or check the voltage of the battery... then check the voltage of the battery thru the rectifier... you should be getting some kind of voltage ac or dc? even .001 volt? Hope this helps until you get a more expert advice.... Like Zuck perhaps? Maybe with a different arrangement of magnets ( :>) Norm.

Re: My Mini Geni isn't working very good ([none / 0](#))  
(#5)  
by JB on Tue Dec 30th, 2003 at 04:34:52 PM MST  
([User Info](#))

I did a little 1/6 hp motor something like that last week. it was a small 6 pole 7.8 amp 1000 rpm ac motor and had only 6 coils in series. They looked about 17 or 18 gauge. i put 6 of the 1/2 by 2 by 1/4 neos on it skewed ns ns ns. It still cogs pretty good. I wasnt terribly impressed with my results but it did show 4 amps 15.5 volts on the dc side of the bridge rectifier on my meter at 400 rpm and 5.3 amps 24 volts dc at 770rpm I think if i had doubled the magnets amd made them 1/2 thick I would have been able to bring the charging voltage down considerably. JB

by kell on Tue Dec 30th, 2003 at 09:38:00 PM MST  
([User Info](#))

For each bunch of little mags fighting each other you've got a distorted multipolar field with flux lines going every which way. I think you'll do better with cheap ceramic magnets of the right size, so you know the flux lines will cut the coils where and when you want them to.

Re: My Mini Geni isn't working very good ([none / 0](#))

by Jerry on Wed Dec 31st, 2003 at 08:30:03 AM  
MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

I did 6 of the little Ed/Windstuff magnets on a smaller version of this motor. Didn't change a thing but machined the armature down to fit the magnets.

It dose cogg hard but I'm seeing 60 watts at 500 rpm. Just try getting 60 watts from a solar panel for 6 bux.

<http://timmythy.home.mindspring.com/timmy.htm>

I was reading somewhere on the board that , lining up magnets like this created a magnetic field that was the same as a bar magnet with the poles on the sides. Thats why I built it this way.

Is this right or not, Many of Zubbly's designs are simular to this approach.

big gap..... ([none / 0](#)) ([#16](#))  
by Norm on Wed Dec 31st, 2003 at 12:51:12 PM  
MST  
([User Info](#))

After taking a real close look at the pictures and especially the last ones ,I think I have the solution...a couple of the ones that replied and said about the gap were on the right track especially Electric Ed where he also referred to the width of the magnets to the width of the coil or something like that, so I'll be back with the solution as soon as I draw a couple of illustrations on one of your pictures. OK? Norm

[ [Parent](#) ]

Re: big gap..... ([none / 0](#)) (#17)  
by Norm on Wed Dec 31st, 2003 at  
02:48:13 PM MST  
([User Info](#))

Okay....on the next one you get like this(this would be an alternative for someone with only simple handtools)after carefully unwinding each coil....cut each pole straight down as on the red line, when you are finished it will look something like the first picture. Now center a block of wood as thick as the laminate and scribe the radius of the rotor and cut the ends of each pole off accordingly take a large half-round file and file the curve to allow clearance of the rotor. Then rewind the coils and put em back. This is far from ideal but it should work. The better way would be as Jerry suggested....Hope this helps....Have Fun! (:>) Norm.

[ [Parent](#) ]

Re: big gap..... ([none / 0](#)) (#18)  
by Harry Luubovv on Wed Dec 31st,  
2003 at 08:30:05 PM MST  
([User Info](#))

Ok Woofer,

Why not try using square magnets to line up one after another instead of round ones ? because the rounds do give trouble to the magnetic paths, that is, pulling and distorting the flux path. Square ones should behave more "Squarely" in this regard, no pun intended. :-

Love experimenters !  
Luubovv

by [Jerry](#) on Thu Jan 1st, 2004 at 10:36:45 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi John. Could you discribe your blades. Size at the root, size at the tip, any twist, how thick, profile, cup, leading edge, degrees of attac tip and root, trailing edge and how many? I've not built a working disc genny yet. Although I've started a couple. I have mostly been doing AC motor conversions. I have seen 1200 watts from my 22 inch plastic blades (49 inches tip to tip) so at least that part is simular to yours? JK TAS Jerry

You would generates some voltage, dependent on speed, size of the coil, the number of turns, and the power of the magnet.

Dr.D

Re: pass magnet inside the coils ? ([none / 0](#)) (#2)  
by [kell](#) on Sun Dec 28th, 2003 at 09:06:01 AM MST  
([User Info](#))

Amethyste, do a search for "linear alternator." Some of the posts are kind of jokey, some are speculative... people that want significant power haven't been building linear alternators because they would have to reciprocate (back and forth, like pistons). Much harder to engineer than something that spins.

The flashlights that you shake to charge them have a magnet on a spring that bounces back and forth inside a coil, from what I've heard.

I've seen several teachers doing science experiment demonstrations, where they were showing the voltage from a coil while passing the magnet through the hole in the coil, or (of course) passing the coil over the magnet.

Kinda similar to dropping a magnet through a copper tube. It's generating power all the way down (which is a dead short) and the magnetic drag greatly slows the magnets drop through the metal tube.

} = - W o o f - = {

Re: pass magnet inside the coils ? ([none / 0](#)) (#4)  
by 5kw on Mon Dec 29th, 2003 at 01:08:51 PM MST  
([User Info](#))

I think the results will depend on the orientation of the magnet as it passes through the coil. If the north pole is facing one leg of the coil and the south pole is facing the other leg the voltages will cancel, via right hand rule or left which ever it is ( I never use these rules for anything but thought experiments as we rarely know or care which pole is north) . On a conventional alternator the legs are cut by opposite poles, but in this case the direction of the cutting is different , because of being on the opposite side of the magnet.

On the other hand ( may be a pun there) if the magnet passes through "pole first" it would generate a voltage as the whole coil would be cut by first one pole and then the other.

Make the wind fun!  
Victor

## [Is this possible?](#)

By [EdParenteau](#), Section [Homebrewed Electricity](#)  
Posted on Sat Dec 27th, 2003 at 10:04:12 AM MST [Alternators](#)  
Can you make a straightline alternator?

What would happen if you had a row of coils and mounted a couple of strong magnets on a rack and sent them on a rail over the coils?

Thanks,  
Ed

Ed;

First let me say that nearly anything is possible but not everything is practical.

We have discussed reciprocating style generators before and while it seems it could be done that they would be fairly inefficient. Maybe a search of this site for comments with "linear alternator" or "reciprocating" in comments would turn up the discussion I found several but the link posting feature on the board seems broken so I didn't put the link in here. I seem to recall that the lack of movement on the end of each stroke when the shaft reverses direction would be a source of lost mechanical power. Just off the top of my head before my coffee.

Oh, and welcome to the board.

Cheers.

TomW

I think this might work if U use a pendelum lke on a clock ,it swings back & forth and never moves from the centre, might be worth a try.

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Look up linear motors. I used to work on very large disk drives that used a linear motor for the read / write heads. It used a chrome etched scale with electronic reading head for indexing the distance moved in or out. The "motor" probably weighed 20 lbs itself and had incredibly fast precise movement. A very large electromagnet coil surrounding the "piston" linear rotor I'll call it and was mounted on rails with ball bearings just like you mention. Wish I had kept a couple of these for just such experiments. If you find one be very careful experimenting, these could clip your fingers off very easily ! Dave

([User Info](#))

Hi Yo, Pardon me if I appear to be bad when I do not agree with you :-). But I think the idea is a waste of time first off, a reciprocating coil/magnet device would induce too much vibration for the blades. Remember an internal combustion engine has good rubber mounts when it has piston(s) going up and down. Still, there are vibrations that you can feel while sitting in the car. But those engines would absolutely indeed need something (Piston) to go up and down because of the function of the fuel system --the fuel needed to be expanded and exploded in order to create powers and so we need top-dead-center position which is the best position to allow the explosions to happen. But this idea again if applied to generator of sorts, would mean wasted power as someone already mentioned, that when the magnet or whatever travels to the top dead center position, it stops for some moments before reversing direction. Hence, you get the loss of energy and wind energy can be too precious to lose this way. Besides again, we would have to have some form of a crank, or at least a cam device in order for that going-up-and-down thing to motion up and down, this arrangement is an additional source for wasted energy. I could think of many other negative areas for the reciprocating idea but I stop here and want to just briefly mention the difference between reciprocating action and linear one. Linear one is the most efficient type of motions since it has no repeated action loss, meaning, something goes forever straight-on forward, NOT REVOLVING around and around ! ! But we cannot apply this linear technology to some generators because a generator is always something affixed stationarily. But if applied to moving vehicles or vessels, then the linear idea I think is the ideal medium for future transportation propulsion folks. In fact, I can remember still in my failing head that we already have this form of motions for some thirty odd years ! I remember some monorail systems did indeed use linear electro induction theory to move forward back from that time ! And some of those vehicles indeed

do not use real rolling bearings neither, they use magnetic powers to float the vehicles above the metal track, so the friction loss is about near zero much like hovercrafts sort of. We did also have other in-plant vehicles moving this way etc etc. However, this gives me an idea, if we can somehow make a continuous "Tube" which is actually a loop of magnet wires and we allow a magnet (Which is magnetically coupled to the blades hub by a spinning disk with magnets affixed to it) to travel inside around and around and at the same time having the magnet inside to float off the wire tube, we can then cut down friction to zero and this will enhance greatly to precious wind power uses I think. But the only obstacle here is, how do we devise some magnets to travel and floats inside a tube of wires without touching the sidewall ? This is the only question in my head folks ! Perhaps we can have the a real tube made of plastic to covering the wires and have the inside of this tubing vacuum filled and have some form of fluids to float the magnet. But this fluid still would not create zero friction. But perhaps then we can use laser beams to float the magnet, this is possible. Think on folks ... but I think we are getting too high tech here, I will have to come down from the sky you would have to say ..... ! Hey last, I am not a scientist honestly, I am someone just like you, who tends to like to fiddle with things just to find out ..... so as a fellow human being, I can be wrong too in areas folks ..... hey !! Ciao ! Luubovv.

Thanks for the comments. What I was actually thinking is probably a goofy idea. I was thinking of what would happen if I were to make a thirty foot or more long string of coils vertically and then use the turbine to haul up the magnet "rotors" which would be dropped down the string of coils(using gravity as the force) one after the other and loop back up again.

And thank's for the welcome Tom!

Ed P

([User Info](#))

Hi Ed,

Don't worry about the goofy ideas, we are all here just to goof one way or another. So lets see if I can goof along longer. I understand your idea, it would be like one round circle standing up vertically, with some benches all around, and this thing turns around and around vertically, and we are the ones who sit in those benches, like what we see in the carnivals ! This will be a true linear motor if you made the circle large enough so that the arrangement will not be seen as a circle anymore. So the magnets and the coils are actually crossing paths one vertically and the other horizontally. Or we can say that the coils stay on the inside of the revolving magnet circle. I like the part about letting gravity help move down the magnets on the return side. This actually would be a noval idea, we are not just letting the wind doing the job for us, but now we are utilizing gravity at the same time, and to think about it, the magnets are naturally heavy so there are going to be great momentum to help the down push motion, and the down motion is really the same effect as the up motion for the other side of the circle ! ! ! But sadly one hitch, because by the same token, the weigh of the magnets when first going up, will balance away the gains from the down momentum.

Happy New Year.  
Luubovv.

## [Static Discharge....Lightning](#)

By [MrResistor](#), Section [Homebrewed Electricity](#)  
 Posted on Wed Dec 24th, 2003 at 04:22:02 PM MST [Alternators](#)  
 Discharge Danger in HV alternator?

Hello,

First a little location info. Farmplace in the middle of a "section"(1 mile square), wind zone 5(avg 7-15 mph). Probable location 150-200ft wire run. My goal is to go "off the grid" completely. The house will be designed with efficient appliances, etc....

I've looked at 100's of posts and a few sites. Right now I'm leaning towards iFred's designs of many thin coils and very high voltages. I'd like to try a propeller configuration like those seen at <http://www.selsam.com/> to obtain high rpm.

My question has to do with static discharge from a 1-phase design like iFred's(or any HV design). Lets say it was very windy, hot and dry. Your alternator is putting out bunches of energy. Is it possible to get nailed by "lightning" discharge from the alternator if you were standing underneath it in the right conditions? Is this a "non-problem"?

I suspect the answer will be something along the lines of "only if you present a better ground" or somesuch. I'd like to be able to put this out of my head so I can get on with coil and magnet testing.....=)

I looked at that website that you showed and it looks like the wind gen design that they are showing looks like if it got slightly out of balance for some reason or other it could really cause a major problem and alot of danger. JUST MY 2 CENTS

While the turbine blade could in theory accumulate a static charge, it will be largely dependent on the dielectric properties of the blade material. And as most blades have a metallic path to the tower, and if the tower is metallic and properly grounded, any charge should be bleed off to the tower ground automatically. Even if there is no direct metallic path to the tower from the blades any discharge would tend to be between the blade and the tower due to it closer proximity.

Up shot of all this is ground the tower.

Dr.d

PM MST  
([User Info](#))

Thanks drdongle, I kind of suspected that. I just couldn't get the tesla coil picture out of my head...: =) It occured to me later the metal tower would always be a better ground. If these props work as advertised the RPM should be significantly higher. Put that together with iFred's many thin coil design and I got a bit nervous.....

My aim was to minimize line losses to the house of course.

Now I'm off to find some carbon fiber poles and little props.....

## [caps voltage rating for pulse charging](#)

By [bob golding](#), Section [Homebrewed Electricity](#) [Alternators](#)

Posted on Wed Dec 24th, 2003 at 01:53:30 PM MST

hi all, on the circuit for pulsing power down the cables that charged talked about what voltage rating should the caps be?.

was thinking worse case dead battery high wind lots of volts out of alternator. will the high voltage cap catch everything. am thinking 3 1 farad 24 volt like the ones jerry has kindly offered me. sorry for the late reply jerry did reply but it must have fallen in the bit box.

trying to find time to have more fun.

bob

[caps voltage rating for pulse charging](#) | 3 comments (3 topical, 0 editorial)

Re: caps voltage rating for pulse charging ([none / 0](#)) (#1)

by [charged](#) on Wed Dec 24th, 2003 at 03:12:10 PM MST ([User Info](#))

First, make sure you are catching the high voltage with at least 1000uf @400v capacitors where the wire comes into the building. Then run a few feet of heavy twin-lead between that capacitor and the low voltage caps.

I would go ahead and get 4 of those large caps and have two in series for .5F @50v. Then parallel the two series pairs for a full Farad of capacity. Also put a HEAVY current schottky diode across each cap. That way none of them can ever be reverse charged enough to be damaged. Better to keep them safe.

You should set up an emergency dead-load. If you are using a simple voltage triggered circuit to charge the battery bank, set up a SECOND LEVEL voltage triggered discharge circuit that's wired directly into the dead load. Set you battery bank to accept pulses at 3v above battery voltage and set up the dead-load for 5v or so above the LOAD breakover voltage. Just hook it up like it's a second battery bank with a slightly higher trigger. If your primary bank connection fails or you have to disconnect it suddenly, the cap voltage just rises a little higher then dumps across the dead-load.

Some of this info is in another thread. But, I don't remember just where. Anyway...

The dead-load:

Basically, a metal drum or a large metal garbage can filled with a mild electrolyte solution. Just fill it with tap water and saturate the water with baking soda.

I'm assuming you have a 12v bank voltage. So, go get

EIGHT 1'x1' square steel plates (stainless preferred).

Stack them like pancakes with 3/8" plastic spacers to separate them. Make a non-conductive clamp to hold the stack together.

Fuse a long piece of heavy multi-strand steel wire to the top and bottom outside plates.

Put a non-conductive block in the bottom of the barrel and drop the stack in sideways so that the gaps are vertical.

The two steel wires come up out of the water and go to a connector block above the barrel.

This is your dead load for discharging the capacitor bank. Each plate-to-plate gap requires about 2v before it will conduct. So, eight plates amounts to about a 16v breakover voltage. It will actually be a little less. Just test it once you have it wired in. Then decide how high to set you trigger voltage to keep it about 5v above your normal battery trigger voltage.

It will simply pump out hydrogen and oxygen whenever you start putting power into it.

It will stand about 140amps of average pulse power before it produces any heat. Just cover the top and vent the gas mixture outside with a small brushless fan. If you're dumping power into a dead load, you have enough to spare for the fan, right?

Just make sure the liquid level is kept up. You can do that with a toilet float valve for automation.

Hi Charged and all happy holidays.

Charged what would be a recommended value for the diode across the caps and the polarity of the diode in relation to the caps. I'm referring to the shottky across each 1 farad cap.

Speaking of caps I took a brief inventory of some of my caps. These were the caps that I could reach or find in my messy shop without renting a backhoe to dig them out.

Cap value in UF price each	voltage/surge V.	count
2,200 uf \$10	400v/475v	1
400 uf \$10	350v/v?	1
60 uf \$1	350v/v?	12
100 uf \$1	350v/v?	9

4,500 uf \$6.50	200v/250v	4
2,000 uf \$5	200v/250v	14
1,400 uf \$3	200v/v?	1
1,000 uf \$2.50	200v/v?	4
640 uf \$2	200v/v?	3
500 uf \$2	200v/v?	2
7,300 uf \$6.50	150v/175v	4
1000 uf \$3	150v/v?	14
15,000 uf \$7.50	100v/v?	240
40,000 uf \$10	90v/110v	40
26,000 uf \$10	75v/95v	40
12,000 uf \$6.50	75v/100v	10

This is a sample list I have many more in voltage down to 6.3v and uf from a few 100 to 650,000 uf plus the 1 farrad 24v special at \$59.95. Some of these are take outs and some are old new stock.

Caps can be siriesed to increase voltage, this will reduce uf or perelelled to increase uf and voltage stays the same.

If you need one cap or more just e-mail my at audiosourcesalem@aol.com.

## [Scale model PMG?](#)

By [doubter3](#), Section [Homebrewed Electricity](#)  
 Posted on Wed Dec 24th, 2003 at 07:54:07 AM MST [Alternators](#)  
 Anyone out there built a 2" diameter radial flux alternator?

Not sure exactly what to post this under, but I guess homebrewed electricity applies in a way. A friend of mine is into building working scale model steam locomotives. Lately, he's been thinking of building a diesel version. From what he's told me diesel locomotives have a genset which produces electricity to run drive motors and he's having trouble finding an alternator with high enough output small enough to fit his model. I suggested building a tiny radial flux alternator and was wondering if anyone on this board has had any experience building something so small. The diameter of the rotor disks would be limited to around two inches.

Matt

[\(User Info\)](#) [change AT: bach\\_on AT hotmail.com](#)

What would he use as a power source? You might be able to find some hobby motors. One could power the other one, which would actually produce the electricity. He might be able to build a shell around one to make it look like a diesel engine.

Frankly, it seems like a stretch (at least to me) to make it functional. Without a miniature diesel engine, it can't actually be authentic. You'd also need motors for each of the wheels. But, hey! What do I know? Maybe he could try some of the more exclusive hobby shops - especially those that deal with model trains. Good luck!

Bach On

Maybe he could use a Kromrey Converter.

It's only two 500 turn windings and 4 magnets. It can be very small.

Just make sure the generator axle is non-magnetic steel.

## Silicon steel

By [windstuffnow](#), Section [Homebrewed Electricity](#)  
 Posted on Tue Dec 23rd, 2003 at 10:44:02 AM MST [Alternators](#)  
 Ordering a new batch...

For those that may be interested, I plan to make an order for some silicon steel once again. I still have some 1/2 inch wide stuff available if your interested and I will be ordering some 3/4" wide M4 grain oriented silicon for some new projects I'm working on. Also I plan to pick up some end rolls of various sizes and grades. Some of these will be available as well.

I'll be picking up the order on the 29th or 30th so if you have an interest let me know.

Windstuff Ed

Ed,  
 I am interested. How do we go about getting together on pricing etc.? will this be offered on windstuffnow?  
 Firefly

Re: Silicon steel ([none / 0](#)) ([#3](#))  
 by [windstuffnow](#) ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Dec 23rd, 2003 at 03:00:01 PM MST  
[\(User Info\)](#) <http://www.windstuffnow.com/main>

If you interested in the 1/2" silicon the formula to find weight is:

$$(OD^2 - ID^2) \times .7854 \times .134 = \text{lbs}$$

This is for the 1/2" stuff, the 3/4" will have a different conversion, I'll know when I get it here.

The cost of the stuff is \$4.00 per lb. for either

You can email me with any specifics.

I'm thinking of putting it on my site but in specific size rolls instead of winding each one specific for an application. So there will most likely be 5 or 10lb rolls as a standard.

Have Fun  
 Ed

## [Progressive winding alternator](#)

By [windstuffnow](#), Section [Homebrewed Electricity](#)

Posted on Mon Dec 22nd, 2003 at 11:14:21 AM MST [Alternators](#)

The beginning...

This is the first attempt at this idea. So far I've had many little problems creep up and the progress is slow.

I started with a junk stator that I started some time ago but my cutters died before it was completed and I couldn't use it for the project in mind. I decided to use it as an experiment with this new idea. First step was to decrease the cogging caused by the magnets lining up on the slots.

This stator was designed for 12 poles and has 36 slots. I set up a disc with 16 magnets over the 36 slots and tested it for cogging... Little to no noticable cogging with the offset over the slots. Unfortunately during the test the magnets sucked the laminated stator off the wood. This was corrected by using 6 3/16 bolts to hold it in place and reglued and bolted.

Ok, now here is my theory... I've been working on this problem for many years, for the most part the star/delta switch worked well but I still wasn't satisfied. Since there is a wide range of wind capturing ( from 6 to ? ). Low range needs lots of turns but typically ends up with high resistance and doesn't perform very well in mid to high winds. And the same goes for the mid to upper range. It occured to me while looking at this stator there could be 3 separate 3 phase alternators. One with lots of turns to capture low speed power, the second with less turns and larger wire to handle the mid range and the last with large wire and only a few turns to handle high winds. Now we have 3 cut in speeds where each winding starts adding power at different speeds. Also, each one would be added to the last, minus the phase difference. This would also give you the option to either parallel or series the rectifiers for different combinations of output. Quite versitile!

Below shows 1 phase in place and the completed single 3 phase leaving 24 open slots for the next windings....

This stator was made using 1018 steel strips, and is 8" in diameter. The first 3phase wound with #20 wire and 33 turns makes 30 volts at 300 rpm and produces about 10.5 amps going into a battery at 13V. The second set will be of #18 wire with about 22 turns and the third will be #18 wire with 16 turns. Just a calculated expected output based on the first phase as below

300. rpm

1. st phase 10.5 amps
2. nd phase 10 amps
3. rd phase 2.5 amps

total 23 amps or 300 watts approx

500. rpm

1. st phase 21 amps
2. nd phase 30 amps
3. rd phase 20 amps

total 71 amps 923 watts

700. rpm

1. st phase 31 amps

2. nd phase 50 amps

3. rd phase 43 amps

total 124 amps 1612 watts

The actual will be somewhat lower because of the phase difference between the 3 alternators but it gives you a basic idea of where I'm going with this. Still not to shabby for a small alternator. One problem that I see which could be corrected with a relay is the fact the smaller wire in higher winds will be pushed to their limit and possibly burn out. My first thought was to put a relay powered by the 3 set to turn off the first set. Could be a fun and challenging problem to ponder.

