Abstract

We successfully cloned and sequenced a full-length cDNA (LeHSP23.8: accession number AB017134) encoding the precursor of the mitochondria-located small heat shock protein (MT-sHSP) from tomato (*Lycopersicon esculentum* Mill.). The deduced protein precursor with a calculated molecular weight of 23.8 kDa was predicted to target mitochondria. A single copy of LeHSP23.8 was found in tomato genomic DNA by southern-blot analysis. Northern-blot analysis revealed the heat-inducible character of LeHSP23.8 mRNA. The LeHSP23.8 mRNA was hardly detectable at 36°C but accumulated abundantly at 40°C in tomato leaves. Among the MT-, ER-, Class I- and Class II-sHSP genes, MT-sHSP mRNA responded most quickly at 40°C in tomato flowers. In flowers on the flowering day, sHSP genes (MT- and ER-) were expressed specifically in the female organs when the plants were incubated under the heat stress.

The molecular chaperone function of LeHSP23.8 was confirmed *in vitro*. The recombinant LeHSP23.8 was able to enhance the renaturation of chemically denatured citrate synthase. Moreover, the recombinant LeHSP23.8 protected citrate synthase from thermal inactivation and also promoted the renaturation of thermally inactivated citrate synthase. Partially purified mitochondria fraction from MT-sHSP transgenic tobacco showed much higher Cytochrome C oxidase activity than the control under higher temperatures.

Protein analysis by western blotting showed that expression of MT-sHSP occurred in leaves, flowers and pollen of transgenic tobacco lines (MT-a, MT-d, MT-e) at 28°C but could not be detected in these organs in the control plant (pBI). However, MT-sHSP was induced under heat stress (37°C) in pBI leaves. Although we could not detect MT-sHSP in pollen of pBI at 37°C, it was overexpressed in pollen of MT-a. We observed *in vitro* pollen germination and comparatively low pollen bursting at 45°C in MT-sHSP transgenic lines, indicating a possible role of MT-sHSP in plant reproduction. We are also trying to analyze the *in vivo* function of MT-sHSP.

Key words: heat-stress; mitochondria; molecular chaperone; pollen germination; small HSP

Introduction

Heat stress is one of the most important constraints on crop production. Plants respond to heat stress by changing their metabolic pathways so as to acclimatize to high temperature. Under heat stress, synthesis of most proteins is repressed and some proteins, which are called heat shock proteins (HSPs), start to be synthesized. In plant species adapted to temperate environments, 20 to 40 different HSPs, which are divided into several classes, are induced under heat

stress (Vierling 1991). Some low molecular weight (15-30 kDa) HSPs, so-called small heat shock proteins (sHSPs), are also expressed in plants. The sHSPs are classified into five classes in accordance with their molecular phylogeny and localization in the cell. Cytosolic I and cytosolic II sHSPs are found in the cytoplasm. The other three classes are found in the chloroplast, mitochondria and endoplasmic reticulum. Most of the sHSPs are believed to help the plants to adapt under stress conditions. During heat stress, some plants can acclimate to high temperature and

accumulate sHSPs up to 1% of total soluble proteins (Hsieh et al. 1992). Accumulation of sHSPs has been reported in endoplasmic reticulum under low temperature (Ukaji et al. 1999) and in chloroplast during oxidative stress (Harndahl et al. 1999). The sHSPs have also been detected in plant organs such as maturing pollen grains, developing embryos (Wehmeyer et al. 1996), growing fruits (Sabehat et al. 1996) and germinating seeds (Arranco et al. 1997).

Experimental results over a period of 20 years have shown that almost all the high molecular weight HSPs act as molecular chaperones *in vitro* and *in vivo* (Vierling 1991). Molecular chaperones are able to help the newly synthesized peptides to fold into a correct configuration, prevent protein from denaturation at high temperature, help denatured proteins to recover their original active configuration and facilitate the passage of signal peptide-processed proteins through cell compartment membranes. Recently, some important experiments also have proved the chaperone activities of sHSPs. Cytosolic I and II sHSPs were found to exhibit an ATP-independent molecular chaperone function *in vitro* (Lee et al. 1995, Yeh et al. 1995, Collade et al. 1997, Helm et al. 1997). In addition, the *Arabidopsis* cell, transformed by the rice cytosolic I sHSP gene, showed a more efficient ability to prevent luciferase from thermo-denaturation and to accelerate the renaturation of denatured luciferase *in vivo* (Forreiter et al. 1997). These results suggested that cytosolic I sHSPs also exhibit a molecular chaperone activity *in vivo* and can contribute to the heat tolerance of plants.