This started from the need to build an alternator to cut in at around 30 rpm but carry good power throughout the rpm range. And of course having fun making things better...

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Really nice!

Another idea:

My friend Taisto had a problem that his alt didn't start charging at slow speeds. He put in between a transformer to double the voltage and run the current through a rectifier then. Also he put there parallel wires going through another rectifier directly to the battery. It seems to be working well.

Any thoughts?

- Hannu

([User Info](#))

hello Ed.

just love to see all that tinkering that you are doing. it gives me many ideas and inspiration.

i am just about completed testing my last induction conversion. the results seem not too bad but have had trouble coming up with something to drive the genny for testing. i will find some drive system however.

i wonder if you have ever considered multiple Y-D. this conversion i am doing has twelve leads brought out from the winding. i can connect for 1Y, 2Y, 1D, or 2D. the open voltage at various rpm's is as follows. 1-Y @70 rpm-26.4 volt, 115 rpm-45.0 volt, 190 rpm-67.7 volt, 300 rpm-106.2 volt. the ohm resistance for the following connections are, 1Y-7.3 ohm, 2Y-1.9 ohm, 1D-2.4 ohm, and 2D-.8 ohm.

i will post all the results when the project is finished. i

just thought the idea of multiple Y-D connections may be of use to you. perhaps you have already tried it.  
good luck with your project!

zubbly

Hi Ed,

Looks really interesting!

I can appreciate the problem with the smallest windings at peak speeds. How about a power resistor switched into the small winding's circuit at a certain point?

Or you could always try one of those capacitive discharge circuits Charged has been posting about, might solve the current problem...

Good luck with this Ed, it's important research, and looks like a lot of fun!

Ted.

Hi Windstuff Ed,

I think your "Progressive Coil" idea is innovative thinking, and I like innovative thinking. I had such a thought also once, but only briefly though because nevertheless (Pardon my ignorance Ed), I think, the various sizes of wires will sum back up to the same output figures as if you used an averaged 3 sizes of wires. If we literally did this experiment it can prove out itself. Because I think it is the matter of total copper and the spaces available for the copper to set in, that makes the difference aside from ..... yes, the only way to optimize outputs for high-low winds situations could only be by switching between parallel and series connections. Another matter I think Ed, in both series or parallel situations, the larger sized wires would be dragged down of its output by the smaller sized wires. One thing I've learn in electronics is never to parallel nor to series two different sizes of wires coils unless you are sure that the smallest of wires alone can handle at least half of the current produced in 2 coils situation, or one third the capacity in 3 coils situations, 1/4 cap in 4 coils situation, etc etc ! But in a windgen, we can never be sure of this because we do not control the speed of the mills, the wind does.

Please correct me if I am wrong !

Cheers,  
Harry Luubovv.

How much power?

I'll be testing the 200 lb genny soon. How much power could I expect from this PM motor?

Motor specs; 185 lbs, 1780 rpm, 15 amps, 36 volts and max stall amps 77 at 200 volts.

JK TAS Jerry

([User Info](#))

Let me try a guess,  
In 60 mph winds using a suitable sized rotor with a TSR of 8 I would guess about 500 watts. Cut in speed for charging batteries will be in the order of 600 rpm meaning about 25 mph winds for that prop.

Let us know what you test out at.

Re: PM motor ? ([none / 0](#)) ([#2](#))  
by [Jerry](#) on Mon Dec 22nd, 2003 at 09:15:10 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Hank  
Well it took me 2 days but I got the 200 lb genny in the test truck.  
That was a scary adventure?

Charging started at 10 mph at 5 amps, at 15 it hit 10 amps at 25 mph the amp meter was showing 20 amps.

The blade was a littel out of balance so i'm going to try a diferant blade.  
This blade was my plastic blades at 5 1/2 ft tip to tip.

I'm going to try a smaller blade. One of my 49 inchers. Thanks for your help I'll keep working on it.

JK TAS Jerry

i dont know personally but if you look at the tesla coil list [pupman.com](http://pupman.com) or the tesla coil web ring you might find someone. i know there are a few tesla coilers in oz who might be able to help. lot of similarities between this list and the tesla list.

bob

## [Net metering with a generator??](#)

By [zmoz](#), Section [Homebrewed Electricity](#)

Posted on Sat Dec 20th, 2003 at 10:40:55 PM MST [Alternators](#)

How do I hookup a generator to the grid?

I know that if you're going to feed power back into the grid from an inverter, you must have a grid tie inverter. What about with a generator that already produces ~ 120 VAC? How does one hook that into the grid?

[Net metering with a generator??](#) | 3 comments (3 topical, 0 editorial)

Re: Net metering with a generator?? ([none / 0](#)) ([#1](#))  
by [wpowokal](#) on Sun Dec 21st, 2003 at 05:18:47 AM MST  
([User Info](#))

This begs the question of why would you want to!

However the least one would need for the generators well being is the facility to synchronise to the system frequency. This ensures your generator is closed to the system in phase at zero volts. A very small generator could be simply crashed onto the system and come into sync, probably without much harm.

Then there is the problem of voltage, the power factor of the grid (inductive or capacitive), frequency (should the system frequency drop your generator may try to supply the whole of uncle Sam)

Then the legality of a system outage, linesman working and your generator electrocuting them. (thus the features of grid interactive inverters)

Allan

I agree with Allan,

It most likely is doable on a small scale, but why bother. It can be feasible to make homebrew power at 2 cents per kwh, but chances are, you most likely won't produce enough power over-time to "contribute" to the grid. Also a good point is the line-mans safety...

If somehow you have managed to assemble a substantial, micro power plant, that can produce 60kw continious 24/7, at 2 cents per kwh, including overhead(equip cost) and fuel cost and will conform to EPA emmissions standards(btw- corn burners do meet these standards). then most likely the local utility will advise you how to do this properly (your results may vary :)

with wind power this is becoming much more popular "ie" wind farms. generally the problems of "freq-sync" to the grid are lessend by stable battery banks and grid-interactive inverters.

back to the original question- use the search feature "of this site" for a -VAR- or VAR power controller. this is part of how you can sync to the grid with a mechanical gen-set. but these systems are difficult to manage(and expensive) and you must consult with the utility comp. to do it right.

([User Info](#))

I was thinking that a synchronous inverter would be the safest off the shelf solution, in that you would take the power you generated and use it to charge a battery bank, or for greater efficiency, an ultra-capacitor bank, and set the inverter(s) to deliver power to the grid when the supply voltage reached a preset level.

This would be doable with a trace sw series or similar inverter. You would of course lose some energy in the conversion/charging necessary to provide the right charging voltage for your battery bank. The Inverter would be UL listed for grid connection, and therefore reasonably safe. As for the economics of such a connection, I suspect that with depreciation of the equipment, it would be a money loser.  
Good Luck.

Hi Rich,

I like what you did and do. It is always nice to see innovatively thinking persons.

Now my criticism if you don't mind. The wave winding is good to the point that it saves wires (And so saves weight) and also saves resistance counts. However, we have to be very careful as to phasing. Because, it is a wave winding so all the coils are wound as one giant coil spread all over the outer perimeter of the stator backing disc. And so all the magnet poles will have to pass the coils in a more precisely synchronized way. Meaning, you will have to have the same amount of coils against same amount of magnets and spacing would have to be same between magnet poles and coils--more cogging. If these rules not observed, you will lose out pretty large due to waveform cancelling one another between coils obviously. In worst of cases, you might end up having zero volt ! If one pole happens to be North cutting while another pole happens to be south cutting at the same instant, both the the peak and valley waveform will cancel out one another--Zero output !

And then, a complete closed-loop of a coil is more in efficiency than a half open coil.

It is known that multi phases are better for battery life than a single phase charging. Just imagine, the wave technique would entail longer wires again even though you can still employ the wave technique, just imagine the picture, I need to say no more because you simply would need to have running wires to bridge between coils of same phases.

This is all the negatives I can give you, now you can pleasantly see that I am that devil to ya :-

-No love loss-  
Luubovv.

## Micro-Hydroelectric System

Click [here](#) to find out more about the complete, detailed, Hydroelectric Design Manual.

### Why Alternate Energy?

Alternate energy is not cheap. In fact, compared to commercially generated electric power, most forms of alternate energy are very expensive. However, you can't just compare the cost of commercial power to the cost of an alternate energy system and base your decision to install or not to install a system on a payback period of three or four years. There are other reasons to produce your own power besides costs.

Perhaps your property is located no more than a mile from the utility company power lines. If that is the case then alternate energy becomes very attractive. Often a utility company will charge you up to \$20,000 per mile to provide power to a remote site! And then you will still have a monthly bill to pay.

How reliable is your commercial power? As I am writing this I have been living "off the grid" for over twelve years and I have only been without electricity twice; about every six years I have to replace the batteries! Power for the color television, computer, radio, ceiling fans, lights, and appliances is never more that a flip of a switch away.

Living without commercially generated electric power gives you a sense of freedom like you have never felt before. You have been dependent all of your life on the utility company. You have suffered at their every whim. Whether your electricity comes from a nuclear power plant, a hydroelectric plant, or a coal fired plant, you are paying for the cost of the nuclear folly through higher utility rates. Alternate energy is "home grown"; energy harvested by you to satisfy your needs. Alternate energy puts you in control of your life and your destiny.

Many people find they have a need for electricity in places beyond the reach of utility lines. They might have a barn a half a mile or more from the house. They might wish to build a house far from utility lines. For example, I have a personal friend who recently purchased the last lot in a series of five. His lot was several thousand feet from the nearest utility line and he was the first of the buyers to decide to build. The local utility company forced him to pay \$27,000 to cover the cost of bringing power to his site! For the next five years, he must pay a minimum electric bill of \$450 each month, no matter how little power he actually uses! The other owners will not be charged any extra when they are ready for power.

Many land owners look wishfully at the creek that flows through their property. They dream of tapping the power of the water, but they are not blessed with a waterfall or with any way to develop a head of ten to twenty feet. (The head is the vertical drop of the water.) All they have is a high volume creek flowing through relatively flat land. I designed this system to illustrate the feasibility of using an ultra low head hydroelectric system to provide "usable amounts" of electric power. This system is designed to be located in the creek bed using a small dam to provide a minimum head. The prototype micro-hydroelectric system operates on a head of about 2.75 feet!

Innovative Aspects

Main

Systems Approach

Home Design

Hydropower

Electric Vehicles

Most small, hydroelectric systems require a head of at least 10 feet before they will generate an acceptable amount of power. During my research, several experts at Eco-Village told me it was impossible to generate usable amounts of power with less than four feet of head. (Eco-Village was an experiment in alternate energy system design and implementation sponsored The Mother Earth News.) The design of this system allows for operation using a minimum head of twenty inches and a flow rate greater than four cubic feet per second. The head on the prototype micro-hydroelectric system is about 33 inches. The basic turbine is a cross flow design, twelve inches in diameter and 5.5 feet long. Normal operation requires a flow rate of 5.5 cubic feet per second. The turbine rotates at approximately 120 RPM and turns a modified Delco car alternator via a belt drive system.

Test Data  
Actual Generating Capacity

The prototype micro-hydroelectric system is capable of producing about 400 watts of electricity or 9.6 Kilowatt-hours per day. I believe that with additional modifications it will be possible to improve the efficiency of the system so it will be capable of producing approximately 500 watts.

#### Dam Specifications

The main part of the dam is located in the creek bed and is less than four feet tall. The dam is about twenty feet long and eighteen inches thick. This part of the dam was poured at one time and required 10 yards of concrete that weighted about 20 tons. Rebar was used throughout the dam. About a year later some additional concrete was required to build a spillway to allow for spring flooding.

#### Creek

The flow of the creek fluctuates greatly. In the late winter through early summer the flow is about 15 cubic feet per second. During late summer and fall the flow decreases to about 4.0 cubic feet per second. This turbine was designed to operate efficiently on a flow of 5.5 cubic feet per second. As water flow decreases, electric power production is reduced to about 100 watts.

#### Investment

The investment in the design and development of this project was approximately \$7000. This includes all expenses associated with the construction of the turbine, turbine nozzle, and dam. It does not include my labor hours. However, with the knowledge and insights I have gained a similar installation would require an investment of about \$2500 (excluding personal labor).

#### Pay-back

In order to estimate the payback on this type of project, I have compared estimated construction costs to the costs of providing electricity to a remote site. If my friend had an acceptable creek flowing through his property the payback for him would have been less than six months.

For several years, we used gasoline generators to provide our power. Each generator cost about \$500 and had a useful life of about two years. It consumed an average of 1.5 gallons of gasoline each day. The annual operating cost was estimated to be \$852. (Assuming gasoline is \$1.10 per gallon @ 1.5 gallons per day, that comes to \$602 dollars per year. Depreciation is \$250 per year.) Assuming a \$2500 installation cost, the pay-back is just under three years.

A solar electric system providing equivalent power would require an array of 40, 47 watt panels that would operate an average of five hours per day in our area. This system would have cost in excess of \$12,000! The estimated life of solar electric panels is 20 years. If the \$12,000 installation cost is prorated over the twenty year life, then the cost becomes \$600 per year. At a rate of \$600 per year, it would require just over four years to pay for the micro-hydroelectric system.

The annual operating costs for the micro-hydroelectric system are very low. The standard V pulley belts must be replaced every six months, this is approximately \$70 per year. Presently, the bearings are replaced each year at a cost of around \$60. The brushes and bearings in the alternator are replaced annually for about \$20. (I have estimated the alternator operates for the equivalent of almost 400,000 miles per year.) The pulley system is replaced every two years, the estimated annual cost is \$25. The total estimated annual operating cost is \$175.

#### Basic System

The micro-hydroelectric system produces approximately 14 Volts Alternating Current, variable frequency. A modified car Delco car alternator is used. The voltage is increased to 140 volts using a step-up transformer. Conventional battery chargers are used to charge golf cart batteries located at three sites. An A-Frame house (1008 square feet) and the well are each powered directly by two, six volt batteries, wired to provide twelve volts. Power is also sent to my earth-sheltered home approximately 700 feet away from the micro-hydroelectric system installation. The electrical system of my earth-sheltered home (1920 square feet) operates from the batteries via a Trace 612 inverter. The six, six volt batteries in the

earth-sheltered home are wired in a series/parallel method to provide twelve volts to the inverter.

### Commercial Systems

The options for home scale micro-hydroelectric systems are very limited. A few companies will custom design and build a system, assuming you have a high enough head. But their systems are not really designed for the single home site. The price is very high! The Alternate Energy Sourcebook published by the Real Goods Trading Corporation offers two hydroelectric systems. Both of these systems are designed to operate on a minimum head of 20 feet and 100 gallons of water flow per minute. The "standard" output is 400 watts @ 12 Volts Direct Current or 700 watts @ 24 Volts Direct Current. In their book they site the following as a "typical" installation:

#### Site Conditions:

Head.....	100 feet
Flow.....	15 gallons per minute
Pipe Length.....	300 feet
Pipe Size.....	2" PVC
Distance To Battery.....	30 feet
Output.....	100 watts

#### Construction Costs:

Pipe.....	\$100
Turbine.....	\$875
Regulator.....	\$340
Batteries.....	\$180
Wire, etc.....	\$50
Total Costs.....	\$1545

I have created a DOS based program (remember DOS?) designed to aid you in the creation of your hydroelectric system. The program will calculate the critical dimensions for the turbine based on the available head and flow rates. You can click [here](#) to download the program now!

## Home-brew Hydro

[Home Page](#)

[Photo Page](#)

[Photo2 Page](#)

This shot to the left is of the home-built paddle wheel made from a 5 gallon bucket, galvanized roofing material, and a couple of mounted bearings.

The drive belt to the generators is a dryer belt that is **VERY** flexible. This helps over come the friction losses. It runs in the top groove of the converted bucket, using it as a large pulley.

Through experimentation it was found that 18 paddles provided the smoothest power from the wheel. Smaller numbers of paddles tended to cause a pulsating in the generator output and some paddles were ripped apart from the vibrations.

### **Shot of both Hydro generators in action**

The water source is from a river running for 1/2 mile on our land. The banks have a flood control levy on each side. We have a large irrigation slough that is about 6 feet lower than the water level of the river. This gives the siphon pipes about 4-6 feet of usable head to the wheels. The "tailwater" is returned back to the river about 1/4 mile downstream. The critters love the steady flow through the slough!

[Servo motors ratings](#)

By [BSparky](#), Section [Homebrewed Electricity](#)  
Posted on Tue Dec 30th, 2003 at 09:07:19 PM MST  
Calculate the output from the nametag

[Hydro](#)

Is there some kind rule of thumb to calculate the output from the nametag voltage and rpm?

Say an Ametek 30 volter around 500 rpm or a 50 volts at 1000 rpm?

I'm looking for a PMM servo type to charge some 12 volt batteries. Power is from a low flow water source so I don't expect much current, couple amps. Thanks Bob

Re: Servo motors ratings ([none / 0](#)) ([#1](#))  
by [drdongle](#) on Wed Dec 31st, 2003 at 05:33:45 AM MST  
([User Info](#))

Info for name plate conversions

Watts ( P) equals Volts ( V) times Current in amps ( A)  
 $W = AxV$  774 watts equals one horse power ( HP)

A motor rated for 500 RPM at 30 volts should produce 1000 RPM ( more or less) at 60 volts, the range is usually linear.

Dr.D

Re: Servo motors ratings ([none / 0](#)) ([#2](#))  
by [Old F](#) on Wed Dec 31st, 2003 at 07:33:42 AM MST  
([User Info](#)) <http://www.oldf.homestead.com>

Bsparky

Divide the rated voltage name tag 50 by the rated rpm 1000 = volts per rpm .05

Target voltage 30 divided by Volts per rpm .05 = 600 rpm

For what you are want to do the target voltage would be 13 volts

So 13 divided by .05= 260 rpm

This will get you pretty close . Just another way of skinning the same cat.

Have fun

Ooops

Thats for working out you cut in speed thats the rpm needed to hit charging voltage.

Oh well you want to know that to.

Re: Servo motors ratings ([none / 0](#)) (#5)  
by BSparky on Thu Jan 1st, 2004 at 09:22:52 AM MST  
([User Info](#))

Thanks for the responses.

So, my understanding there's no great loses with these motors. I've located a motor rated for 99 volts at 535 rpm current 0.6 amps. If I could get spinning over 75 rpm should get around 13 volts factor in for some loses, right?

Now the current question you think this generator will produce couple of amps (or more) at 75 rpm? Thinking the windings could take couple amps. Nothing more than a little heat build up, and motor is under the demagnetization concerns.

Woof, yes thanks. I was looking for that link couldn't remember where in this vastness of the net ... I've saw it.

BTW OldF maybe off topic But, I've notice the TV mast tower on your house. The picture of your current mast project.. I've have a tower similar to that one but in need of another ten foot section for my windmill slated for this spring. Looking for the name of the manufacture in helpful in searching for one. Mine has 11" centers on the legs.

Bob

The tv tower I have on the house I got from a TV repair shop. Its generic tv tower The stuff is getting harder to fine with cable an satellite taking over most people aren't putting up towers. At on time you could find it at places like Wal-Mart. This is one of the reasons I started my tower project. I am trying to work out some middle ground for towers Right now all we have to work with on one end is pipe tower and on the are commercial tower no one can afford. What size blade are you planing on using? And how is your tower set up now? Even a 4 foot diam blade set like The Jerry blades. Can put a good wind load on a tower.

Old F

[Hydro](#)

Searching for a water pump with or without motor for reverse generator....

.... I would like To install a water turbine/pump on the 3/4" PVC water line serving my home. I have 4 40v Amtek PMA motors and will attach one to the turbine/pump hoping that when water is used in the house the flow will turn the turbine/pump with the PMA attached and generate DC to help charge batteries. I realize the only time I will gen electricty is when water is being used but that is better than nothing at all (6 showers, dishwashing, clotheswashing ect...) Any comments or questions are welcomed.

([User Info](#))

I don't want to be negative but I suspect that it would be a wasted effort. I don't think that you will ever get a useful amount of power from it.

Dr.D

Re: Reverse pump ([none / 0](#)) ([#2](#))  
by [wilber256](#) on Fri Dec 26th, 2003 at 05:34:11 AM MST  
([User Info](#))

Also... This setup will be in addation to some solar panels charging the same batt pack, Just think of it for a second...every time a toilet is flushed, shower taken, teeth brushed, clothes washed, dishes washed, car washed, ect, ect...the turbine will be producing DC (3/4" stream @45-55 psi) I would think it would act like a "fast charger" spinning the gen at a very fast speed for a short period of time. Almost like a Boost charge on a car battery. I have the PMA already, and the water usage will be there anyway, So no waste involved.....I look at it as utlizing what is already there being used anyway. How about all 4 PMA's in line somewhere in the water stream, 4 times the energy that would otherwise not be captured and put to use. Family of 6 uses a lot of water.....

Re: Reverse pump ([none / 0](#)) (#3)  
by Electric Ed on Fri Dec 26th, 2003 at 06:01:49 AM MST  
([User Info](#)) <http://www.electric-ed.com>

The energy that is delivered to your home by way of the water flow was put there by your water utility company for a purpose, that is to force the water through your appliances, such as faucets, shower heads, and automatic washer.

The more of this energy you extract with a turbine, the less pressure is available for your appliances.

None of these appliances will operate properly without adequate pressure. Imagine trying to water the lawn or wash the car with little or no pressure.

Electric Ed

[Hydro](#)

For micro hydro experiments.

I have found 2 squirrel cage fans that the motor is belt driven for hydro experimenting. Bought at auction for \$7.00 one is about 1.5 x 1.5 feet and the other about 2 x 2 feet and some other small 12volt blower with what looks dryer hose attached? Anyway looking for a few inexpensive generators to experiment with, I already have a gm alternator. The tape drive motors on ebay are getting a little expensive. I also dont know what to look for in a motor I find at the scrap pile. like hoe to tell if it is pm or not? and how dc and ac applications affect its ability to produce energy? If you have anything you dont use anymore I will pay a reasonable price for your old junk to get me started.

Was gonna start modifying the squirrel cage to direct the water onto the blades better, but have decided that mounting a generator on it and getting some readings as-is and after mods would be helpful. I will submit results as sson as it starts turning, I feel trying at least two different motors between changes to fan will give more info. thanks for any input

[\(User Info\)](#)

1500 GPM & 10 feet will give about 1.7 KW of constant power  
For this set up a Banki Turbine would be the best arrangement.

Give more info to see what variants you my need

Nando

## [Generator to Battery Storage Distance](#)

By [cvo](#), Section [Homebrewed Electricity](#)

Posted on Mon Nov 24th, 2003 at 07:58:12 AM MST

[Hydro](#)

Newbie: Component Locations

Newbie Question: If my power source (hydro generator) is at "A", how far can my storage batteries be from this source of power? And then distance from the batteries to outlets? What determines this? Volage/Wattts produced? I'd like to install a microhydro system on my farm, but I question the location of components. I can't generate alot of power (low head/water volume), but one thing at a time. I understand there's voltage drop due to distance? I'd be happy with D.C. to run a few lights. If there's enough power to convert to A.C. great! I'll not use the power 24/7, just seasonal. I'd like to be able to run a wood stove blower and a couple of 100 watt lights. I'll be using a low rpm alternator. Any thoughts or suggestions would be great Thanks for the help children.

Owen

Re: [Generator to Battery Storage Distance](#) ([none](#) / [0](#)) ([#1](#))

by [dburt](#) on Mon Nov 24th, 2003 at 10:41:56 AM MST ([User Info](#))

Owen,

The question becomes how much power and voltage are you willing to loose versus how much do you wish to spend on wire. Bigger (and more expensive) wire will allow you to transmit electricity longer distances without so many losses. The equations that govern this are:  $E=I*R$  and  $P=I*I*R$  where E is volts, I is amps, R is ohms, and P is watts. There are wire tables on the internet where you can look up the resistance of various wire sizes. For example, 10 gage (10AWG) wire has a resistance of about .998 ohms per thousand feet. For DC current, you use 2 wires to carry the current, so if it's 200 feet from your generator to the house, the electricity will be traveling through 400 feet of wire... The resistance of that wire will be  $400 * 0.998/1000$  ohms, or about 0.4 ohms. If we assume that your generator will put out 5 amps, then the voltage drop will be  $E=5*0.4$  or 2 volts. Power lost (to heat) in the wire is  $P=5*5*.4$  or 10 watts.

So, you can cut down on your losses by moving the pond and the house closer together, buying bigger wire, or transmitting less current (by transmitting higher voltage).

If you need to transmit 500 watts of power, that would be about 40 amps at 12 volts, but only about 20 amps at 24 volts - therefore much less losses.

Dave in PA

Oh, one thing more... With Hydropower, you will probably be generating a small amount of power steadily 24 hours a day. But your loads will be variable, depending on how many lights are on. So my point is that it would be more efficient to place your batteries very close to the load. You'll have less transmission losses that way.  
Dave

"I'd like to be able to run a wood stove blower and a couple of 100 watt lights."

Sorry if I'm pointing out something you already know but that's a lot of light for compact flourescent. If you were thinking incandescent, CF will save you a lot of energy. The AC units are better and cheper but you can get them in DC.

([User Info](#))

I just did this - I found that using heavier wire you wont notice. What do you want? 3 miles? I would say you can go as far as the wire you can afford the loss is calculatible also by any extra gains you get by getting more flow of water to pay for loss of electricity. If you use a generator that creates ac (PMG alternator) this is better for distance and convert it to dc at the other end. Dc will measure funny at a distance as its physics will show a stored value and upon load it will show an actual value. Some is lost but not much, which is why they transmit it over hundreds of miles. Some say that over 99.99% of the electrical energy is lost to its "feilds" to the mere fact that it is conducted anywhere. Tesla was trying to use this "lost energy" and apply it to another form of transmission. But practically speaking something just over the size of standard house wire will work and under 1/8 inch. You can probably buy a spool on ebay or an industrial liquidation for a 5th of the full cost otherwise if you are patient and keep trying. I was suppresed to get a 70 lb roll of new 18 gauge copper wire for 97.00 Incuding shipping! So its possible. Its pure copper - it will work.

Re: Generator to Battery Storage Distance  
([none / 0](#)) (#7)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on  
Wed Nov 26th, 2003 at 09:42:57 AM MST  
([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

Using the Voltage drop Calculators above.

Using 100 feet of wire at 24 volts at 5 amp load  
18 gauge wire will lose 7.7 volts  
10 gauge wire will lose 1.2 volts

18 gauge wire is not good for power transmission  
it's only good for about 8 amps max and tons of  
resistance

Re: Generator to Battery Storage Distance ([none / 0](#))  
(#8)  
by hydrosun on Wed Nov 26th, 2003 at 04:44:15 PM MST  
([User Info](#))

Most of the hydro systems I've been putting in have been at 48 volts dc to keep down the cost and voltage losses of the wire from the generator. (the exception was where the distance was under 150 feet and the 12 volt inverter was already install.) The use of dc-dc converters from Solar Converters has given me more flexibility in design. Using the higher voltage for long distance transmission but still having the option to drop the voltage to 12 volts or 24 volts for use. If most of the power is used at 120 volts ac then a 48 volt inverter is the most efficient route. But only the bigger more expensive inverters come with a 48 volt input (Trace 4048, Outbackpower Fx2548 , I've installed both, the outback has lower output so lower cost) So dropping the voltage at the battery to 12 volts allows the use of smaller lower cost 12 volt inverters . The smaller dc-dc converters are under \$150. What you really need is some real numbers, watts produced and distance from generator to battery , cost of wire to come up with a design that keeps the total price down down.

I ONLY WANT TO DESING THIS ONCE

I HAVE A BYPASS POND AND WHERE THE WATER LEAVES THE POND THE CONCRETE DAM NEEDS TO BE RIPPED OUT AND REPLACED. I HAVE ABOUT A 4" PIPE WITH FULL FLOW AND ABOUT 5' OF HEAD. I WAS THINKING OF PUTTING IN A 6" PIPE ALONG SIDE OF AN OVER FLOW. I WAS THINKING IF THE PIPE WAS 12" BELOW THE OVER FLOW THAN I WOULDN'T HAVE ANY PROBLEMS WITH LEAVES OR ICE?

I THINK AT THE DISCHARGE END OF THE PIPE I'LL HAVE 5' OF HEAD. HERE I CAN REDUCE THE PIPE DOWN TO 2" IF NEEDED. I WAS THINKING THAT I COOULD RUN ONE SHAFT WITH CUPS IN THE MIDDLE AND A GENNY ON EACH END???

ANY IDEAS OUT THERE

THANKS ROSCOE

How long is the pipe?

"filling" a 4" pipe will not help until we knwo the legth of the pipe as well as the head. The we have an idea of the flow.

You might lose the head in the bigger pipe too.  
Hugh Piggott <http://www.scoraigwind.co.uk>

The maximum flow in a 4 inch pipe with a gradient of 1 in 48 is about 200 US gallons per minute. You can also measure the time it takes to fill a drum or box to confirm this flow.

With a 5' head you could get up to 100 watts from this flow.

Maybe there is a 'powerpal' product to fit this site. A propeller turbine of some sort would seem ideal. The usual approach is to build an elevated flume with shallow slope and large section which carries the water slowly to the turbine with minimum loss of height. The turbine is at the flume level and the draught tube below sucks the water through.  
Hugh Piggott <http://www.scoraigwind.co.uk>

I would seriously consider a "mitchal" low head system these work great on as little as 3 feet of drop. They rely on large volume as opposed to peltons which need a long drop and small volume.

([User Info](#))

Hey Zmoz-

I too live in Oregon; I'm a few miles outside of Salem. I tinkered with such a setup a while back, it did.....okay. It was some output, which is always better than nothing. But I'm talking a few mili amps. I used a home built water wheel made out of a soup can and some blades made from coffee cans, pop riveted together. I mounted it in a hole I cut in the bottom of a drain pipe, and used a drive belt and pulleys from an old tape player and drove a tiny stepper with it. More experimentation would yield better results, but even as much as it rains here, I didn't think the measly output was worth the hassle. Good luck, and keep us posted. If you have better luck with a better setup, I may look into it. The neighbors didn't complain about that one.....

Demetri

MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Demetri  
Have you come by the store yet? The Audio Source.  
Have I met you yet?

Just curius. To the other poster above. Have you totally given up on wind?  
I think more power could be collected from wind than rain gutter even if your wind situation is very pore. My plastic blades with a steep pitch on a tape drive motor will yeild 1 to 3 amps in 3 to 5 mph wind. I'd guse this wind system would be easier to build. Posably overall collect more power. Fairly cheap to.

Wich part of NW Oregon are you located in? I'm in Salem.

JK TAS Jerry

[Hydro](#)

Generator powered by water from the rain gutters?

I live in the NW corner of Oregon, and as you may know of of the things we have plenty of is rain. Solar panels don't do so well...and there's hardly any wind around here. I have about 2000 sq ft of roof, and I was just thinking today, would it be worth my time to try and use the water that runs out of the gutters to spin a generator? I'm guessing it would probably have to be pretty small...do you think it would even be worth the trouble?

([User Info](#))

zmoz,

I think if you calculate how much water falls on your roof - and the distance it falls for -generating purposes-, you will find it will only generate a miniscule amount of power.

One might also need a -holding tank- to store the water so generation and consumption of the energy would not require batteries. Then there are the permits and the visits to the mental ward when they read the permit application.

Best do the calculations first - then decide if the expense will warrant it.

<http://www.rainwatercollection.com/homepagenew.html>

Deals with using the water for domestic purposes. BUT, there is a note - One inch of rain on 1000 square feet of roof surface yields around 550 gallons of rainwater (562 to be exact, although this can easily be reduced by as much as 25% outside the laboratory in our imperfect world due to evaporation and leaking gutters. I mean, when's the last time you followed a cookie recipe precisely and came out with anywhere near the six dozen cookies it supposedly would yield?)-

And this site: <http://www.suntrekenenergy.com/hydro.htm> states - As little as 100 gallons per minute (GPM) falling 10 feet through a pipe or 5 gallons per minute falling 200 feet through a pipe can supply enough power to comfortably run a small household. In areas where there is a long rainy season, and there is a mountain stream that can be used, a small hydroelectric system can work well with solar modules, both charging the same battery. When it is rainy and the solar modules are putting out less power, the hydroelectric system will be at its peak.-

From there, you might get and idea how much energy you can expect....

[Hydro](#)

trying to post this in correct category duplicate in quarantine.

Haveing trouble getting category right for some reason sorry for wasting space.

I have a small stream with limited flow 3-4 foot head after dam, solar is limited due to cabin located in woods with trees very close, wind is not reliable and a 100 foot? plus climb to get above tree line.

Does anyone have info or pic of a small stream other than the one on this site (mine is similar) with some real world info, not just theory.

Also would be interested in your web sites (not that otherpower isnt the best) on specific apps of very micro hydro power. It seems there is very little info on the web about homemade micro hydro units.

Any input will be welcome.

I really admire the guys building stuff from scratch and hope to see more

I think the reason for so little info on micro hydro is that very few of us are fortunate enough to have a stream running through our back yards. I am going to build a small hydro genny and test it a small stream just couristys sake. Are you planning on building your own alternater? The hydro genny on this site is rated as 2amps and as it says its not a lot but its 24/7. From the sound of your stream im sure it wouldnt be that difficult getting an amp or more without having to all techy about it. I would myself convert a induction motor and take it from there and make a wheel or a prop of a boat has been one my ideas but never got round to it yet. I have so many thing s going and so little time, my site is waiting to be updated but will have to take its turn like everything else. Go for it and you dont have to spend a fortune in doing it.....sean

([User Info](#))

www.homepower.com has published several articles on micro hydro, and also lists many suppliers for alternators, pelton wheels, some of which are very reasonable. You can download the entire current issue, complete with ads (that's half the fun) at no charge. It's the best homebrew electricity periodical in the world and it's free on the web.

Good luck and have fun!

troy

### [Will a more efficient Genny slow my waterwheel down?](#)

By [turner](#), Section [Homebrewed Electricity](#)

Posted on Sun Oct 5th, 2003 at 06:42:14 AM MST

[Hydro](#)

I have a homemade hydro setup I am using to charge some batteries. It consist of a couple of

squirrel cage fans (my turbine) linked by chain to my 8 pole, dual rotor genny. I only have about 3 feet of head but alot of flow so it works OK. I am getting about 110 volts out of it now and I know it is overkill for charging my batteries. I am not electrically inclined and have gleaned most of this project from this site.

Am I correct in assuming that if I rewire my coils from series to parallel I will (1) Get lower voltage. (2) Get more current. (3)Cool my coils. (4) Get more total output?

Also....as I have increased the voltage by using better magnets the waterwheel has slowed down. Does the high voltage I am producing have anything to do with this or is it simply total output related? If I rewire to parallel will the drag at the turbine be reduced?

Any help or suggestions would be appreciated!

[Will a more efficient Genny slow my waterwheel down?](#) | 7 comments (7 topical, 0 editorial)

more efficient Genny slow my waterwheel ? ([none / 0](#)) ([#1](#))  
by [drdongle](#) on Sun Oct 5th, 2003 at 07:16:21 AM MST  
([User Info](#))

Every thing you do will affect the generator and hence the water turbine. The new magnets impose a greater load on the generator and as a result it slows down.

1. Yes
2. yes
3. not necessarily coil heat is a result of the load , more load more heat
4. again not necessarily it depends on what you plan to do with it.

If the out put is AC you might consider using a transformer to reduce the voltage, that would allow you to send the out put farther and reduce it to a usable voltage where you need it.

Perhaps if you briefly described your set up we could make specific suggestions.

Dr.D

[quote]"I am not electrically inclined and have gleaned most of this project from this site."

I'd say you're doing fine. If you weren't electrically inclined, you are making great progress.

[quote]"Am I correct in assuming that if I rewire my coils from series to parallel I will" -

(1) Get lower voltage. - - - Yes.

(2) Get more current. - - - That depends on the load. The alternator has the capacity to deliver twice as much before it overheats.

(3) Cool my coils. - - - Yes, if the load remains the same as it was when the coils were in series.

No, if you double the load current. (See #2)

(4) Get more total output? - - - No. The maximum power output depends on the temperature rise your alternator coils can withstand before insulation damage occurs. Let's assume that in series your maximum was 5 amps at 100 volts = 500 watts.

In parallel, it will be 10 amps at 50 volts = 500 watts. Each individual coil will still be carrying 5 amps.

Electric Ed

Re: Will a more efficient Gen slow my wheel ? ([none / 0](#)) (#3)  
by turner on Sun Oct 5th, 2003 at 08:14:40 AM MST  
([User Info](#))

Thanks for the quick answers! I ask these questions of the electrical engineers at work and I just get a blank stare.

More detail on my setup. I am running the genny output through a rectifier and then into a bank of batteries parallel wired at 12 volt. They are regulated through a Trace controller which dumps the excess into some decorative lights around my yard.

I use the batteries for when the power goes out which is not often but it's just cooler to do it this way than to buy a generator. (too much discovery channel I guess)

The genny rotors are cast stainless (salvaged from work) with double stacked 1" x3/8" neos. I just realized (reading other posts) that I am losing flux because these rotors are stainless. I guess I have compensated for that by doubling the magnets. (not elegant but I guess it works) Since the genny is slowing the turbine by at least a third in this configuration am I to the point that I must look at my turbine efficiency to get more juice?

So I guess the load is my battery bank? If I add batteries does that increase the load and slow things down further??

I assumed that the heat in the coils was lost energy....interesting. So warm coils aren't necessarily bad.

[ [Parent](#) ]

Re: Will a more efficient Gen slow my wheel ? ([none / 0](#)) (#4)  
by Electric Ed on Sun Oct 5th, 2003 at 09:15:26 AM MST  
([User Info](#)) <http://www.electric-ed.com>

Ordinary mild steel plate would have less reluctance (opposition to magnetic flux) and should increase the flux available at your coils.

If the present configuration/load is slowing the turbine, any increase in load (watts) will slow it further, and will also heat the generator coils more.

That heat is, as you assumed, wasted, except for the fact that it helps keep the coils dry.

You can get more electrical OUTPUT from the generator by increasing the mechanical INPUT to it, which is the output from your turbine.

This would require a more efficient turbine, to extract more energy from the present water supply, or increase the water flow and/or head.

This might also require a higher capacity generator to handle the increased input - larger wire size, more magnets, etc. Every energy-conversion component of the system has it's maximum power limit, and the overall system efficiency is better if the components are well matched.

Excuse me for rambling on.

Hot coils,Just a thought, wouldnt it be nice if he ever has to make a new stator, to cast in some water tubes for cooling since the water is flowing by anyway. dont know if it would affect flux lines?

signweld

Re: Will a more efficient Gen slow my wheel ? ([none / 0](#)) (#6)  
by troy on Mon Oct 6th, 2003 at 01:49:02 PM MST  
([User Info](#))

I have seriously considered casting a single copper tube in the fiberglass encased stator around the outside perimeter to at least cool the edge of each coil. Since copper conducts heat well, that will help cool the whole coil, and the whole stator. But I would install it with a thermosyphon driven small radiator on top of the wind gennie.

Now if only they would let me install a tower in town...

Best regards,

troy

<http://timmythy.home.mindspring.com/timmy.htm>

Don't use metal pipes in there. Magnetic eddy currents will cause more heat in the copper pipe and slow down the rotor from magnetic resistance. Use plastic or rubber pipe.

Thats Nice! Ok, Question: what is the fuel source and how much power can this puppy produce? Whats the total speed that it can rotate at or what is the optimal speed that it rotates at?  
Thanks!

Re: Pelton rotors/buckets - pictures ([none / 0](#)) (#3)  
by DanB on Mon Sep 22nd, 2003 at 10:36:00 AM MST  
([User Info](#))

The fuel source is presumably running water... and it's neat how they bolt on so one could use different sized wheels!

Is there a website with more details on this? Looks like a great setup... (of course I know nothing about hydro)

[ [Parent](#) ]

Re: Pelton rotors/buckets - pictures ([none / 0](#)) ([#4](#))  
by EcoInnovation on Tue Sep 23rd, 2003 at 02:44:08 AM MST  
([User Info](#))

Our web site is very out of date, hope to get it updated soon. You make the rotor the size required to optimize the efficiency of the generator. We match them to Smart Drive PM generators so the speed is normally from 300-1000 rpm.

The plastic buckets are for sale for those keen to have a go themselves. If interested email me and I can send you a spec/price sheet.

## [Plastic Injection Buckets](#)

By [EcolInnovation](#), Section [Homebrewed Electricity](#)

Posted on Sat Sep 20th, 2003 at 01:48:23 PM MST

[Hydro](#)

**Plastic injection moulded buckets now available**

Hi All,

EcoInnovation has finally got an injection mould for making plastic pelton buckets. With them you can make a rotor to any diameter starting at 180mm Pitch Diameter (18 buckets). They bolt onto an Aluminum disc, made to suit. They are priced from US\$2 each (25 rate) to US\$1.2 each (1000 rate). The buckets are a reasonable size and can accommodate a 20mm jet. If interested in being sent a data sheet email me at [ecoinn@paradise.net.nz](mailto:ecoinn@paradise.net.nz)

We are currently working on a large Turgo bucket that should be available in a few months.

We also have complete pelton turbines designed for your site from US\$750-\$1000 excluding freight, can send details if interested.

Regards

 ?

[Hydro](#)

Don't hate the noob, but of course I have a few questions. I have searched both this site and homepower.com without really getting the answers I'm looking for. Ya'll will more than likely be hearing a lot from me within the next month and a half or so. I have two main questions. I don't really know where to start with the water wheel. The site itself has a good bit of head but not too much flow. I intend to measure both the flow and head today so I can be more specific with that info later. But right now I'm guessing when I say that there is at least 3 feet of head and maybe 4 gallons a minute. I could very easily get 4 feet of head. Also, I was wondering what type of alternator/generator I should use. My best guess would be to build an alternator similar to the disc brake designs on otherpower but you can't beat the idea of a cheap, readily available car alternator. I guess it could be rewound with the voltage regulator broken out but I'm kind of fuzzy on that idea. I'm not too sure how that works. What i'm mainly looking for is the opinions of other people who have been where I am and now simply know the do's and don'ts of homebuilt hydro power, the what works and the definetly don't works. <If that makes sense. Thanks.

Gettoride,

I went to the "power conversion" website and to put in the parameters of your power - 32 pounds of water falling 4 feet. As you stated the 4 foot was "maybe" and "maybe" four gallons a minute and hte site has a conversion of Kw with Ft-lb/sec, I used 1/2 lb of water falling 4 feet every second the result: 2 Ft-lb/sec = 0.00368 Kw

Of course that is before loses of friction and efficiency and before multiplication of the effeciency of any conversion device or a multitude of "loses" that occur when energy goes from one form to another.

Good luck on fonding a waterwheel in the "2 watt" size range. Better luck still on rewinding one that small.

Ron

I neglected to mention that this waterwheel is mainly for looks. The water source is indeed 4 gallons a minute. I was just hoping to get as much power out of it as possible. A LOT of gearing hopefully will get something to turn. Can anybody else relate?

[ [Parent](#) ]

Re: What are the hydro do's and don'ts? ([none / 0](#)) (#3)  
by troy on Fri Sep 5th, 2003 at 10:35:47 AM  
MST  
([User Info](#))

In the original comment, you state, "The site itself has a good bit of head..." Just for comparison, a good bit of head would be at least 15', and 50 to 100 feet of drop makes the site really worthwhile.

There are setups that work for high head (>50') with low flow. There are also setups for low head (<10') with high flow. But no amount of gearing will squeeze out any more power from a low head, low flow stream. On the other hand, since this sounds like a fun little demonstration thing, without the need for "real" electricity, you could probably rig up a small bike generator to light a couple small bulbs.

This comment is absolutely not meant to be negative or discouraging, just don't want you to invest a lot of time and money if the potential is very modest.

Best regards,

troy

Well it mite work if you do what I did, I had more head but way less flow, I took and dug the stream out and built a dam, I then ran 10 feet of 1 inch pipe down to 10 feet of 3/4 pipe, then down to 1/2 pipe, to a garden hose preesure nozzle. I then took a 10 inch pulley and some half inch metal pipe. I cut one inch slots every 1/4 of a inch the pulley. I then took my metal pipe sawed it in half and welded 2 inch pieces into the pulley. The pulley is on the shaft of a 90v dc PM motor, I get about 3 amps constantly going into my battery bank at a voltage of about 13 volts. It can work, and does help, but dont expect anymore than you could get out of a cheap solar panel, the only good thing about it is it produces 24\7, and that makes 72 amp hours a day into my battery bank, so keep trying its possible.

### [Hydro system and how to setup](#)

By [shane](#), Section [Homebrewed Electricity](#)

Posted on Tue Sep 2nd, 2003 at 06:40:11 PM MST

[Hydro](#)

What do I need?

I have an alternator, an old car generator from an old car and an ametek 40vdc motor. I was wondering what the heck do I need? It's a hydro system so I dont really need Batteries since it will be on all the time. I need to power a few lights and 2 fans. I have the wires and all. I have been checking out those diodes and bridge rectifiers but I dont know what they are for or how to 'heat sink' them.

[Hydro system and how to setup](#) | 5 comments (5 topical, 0 editorial)

Re: Hydro system and how to setup ([none / 0](#)) (#1)  
by TomW on Tue Sep 2nd, 2003 at 07:28:00 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Shane;

First off the rectifiers are mostly there to keep batteries from driving the generator as a motor when its not turning.

If the "car generator" is truly a generator you won't need any diodes at all because a true generator will put out dc to begin with so you won't need to change ac to dc with a rectifier. Same with the Ametek it puts out dc voltage.

Thats my opinion no diodes if no batteries and dc sources.

Cheers.