As an important organelle in plant cells, mitochondria perform many essential functions. The structural breakdown and any abnormality of the metabolic activities of the mitochondria at high temperature affect cell viability. Therefore, the capability of mitochondria to tolerate heat has a great impact on the whole cell activity and survival. Since heat-stressed plants accumulate much more MT-sHSPs than HSP60 and HSP70 (Vierling 1991, Lenne and Douce 1994, Lund et al. 1998) and the accumulation of MT-sHSPs is synchronized with the enhancement of the heat tolerance of plant mitochondria (Chou et al. 1989), it is suggested that MT-sHSPs play a major role in the heat tolerance of plant mitochondria. However, still little is known about the cellular functions of MT-sHSP in heat tolerance of plants.

We aimed to clone mitochondrial sHSP cDNA from tomato leaves, evaluate the transcription of the mitochondria-sHSP gene at various temperatures and assay the molecular chaperone activity of mitochondria-sHSPs *in vitro*. We are also analyzing the function of MT-sHSP *in vivo*, especially in reproductive organs.

Results and Discussion

Cloning and expression analysis of LeHSP23.8 gene

Poly (A)⁺ RNA was purified from tomato leaves treated at 40°C for 6 h. A cDNA library was constructed with ZAP-cDNA/Gigapack Cloning Kit (Stratagene). PCR-amplified fragment, which encoded the tomato MT-sHSP gene conserved region, was used as a probe. The longest clone, with an insert of about 0.8-kb, was sequenced and designated LeHSP23.8. Its DDBJ accession number is AB017134. The complete nucleotide sequence of LeHSP23.8 and the amino acid sequence translated for the open reading frame (ORF) are shown in Fig.1. The whole sequence of the LeHSP23.8 gene is 827 nucleotides. The ORF of LeHSP23.8 begins with ATG at the 50th base and ends

Fig. 1. Nucleotide sequence of LeHSP23.8 cDNA and deduced amino acid sequence of LeHSP23.8. A putative pre-sequence targeting of protein LeHSP23.8 into mitochondria is underlined. The nucleotide sequence reported here appeared in the Genbank, EMBL and DDBJ Nucleotide Sequence Databases under the accession number AB017134.

with TGA at the 680th base. Since the length of the LeHSP23.8 cDNA agreed well with the estimated size of the mRNA (see Fig. 3), the clone LeHSP23.8 cDNA was considered to be a complete sequence. The deduced molecular weight of the precursor protein was 23.8 kDa. By using on-line PSORT software, designed according to the method reported by Gavel and Heijine (1990), the probable subcellular compartmentation of LeHSP23.8 protein was predicted. A putative pre-sequence targeting of protein LeHSP23.8 into mitochondria was detected by PSORT. The pre-sequence consisted of 31 N-terminal amino acids of the LeHSP23.8 protein.

The amino acid sequence alignment between the LeHSP23.8 protein and other reported MT-sHSP proteins showed two consensus blocks, both of which were located at the C-terminus of proteins and represented the basic character of the MT-sHSP family (Fig. 2). Another amino acid sequence alignment between the LeHSP23.8 protein and the three sHSPs of tomato (Cytosolic-I, Cytosolic-II and chloroplast-sHSP) revealed that two typical motifs of sHSPs, P---GVL--- and PGL---E---, are present in the consensus blocks (data not shown). These two motifs widely occur in

Fig. 2. Alignment of LeHSP23.8 with reported MT-sHSP amino acid sequences. The boxes indicate the consensus amino acid residues in the sequences.

sHSPs from various organisms (Waters et al. 1996).

Southern-blot analysis revealed the existence of a distinct LeHSP23.8 gene in the tomato genome. The genomic DNA blots probed with LeHSP23.8 showed that only one band was detected on each lane (data not shown). The signals of southern blots suggested that only a single copy of the LeHSP23.8 gene occurs in tomato genomic DNA.

Heat induction of MT-sHSP mRNA in leaves was confirmed by northern-blot analysis. The threshold temperature was around 36°C (Fig. 3). Expression of

Fig. 3. Northern-blot analysis of temperature-dependent LeHSP23.8 mRNA accumulation. Lane 1: tomato plant grown at 25°C (control), lanes 2-5: tomato plants treated at 28°C, 32°C, 36°C and 40°C for 2 h, respectively.

MT-sHSP mRNA in flowers was compared with other sHSPs (Class I-, Class II-, ER-). Although all the investigated sHSPs' mRNA were expressed at 40°C, the peak of MT-sHSP gene expression was the earliest (Fig. 4). The MT-sHSP mRNA showed a very sensitive response to change of temperature. This fact suggests the presence of sensitive heat sensor(s) and systems of feedback regulation for MT-sHSP in the tomato cells.