TomW

okay that sounds simple but I think I need to get a diode for the alternator if Im going to use it cause i heard they need there own power to make power.

Yes im pretty sure my car generator is real cause it has only a negative and positive outs, no others, the problem is I think it is run by brushes which is a problem, they wear out. Thanks for the info now I have to think if I need a inverter.

Shane;

Not sure how to say this but adding an inverter will likely require a battery to work properly. Your question was about direct driving dc lites and fans [I thought].

Adding an inverter negates what I told you cuz its gonna need a battery to protect its input from spikes in the supply.

You kinda changed things after i answered. I suggest you do some reading here on the board and see if you get a handle on things before you dive in. At least until you understand how the alternator, generator and ametek work as voltage sources.

Cheers.

TomW

[Hydro](#)

would this work

I live in Arkansas so evaporative air conditioners are not practical...to humid, BUT I was trying to think of a way to cool my house that would use a minimal amount of energy and not increase the moisture in the house.

Could you put a radiator in a window with a fan behind it. Hooked to the radiator would be approximately 200 feet of 3/4 inch pex pipe going 80 feet into a well and then back up creating a loop to the radiator with only a low voltage pump circulating the water. Anyone have any ideas, it seems fool proof so what am I missing...if it were really this easy it seems that everyone would be doing it.

Benton

by Seth on Sun Jul 13th, 2003 at 12:48:11 PM MST  
([User Info](#))

yes i think it would work.... but getting the hose primed first might prove to be a problem... buit if u have a well pump.. then no problem.... prime the hose with the pump.. then hook it up to the cooling system,.... and bleed the air off.

Lots of people also just run hose underground instead.... cools in the summer-- heats in the winter.....

Re: Homemade Air conditioner ([none / 0](#)) ([#2](#))

([User Info](#)) <http://home.cogeco.ca/~woproject>

I have been experimenting with something close to that myself. What I found is you need a lot of underground water to make any real difference in temp or a lot of pipe burried to be able to transfer the heat without saturating the ground. If you have the means to drill a few more wells at least 10ft apart and deep enough to get the majority of the pipe depth in 64°F or lower ground then you can create a closed loop system. From what a geothermal installer has told me those small pumps work just fine in a closed system, being closed loop it dosent have to fight the head pressures of trying to push water up hill because you have the same amount going downhill and they balance out. In an opened system the power needed to push the water up a pipe is considerably more.

Hope this ifno is of some use.

Tom S.

I've got an old copy of a Popular Mechanics article where a guy built a closed loop system to cool his house. He used several truck radiators stacked back to back and had two wells...one to pull cool water from and another well (opposite end of the yard) to re-inject the warm water after it had passed through the radiators. I always thought that was a cool idea.

Dear Benton and others,

Your idea will work if you have access to enough cool water as mentioned by others. But just like a "real" AC unit, when the hot humid air hits the cold radiator, you will get a lot of condensation. So long as you're set up to deal with that condensate, it's a good thing as it will lower the humidity inside your house.

Best regards,

troy

Hey, this just happened yesterday.

A friend of mine and I built an air conditioner for his farm's office using a monster oil cooler (I'd found it in the junk yard months before and grabbed cuz it looked new, even though I had no use for it), and a good length of garden hose. We got cool water from one of his big agricultural wells (brazing a nipple into the side of a six inch water pipe is a pain in the butt), which he had to run anyway to water his fields. We used the 'exhaust,' after having gone through the cooler, to water his private veggy garden. Put a 120v. ac fan behind it after removing the stock 12v electric cooling fans, and it worked great. Not as cold as a commercial unit, but for the \$15 we spent on garden hose and couplers, neither of us were complaining. After ten minutes running the room was noticeably cooler. The idea

certainly is workable; good luck with finding/making a source of cool water.

([User Info](#))

The largest problem I see is the 64 degree water. Most "air-conditioners" I have seen and worked on get a 30 degree or more temperature drop "across the coil". This is achieved with a coil that is about 40 degrees less than the desired temperature.

Any reduction in temperature and/or humidity is a bonus in muggy conditions. Folks have already mentioned the need to get rid of the water "squeezed out". Try it and see - large radiators and slow air-flow will help with the temperature exchange. AND, don't forget to filter the air so the radiators won't clog up.

I just wanted to add one thing that we haven't touched on yet and that is using ground water in a closed loop to help cool the compressor coils of a traditional air conditioner...like using a tube-in-shell heat exchanger. This would reduce the thermal load on the compressor and probably save you some good bucks on your electric bill. I've seen commercial versions of this idea using evaporative cooling to help the compressor, but I would think the same thing would apply to a closed loop geothermal setup.

Re: Homemade Air conditioner ([none / 0](#)) (#8)  
by jubalearly on Tue Jul 15th, 2003 at 01:26:07 PM  
MST  
([User Info](#))

You can't go too far with this without making adjustments in the expansion valve. By that, I mean that the expansion part of the cycle (for cooling in the in house radiator) is meant to occur at certain rates and it won't work well outside those limits.

It's probably worthwhile with a small (window) unit if you don't spend too much money or energy pumping the water. But if you have cheap well water, you can still get considerable evaporative cooling even in wet climates by various strategies. I'll go dig up some web references - I'm been researching this for a couple of years. I'm probably going with a large ground loop, water storage in septic tanks, an auto compressor driven by alternative energy if possible, and cooling down at night & storing the "coolth".

Backwoods Home, March/April 1999, issue #56 had an excellent article on this (see refrigeration). I think it is only available now on the CD or by ordering the back issue. IIRC, it covered a number of options for cooling a refrigerator, but a number of them would work as well for AC. More to come.....Russ

Hi,  
DanB and JimU were nice enough to post on our forum, so I thought I would share here too.

There are certain things we know. Hot air rises. Soil temperature is stable at depth. Evaporation cools. Simple yet profound.

First, install a ventilated ridge on your home and plenty of soffit vents to keep the attic cool.

We can't all live underground, although it is an efficient and viable alternative. But we can duct the earth.

Not knowing your situation or knowledge of construction I hope to be simple.

First, dig trenches and bury 6" ABS at a depth of 24" minimum. If you live on a hill you can pop them out to gather fresh air. Otherwise, bring them to the surface with an ell and cap with a mushroom vent.

Bring these "intakes" to your living space.

At the high points of your home create stacks that have dampers to control flow and vent them up

through the roof.

That is it!

Hot air rises and creates the draw necessary to pull the cooler air from below, (the intakes are underground. \*You can filter this air" That is all it takes! If you put the ABS underneath gardens or trees it will improve the cooling effect. No electricity necessary. It is called tower of power.

If you built your house from scratch you would want an atrium to create max draw and airflow. You generally want your underground ducting to be shaded.

I'd tell you how our greenhouse heats itself in the winter with no electricity, but... I am a nutcake. Kinda nutty, huh?

[New to power generation. Need help with best setup for hydro system.](#)

By [Anonymous Hero](#), Section [Homebrewed Electricity](#) [Hydro](#)  
Posted on Mon Jun 30th, 2003 at 08:43:41 PM MST  
New to power generation. Need help with best setup for hydro system.

Hello, I have a 100 watt pump for a fish pond. It's stats are as follows.

Volume of water pumped = 10,300 Liters (3000 gallons) per hour.  
Can pump 4.65 meters (15 feet) high.  
the hose it pumps through is 1.5 inches in diameter.

Right now it pumps up about 5 feet to a waterfall.

So basically I am wondering what is the best setup to get the most bang for my buck. I only want to generate enough power to run about 15 garden lights.

I was thinking about using a small turbine and a car alternator and car battery. Maybe something from an autowrecker. (Always looking for the cheepest way but not something that will die in a week either.)

Any suggestions?  
Any sites on making a turbine. I was thinking from pvc pipe, etc..

Thanks..

Your post is a little confusing.  
Did you mean you are going to make a small water wheel or something from you little fishpond waterfall? If so, why are you doing this? The fish ponds runs on 120ac why cant you run your lights off of it. It just doesn't make sense.

-Andrew

I could run my lights off of ac, but this is a learning project for me. If I can get this to work and if it is efficient, then I will probably set up a larger system to run my house off of. But for now, I just want to make the most efficient do it yourself project from my waterfall. :)

Hi,

do you have a waterfall, which runs by itself or are you making the waterfall artificially with that pump of yours?

- Hannu

[ [Parent](#) ]

Re: New to power generation. Need help with best s ([none / 0](#)) (#4)  
by Anonymous Hero on Wed Jul 2nd, 2003 at 03:18:18 PM MST

It is a pump. The stats of it are in the first post.

[ [Parent](#) ]

Re: New to power generation. Need help with best s ([none / 0](#)) (#5)  
by hvirtane on Wed Jul 2nd, 2003 at 04:38:06 PM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

Hi,

if you are making a waterfall using an electric pump and using that waterfall to make electricity for lamps, it is of course more efficient to use the electricity used for the pump for the garden lights directly?

However, I think that your waterfall is necessary for the decoration or for the fish as well?  
So nothing prevents you to use it to get

some of  
the electricity back  
and to make there  
some home-made  
water technology as decoration?

The basic equation how much there  
is power in falling water is as follows:  
 $P(\text{watts}) = (1000Q) \times 10H,$

where Q is the flow of water in cubic  
meters  
per second, and H the head of the  
falling  
water in meters.

In practice the best turbines can make  
of that  
power even about 90% into electricity.  
(Of course there cannot be more power  
available than your pump is pumping  
up,  
so you can easily estimate  
the available maximum power to be  
less than the power  
of the pump pumping water up.)

From articles of the magazine Home  
Power  
you can find some descriptions how  
to make waterwheels or home  
made crossflow turbines.

Your waterfall is quite small,  
because your pump is small. You might  
use the  
waterwheel or the turbine to power a  
couple of  
bicycle dynamos, which could make  
electricity  
for led lights?

But nothing prevents you to make  
yourself  
an permanent magnet generator,  
something  
similar as many people of this board are  
describing  
to make for their wind turbines?  
You could use an extended axle of a car  
wheel hub  
for fixing the waterwheel The same  
axle, where  
your self made generator is.

Later when you've  
made one generator, why not making  
another  
one for a wind genny...

- Hannu

## [Still Water Makes Deep Power for Cryonucleator](#)

By [cryonucleator](#), Section [Classifieds](#)

Posted on Wed Jun 25th, 2003 at 04:47:30 AM MST

[Hydro](#)

Low-flow water, or "cool" geothermal can make tremendous power.

Wow! Wotta board. More active than any I've seen. Cut to the chase... I've worked for years on this and finally filed a patent app so it is patent pending. It's the blackbody cryonucleator(tm). It's simple to build, uses no fuel whatsoever, and produces from 40,000 to 500,000 ft-lbs of energy per cubic foot of water used, and the water remains unchanged and reusable.

Now, the subject of my post is that if you have access to a small water body, but the current speed is too low for a practical hydro, don't despair- you're ideally positioned to use the stream for cryonucleation. Likewise, if you have access to geothermal but it's below the recommended minimum temp of 170 C for running a steam turbine, you can use it instead for a cryonucleator. In fact, if you have a substantial land area (or large cave under you), you can use that slight heat energy to cycle the device.

After reading some of the hilarious posts on "Bad Board" about uploading images, I think I'll wait until I'm well-rested before trying it. So, to see an illustration of how to use these "useless" energy sources, just go to [Using Useless Energy](#) .

This device uses winter weather to convert water to ice, captures the expansive force hydraulically, and sends that hydraulic power to turn a turbine to make electricity. Excess power can be stored gravitationally to provide year-round power, or used to make hydrogen from water (storing the hydrogen for later use). So obviously, you have to have a way to "cycle" a cryonucleator from frozen to liquid state, or use a design with an ejection-replenishment system to dump the ice and refill with liquid water. That's where the stream and geothermal stuff comes in (or solar collectors).

Containment is a big issue with a cryonucleator. Your working pressures range from 3,000 psi to 40,000 psi, so you need a strong-walled breeder to handle it. That means thick metal. Amortizes quickly, but costly to start. So if you know anything about concrete composites, folks would love to hear about it (myself included). If I see those kinds of ideas here, I'll start referring my licensees here to join in. Or if you've got ideas about unique containment geometries...?

Anyway, long post, but I figured it best to answer as many questions as I could before they get asked. Hmm- if you want to build one, you'll need to get in touch with me about a license. Cheap and permanent.

---Dennis

[Still Water Makes Deep Power for Cryonucleator](#) | 18 comments (18 topical, 0 editorial)

Re: Still Water Makes Deep Power for Cryonucleator ([none / 0](#)) ([#1](#))  
by [cryonucleator](#) on Wed Jun 25th, 2003 at 05:08:01 AM MST  
([User Info](#)) <http://www.makehydrogen.com>

Forgot to mention. If you have a small forge or machine shop, there's a need for small-vane actuators for any turbine that uses a cryonucleator. It should be able to handle the pressures mentioned. I think about .25 cc displacement per vane would work. Actuator diameter should probably be about 1 inch or less, which means great torsional stress on the shaft. This device hasn't really taken off yet, but in time folks will be wanting these actuators and they're just not available out there. So post here if you can do this.

Also, forgot to mention that low-power breeders work well too, so there's no absolute need for a strong wall, i.e., an empty propane tank will work, or even very strong plastic. The trick is to just cycle faster using a stream or lake, in order to compensate for wasted power.

---Dennis

Hi Dennis, you mention that your device is patent pending which means it has a patent number assigned? You didn't mention the number on your site.

Also, I see lots of graphics and no pictures. Could you post a picture of a complete one (on your site or here, doesn't matter).

Martin.

Re: Still Water Makes Deep Power for Cryonucleator ([none / 0](#)) (#3)  
by cryonucleator on Wed Jun 25th, 2003 at 07:13:11 AM MST  
([User Info](#)) <http://www.makehydrogen.com>

Martin-- thanks for comment. No pictures of one yet- have been busy with theoretical, legal, patent stuff. Will post one as soon as I can build it. Live in an apt in New Mexico, with postage-stamp backyard. Need a place to build one.

On patent, anytime you file an application, it is "patent pending". The "patent number" issues when the patent issues. Meanwhile, it's not a good idea to give out even the filing number. Also, if you're planning to patent something someday, recent USPTO rules permit you to file "Provisional Application for Patent", which is also a true patent application. If using this, the nice thing is it can be very informal, and costs only \$80. But tricky, so read the fine print. Also, recent USPTO law creates retroactive liability for unauthorized use of a patent-pending device or process. For the record, I'm not a lawyer or patent attorney, just a country doctor. So don't take my word for anything, and call me in the morning. ----Dennis

by Anonymous Hero on Wed Jun 25th, 2003 at 11:46:57 AM MST

Mr. Dennis, So to clarify, you are not actually selling these machines, but indeed selling licences to build that which you do not actually have in fact? Are you related to Dennis Lee, by any chance? I built a BBQ tank one of these in 1998. I hope I was not infringing on your patent, but I guess my affirmative defence was, I did not know such a patent existed. My findings were conclusive and concurrent evidence with already existing science text that ice freezing expands a total of 9% in volume. And when pressurized, with the extreme cold, tremendous pressure can be exerted. Yep, that is a fact. My BBQ tank experiment proved that, but I could not get the figures of 80,000Ft /Lbs to 1,000,000 ft lbs of dead lift torque with a BBQ tank. Perhaps my crude experiment using flowing 40 F water to thaw and approx 10 F to refreeze was not refined enough. I was successful in raising several hundred pounds a few inches with not complex moving parts as a dead lift experiment, but not anywhere near your figures. What was I doing wrong? The other thing you did not tell us was the function of time as the denominator to the ft./lb figures. My BBQ experiment was capable of raising the max weight a couple feet over several hours. I was wondering what the time denominator of your equation was. After all the equation does require that

denominator to achieve a power function to equate work done. The melt / freeze cycle has fascinating possibilities, however could you provide more info as Martin, Dan and Brian ask? Thanks, Jungle Bill

It's an interesting idea and interesting web page you've got. There are some things I don't quite get here.

"and produces from 40,000 to 500,000 ft-lbs of energy per cubic foot of water"

in my understanding, ft-lbs is a measurement of torque, which I can imagine you might be able to develop a good bit with frozen water. But it is not in and of itself a measurement of "energy" like you say. Energy would be measured in something like KWH... is that right? or horsepower hours?

I think what would be interesting to know is some real numbers about temp differences, size of the machine, how often it would cycle and how much power (in either horsepower or watts) it could generate continuously, Or - a measurement of total energy that would be generated (in KWH or something) over a certain course of time, because this is what's important with all these sorts of things. It would also be fun to make some comparisons with this vs say... a sterling engine.

Not to be a critic, but I think that before you offer plans for sale here, it would be nice to see these sorts of numbers, comparisons - and possibly some real data from a real working machine! (that could make me a believer!)

Re: Still Water Makes Deep Power for Cryonucleator ([none / 0](#)) (#5)  
by Brian on Wed Jun 25th, 2003 at 11:22:03 AM MST  
([User Info](#))

I'm with you. Being a math kind of guy, I would love to see the numbers as well.

Regarding units of energy, ft-lb is the appropriate unit for torque as well as work and energy in the US system. Example: Friction, when applying work and energy to a system of particles is  $1/2(mv^2)$ . If an object being acted upon by the frictional force weighs 3500 lb and is moving at a velocity of 20 ft/sec,  $(1/2)[3500 \text{ lb}/(32.2 \text{ ft/s}^2)][(20 \text{ ft/sec})^2]$ . Cancelling the units yields ft-lbs. The US system is funky like that.....:-)

Re: Still Water Makes Deep Power for Cryonucleator ([none / 0](#)) (#7)  
by cryonucleator on Wed Jun 25th, 2003 at 03:12:41 PM MST  
([User Info](#)) <http://www.makehydrogen.com>

Looks like I'm being forced to use image upload after all. Didn't expect such busy response. First, Jungle Bill, if you didn't know of my previous patent filing on this, I don't think the law applies, though I'm not worried about it and I'm sure you're not either. Also, I "think" your barbecue barrel experiment was before the retroactive element was enacted anyway. Thanks for everybody's comments.

Okay. "Energy" is technically defined in most physics books as "the potential to perform work." A definition accessible to most of us is found in the dictionary of Microsoft Bookshelf as "the potential of a physical system to do work." It might be more technically correct to refer to "ft-lbs" as work rather than energy, but I try to write in terms that are familiar to everyone.

Now, the \*work\* figures obtain from this:  $W = FD$ . i.e., Work = Force x Distance. In fluidics (or hydraulics), the implication of this is that  $F = \text{pressure}$ , and  $D = \text{displacement}$ . The figure 9% expansion has been mentioned, and I'm not arguing, but 10% is the more commonly used figure. This kind of discrepancy is normal- for example, the temp of dry ice is given as -70 C in some references, and as -78.5 in others. You'd think physicists could agree on this stuff, but duhhh?

So, in an isostatic system having a volume of say, 1 cubic foot, and the capacity to expand 10%, with a pressure of say, 1000 psi, here's what you get...  $12 \times 12 \times 12 = 1728$  cu ins. So you have an expansion potential of  $1728 \times .10 = 172.8$  cu. ins. If you imagine this in a cylinder exactly 1 cu-in in area, it will lift a mass of 1000 lbs exactly 172.8 ins. If you divide 172.8 by 12, you get exactly 14.4 feet. This means the system can perform exactly 14,400 ft-lbs of work. I took the long way around to make this easier to visualize- we could simply have taken the square area ( $12 \times 12 = 144$ ) and multiplied it times 10% to get the 14.4 sq ins, implying 14.4 feet of displacement.

Onward. At the initial freezing point, water exerts a pressure of about 3000 psi. As it gets colder, and is not allowed to freeze, it exerts more and more pressure (going to try to put a chart in here in a minute). This varies, as the chart shows, (Tamann, c. 1900, Handbook of Chemistry & Physics, Chemical Rubber Publishing Co., 36th edition), on roughly a 45-degree slope with temperature, and reaches 31,226 psi at -7.78 F (-22.1 C). This is a naturally occurring temp, and if we do the math, it yields 449,400 ft-lbs of work per cubic foot, which is where the "500,000 ft-lbs" figure comes from.

Sure, it would be better to have a working model first, but I know the physics of this and I'm comfortable with my marketing approach for now. But the suggestion is certainly valid and appreciated. I don't know what happened with the barbecue barrel experiment, but Jungle Bill if you had allowed full pressure to develop for maximum energy capture, it would have torn the thing apart. Or worse, caused a hairline fracture and fluid jet that would have created two Jungle Bills where only one had stood before. These kinds of fluid pressures are used to cut steel, especially at the 4 degrees you mention. My best theory is that your ram size had a lot to do with it, as well as your load. Bigger load and smaller ram would have resulted in higher lift. In effect, your load/ram situation "wasted" most of the energy, luckily, I think. ;-)

Alright, let me try this image thing... and thanks again, everybody.  
---Dennis Okay. Doesn't work. I uploaded two graphs, clicked "insert image" and all it did was insert "null" in this text. So these are on my server: [Force of Ice](#), [Output](#)

([User Info](#)) <http://www.makehydrogen.com>

Dan B & Bryan-- forgot to answer your question directly, but the charts in my long response answer indirectly. Kwh equivalents are in one chart. That, as you both indicate, is the only meaningful way to express output, i.e., work divided by time = power. The conversion of ft-lbs to Kwh is...

1 hp = 550 ft-lbs/sec, 1 hp = 746 watts. And 1 Kwh is the continuous expenditure of 1 kilowatt for 1 hour. So if you have available 40,000 ft-lbs of work to use up in say 1 hour, divide by 3600 sec = ~11 ft-lbs/sec. Then 11 fps divided by 550 = .02 hp. Then .02 x 746 = 14.92 watts. So each cubic foot of water under these conditions yields .01492 Kwh. So 1000 cu-ft of water yields 14.92 Kwh (this is the rough amount at the freezing point, but the chart shows output starting a little colder, for 25.7 Kwh).

Thanks for friendly comments on my webpage. The spring-loaded storage device is actually not ideal, due to Hooke's law, which would result in 50% energy loss. Gravity storage is better. Used the spring because I thought it more understandable to folks. But thinking of changing it. Thanks again.

---Dennis

Damn this HTML formatted option!! Sorry for the large block of text. The previous post is below with the appropriate "white spaces"

"Okay. "Energy" is technically defined in most physics books as "the potential to perform work." A definition accessible to most of us is found in the dictionary of Microsoft Bookshelf as "the potential of a physical system to do work." It might be more technically correct to refer to "ft-lbs" as work rather than energy, but I try to write in terms that are familiar to everyone." Potential energy, yes. Let's not forget kinetic or internal!!

The units of ft-lb is just fine by me for work and energy as they both can have the units of ft-lbs (which is required for applying the conservation of work and energy). My previous post showed just one example of how the units work out. I assume you used conservation of energy to calculate the potential energy output of the system you're designing so you should more than familiar with the concept. You're conversions look good to me. The only problem I have with the system proposed is if you're going to be able to freeze the water fast enough to generate the kind of power numbers you propose. Most people live in moderate climates and water doesn't freeze often and the temps don't get low enough to completely freeze that amount of water, which would limit the potential of the system making it difficult to get the kind of numbers you suggest in your power calculations.

In addition, the use of a ground water source at a temp of around 55-60 deg F would take way too much time to thaw the block of ice. I won't bother calculating it, but I know it would take a substantial amount of time at that temperature. The idea of using a geothermal ground source is a great remedy but most don't have access to such a supply. It would seem to me that using such a heat source would also slow the re-freezing of the water as the temperature was raised well above freezing temps due to the temps of the geothermal water supply.

Don't get me wrong, it sounds like a very promising design. One question, what fluid will you be using in your hydraulic system in addition to the water? If the temps are low enough to freeze the water in the expansion vessel, you would have to use a fluid other than water in your hydraulic system as it would freeze as well.

I look forward to hearing more. Brian

Cryonucleator: Power, Cyclic Rate, Drive fluid ([none / 0](#)) (#11)  
by cryonucleator on Wed Jun 25th, 2003 at 06:29:16 PM MST  
([User Info](#)) <http://www.makehydrogen.com>

Yeah, Brian, all good points to ponder. Will be facing these issues shortly, probably with the local university folks.

Well, once operating temp is reached, the user controls the rate of discharge, and therefore controls the power output. Or if using gravity storage, same thing. The rate at which fluid is allowed to escape is what determines power.

Drive fluid is non-freezing and can be almost anything that does not freeze. Oil, antifreeze, glycerol, etc. Sophisticated versions use a bladder to segregate the water charge from the drive fluid.

Really good point on cyclic rate you raise, i.e., specific heat. This depends on good heat exchange systems. With lots of conduits embedded in the charge. This applies to warm and cold sources. Actually, with adequate number of conduits, would cycle fairly rapidly. But would not cycle rapidly without embedded conduits, obviously. And melting does not mean getting the charge that warm. Fact is, you only want to raise its temp just above freezing, then start the freezing end again. Maintaining this narrow range operates like a switch and enables rapid cycling. Also, differential nucleation or choreographed nucleation (charges mixed with antifreeze) make the cycling possible at any temperature, even 'way below freezing.

What I really want is a reinforced concrete design that can take the pressure, so that anyone can build this as cheaply as possible. Looking forward to your comments.

Dennis

Re: Cryonucleator: Power, Cyclic Rate, Drive fluid ([none / 0](#)) (#12)  
by Brian on Wed Jun 25th, 2003 at 07:40:11 PM MST  
([User Info](#))

The internet troll ate my first attempt at a response, so I'll try it again.

It's been quite a while since I touched any strengths of materials type problems so I can't really offer any suggestions on the design. Sorry

Regarding the conduits, I understand what you're saying. The greater the mass flow rate of water to thaw the ice the faster it will thaw, allowing for a faster cycle. Are you actually going to embed the conduit in the concrete? Concrete isn't the best thermal conductor with a thermal conductivity of around .81 Btu/(h\*ft\*deg R) so it would seem to me that the stronger the pressure vessel, the more concrete.....the more concrete, the longer it will take for the heat to be transferred from the water in the conduit to the ice. If there were a conduit available that could withstand the internal pressures associated with the device, it would be ideal to place them in direct contact with the ice to make the thawing process that much faster. It would also cut down on the losses....

Another possible problem I see with a concrete design is that it will actually make the freezing process slower as well. If it were possible to manufacture a container out of aluminum that would be able to withstand the pressures associated with such a process, that would definitely help get the cycle time down which would obviously increase the power production potential of the system. The downside to an aluminum design is the cost!!

During the freezing process, obviously the water in the conduit will not be flowing as this would substantially increase freezing time, if not preventing the water from freezing at all. If the water in the conduit is not flowing, it will freeze as well....rendering your system useless until the lines thaw out. How will you prevent this??

Also, how will you control the flow of water through the conduit? Seems that a micro controller utilizing a temperature probe which would control an electronically actuated valve would be ideal for keepng cycle times to an absolute minimum. Also adds to the cost though.

I look forward to hearing the actual numbers when you get around to building one!!

Brian

by cryonucleator on Thu Jun 26th, 2003 at 06:27:45 PM MST  
([User Info](#)) <http://www.makehydrogen.com>

Brian, I have a hunch you're going to go far as an engineer. Yup, from the way you approach it, I agree that high heat transfer AI would be great. But the walls don't really have much to do with it... what I said was "This depends on good heat exchange systems. With lots of conduits embedded in the CHARGE." (my emphasis added). That means conduits inside the ice block. Remember I mentioned a "bladder"? That's where the water would be, and where the ice would be, and where the conduits would be.

Yes, of course a valve- for both hot and cold. And I mentioned before that the fluid in the conduits would be non-freezing, so by standing still they won't freeze. Your micro controller is a great idea too. The schematic for this is in the e-book that I issue with licenses. Lemmee see if I can find it on my server... give ya a preview... aha! got it- (my troll must be asleep ;- ) ) [complexsys.JPG](#) . Uh, this also shows the antinucleator injector/replenishment system. Thanks again, Brian. Was misspelling your name before. Sorry.

Thanks for the compliment. It means a lot coming from someone with your obvious expertise. I'm just a 23 year old trying his best to make a future for himself! But if you talk to a certain other member....I'm just a would be patent thief stealing ideas!! Better watch out.... :-)

Thanks for posting the schematic. You never mentioned using heat exchangers at the hot and cold resevoirs (at least I dont think so...) which explains the problem I was having with the concept. I was under the impression that the fluid would be circulating through the system to melt the ice, then returned to the original source.....which was why the use of an anti-freeze wasn't fitting into my interpretation!! Poor fish.....

I can clearly see that you will have no trouble keeping the fluid from the hot resevoir from being frozen as it is a closed system, meaning you can utilize just about any fluid with a low freezing point and a high thermal conductivity without worrying about environmental issues.

I like the idea of using electrolysis to extract hydrogen from the additional water source. Makes the system that much more useful.

I hope it all works out for you. I look forward to seeing your device advertised and hope it takes off. A lot of money to be made out

there!! Good luck! Brian

Go to electrical and there are a lot of catagories in that catagory as well. But if you put it under "Wind Generator" or "Windmill" alot of people use both (water wheels & wind) or like to dink around with both.

Those people come into discussion boards like this and word of mouth may find a home for it. There is alsos a "For Sale" section on this board.

AC vs. DC... ([none / 0](#)) (#1)  
by [xeroid \(centurion27@lycos.com\)](#) on Fri May 23rd, 2003  
at 07:05:44 AM MST  
([User Info](#))

You could run a dynamo from a wind prop, but I think most folks around this board will agree that the downside of dynamos is the maintenance required on them. They require removal of the carbon dust from time to time, cleaning of the commutator etc. That's down time. It's also the hassle of tilting your tower up and down - a tricky and potentially dangerous operation that would best be done as few times as possible.

Also, if you're running DC direct to the inverter, keeping the power consistent when the wind is waxing and waning can be tricky at best. Scientists have proven that AC transmits better over distance, since the electron flow is just travelling back and forth in the conductor, rather than travelling the entire length of the circuit from your generator out on the tower to the inverter and back.

As for keeping the voltage between 12 and 14, honestly, I'm not sure how necessary that is. I do know that prolonged exposure a charging voltage that is too high for your batteries is a bad thing, but in quick bursts, your batteries can probably bear it (as in a gust of wind spiking the power for a few moments). To keep the voltage around a certain amount, you will need to set your machine up to furl before the wind can drive it to overspeed and produce to high a voltage. Also, with alternators, you can wire the machine in "star" wiring for 3 phase, to start, which gives higher voltage, but less amps. Then, once your machine gets going a little faster in higher winds, have a switching device to change the wiring to "delta", which gives double the amps but half the voltage of "star" wiring.

Check out Ed's site at <http://windstuffnow.com> for more details on 3 phase wiring and furling the wind generator.

Sorry for the book, but I hope this helps.

Regards,

Xeroid.

by kurt on Fri May 23rd, 2003 at 12:51:17 PM MST  
([User Info](#))

the reason for using batteries in a hidro set up is that you can store power so that you can draw off more amps than your genny is making at any one time and make it up when the demand is less than the output. without batteries you have to size your genny to handle the max amp load you will ever draw but with batteries you just have to generate the same or more watts than you use. i.e.. use during the day charge at night. if you are not going to use batteries then you will need to control voltage by maintaining a constant speed. and if you are going to go to all that trouble it would make more sense to generate at 120v AC in the first place.

Kurt ([none / 0](#)) ([#3](#))

by Anonymous Hero on Fri May 23rd, 2003 at 04:54:43 PM MST

Okay that is the question, does anyone out there generate 120, with a hydro direct to the usage and how difficult is that? Or, if I use batteries, would the hydro pretty much keep them charged all the time since the hydro is running all the time? Thanks

[ [Parent](#) ]

ac dc hydro ([none / 0](#)) (#5)

by Anonymous Hero on Fri May 23rd, 2003 at 09:38:46 PM MST

You can run 12 volts into the inverter and run that so long as the supply is constant. It is not easy. Power supply fluctuations and load fluctuations can dump the voltage below 10 volts temporarily which will shut down the inverter. Thus the battery. It gives you elasticity, even if you are consuming all you produce continuously. In lieu of a battery, maybe a huge electrolytic canister? (for the surges and load voltage dumps) Why don't you want to use batteries? Is there some logistical problem in your project? jungle Bill

Hydro AC ([none / 0](#)) (#6)

by Anonymous Hero on Fri May 23rd, 2003 at 10:18:09 PM MST

Hi Anonymous,  
Thanks for the info. Yes if I can get a constant 15 or 16 volts from a steady hydro and regulate it somehow so only 12 or 13 volts are making it to the inverter, that is what I want to do.

I'm thinking batteries are just more maintenance, unless there are other benefits to batteries I'm not looking at? I'm thinking the inverter can run a half size refrigerator, TV and cable box, on an extension cord. Is this possible? Thank you.

[ [Parent](#) ]

inverter ([none / 0](#)) (#8)

by Anonymous Hero on Sat May 24th, 2003 at 01:43:06 PM MST

I have a small 1/2 size fridge . It is like a college dorm thing. It consumes 75 watts , but when it turns on there is likely closer to 700 watt punch for 3-4 seconds until the compressor is up to speed. Fridges can create huge voltage drops when coming on. Thats where I see the problem that in my eyes could be solved with a battery. For what you want to do, just an old junker would likely work. Just to act as a bumper so as not to shut down the inverter when the fridge comes on . the tv and cable box are nothing. However TVs work better on high quality inverters. My el cheapo Stat power one of 300 watts ran the vcr and tv , but the tv was ugly with poor color and resonance. It also made a disturbing noise that could only be construed as low grade power supply. Jungle Bill

by Anonymous Hero on Sat May 24th, 2003 at 06:59:55 PM MST

That does help thanks. But I've always wondered what .PDF files are for? Are they to prevent people from saving it to their own files? Do I have to go to that site everytime I want to look? Ink cost a bit and I don't want to print the whole thing if I don't have to. Does anyone know a shortcut around that? Thank You.

[ [Parent](#) ]

PDF files ([none / 0](#)) (#11)

by Bach On on Sat May 24th, 2003 at 07:30:32 PM MST  
([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

The reason many sites put stuff in PDF format is that it is very portable and doesn't take up as much disk space (bandwidth) as putting the stuff in HTML for a webpage. Some folks don't have Word. And not all word processors can read stuff written in other formats.

The Acrobat Reader program is free. Once you have the PDF file loaded, look up in the left corner and you will see a diskette. You can use that to save the file to a drive or anyplace else. It can be opened later - no need to print it.

Adobe makes its money by selling the program used to create PDF files. I don't think you can do that with just the reader.

800 watt inverter. ([none / 0](#)) (#12)

by Anonymous Hero on Sat May 24th, 2003 at 10:16:11 PM MST

Yep , that should do it. You can get a 700 watt unit ( eliminator from motomaster for about 40 USD ) but it is a cheapo. square wave. Who knows, for that amount , I'd try it. fridge motors are not that delicate. It has a 1000 watt surge and can hold 700 watts for 10 minutes/ 500 watts permanently. You may want to exercise the cheap option first. Find a trasher battery from a local garage or just about any one has one kicking around. As long as it is not broken or leaking , you can use it to balast the surge. (If it can light up a car head light for 30 seconds) . You might even find 4 or 5 for FREE and actually have a half decent battery bank. Maintenance? who cares, you did not pay nothing, keep finding old ones and put them in. Have fun . It really is when it comes next to free. Jungle Bill

jdanhk: to cool pants: water power. My research in developing water/anti-freeze power is feasible to use the same quantity of water over and over again less evaporation. With the first fill for power source a well can be driven to supplement the evaporation or catch rain water or any small stream. The system is portable to erect and be used almost anywhere in the world. If interested e-mail at [jdolci@ij.net](mailto:jdolci@ij.net) jdanhk

AC genny back into grid feed

Hi, Do I have to call the power company and have them hook up the feed from my AC genny back into their power grid?

If so, will they do it for one simple waterfall on my property? It runs year round.

Also is there an AC motor I can use in reverse or do I have to rewire one? Thanks.

Feed back ([none / 0](#)) ([#1](#))

by [wpowokal](#) on Mon May 12th, 2003 at 05:20:15 AM MST ([User Info](#))

What no takers on this one, all busy arguing I guess, he he.

Wherever in the world you are, you should, consult you energy supplier before backfeeding into a grid. There are very important safety issues, but alas I will refrain.

Certainly in OZ energy suppliers are interested in buying renewable energy, a continuous stream would be very viable.

As to what type of generator, I will leave that to more experienced posters, but a similar project I reserched here in OZ was very viable so go for it.

regards Allan

Yes, you have to call the power company. After you fill out pages and pages of forms, and pay them money (lots or only a little depending on where you are) they will install a meter (or re-configure your existing one) that tracks power going both ways instead of only one way. This depends on the net metering/net billing laws in your state, and your state PUC rulings on the subject, determine whether your production counts as retail or wholesale electricity rates.

Or, you can go "guerilla hydro" and feed your extra power back to the grid whether they like it or not. Your excess power production will not affect your bill this way, but the current crop of grid-tie inverters (whether large and expensive or tiny and cheap) will NOT let your power source electrocute a lineman working on a downed line. If the grid fails, so does your power feed to it.

If you do your own grid-tie system with a synchronous genny on your hydro plant --you could easily put a power company worker in jeopardy.

DANF

### [Waterwheel power for \\$20.00](#)

By [Juliang](#), Section [Homebrewed Electricity](#)  
Posted on Mon Apr 14th, 2003 at 05:02:26 AM MST [Hydro](#)

Hello all This is my 1st posting. I've been reading this(and the old discussion board) with quite some interest for the past 3 or 4 months.

The information here in has been invaluable. Thanks to you all I've been inspired to try my own project (and of course the wife nagging me to get out of the house). With a whole lotta luck, some good contacts and a bunch of stuff lying around the property I've made a simple waterwheel that after the nagging lights up my wife's life. OK OK it generates power to charge batteries for lights in our horse barn. She got tired of carrying the batteries back to the house for charging. I've managed to spend only \$20.00(for the sprockets and chain) everything else I acquired for free. If you are interested check out at our web page <http://www.twobitranch.net> PS please excuse the mess I was pretty excited to have it running so didn't even bother to clean up when I took these photos.

([User Info](#)) <http://windpower.jkcc.com>

Too cool. Did you have to dam the creek any or did you just run the old eaves trough back far enough to get a bit of a head?

How much of the year do you think it'll produce power for you? I guess even if you get snow/ice, you'll never have to worry about the eaves trough rupturing/bursting on you :)

[Windpower - first attempt](#)

Waterwheel power ([none / 0](#)) (#3)  
by Juliang on Sun Apr 6th, 2003 at 08:43:59 AM MST  
([User Info](#))

I was lucky to not have to dam the stream. Where the guttering picks up the water there is a natural waterfall of about 2-3ft. The ground also slopes away to get enough head for the wheel, which is 4 ft in diameter. I'm guessing about 7-8 months of the year it'll run. I'm finding that since I don't have a regulator at this time I'm slowing the water intake to produce less power to my batteries so it remains to be seen how long it will run. So it may run well into the summer even when it gets very low. Of course the system is really intended for the winter (when there is lots of water). The Horses stay out of the barn during the summer. Here in Oregon's Southern Willamette valley we get very little snow or hard enough freezes to worry about rupturing/bursting.

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

I like it and I am jealous. No hydro available on our land.

Very good example of what you can do for a minimum of \$\$.

Any figures on out put like how big is the battery it charges or how many hours of lighting do you get daily from it?

Any amps is good amps and with hydro its 24/7 so it adds up nicely.

What kind of motor is it driving as a genny what gearing, rpm, whats going on at the upper end of the eavespouts, etc? More questions but I'll leave it for another time.

Anyway, BRAVO, give yourself a pat on the back and hope it gives you a warm fuzzy feeling harvesting that hydro. It would here.

Cheers.

TomW

Specifications ([none / 0](#)) (#7)

by Juliang on Mon Apr 7th, 2003 at 08:31:35 PM MST

[\(User Info\)](#)

Thanks guys. The motor is a Baldor DC 1/2hp permanent magnet motor rated at 90V 1725rpm 4.8amps It's off a stretch wrap machine. There is a 60 tooth 40pitch sprocket on the wheel shaft and a 12 tooth 40 pitch on the motor shaft. The wheel when running flat out generates about 9.5volts. I charged the batteries, 2 x 6 volt Electric pallet jack batteries which where going to be thrown away by a local fork lift shop, before I wired them up. A couple of the cells didn't look so great but the price was right so I filled them with water and away they went. For charging I hook the batteries up in parallel(6v) and for lighting I switch them to series(12v). I still have to figure out a switch that will do this in one movement. I ran the lights for a while watching the volts drop I then hooked up the wire from the wheel. The volts from the wheel dropped to about 7.5+ volts at about 1/2 an amp. (there is no voltage drop from the wheel to the batteries about 60ft with no load) I'm going to run the batteries down and then see what the readings are and how long it will take to recharge. So far with the wheel running 24/7 I've got to much charging power to keep the batteries hooked up all the time. Julian

## [Miniature Axial Dual Rotor Generator tests Cont...](#)

By [bill541](#), Section [Homebrewed Electricity](#) [Magnetism](#)

Posted on Wed Dec 31st, 2003 at 07:13:51 PM MST

This is a continuation of tests performed on a small generator. These are the results of a cogging test when ferrous cores are used.

Hello all, this is a continuation of the same project as described in a previous posting.

<http://www.fieldlines.com/story/2003/12/27/202634/91>

Concerns of cogging were raised when I introduced ferrous cores between the two magnetic rotors.

To set up the test, I used the same dual 8-magnet rotors as before. Instead of installing all the cores, I used steel washers to simulate the ferrous "spool" cores. Gluing the washers on a plastic mayonnaise jar lid (represented by orange in the picture) provided a method to test the cogging torque caused by the ferrous material. I used a length of fishing line and wrapped it around the jar lid and then hung washer weights until the stator section began to rotate.

**Washer Weights**

By using this method, I could change the configuration and measure the differences in cogging resistance. Each washer weight is 1/50 of an oz. (0.567 grams). See the

▪ [Also by bill541](#)

following tests.

1. No washers mounted on plastic lid. It took (0.567 grams) of force to turn the stator section. This is mainly due to friction. This friction applies to all other tests.
2. 8 washers mounted on plastic lid with only a single magnet rotor. It took (11.9 grams) of force to turn the stator section. Simulates 8 spool coils in stator.
3. 8 washers mounted on plastic lid with dual magnet rotor. The magnet rotors were aligned to attract each other (Same as in the picture). It took (3.4 grams) of force to turn the stator section. Simulates 8 spool coils in stator.
4. 8 washers mounted on plastic lid with dual magnet rotor. The magnet rotors were aligned to repel each other. It took (26.65 grams) of force to turn the stator section. This would not generate electricity, but I wanted to see what it would do.
5. 7 washers mounted on plastic lid with only a single magnet rotor. It took (4.54 grams) of force to turn the stator section. Simulates 7 spool coils in stator.
6. 7 washers mounted on plastic lid with dual magnet rotor. The magnet rotors were aligned to attract each other (Same as in the picture). It took (2.84 grams) of force to turn the stator section. Simulates 7 spool coils in stator.
7. 7 washers mounted on plastic lid with dual magnet rotor. The magnet rotors were aligned to repel each other. It took (7.94 grams) of force to turn the stator section.

What surprised me the most was when I added the second magnetic rotor, the cogging resistance went way down as compared to a single magnetic rotor.

When using the 8 "spools" and dual rotors, the turning resistance was quite smooth and even. When I changed to a 7 "spool" dual rotor configuration, the resistance was a bit "coggy" and also made the jar lid wobble sideways.

I did not have enough room to place more than 8 "spools" on the jar lid, but I think an even number of coils is the way to go for smooth operation. Even with 8 coils, a person could run a split phase output and have the option of series or parallel winding connections.

Question: Since I am using round magnets and round stator cores, would this show less cogging than a rectangular magnet/ coil generator?

When a generator is under load, there is current flowing in the stator windings. With current flow in a coil of wire, there is a corresponding magnetic field generated around the coil.

Question: Why would the magnetic field generated by an air core coil under load be any different than a ferrous core coil under the same load?

It seems to me that for a given current and inductance, the cogging effects would be the same for a given generator configuration.

A dual magnetic rotor and ferrous coil cores thus far does not seem to have much adverse effect when compared to power gain to be had.

Any thoughts on this guys?

Take care, Bill

## [Magnetic Brushes for Axial Flux Path](#)

By [SteveM](#), Section [Homebrewed Electricity](#)

Posted on Tue Dec 30th, 2003 at 07:10:48 PM MST

[Magnetism](#)

<br> Need help to understand how generator brushes and comutator contacts work?

---

I have been following this board for some time now and really enjoy the diversity and range of talents. Just reading all of the ideas has inspired a lot of thought toward the conception of a unique design. I am currently in the planning stage but hope to start a scale version of an axial flux design for experimentation.

This brings me to the heart of my inquiry. What if the magnetic circuit in a axial flux design was improved to increase the flux in the coil centers. In Wild Bill's recent post, he showed a 400 % improvement by adding high permeable material in the center of the coils. The flux still had to leap across two air gaps in its path.

What if we take it a step further, and add brushes that conduct magnetic flux across the air gaps. When the magnets rotate inline with the spool, a brush or button or something contacts the magnet directly, providing a more efficient physical path for the flux to travel along. The ends of the brushes would be connected to the material in the center of the coils.

I know a cogging question was raised about this proposal. I thought that the magnet patterns between the disks could be clocked a 1/2 diameter of the magnets width to reduce this effect.

Looking for ideas and design suggestions for experimenting. I haven't taken apart a commutator or brushes in a generator set to get a grip on how they have solved these problems. It occured to me to post the question and see if anyone can help with this one.

Regards,

Steve M

Interesting idea, though I can foresee problems with added friction between the "magnetic" brushes and the surface they bare against, as well as the eventual wearing away of the "magnetic" brush material.

Dr.D

([User Info](#))

You'll make your brushes out of some ferromagnetic material to increase permeability in the coils? Silicon steel, soft iron, ferrite, powdered iron, whatever... I can just see a ferromagnetic brush glomming onto the first mag it touches, not just cogging but mechanically locking up your genny. In other words, your brushes would have to be made of something that is not attracted to magnets. But what?

Anybody out there know: Is there some non-ferromagnetic high-permeability material?

Excellent point, the brushes would have to pass or channel the field but not be affected by it, can't be done.

Dr.D

Thank you for your comments?

Have a few more thoughts to explore with this one and would greatly appreciate reply's.

I have been trying to compare the advantages and disadvantages of a physical path for flux. I wonder if a very small brush (lets say strands of wire) would increase the flux without the penalty of a cogging problem?

How about a radial arrangement of magnet and brushes that minimize the attraction at one angular position. Each sequential magnet and brush would have a unique position such that when one brush is in the center of a magnet their is another pulling toward the next?

I really hadn't invisioned a brush contacting the polar face of the magnet directly. I was thinking of some type of shallow sloped thin steel strips on boths sides of the gap that gentally touch as they passed each other. I was planning on a minimal interference say (.002 inch) between the strips.

The attraction issue really has me puzzled about this concept. If a means was develeped to provide a good physical path without a cogging problem, would the generator need more power to drive the machine?

Regards,

SteveM

Hi Steve M.

I like your idea of brusing along to pass the mag flux. However, we must not forget, that the coils would have to pyhsically pass and actually cut off the flux in a timing fashion. How can the coils pass the brushes when they are two real physical items one bearing against the magnet one direction, while the coils travel across in the other direction ? Aside from this physical bound, then if the brush were to continue to pass flux over, how can the flux be cut ? If the flux path is not cut, there is no electricity produced.

Ciao,  
We have to keep thinking.....  
Something good will happen one day.... I guess :-)  
Luubovv.

by SteveM on Thu Jan 1st, 2004 at 07:02:34 PM MST  
([User Info](#))

I have been reviewing magnetic permeability which is a substances resistance to magnetic flux. Materials with higher values conduct flux more easily. Relative values are how many more times that material will conduct flux. Studying web site <http://www.ee.surrey.ac.uk/Workshop/advice/coils/terms.html#seq> it mentions that air, wood, and plastic have values around 1. Iron has a value of 5000, and silicon steel near 40,000 (wow). I need to look at this in more detail to investigate, saturation, eddy currents, temperature, and other concerns. (Silicon steel sure looks interesting as a core material) I have also seen magnetic flux references that suggest that a magnetic circuit crudely performs like a simple electric circuit  $v=i*r$ . If resistors are in series then we add the values and solve for current. If we have an axial flux magnetic circuit then  $EMF= I*(R \text{ air gap } 1 + R \text{ spool } + R \text{ air gap } 2)$  If any of the r's are large than the performance across the circuit will be poor. Bill541 in showing a good improvement by adding a magnetic conductor in the coil center. I am trying to add to it and create a physical instantaneous link to lower the complete magnetic resistance across the circuit. (Plus I would like to avoid a cogging problem) I will try to add a paint picture to represent this concept (excuse the art it's a little ruff). The red blocks represent magnets in an axial flux section. The yellow shaped sections could be either a strip of metal or a formed metal button. These would be glued to the magnets and would create a ramp for the brushes to contact. The component between the magnets is a spool made of a cylinder and two round plates. The cylinder has two brushes in the center seperated with a coil spring to keep them pushed out. When the magnets rotate the center of the ramp will contact the brush and provide an instantaneous direct flux path while the magnets are inline with the coils. The path is broken once the contact seperates from the ramps. Love the comments please tell me what you think. Regards, Steve M

Sorry for the continuous text block. Not sure what happened but it got compressed to look like a neverending paragraph. I had trouble with the paint attachment so I put it in the my photo uploads called magnetic brush. The small black circles are the coil windings around the spool.

Regards,

Steve M

I AM HAVING TROUBLE WITH POSTING QUESTIONS. I HAVE POSTED THIS QUESTION BEFORE BUT I AM HAVING TROUBLE FINDING IT POSTED.

I WANT TO KNOW IF IT IS POSSIBLE TO CREATE A MAGNET THAT HAS A MAGNETIC PULL THAT EXTENDS APPROXIMATELY FOUR FEET SO THAT IF A HAD A SOFT MATERIAL OBJECT FOUR FEET A AWAY FROM ME IT WOULD ATTRACT THAT OBJECT WITH THE SAME AMOUNT OF POWER THROUGH OUT THE FOUR FEET.

What do you mean "soft material?" It has to be something that a magnet will attract, which for all practical purposes means iron or steel.

No magnet exerts the same amount of force regardless of distance. All magnets exert less force at greater distance, and you get to a point where the attraction is so small you can't even measure it, let alone make use of it. Also: four feet is way too far. If you're talking about permanent magnets you could never hope to get your hands on a permanent magnet strong enough to exert useful force at four feet. Electromagnets are another matter... if you've got the dollars to build on an industrial scale.

Also, just for the sake of argument, if you could find a permanent magnet that strong you would be risking permanent injury or death just handling it around everyday objects. Get between it and a hunk of steel and it would crush you.

Or maybe I just misunderstood your post.

Re: QUESTION ON MAGNETS ([none / 0](#)) ([#3](#))

Kell is right, you won't find a magnet, electric or permanent that will have a force that you describe. If your looking for a magnet that has a large field, your looking for a ceramic magnet. I have some ring magnets that will affect a TV from 4 ft away. They are 8 inches in diameter with a 4 inch hole and are 3/4" thick. They aren't real strong in the sense a neo is but the field size is impressive.

Have Fun!  
Ed

LOTS of cool stuff here!

Here is a link to the German Patent Office's web-server. There is an English page, and several search engines. Lots of cool stuff from Stirling to generators to anything you can think of. Not just German patents, either, but patents from many countries, US CA FR JP, etc.

Below is a link to a Canadian patent for an Improved Permanent Magnet Generator. Don't know if the link will work as is but the website has lots of stuff.

<http://depatisnet.dpma.de>

<http://depatisnet.dpma.de>

Here is the link for the main website. If you do a Dogpile or Google search for German Patent Office, you will be able to find it.

Lots of the patents are in .pdf format. At first I thought that only the first page of the patent was available, but finally I noticed the page forward buttons on the Adobe Acrobat reader, and I was able to look at each page.

If you go to their search engine and paste in this document ID number you can find the patent that I mentioned specifically:

CA0002368426A1-24862821926

Experiments on a small axial flux generator using ferrous cores in the coils.

---

Hello All,

I must say it has been fun reading all the postings on Fieldlines. I have come to realize that there are a lot of talented tinkerers out there!

I've been interested in VAWTs for a while and the thought of building one is very intriguing. I have been playing with some very small models to help me learn about them as well as extensive reading on the Internet. I have a few "lawn toys" out spinning in the wind as of this writing.

One thing about home brew projects is that they must be reasonably simple to build. In visiting Hugh Piggott's web site I was introduced to the axial flux generator. What a great design and simple to build! I was especially interested in the dual rotor design. So I sat down and began building a miniature version to test on the bench.

My wife had 20 or so 1/2" diameter (very weak) refrigerator magnets that looked like they would work fine for my tests. So I built up two 2" diameter steel disks and mounted 8 magnets to each. Then used a 1/4-20 bolt and nuts to form a mandrel that holds the disks in proper alignment. An old power drill was mounted to a board and holds the dual rotor assembly. The drill motor is powered from a light dimmer to control the speed. Since the drill motor is small, a light dimmer works fine.

Now I could begin testing coil configurations. In viewing the designs presented on the Internet, I noticed that the dual rotor generators were always using air-core coils. In working with electronics for many years now, I was curious if the coils would benefit from using a ferrite or iron core.

For the tests, I used a single coil mounted on a test fixture and placed between the dual magnet rotor. I made measurements from 250 to 1500 RPMs. Each coil was 66 turns of 28AWG around a 0.25" core. The coil was loaded with a 1.5-ohm resistor and the voltage was measured across this resistor to be used to calculate the power output during each coil test.

Measurements were done with a Fluke model 187 DMM. This meter can measure the frequency of the sine wave produced as well as the RMS voltage across the resistor. Simple calculations were made to determine the frequency at various RPMs. This way all of my measurement points would be the same.

Keep in mind the power output is not impressive, but that was not the intention of the experiments.

To keep the tests consistent, I wound a 66-turn coil around a rubber grommet with a 1/4" diameter hole in it. This way I could change the core material out without disturbing the coil itself.

First was the Air Core, it produced a whopping 41 mV across the resistor at 1000 RPM. This equates to 1.121 mW of power.

Next I inserted a Ferrite core into the coil and repeated the tests. I was a bit surprised at the magnitude of gain. The coil now produced over 4 times the power (4.7 mW) under the same load.

Next I tried a mild steel solid core and also a steel tube with similar results. These also provided a substantial improvement over the air core.

To satisfy my curiosity, I also tried an aluminum core. No big surprise here, the output was very similar to that of an air core.

The final test was with an all steel coil form in the shape of a spool with a hollow center. My thought here was to make the spool outside diameter the same as the magnet diameter. I tried to be very careful and duplicate the dimensions of the first coils, with the same number of turns. This configuration seemed to produce the best results with 5.64 mW at 1000 RPM.

In the following picture, figure "A" shows the coil with a core between two magnets. Figure "B" shows the spool form used in the final test.

#### Conclusions:

It was interesting to note that an improvement of about 400% was noticed across the whole RPM test range when using the ferrous core materials. I did notice that while watching the sine wave on the scope, that harmonics appeared at 570 RPM and again at 1140 RPM. I'm not sure if this would cause problems on lower speed units or not. This effect may be more pronounced on multi-coil generators.

While the addition of a core material improved the output significantly, would the same be true of higher power units? I'm not sure if the core would become saturated to the point of being useless under a high current load. That being said, could the core be beneficial under low wind speed and cut-in sooner than without the core? If under high wind speed and load, if the core becomes saturated, could this help limit power and prevent burning up the windings?

Having a hollow spool type core would make it fairly easy to build coils of even height. This may help in decreasing the distance between coils and magnets as well. The spool form would also make it very easy to wind coils, as no form would be required.

Since the inductance of each coil is increased substantially, fewer but larger windings could be used to reduce  $I^2R$  losses and still maintain the voltage levels required. As an added benefit, the core would also act as a heat sink to help pull heat out of the windings.

The use of the spool core seems to help channel flux through the coils. I think of it as a magnet extension that in essence brings the opposing magnets closer to each other, thus narrowing the gap between them. Similar to when you hold opposite poles of a magnet closer together, the attraction gets stronger.

I would be very interested to hear from any body else who has run similar tests maybe on higher power units. It would be very interesting to try a similar experiment with Silicon Steel, which has a very high permeability.

Still having fun, Bill.

by charged on Sun Dec 28th, 2003 at 01:10:48 AM MST

([User Info](#))

Here's one more you'll enjoy.

Get yourself a roll of .030 MIG welding wire.

Make your coil form so that there is very little airspace at the center of the winding.

Wind the steel wire in tandem with the copper wire on the same form.

What you have there is an integrated, ultra-low eddy-current ferrous core.

You can also do this with regular mechanics wire. But, it's usually kinda dirty and oily right on the roll. MIG wire is nice and shiny.

Enjoy!

Re: Miniature Axial Flux Generator Experiments ([none / 0](#)) ([#5](#))

by Jerry on Sun Dec 28th, 2003 at 09:33:11 AM MST

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

The only problem I see is sevier cogging. When the magnet is centered over the steel spool it will be very hard to move it.

This is a very efficient way though to increase magnetic flux through the coils. This is why I prefer ac motor conversion. The ac motors I most commonly convert have 36 slots so its very easy to move the magnets past these narrow slots. AND you want to talk about awesome laminations. Motors have the best steel lamination posable and your coils are allready wound.

Some people say the small diameter of the motor is a limiting factor but as deminstrated above the increased output more than compensates for this. This is why I see charging start at 5 mph on motor conversions whith 49 inch tip to tip blades.

WE gave up on the curved neo,s way to soon. JK

([User Info](#))  
<http://www.dplusv.com/Photo-03.html>

PS and you want to talk about narrow gap. I set my gap at 1/16 inch but it could be 1/32 inch. Because of the motor lamination efficiency I've done 1/2 inch gaps with surprizing output.

JK TAS Jerry

by bill541 on Sun Dec 28th, 2003 at 05:12:07 PM MST  
([User Info](#))

Thanks Jerry,

I didn't really think about cogging being much of a problem, but it sure could be in low winds. It might turn into a magnetic brake of sorts.

What do you think of the following solution?  
The red indicates more ferrous material.

By providing a few more paths for the flux when the cores are off center of the magnets, wouldn't this smooth things out? The trick would be to balance the flux out so that there was an even pull at every degree of rotation.

This may be easier to provide on a rectangular magnet set up. This way you would only need pie shaped pieces around the perimeter.

-Bill-

([User Info](#))  
<http://www.dplusv.com/Photo-03.html>

Hi Bill

Very nice drawing. It looks as though this design would reduce cogging a bunch.

I'm not sure what effects there would be on flux path or efficiencies? your drawing is now resembling an ac motor. Coils and narrow slots. Very efficient and reduces cogging But dose away the need for curved magnets.

I do hope you build and test your idea.

To smooth things out use a gap in the spacing of one magnet or use an odd number of magnets.

This looks very much like a standard alternator with the exception of the ferrites.

RobD

[quote]"Next I tried a mild steel solid core and also a steel tube with similar results"

[quote]"the addition of a core material improved the output significantly, would the same be true of higher power units?"

In a higher power unit the core would have to be made of silicon steel, and laminated, to prevent hysteresis and eddy current heating.

I believe construction methods that result in reduced air gaps will yield as good, or better, power outputs.

Electric Ed

([none / 0](#)) (#3)  
by SteveM on Sun Dec 28th, 2003 at 07:46:26 AM MST  
([User Info](#))

Bill,

I have been thinking along the same lines about using a material with high permeability in the core of the coil to reduce the resistance to flux through the core of a coil in an axial flux arrangement. I have enjoyed reviewing your experiment results on the subject and believe it looks promising.

I had an additional thought on the subject to see if the elimination of the magnetic air gaps would provide any additional improvement.

I was thinking of running some kind of brush between the magnet poles and the spool surface. As the magnets pass over each coil the material in the center of the coil with cooresponding brushes contact the magnet poles and complete a straight line gapless magnetic curcuit. Haven't try it but have been giving it some thought.

Enjoyed your posting, Best Regards,

Steve M

If you omit one of the magnets in illustration 'A' you would still produce power.

What is the ferrite core material you used?

RobD

Re: Miniature Axial Flux Generator Experiments ([none / 0](#)) (#8)  
by bill541 on Sun Dec 28th, 2003 at 12:39:23 PM MST  
([User Info](#))

Rob,

"What is the ferrite core material you used?"

For this small setup, I used a ferrite bead commonly used as a filter choke in electronics work. It is 0.25" diameter, 0.5" long.

Did you measure the increased drag you got when you started sticking metal inside of the coil ?

}=- W o o f -={

Re: Miniature Axial Flux Generator Experiments ([none / 0](#)) (#9)  
by bill541 on Sun Dec 28th, 2003 at 12:48:04 PM MST  
([User Info](#))

"Did you measure the increased drag...?"

Thank-you, that would be a good test to perform.

Since I'm using a brush type drill motor with a reduction drive, it is difficult to tell the amount of drag at this point.

If I used a low friction motor to drive the rotors, maybe I could check the no load drive current of the motor and then compare with full load drive current. This may be a way to test the efficiency as well (power in vs power out). Maybe an induction motor with very good bearings would work here.

Thanks, Bill

Re: Miniature Axial Flux Generator Experiments  
([none / 0](#)) ([#14](#))  
by SteveM on Tue Dec 30th, 2003 at 06:13:41 PM MST  
([User Info](#))

Bill,

I like your thought process to channeling flux in the coils by adding material with high magnetic conductivity in the center of the coil. Your second option that you posted showing other iron material next to the coils to reduce cogging has questionable performance. This material would compete for the magnetic flux and diverge some of it outside the coil centers (High price to pay). How about misaligning your magnet patterns so that they are 1/2 of a diameter out of alignment. As one magnet aligns with a coil spool the opposite magnet is starting to pull toward the next spool. Your flux patterns would still be focused in the coil centers but your axial magnet pattern would be skewed. Just a thought anyway.

Regards,

Steve

Re: Miniature Axial Flux Generator  
Experiments ([none / 0](#)) ([#16](#))  
by bill541 on Wed Dec 31st, 2003 at 10:16:37 AM  
MST  
([User Info](#))

Steve,

Good points, getting the majority of flux lines to cut through the coils is certainly the goal.

I have been thinking along the lines of varying the coil numbers and spacing while still keeping the magnets at an even number and spacing. It would turn out to be a multi-phase system, but if you were to rectify the output, who cares how many phases you have. It may work out that you can still parallel or series some of the windings.

This would be worth investigating as coil arrangement would be easier to build than adding more ferrous material to the stator.

Thanks for the input! -Bill-

([User Info](#))

Joseph,

You probably could do something like this, but you may still need some ferrous free boundary areas between the stator coils.

The way I view it is that flux is like electricity, it will always take the path of least resistance. If this path doesn't take it through the stator coils, power is lost.

Maybe someone more versed in magnetics could shed some light on this.

-Bill-

I was looking for information on the web to better understand coils. I found a great university site.

There is a lot of detail and equations to help under Faraday's law, transformers, coils, and magnetism in general. I found the site very helpful and have reread a few of the sections several times to clarify my understanding of the material.

If you look in the air coil section it shows the ideal shape of a coil for optimal efficiency.

There is also a section that breaks down the equations which define the process of induced voltage from a coil

1. Magnetomotive Force (Fm) = current (I) \* coil turns (N)
  2. Magnetic Field Strength (H) = (Fm) / effective magnet path length (Le)
  3. Flux Density (B) = Permeability (u) \* (H)
  4. Flux (PHI) = (B) \* Effective Area (Ae)
  5. Induced Voltage (e) = N \* delta PHI / delta time
- (e) = Inductance (L) \* delta current / delta time

where  $L = (u) * (Ae) * N^2 / (Le)$

Take a look I think you will find it interesting.

Regards,

Steve M

It makes me wonder about some things about winding coils...

Is there a good inductance to wide the coils for ?

Does Resonate Frequency affect power generation ?

And the optimum shape for the coil thing is interesting, The cross-section of the coil leg is a Square . . .

} = - W o o f - = {

[Magnetism](#)

Soldering Iron heating up as we speak...

Hi All,

Oh dear. I feel an overwhelming need to build one of these Bedini motors. I don't really care about over unity. But I am interested in high efficiency and the thought of having one of these critters spinning away on my desk for a long while on a battery is strangely appealing!

So I don't have to repeat anything others have done before that didn't work too well - here's what I've got so far -

- Read the Bedini motor patent over several times
- Downloaded the twin battery circuit available on the Web
- asked a few preliminary questions - and here are a couple more:

It seems that one of the more important things is timing, of both the primary and secondary sides of the circuit.

The primary side is pretty well explained and I kind of 'get' what's going on there. But the secondary side, with the capacitor charging the battery I must admit to some confusion on that point. I've read some very helpful stuff from "charged" here, that basically says the cap will sit at the battery potential, then gather up charge from the back EMF on the coil, then at some point (designed to be not in-line with any rotor / stator magnetic activity) be discharged into the battery. So my question is - instead of using a separate timing wheel and discharge switch - could I mount a commutator (either mechanical or electronic) on the main shaft and have it discharge once per revolution? Or would that not give sufficient time for the cap to charge?

My knowledge on caps in general is pretty shaky - other than my electronics shop teacher many years ago who had a device about the size of a toilet paper tube, covered in tin foil with two insulating spaces down the sides on his desk. As I came to know there was some kind of cap inside it because when curious visitors picked it up there was a pretty decent shock in store. (OW - voice of experience...)

One of the appealing things about this motor - I just searched through my junk drawer and found everything on the diagram for this motor except the batteries.

Having fun!

Ted.

Hi Monte,

I haven't built a "bedini" motor per say, I've built a few based on the original "Lenz" concept which was used to prove the "Lenz law" then later went on to experimenting with the "Adams motor" which is what I believe the bedini motor principal is based on. One of my early models ran for 6 months by switch charging 2 dead 9V batteries. The coils ran about 20 degrees below ambient for the whole time. Later I went on to building some more advanced models the last one shown below...

This one had dual rotors with 4 coils. Each coil had 2 windings (primary and secondary) for extracting back emf. The voltage going into the caps sometimes exceeded 1500 volts. When connected to 2 8ft flourescent bulbs, had no trouble powering them up to full light. The motor ran at 7200 rpm and ran from a 12V battery drawing about 5 amps. It never made an "over unity" output but It did come in at around 97% as long as it only ran itself and powering flourescents or recharging the secondary battery. So basically it was extremely efficient as long as it did no real work. I used a hall sensor for the timing and mosfets for powering the coils. I must have spent 2 years playing with about 40 different motors I built before I decided to move on to other things. Then built a magnetic rotary engine followed by a new hobby into the stirling engines... and on and on and still going!

Have Fun

Ed

I believe Bedini does it every 3 turns , I plan on doing mine with a divider ic or a few flip-flops ic's , look on his page <http://www.icehouse.net/john1/intro.html> you will a circuit for a pulse charger ,also look here

<http://appft1.uspto.gov/netacgi/nph-Parser?Sect1=PTO2&Sect2=HITOFF&p=1&u=%2Fmetahtml%2FPTO%2Fsearch-bool.html&r=0&f=S&l=50&TERM1=bedini&FIELD1=IN&co1=AND&TERM2=&FIELD2=&d=PG01>

From: "roamer1952000" <roamer@c...>  
Date: Thu Sep 11, 2003 4:19 pm  
Subject: Re: Bedini motor

look at the pulse charger one

this even tells what all the parts are

also this will help you with the coil and setting it up

found this in the yahoo group free\_energy

From: "roamer1952000" <roamer@c...>  
Date: Thu Sep 11, 2003 4:19 pm  
Subject: Re: Bedini motor

Ok, start with an EXACT replication (same proportions and layout) of the full motor diagram of patent #6,545,444.

To make the Stator winding assembly:

First, cut a 1" long piece of 1/2" cpvc tubing.

I then picked up a couple of the PVC "electrical outlet boxes" and cut the spool ends out of the flat sides. Just use a circle cutter on a drill. After cutting out the two circles, drill out the center hole in each to match the OD of the CPVC tube. Then just use regular pipe glue to put the ends on the spool.

Make a trifilar winding of 500turns, using #23 magnet wire. Make sure the winding is tight, then wrap it with tape to hold everything in place. Or, you can glue it all up or whatever. Just be sure the windings aren't loose.

Match up the winding ends for input, output, and feedback windings.

To make the stator core:

INCREASING INDUCTANCE is the key here.

Increasing ANY ONE of three main factors increases the inductance of

the core.

1. Cross-sectional area of the core (view from end)
2. Number of turns
3. Permeability of the core material
4. Decrease core length (pole-to-pole)

The stator core must be made from a low-loss material. Something with low hysteresis, low eddy current losses and high permeability is preferred. Pure iron wire would be great.

I've been using a bunch of 1/16" steel welding wire strands, pressed into a 1/2"x1" CPVC tube spool. I clipped them all to fit inside the length of the spool, leaving about 1/2" extra sticking out one end.

Take them back out of the spool and stand all of the core wires in a foam block. Only stick them in about 1/4". Then coat each strand with spray enamel. This insulates each wire INDIVIDUALLY and greatly reduces eddy current losses when you pack them into the core.

Once the paint has cured and is HARD, jam the wires into the core as smoothly as you can, without chipping off any paint. Leave the uncoated ends sticking out the BACK SIDE of the stator.

Squirt superglue into the pack of core wires to lock them in place. Once it's fully cured, cut off the unpainted ends flush with the back side of the core. Use some fine sandpaper and a wire brush to make sure that end of the core is free from overhanging burrs and metal dust. Put a little more superglue into that end.

Ok, so now you have your stator. Most of the real work is done.

Go take a look at patent #6,292,370.

You'll see that it shows TWO stator windings. Ignore that part for now. You'll also see that there is another permanent magnet at the BASE of the stator pole. It's set in ATTRACT mode with the rotor magnets.

This "backside" magnet puts a "field tension" on the core. When you apply current to the core windings in opposition to this pre-existing "hard" field, YOU don't have to waste energy on hysteresis in the core. The PM has ALREADY ALIGNED AND TENSIONED all the magnetic domains in the core FOR YOU. It's kinda like blowing up a balloon. You don't get ANY TENSION on the balloon surface until you take up the slack inside with YOUR AIR INPUT. Once you pass that point, YOUR AIR INPUT starts stretching the balloon surface. THAT is the only energy you'd get back when you release the air from the balloon. It works the same way with the domains in the steel. The very first part of the current YOU put into a plain steel core is spent ENTIRELY on getting the domains organized and aligned. Once aligned THEN the field starts to build and store energy. The PM takes care of this for you.

- > In the case of the Bedini motor it was never said if it attracted or
- > repelled and the coil direction winding (not specified clockwise or
- > counter clockwise) would make it work either way. We are
- > pretty sure but not certain that it had free magnet to core attraction
- > and then the positive pulse came from the trigger coil a few degrees
- > after dead center to turn on the transistor and
- > repel it past the lockup point of the free attraction.
- >
- >
- > Norman

You didn't study the patents enough. EVERYTHING about this device is in those patents. I mean EVERYTHING. Start reading with a "lawyer's eyes".

The primary winding is FULLY energized in REPULSION mode, just as the rotor reaches TDC. Bear in mind that the bipolar transistor IS already starting to turn on once base-lead threshold is reached by the incoming pulse. It is an "increasing ramp turn-on" that coincides with increasing positive current slope coming from the "sense" winding. This "RAMP" is important. Re-read.

Ok, now think about this one. In a circuit with a common ground on two batteries, one battery being a 12 volt and the other being a 9 volt, what happens if you connect the two positive terminals together on those two batteries?

What if both batteries are 12v?

What if a generator is putting out exactly 12v pure DC and you hook it to a battery at exactly 12v. Does any current flow in either direction?

The transistor must come on just enough to make a "null" field zone between the stator and the rotor. NOT A PUSH.

\*\*\*\*\*

Ok, let's now assume that your motor is assembled JUST LIKE THE PATENT, with 3 magnets spaced at 120 degrees on the wheel.

YOU MUST mount your stator in such a way that you can ADJUST THE GAP between the magnet and stator core. Without this, you'll probably fail.

This GAP is set to match whatever battery you're using to "power" the motor. It's REALLY SIMPLE TO SET.

First, get a couple of alligator clip leads and hook them up to your battery.

Find out what the stator polarity needs to be to PUSH the rotor magnet away. Once you've found that out, you can begin adjustment of the gap. I usually just put a piece of masking tape around those wires where they come out of the stator, and mark them positive and negative.

With the battery shorted into the winding, find the distance where the rotor magnet is neither pushed away NOR pulled in. There IS a sort of "bobbling point" in there somewhere. Get it as close as you can THEN set it SLIGHTLY on the repulsion side of that "null" zone. When you're using the transistor, it will drop the battery voltage a bit. This then drops the field slightly and, Voila! You're in the "null" zone, or, ahem..... The Zero Point. heh.

NOW, when the transistor is energized, you won't be wasting any energy to PUSH the magnet away. It will do IT'S OWN PUSHING as it's leaving TDC. You will ONLY provide a little "null" zone for the magnet to be "free" to do what it wants. This means that ALL THE TORQUE on the shaft is PURELY from the magnets own attractions and repulsions. It can't be anything else doing it since you ALREADY know YOU set the gap to be a NULL at FULL BATTERY VOLTAGE. You couldn't PUSH it if you wanted to. The transistor is even DROPPING some of your original voltage, so you're actually just BARELY nullifying the field at TDC. Ok, if you don't get it, re-read.

You now have ENOUGH info to accurately reproduce the device.

Here's a snapshot of what is really happening.  
First, we'll review "Lenz Law" which states:

"An induced current flows in a direction to create a magnetic field which will counteract the change in magnetic flux."

In other words ANY TIME a magnetic field APPROCHES a closed loop of conductor, a CURRENT flows in that conductor loop. That current flow causes an OPPOSING field to the approaching field and creates DRAG.

The same thing happens when you REMOVE a magnetic field from a closed conductor loop. It PULLS at the field and DRAGS it back.

This is why conventional generators ALWAYS require more torque on the shaft when you have a LOAD on them.

IF that aforementioned conductor is NOT in a closed loop, no current flows and there is NO DRAG, Just a measurable "open circuit voltage".

Keep all this in mind while you follow along here.

1. Rotor magnet approaches the stator.
2. sense winding triggers the base with an increasing current RAMP as the PM field SWEEPS INTO the stator core. NO LOAD is applied during this phase (except for base lead) SO ALL the PM attraction goes into ACCELERATION of the rotor. This is REAL TORQUE as offered up by NATURE, NOT YOU.

3. Slightly before and AT TDC, a little dance occurs.

- a. the transistor RAMPS "on" to NULLIFY PM FIELD ENTRY into the core. This is actually a very small expenditure of battery current, just to bring the two fields into the "null". This CANNOT BE A PUSH since your battery's voltage isn't high enough to do that.

- b. AT TDC, the rotor no longer "sees" anything to be attracted to, it's field is no longer EXTENDING in attraction to the stator core. The core is "stealthed". The rotor skates merrily on by, thinking nothing is wrong. Tum-te-tum-te-tum..... heh.

c. JUST AFTER TDC, the transistor is SLAMMED into "off" mode and the rotor is already moving AWAY. BUT, it's field now WANTS to extend to the nearby core and ENTER IT. Hmmmm...

d. The magnet's FIELD is trying to EXPAND and enter the core. The windings are now LOADED by the storage capacitor, a practically dead short on the windings. Hmmmm.....

What does Lenz law say? Something about when a FIELD APPROACHES a CLOSED LOOP CONDUCTOR, that conductor produces an OPPOSING FIELD that PUSHES BACK at the approaching field. RE-READ until you SEE IT in your head.

The physical magnet and it's FIELD are TWO SEPARATE ENTITIES, NOT ONE.

The magnet is moving away and it's field get's a PUSH from the EMF extraction through the capacitor.

Shake you head a little. Go slam a door a few times. Yell at the cat.

Now, re-read and recognize the implications of what you just learned.

Lenz Law can NEVER BE DEFEATED. And, it doesn't need to be. It works FOR YOU with this design.

ok , then this is from Bedini's page  
US Patent# 6,545,444,and US2003/0117111A1 now granted.

Their is one thing we should get straight right now, the dimensions of the coil are not important. The resistance of the coil is not important, the windings are not important, the magnets are not important. None of these things mean anything. All of you are wasting your good earned money on neo- magnets, dime store magnets will do just fine stacked together. There is no secret to this machine, it's the process and the switching that's important!!!! I have never counted one winding when I was making these motors with Peter, I'm not saying one turn of wire will work because it won't, again what is important is, THE PROCESS AND HOW YOU COLLECT IT AND SWITCH IT. Why are you all thinking that it makes a difference in how the coil is wound, here is a number for you 500 turns number 23 tri-filer wound wire, see no step up no step down, just 1 to 1 ,welding rod for the core, roller-skate wheel, all north poles out, 2n3055 TO-3 case Junk but better, Do not use TIP 3055 it's just real junk , 330 ohms base resistor, 1N914 diode, hooked up the way I said. that's it. This makes your mechanical inductive coupled oscillator no big deal. By the way you are right about the terminology, we are babies at this to, just trying to (DEAD MAN FUSE IT), Nature does not care what the coil looks like. OH forgot the 1kv diode bridge on the third winding, and a 10Uf 500 volt cap, be careful you will fly across the room. I said I broke the machine into three patents, third patent, use the bottom half of switcher only. Do we all get it now?, By the way this is a limited machine to just study the radiant current to the battery. Thomas Bearden has defined it!!! "Everything in nature is simple this is the most complicated to the human mind, let's keep it simple".

Most of the problems with what you are doing is, the magnets, using a bolt for the core is not right, I said cut welding rod and you are not selecting the correct resistor for the base current for this mechanical oscillator. Save your money you do not want to use NEO-MAGNETS, just use radio shack cheap magnets!!!!

WHY?

This motor energizer is a mechanical oscillator whose speed depends on the lowest amount of current you can put into the coil. If you apply too much current, you cause the transistor to cross conduct (known as cross conduction current). When you do this, the semiconductor over heats, because the current to the transistor stays on and the mechanical oscillator runs slow.You cause the same thing to happen by using NEO-MAGNETS. Once the mechanical oscillator is running , YOU MUST ADJUST THE BASE RESISTOR TO THE HIGHEST VALUE that gives you the highest speed with the lowest current draw. The more magnets you get around the wheel the better the collection process will be. The magnets can not be too close together and must be spaced evenly around the wheel. You can find the right magnets at Radio Shack or a hardware store.

For the coil, just use an old solder roll or a bobbin you get wire on, cut and fill the center hole with .030 welding rod . This works really well.

Re: Bedini questions ([none / 0](#)) (#3)  
by charged on Mon Dec 15th, 2003 at 01:23:52 PM MST  
([User Info](#))

Hi Monte!

This one is running on what used to be my nightstand. Yep, there's nothing quite so soothing as clicking and rumbling bearings when you need to fall asleep. heh.

This one is using about 350uf (2 photoflash capacitors) rated at 400v each. The pulse rate is about 4hz. Why? Well, if you look at Bedini's charger patent, it says to keep the capacitors near the 20v range for max efficiency for each pulse. The less capacitance you have, the higher the voltage will rise between commutator pulses. I just built the commutator with 4 copper strips (cut from a scrap pipe) and then put caps on to see how high the voltage would climb on them between pulses. Turns out I only needed two caps on this one.

The Bedini and Adam's motors are two different creatures. I'm not going to go into the differences because others have done it elsewhere.

Take a real good look at the stator winding. What you have there is a 1:1 transformer.

Under "normal" use as a transformer, if you hit the primary with a 12v sinewave, put a full-wave bridge on the secondary, and then charged an electrolytic capacitor, you'd have 12VDC on the cap, maximum. If you put a resistive load across the cap, like small bulb, you'd see the primary side current draw increase as the bulb draws the cap charge down below 12v.

That much is conventional transformer theory.

This motor something different. An incoming magnet generates a positive sine which does no work except activating the base of the transistor.

The transistor switches the primary battery on just as the magnet reaches TDC, and creates a "null" in the field interactions, allowing the magnet to float past TDC as if the stator isn't there.

Due to the slight delay in the transformer action, it takes a tiny fraction of a second for the feedback winding's output to invert to negative, clamping the transistor OFF.

The magnet's field once again tries to reach out for the stator and THIS action does two things.

1. Voltage is a function of FLUX VELOCITY, CORE PERMEABILITY and NUMBER OF TURNS. So, the re-expanding magnetic field from the rotor magnet SLAMS into the core at nearly the speed of light. This generates an extremely high voltage that is WAY above primary battery voltage. This pulse EASILY fills a capacitor above primary voltage. Once the cap is above that primary voltage, the only current used from the primary is for field nullification. Nothing more.
2. That capacitive LOADING on the secondary causes the stator core to develop a counter EM field that resists the incoming PM field from the DEPARTING rotor magnet, giving it an elastic SHOVE away from the stator.

In a nutshell, as long as your collection capacitor is NEVER DRAWN LOWER THAN PRIMARY BATTERY VOLTAGE, the stator winding arrangement effectively isolates the primary from the secondary and you don't need to worry about timing your output pulses against primary input pulses. The fact that your motor/gen gives you nothing but CEMF to work with in the secondary means the primary side will never notice ANYTHING that you do with the cap charge, UNLESS you draw that cap lower than primary voltage.

Once you get yours going, Get a small fan-blade and put it on the main rotor. Then watch what happens to your primary input power. Oh, ok, I'll just tell you. The input power drops as you load up the output shaft.

Sounds a little counter-intuitive. But, it's not. Just don't load it down so much that you stall it out. Every motor is different. This needs to be mechanically loaded the same way you load an IC engine with a fixed throttle, like a lawnmower. You can only cut so much at a time without binding and stalling. Same thing with the Bedini system.

Make sure you posts some pics when you get it finished!

Re: Bedini questions ([none / 0](#)) ([#6](#))

## [Magnet Strength vs Thickness](#)

By [dburt](#), Section [Magnets & Magnetism](#)

Posted on Fri Dec 12th, 2003 at 12:51:22 PM MST

[Magnetism](#)

How much does field strength increase if I double magnet thickness?

How much does field strength increase if I double magnet thickness? For example, if I have 3mm x 25mm x 25mm zinc coated neo N45 magnets, will the magnetic field strength at a point 10mm from the surface of the magnet double if I place 2 magnets together for a 6mm thick magnet? If not, what is the formula to calculate this?

Thanks,  
Dave in PA

Hi Dave,

Here is a site I found extremely useful for this kind of thing:

<http://www.magnetsales.com/Design/Tools1.htm#disc>

You can just punch in magnet thickness, size, type (ie. Neo 35) and the distance from the magnet, or between them if they're on a dual disk and it will return the gauss at that point.

It really illustrates that small air gaps are good - a small magnet on a small air gap can give the same results as a much bigger magnet with a corresponding big air gap. So I think you can save money on magnets to some degree if you up the diameter and close the air gap down... Just my two cents worth!

Have fun,

Ted.

Thanks Ted,

That's a super calculator! I used the one for rectangular magnets yoked in steel path. I think that answers my needs perfectly!

Dave in PA

That's really a handy tool! Thanks for the link!

One thing it learnt me (that's proper English in my dialect) was that paying for the Neo 48s is probably not worth the price difference over the Neo 35s.

Another thing is that a 1/8" air gap is probably a worthwhile target.

(If I ever get around to building one.)

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

My gap is 1/16 or less in motor conversion. Also with the very best possible lamination material. Also no problem with plenty of copper. Just a thought for the disc builders. We gave up on the curved neos way to soon.

I was real excited about the site with magnetic gauss calculator, but then I hit a feature that has me concerned about accuracy of equations used by the calculator. If you use:

[http://www.magnetsales.com/Design/Calc\\_files/FluxDensityRectYoke.asp](http://www.magnetsales.com/Design/Calc_files/FluxDensityRectYoke.asp)

(supposed to calculate gauss at the center between 2 rectangular magnets in a steel yoke) and put in 3 by 3 by 1/4 neo N45's with .75 gap between magnets, it calculates about 4149 Gauss... Increase the size of the magnets to 5 by 5, with everything else remaining constant, and the Gauss calculation decreases to 3606!?! I cannot think of a reason how that could be correct. What am I missing here?? Sure wish I had access to the formulas they're using...

Re: Magnet Strength vs Thickness ([none / 0](#)) ([#17](#))  
by 5kw on Mon Dec 15th, 2003 at 04:15:26 PM MST  
([User Info](#))

dbert,

It's true. The wider magnet causes a demagnetizing force on the center point.

You can verify this with a flux meter.

Flux lines repel each other and cannot cross but there all "trying" to get to the same place. The more the crowding the higher the reluctance.

Make the wind fun!

Victor

I think we are using two different definitions of airgap. The airgap between the magnet and the nearest face of the coil to the magnet, and the airgap between the two magnets. I bet that the proper definition is really the distance between the face of the two opposing magnets (or the magnet and the non-magnet bearing stator), which would be the "field airgap". The distance between the nearest face of the coil and the magnet would be the "mechanical airgap". (Again, this is only based on my limited understanding of what is being discussed.)

Either way, minimizing the distances involved makes a big (theoretical) difference on the magnetic force available for generating electricity. I think that probably the distance between the face of the magnet and the nearest face of the coil to that magnet is probably the distance that requires the most manufacturing skill to reduce. If the stator has an unnecessary thickness of fiberglass and resin over the faces of the coils, then the magnets will be farther from the coils even if the magnets are scouring the surface of the stator as they rotate: while that fiberglass thickness is not an "air" gap, it is an effective airgap between the coil and the magnet. If the stator's thickness is uneven, then the magnets will have to be placed so as not to contact the thickest part of the stator, which means that the magnets could be closer to some of the coils if it were not for the uneven thickness of the stator.

One thing that I have thought about is reducing the thickness of the stator to the point that the coils protrude from it...that is, that the stator should be a web between the coils instead of a thickness of fiberglass encasing the coils. This would require molding techniques slightly more complicated than the "hamburger press" molding in use, but it would eliminate from the "mechanical airgap" the fiberglass and resin that covers the faces of the coils.

Re: Magnet Strength vs Thickness ([none / 0](#)) (#9)  
by Electric Ed on Sat Dec 13th, 2003 at 01:04:42 PM MST  
([User Info](#)) <http://www.electric-ed.com>

I agree, the significant airgap, from a performance point of view, is the portion of the magnetic circuit that isn't either in iron or the magnets.

The answer is coils with a wide, flat cross-section. In motor winding lingo, they would be called "mushed" coils.

The problem, as you stated, is how to fabricate a thin, but strong, supporting structure.

Electric Ed

**When winding coils that have a wide, thin cross-section try to keep the "span" of each turn as close as possible to the center-to-center distance between the magnets.**

**This will result in less voltage cancellation and higher terminal voltage, and improved waveform.**

([User Info](#))

I was wondering how to do that, too. The idea i come up with is using a slanted form in the coil winding spool. That is, instead of having the piece between the sides meet the sides at a perpendicular angle, have it slanted at a 45 degree angle between the spools. Then the coils would seem to come out as described at left.

(Mind you, this is entirely theoretical. I've never wound a coil in my life.....although I have been around winches and things.)

[quote]"I can't think of a way to wind the coils like the drawing on the left?"

It's hard to describe, and even harder to draw a picture of.

Have you ever seen the kid's toy called a "slinky". I think that was the name. It had a wire spring joining the body parts.

Wind your coil so that, when removed from the winding form, it resembles such a spring sitting on end, one turn on top of another.

Then just push the top turns over to one side, like you'd fan out a deck of cards, sort of.

Make any sense?

Now if I could just figure out a way to mount them- - -

Electric Ed

by dconn on Tue Dec 16th, 2003 at  
04:16:58 PM MST  
([User Info](#))

I think it looks great. I wonder though would the coils be too wide (with enough turns) - coils normally dont seem to fit well at the best of times (I've only wound a set of coils once and they were nearly too bulky).

I wonder how think the stator needs to be to ensure that it stays stiff and secure?

All the best,

Derek

Re: Magnet Strength vs  
Thickness ([none / 0](#)) (#21)  
by Firefly on Wed Dec 17th,  
2003 at 08:53:03 AM MST  
([User Info](#))

I have been working with the stiffness of thin colis and coils in general. The method shown in the photos below tell the story.

These two photos show a wooden form that I made to compress the coils tightly

together

Putting epoxy on the coil legs

The form is covered with plastic film so the coil can release and don't get glued into the form  
Coil shown in the form

putting the top block on

The big squeeze. This forces the coil legs into shape.

Cose up of one leg of a finished coil

A vey thin coil made with this method

These coils are very strong and ridged I think that they will have enough to support through the air gap if they are cast in resin around the outside and inside of the coils. I have made test with the air gap between the magnet faces of less than .25" with these thin coils. However the gain that I seen with less air gap don't seem to match the opinion of others. i.e. if you have half the air gap we should see 4 times the voltage. As shown in the original test this seems not to be true. A balance has to be reached between voltage output, air gap, turns per coil, and wire size to reach the highest wattage output.

([User Info](#))

Hello,

You can create your own magnet using a magnet and a small piece of rectangular iron (ie a small saw blade)

put the saw-blade on a table, and use the magnet to sweep from one end of the blade to the other - allways in the same direction.

When you have done this you can verify the result with a compass.

The magnet you can buield using this method is not very strong, but it make the compass react, and you can pick up very small nails.

Remember that the stronger the magnet - the stronger the resulting magnet will be.

Thou this will make a nice experiment, the magnet you can create at home will not be of the same quality and strength as the industrial made magnets.

/Steffen

### [Ball Bearing question...](#)

By [CrookedScepter](#), Section [Magnets & Magnetism](#) [Magnetism](#)

Posted on Wed Dec 10th, 2003 at 08:38:16 AM MST

If I were to put 2 ball bearings together....

If I were to put 2 ball bearings together, and they were to be arragened vertically and they would only touch each other to one point while the bottom one spins and the other stays still...

At 300rpm, how long before that point would wear away so that the bearings would have to be rotated to keep friction and surface contact down? a day? a week? a month? not an exact answer is needed, just a guesstimation...

Thanx-

[Ball Bearing question...](#) | 4 comments (4 topical, 0 editorial)

Re: Ball Bearing question... ([none / 0](#)) ([#1](#))  
by [charged](#) on Wed Dec 10th, 2003 at 11:45:46 AM MST  
([User Info](#))

You mean the bottom bearing is spinning around the virtical axis, like a top?

Depends on the hardness of the bearing material, mainly. If you get something REALLY hard, the contact point will remain small (no flattening) and the friction would be minimal. I'm assuming you'll probably use a drop or two of oil at that contact point to, right?

What diameter are they?

Re: Ball Bearing question... ([none / 0](#)) ([#2](#))  
by [CrookedScepter](#) on Wed Dec 10th, 2003 at 12:07:57 PM MST  
([User Info](#))

the bearings are 1/2" diameter, and I got them from [www.rare-earth-magnets.com](#) they say that they bearings have high hardness and excellent wear. I'm just trying to get a general timeframe for how long that contact point will be good for low friction. Kind of a hard question, I just like to hear a ballpark figure

Thanx-

([User Info](#))

How long will depend greatly on how much load you put on the assembly, lubrication and any possible temperature rise. the proposed 300 rpm is actually quite slow.

In a sealed lubricated enviroment I would say 12 months plus. I base this on the fact that rollar bearing spend their life rolling around with a minimal contact( in theory no metal to metal contact, as lubricant should come between both bearing surfaces)

I have never replaced a roller bearing that has developed a flat, generally they fail due to pitting caused by moisture in the lubricant.

regards Allan

Re: Ball Bearing question... ([none / 0](#)) (#4)  
by CrookedScepter on Thu Dec 11th, 2003 at 08:56:44 AM MST  
([User Info](#))

12 months plus? Wow, as far as the load goes, how I have my project setup, is that there is almost no load on the contact point between the bearings. all that is keeping the points in contact is magnetic attraction that cancels out the weight of the load.

If I tell ya any more, I'll have to kill ya ;) j/k

Thanx-

Wayne,

The reason you didn't succeed in making one of these motors is the same reason nobody else has or ever will, it isn't possible! I don't care how carefully the magnets are spaced or what arrangement they are positioned the laws of this universe prohibit the extraction of power from a device without a greater ammount of input.

The government is an easy target, "they" really want to keep us commoners down, not! Hell, I bet you could get a massive grant to try to build one of these over unity devices if the proposal was worded correctly. (I am not a supporter of the gov. either)

Roger,

I'm not the government conspiracy type either, however about 35 years ago an artical came out in popular mechanics magazine about a guy that invented a device that he called a water injector for use in automobiles. I was facinated. At the time my mechanical inclinded Uncle (was in charge of maintaining deisel powered radar station, part of the early warning system) said that other than steam it would be impossible to run an engine on water absolutly impossible. Now we are playing with engines that will run on hydrogen and oxygen (the 2 components in water). I have built one of the oxy-hydorgen generators and I can't run an engine on it (yet) but I have used it with a torch tip and got a very hot flame. Rumor has it that the military uses some of Tesla's inventions, but are they readily available to the general public? No.

35 years ago that same uncle who was also an avid mariner and using LoranC locator technology would have sworn that no satellite 20,000 miles up is going to place your location as close as 3 meters, or closer if the US military would allow it. At the timr Loran C was top of the line and very expencive. Now we can buy a GPS for less than 100 bucks. I beleive almost anything is possible if you don't accept it as being impossible.

Bill

The magnetic field on an alternator is known to be very strong

and since i have just ordered 24 1x2x.5" magnets and the axial flux alternator plans, I was hoping that someone would illustrate just about how much force and at what distance i should expect when assembling this alternator. - breaking fingers is something i usually try to avoid ;-)

Well - I did buy a magnet about half the size, just to get a feeling about the strength before i start playing around with the "real stuff"

Thanks in advance.

/Steffen

Steffen,

If these are neo magnets I would be very carefull. Though I am not exactly sure 24 of these magnets assembled correctly would probably have enough strenght to pick up a full size car and some. From personal experience, make sure you have a firm grip on these magnets when assembling your alternator, always slide them onto a steel disk never try to place them on directly and keep all magnetic material (iron, steel, nails etc.) far away from your work area. Magnets can be deceiving in that they may not appear to have any force in them until they get close to another magnet or steel/iron object then watch out. I beleive that the magnetic force is reduced by the cube of the distance away from a magnetic object and the converse is true.

Neo magnets are very brittle and can shatter into small pieces when slammed together or against a piece of steel so watch out for shrapnel should that happen (it has to me).

Above all be extremely cautious and vigilant when working with these. Keep them away from electronic equipment (TV's, computers, etc.) as they will damage or destroy them.

Good luck and have fun.

([User Info](#))

Hello,

Thank you for taking the time to reply.

Sorry for leaving out such a vital piece of information, but yes, the magnet's are Neo's (Wondermagnet.com item #76)

I saw an interesting slideshow of the manufacturing of an alternator, and I noticed that they used two chains when they assembled the two rotors. - unfortunately the pictures and the story didn't tell what the chains was connected to, but the chains was very heavy duty, and I can understand from your posting, that there might be a good reason for that.

Maybe I can make a simmlar arrangement when i get to that point of the construction.

What does other people do? - i mean, if the magnets are strong enough to lift a car, then a working table would be an easy task to move?

/Steffen

([User Info](#))

Its very easily done with jacking screws. On my current alternator project I have 3 jacking screws, 1/2" - 13 threads, and the magnets are huge (much larger than those in Hughs plans) - it goes together very peacefully and quite easily. Chains - jacks... etc, are not necessary and probably not the safest way. In other windmills Ive made I just made a special "puller" - kind of like a wheel puller you'd use on a car. It's really very easy.

[ [Parent](#) ]

Re: Magnet safety ([none / 0](#)) (#2)  
by DanB on Mon Dec 8th, 2003 at 08:04:49 PM MST  
([User Info](#))

Those are very strong magnets you've got coming there!

I'd advise dont play with them too much before you get 'round to building the rotors for the alternator. When you get to that point - follow Hughs instructions! (he's got it pretty well layed out I think about how to handle them safely). Handle only one at a time, and keep all the xtra steel tools - etc, away from the work area. Definitely keep the two rotors are safe distance from each other.

If you follow Hughs instructions, you'll be drilling/tapping some holes for jacking screws in one of the rotors, so that you can assemble them in a slow and safe manner! It's not so bad just so your careful! If you take care in doing all this, it's perfectly safe and lots of fun!

Love to see some pictures of your project if you feel like it!  
It's a real good wind turbine.

Re: Magnet safety ([none / 0](#)) ([#6](#))  
by stm on Wed Dec 10th, 2003 at 03:40:57 PM MST  
([User Info](#))

Thank you everybody for helping me out on this matter.

I believe that i have an understanding about the power involved, and I feel better prepared for the challenge. The main reason for asking this question was that i wanted to be absolutely sure that I knew what I was doing - before I opened the box and destroyed my monitor and everything around me ;-)

The advice with the Jacking screws sound like the right approach for me. I was looking very closely at the picture with the heavy duty wires, and I believe that it was a task in itself, just to align the rotors, without doing damage to the bolts.

I'm looking forward to be reading Hugh's book, a lot of people has been refering to the book as a very good construction manual.

GPS wrote: "A bit of heightened awareness is a good thing and, with knowledge, fosters safe handling." - This was exactly what I was thinking about when i wrote my post. I have a few powertools both at home and at work, and they're all dangerous if they are used unwisely.

I did'nt get any second thoughts, but my respect for permanent magnets has been increased.

I've really enjoyed looking at pictures and reading the stories written by a lot of members of this board, and I'll take a few pictures during the development of this genny, and hopefully they will help other people getting success, and to avoid the problems I would be running into.

Have fun

/Steffen

Re: Magnet safety ([none / 0](#)) (#5)  
by [gps](#) on Tue Dec 9th, 2003 at 10:58:59 AM MST  
([User Info](#))

Just sliding one off the stack they ship them in requires significant effort - they are obscenely strong! The jacking screw approach described above is definitely the way to go, as well as being very careful about tools, etc. generally.

Most people work with numerous things in the course of their daily lives that have the potential to inflict serious harm or injury and don't give them a second thought because they are common place and the protocols for safe handling are learned to the point that they are second nature. Less familiar hazards are more intimidating because they are unfamiliar. A bit of heightened awareness is a good thing and, with knowledge, fosters safe handling.

Happy construction

DanB Magnet availability

Hi Dan.  
I'm working on a new design and want to know the long term availability of item # 0005 1.5 x 1.5 x .375 . You have plenty in stock now, but it doesn't seem to be a popular size.

Make the wind fun!  
Victor

[Magnetism](#)

somebody, anyone?

I'm looking for a rare-earth magnet block shaped as 2"x1"x.25 or 2"x1"x.5"

it seems the one wondermagnet has is a bit too thick and expensive for what I want to do, I'd like to see if I can get 16 of the ones I want.

Does anyone sell such a magnet and not require a minimum order?

Thanx-

The PME Project

---

### The PME Story; A History

Our company began in May of 1952 initially as a manufacturing plant for the military. The plant was located at an undisclosed area for secrecy. Although most of our projects cannot be described in detail, many of the engines and motors we designed were invaluable to our nation's department of defence. In 1963 we branched out into civilian applications. Our company continued to grow as we developed ways of producing the most efficient and light weight electrical motors and relays in their class. In 1975 our company began to be in severe financial distress. Some of our corporate managers were funnelling company funds for their own personal gain. Our company began to plummet into bankruptcy and chaos. It looked like we were about to become another ENRON. Only after these people were caught and fired did our president and founder, Dr. Dvorak Schlovowsky give the final word on hiring personnel for the company. "Dr. D" was not satisfied with mere financial gain but was always seeking new people, new ideas and innovative, history making inventions. Perhaps this is why we found among us one of the most truly innovative minds of our time. Around April of 2001 I began to notice the elderly Dr. D had become preoccupied with magnets. He carried them in his pockets and played with them constantly during board meetings. Once he even spoke to me personally of why he loved magnets. He said "They were an unexplained mystery men could only theorise about but never really understood. To see one piece of metal make another piece move away on it's own accord was a fascinating paranormal phenomenon, although most men take magnets for granted." I remember thinking he was getting senile in his old age. Nevertheless I believe his words are worth mentioning here since it marks the true beginning of our company's odd and intriguing history. On June 3, 2001 it was announced that two research teams were assigned a grant of over a half of a million dollars by our company to create a motor than could run by an internal permanent magnet system without any power supply or fuel. Although Dr D was convinced his "P.M.E." project would succeed and could not be persuaded otherwise, scientists had long considered such a motor which is powered exclusively by magnets as an impossible phenomenon. They held to the long standing rule that an electric current was always needed to convert a motor's magnetic potential energy into kinetic energy, making the motor's rotor spin. At the end of 23 months both teams were stumped. All of our top scientific personnel were left scratching their heads. Most of the staff believed it simply could not be done and called the PME project the DUD project. The grant money was used up, mostly because some of our educated ideas required us to use costly, huge equipment that super cooled different materials. The last of our theories were tried and trashed. We even tried

ideas from the internet that others claimed to have worked, yet nothing did. Nearly everyone had thrown in the towel. On July 3, 2003 a lowly but devoted technician named Nikita Nelson, having wrestled with the problem in her mind month after month, working after hours on her own time had finally created a crude looking little prototype motor.

It's outer shell was actually made from a tomato soup can. Later Nikita admitted she had worked alone because the other researchers were always too busy and refused to listen to what they called her "ding-ee" ideas. Even our upper echelon researchers dismissed her latest idea that day, insisting it was too simple to work as she tried to explain it to them. During her presentation Nikita placed her little home made motor on the lab table and inserted one small magnetic rod into it. As the motor began spinning it's rotor without any exterior power supply everyone was speechless at first, then someone burst into a fit of laughter. "Our project is saved!" some mocked, thinking it was a gag. Laughing researchers gathered around to jeer. I suppose the staff laughed so hard because it was a relief to all of our failures during the project. Seeing the motor made from a little tin can for the first time, I found myself laughing also. Something that small could only be a prank, I thought. But glancing over at Nikita I could see a look of desperation as she tried to convince them otherwise. A few of the staff actually rolled on the laboratory floor in fits of laughter in front of her, ignoring her protests that it really worked. This infectious humour spread throughout the whole laboratory as Nikita stood, again ignored while a small mob of gathering researchers bumped against her shoulders from behind, brushing by her to see the little tin can motor. She had given up shouting for them to stop. They pointed, laughed and ribbed each other with their elbows, making witty, funny sayings about her homely little creation as she just stood there outraged. To them it was a practical joke from a mere technician who's only assignments were cleaning up the lab, dusting and book keeping. But Nikita, having observed their history of unsuccessful experiments had thought "out of the box" and made a working model of her own imagination. After the last of the chuckling died down, and people began to leave for the day, seeking their coats and belongings, a few technicians asked for Nikita's permission to dissect the engine. With an offended glare Nikita said nothing except "Sure, whatever..." Once the motor was taken apart the technicians could find no internal power supply. They used meters on all of the motor's parts but could detect no voltage or battery anywhere. Finally they excitedly called for the project engineers. You can imagine our elderly project engineers being pulled reluctantly by their arms to gather around the dismantled motor, some smiling at first, shaking their grey haired heads in doubt, expecting to find the little trick that made the motor work. Then came the puzzled looks, the murmuring and then finally the stunned expressions as their excited conversation grew fervently louder. They even accused the technicians of hiding the motor's batteries until the technicians reassembled the motor in front of them and inserted that last, little magnetic rod. When the motor delayed, then suddenly sprang to life it startled them all. Once again all of the lab workers began to gather around the little motor due to the commotion and exclamations that followed. Those who were leaving were compelled by others to rush back inside the laboratory. In the lab someone shouted for all of the loud scientific bickering to stop, and there was a profound silence, except for a single snapping sound which I noticed came from a pencil Nikita had broken between her trembling fingers. Then it was that all eyes fastened upon

her; the cute, young lady in the white lab coat who had just knocked over their Goliath problem with her simple, small stone. She had solved their impossibly huge enigma with one of the simplest yet greatest ideas of this age. Everyone could now see that Nikita was deeply offended and hurt; a tear trickled down her cheek, which she wiped quickly away. Knowing her feelings were exposed to those who had least esteemed her, Nikita's head lowered and her eyes darted defensively around at everyone as her chin trembled. For so long she wanted to be a part of the team but no one would accept her advice or ideas. Finally, we could all see what we had been doing to her; always waving her away because we were too busy. No one had realised how deeply her very heart was into this project. Through all of her labour all she wanted most was to be believed, respected and accepted. For a while no one knew what to say. A few of the female staff members drew near and encouraged her softly with the words "You did it Sis" and "You go girl" but their hugs seemed to squeeze more tears from Nikita's forlorn eyes. The head project manager cleared his voice in the silence and seemed to be about to make an apology but Nikita, trying to control her girlish, faltering voice, began asking why no one would ever give her a chance. She muttered that she was tired of being treated like dirt and ripped off her I.D. badge, letting it drop to the floor. Then she walked over, snatched up her little motor made of coiled wire, some 25 cent magnets, a capacitor, a rectifier, all housed in a shell of a tomato soup tin can, and walked hurriedly out of the building. I could never have imagined the success of the project would end up like this. Looking back on that day I realised it is not education that makes people great or special, but their hearts and their passion to follow their dreams. I learned never to underestimate people like her and to never think of anyone as lower than myself. On August 25, 2003 the military learned of Nikita's prototype motor and made an attempt to keep it under "Area 51" secrecy. Their aim was to use the PME for combat vehicle and other war applications. I was speaking with Nikita at her home, having convinced her to come back to the project when the military, having obtained a search warrant barged in, searched the whole house and found the motor in her garage. They detained Miss Nikita Nelson at the military base and confiscated all data of the PME project from our labs. Most of the lab workers were also detained, I suppose because we had seen too much. We were not allowed to communicate with our families or loved ones due to what the military described as national security reasons under penal code statute 0092B. On the night of September 11, 2003 at 3:00 AM there was a fire at the IMR plant. The PME project building was completely destroyed in the flames. The Fire Marshall could not find the cause of the fire. Two of our security personnel were burned to death in the incident. I quickly realised our project was about to go the way of the UFO; proof that the PME ever existed was disappearing fast from the public eye and there was nothing we could do about it. Back at the military base where we were all being held there was an "accidental" death of one of our project engineers during his detention. Upon hearing this news Dr. D spat at the feet of top military officials. Most of us who were detained became quite terrified, especially after we learned of the death of PME project engineer Dale Edwards while he was in the hands of the military. Soldiers claimed Edwards became so violent that they had to use force which proved to be lethal in order to prevent his escape. Those of us who knew Edwards also knew he was a well mannered church going family black man who always tried to keep the peace, never raising his voice. Two days later I overheard the chilling words "All targets

are expendable." as two lieutenants talked quietly together. After I told this to Nikita she remained strangely cool and confident. Nikita had foreseen the military's greedy interest of the project. Before being detained she had pre programmed a hidden computer to spread the PME project information by the internet. As they interrogated our personnel and as Nikita stalled them, the military eventually learned from other sources that the PME information was already leaked out into the international cyber community. Only then did they finally release every one of our employees. Consequently with Nikita Nelson's permission we have succeeded in keeping the PME lawfully available to all companies who wish to be a part of our progress. Who needs nuclear energy? Magnetic energy is not only more easy to regulate and control; it is safer. Those of you who are familiar with the power of rare earth neodymium magnets know that such magnets as small as the size of a child's hand can drag a full sized refrigerator across a concrete floor. A fluid cooled PME engine using such an array of magnets has easily propelled one of our prototype six passenger vehicles well over 200 MPH, and yet the PME that powers that vehicle is only 1/4 of the size and under 1/5 of the weight of a conventional gasoline engine. After I witnessed the power and speed of our prototype vehicle, which pulled up along side of our PME team, I looked over at Dr. D as he sat in his wheel chair. He had suffered a stroke recently. Nikita, standing at his side took hold of his hand, looking into his eyes with her girlish grin. Although Dr. D could only look up and return half of a smile due to his stroke, I could tell both of their hearts were happy now that their dreams were finally fulfilled.

We at Industrial Motor and Research Corporation would like to thank you for your interest in our history. We are also proud to announce this fantastic technological achievement called the PME and invite you to join us as we follow a new horizon toward everyone's future.

For further information please feel free to visit IMR marketing report web site at [www.imr.com](http://www.imr.com)

Sincerely,  
William Elliott  
Executive Superintendent

## [Electromagnetic Halbach Arrays](#)

By [TheTyckoMan](#), Section [Magnets & Magnetism](#)  
Posted on Wed Dec 3rd, 2003 at 09:51:51 PM MST [Magnetism](#)

Has anyone made one of these?

would a electromagnetic halbach array work?  
I don't see why it wouldn't work, and if it does work then you could make a really strong halbach array much easier then using permanent magnets.

There would be a lot of things you could use it in, like Motors, Generators, Electromagnets, etc, I thought about this the frist time I saw a halbach array.

filico;

Check out this website:

<http://www.matchrockets.com/ether/halbach.html>

But, in a nutshell, a halbach array is a way of assembling multiple magnets so the assembly has only one magnetic pole. That page tells all however.

Cheers.

TomW

Best method depends a bit on what youve got around!

As was said below, a compass works well. The needle will point towards the South pole.

Or you can float the magnet on water (on a cork or a bit of wood or something) with the poles perpendicular to the ground, and the North pole of the magnet will point North.

Or you can tie a string to it and do the same thing...

Most fun way - simply hold the magnet flat in the palm of your hand and lightly toss it into the air (not too high). 9 times out of 10, if the South pole is facing up, the magnet will go up into the air, and land flat back in your hand without ever turning ver. If the North pole is facing up, it will flip in the air and usually land with the South pole facing up. This is how I usually tell.... although - there is rarely a reason to know or care which pole is North or South, that I can think of.

Be careful Dan - has this method been tested in Australia and other places south of the Equator?

Ron

yes, I suppose it'd the opposite further down south of the equator and probably not work at all near the equator.

Sure works well here though!

Okayyy...this might sound silly  
'Or you can float the magnet on water (on a cork or a bit of wood or something) with the poles perpendicular to the ground, and the North pole of the magnet will point North'.  
wouldn't that be the South pole of the magnet pointing North? Opposites attract...Likes repel?  
Course I realise this is an arbitrary thing.... but like you said there is rarely a reason to know or care.And like I said this probably sounds silly. (:>) Norm.

Norm, I believe that the geographic North Pole has the south side of the Earth's magnet. It's called the North Pole because because the north poles of magnets point that way. All the names were set in stone long before we had the magnets sorted out.

Martin.

## [Rail Gun](#)

By [kevinenglish](#), Section [Quarantine Zone](#)

Posted on Thu Nov 27th, 2003 at 02:24:04 PM MST [Magnetism](#)

small question

Hey everyone,

For a personal project I am trying to develop a small rail gun, one that'll shoot a couple hundred feet with a 1/2 inch steel ball bearing. So far I have made the electronics, an extremely strong electromagnet and the switch, with a safety (so I don't shoot myself). So far what I have (not put together yet) will shoot the ball bearing ~20'-30', but that's not my goal. What I want to do is add 5 more of these electromagnets to what is going to be the barrel to accelerate the ball bearing even faster since one electromagnet isn't enough.

Now to my question, is there something that I can put in between each electromagnet that could delay the flow of electricity for about 1/500th of a second? I need this to make a ripple effect on the electromagnets so each one pulls the ball bearing in sequence until it exits the barrel at the end.

([User Info](#))

Hey,

I just thought that something like this would be an interesting project. To tell you the truth, I am really into things that can propel objects large distances. So far I have 2 potato cannons, air rifles, 2 air soft guns and more. Basically it's gonna be something to do just for a project, something neat that no-one else has.

kevin;

Have you considered a electromagnetically activated trebuchet? Just an odd thought i had while reading this.

After seeing those electromagnetic can crushers I am convinced you could build an awesome trebuchet with an electromagnet rather than weights.

Cheers.

TomW

Grab bag

Hi, I've been happy with you in the past and was about to buy 5 grab bags as a present for myself. Can you email me when they're available, or alternatively can I pay in advance? Thanks! I was very satisfied with the magnets in the first grab bag, and didn't mind the chipped corners.

 Electromagnets-how to

Hey, this is the first time that I have posted on this site for about a year. But once again I have a question.

I have been dealing with electromagnets for a while now, I built one that off of a 9.6 R/C 1 amp battery lifts ~ 10 pounds. But now I am stepping up and I want to start using a car battery for a personal project. What I would like to know is using a 1/2 steel core, how many turns and what gauge wire I should use to make the most powerful magnet possible (over heating was the problem with my last magnet) that doesn't over heat after 1 solid minute of use.

Thanks,  
 Kevin

 by [charged](#) on Sun Nov 16th, 2003 at 09:24:46 AM MST  
[\(User Info\)](#)

"Electronics Conversions Symbols and Formulas", by Rufus P. Turner and Stan Gibilisco  
 ISBN# 0-8306-2865-7

This is a great book and contains all the electromagnetics formulas that you would need to work out your magnet detail ahead of time.

Basically, the heavier gauge the wire, the more current it can handle before it begins to get hot.

Your "magnetizing force" is determined by the following formula:

$$H = (3.14159 * .4NI) / L$$

- H= mag force (oersteds)
- N= number of turns in coil
- I= coil current (amperes)
- L= length of magnetic path (core length in cm)

In order to hold more weight with the same amount of power input you should be using both poles of the magnet to grab the weight.

Get a small block of iron or steel about 2 inches on a side. Drill a 1.5" diameter hole, 1.5" deep into the center of one side. Drill a 1/2" hole down in the center of that hole so the it goes the rest of the way through the block. Thread that hole so that a fine-thread 1/2" bolt will screw into it with the head of the bolt flush with the surface of the block inside the larger hole.

Take the bolt out and mark it 1.5" from the top of the bolt head. Between this mark and the bolt head wrap you windings. But, make sure your windings do not get wider in diameter than the 1.5" block hole.

Screw the bolt winding assembly down into the hole in the iron block. When you apply power, the bolt head will be one pole and the upper surface of the block all around the bolt head will be the other pole.

You will want to grind the top of the bolt so that it is perfectly flush with the face of the block.

Now, when you stick this to a weight, you will be shocked just how much it can lift for only a small power input.