Flowers on the flowering day were subjected to the *in situ* hybridization analysis. The plants were incubated in the growth chamber at 32°C or 40°C, for the detection of MT- and ER-sHSP mRNA, respectively. On the day of flowering, sHSP genes were not expressed in pollen, but were expressed specifically in the female organs (type MT in stigma and ovule, and type ER in ovule, respectively) (data not shown). No expression of MT- and ER-sHSP genes in pollen suggested one of the reasons why the male organ is more sensitive to heat stress than female organs.

Fig. 4. Northern-blot analysis of heat-induced sHSP genes in tomato flower. Tomato plants grown in the greenhouse were transferred to the growth chamber on the day of flowering, then incubated at 25°C or 40°C. The flowers were collected 0 min to 48 hr after the incubation. Panel MT, ER, Class I, Class II shows the expression of the genes for MT-, ER-, Class I- and Class II-sHSP, respectively.

Characterization of the molecular chaperone activity of tomato LeHSP23.8 *in vitro*

The recombinant LeHSP23.8 and citrate synthase (CS) were used for the *in vitro* assay of the molecular chaperone activity of LeHSP23.8 according to a standard experimental procedure (Lee, 1995). A very high level of activity of molecular chaperone was observed with LeHSP23.8. When the recombinant LeHSP23.8 was mixed with CS denatured by guanidine hydrochloride, the activity of CS was recovered gradually. After 60 min of incubation, 40% of the native CS activity was recovered. This value was two times higher than that of the control experiment in which LeHSP23.8 was replaced by lysozyme (Fig. 5A). In another experiment, recombinant LeHSP23.8 protected CS from thermal inactivation and also promoted the renaturation of thermally inactivated CS. The loss of CS activity was relatively slow when CS was incubated with recombinant LeHSP23.8 at 38°C. After 60 min incubation at 38°C, the remaining activity of CS was 39%, which was two times that for the control experiment with lysozyme. Furthermore, when the incubation temperature was shifted to 22°C, a rapid renaturation of thermal-denatured CS was observed within 10 min, and 90% of CS activity was recovered (Fig. 5B). The molecular chaperone efficiency of recombinant LeHSP23.8 protein in promoting the renaturation of thermally denatured CS was higher than that in promoting the renaturation of chemically denatured CS. These results were consistent with the

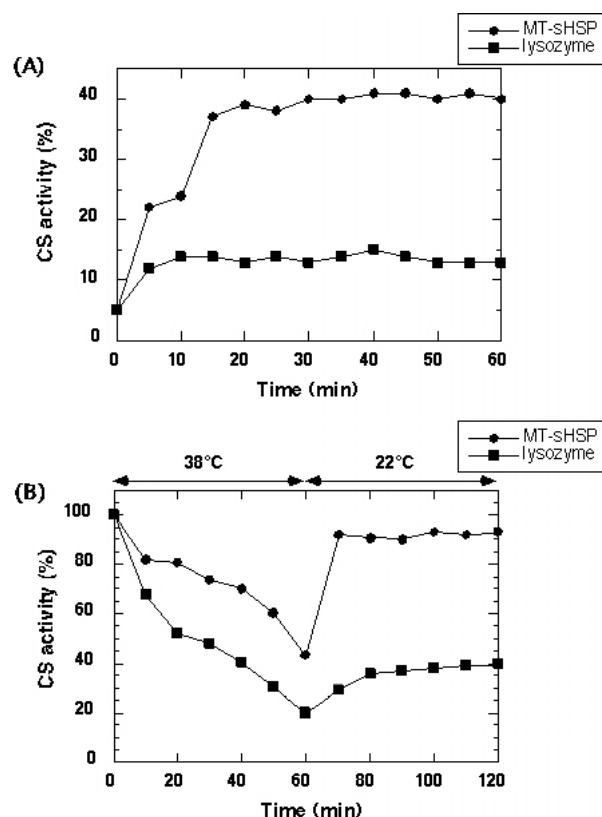

Fig. 5. (A) Effect of LeHSP23.8 protein on the renaturation of chemically denatured citrate synthase (CS). CS (15 μM) was denatured in 6 M guanidine hydrochloride for 120 min and then diluted 100-fold into a solution supplemented with 150 nM lysozyme () or with 1.8 mM recombinant LeHSP23.8 (). (B) Effect of recombinant LeHSP23.8 on the thermal inactivation of CS. CS (150 nM) was incubated in the presence of 150 nM lysozyme () or 1.8 μM recombinant LeHSP23.8 () at 38°C for 60 min and then at 22°C.

observations made by Ehrnsperger et al. (1997). It is suggested that sHSPs can prevent the irreversible aggregation of CS units due to thermal treatment, but sHSP does not play an important role in the renaturation of the denatured protein because sHSPs only provide unspecific intermediate surfaces for substrate proteins (Ehrnsperger et al. 1997).

Partially purified mitochondria fraction from MT-sHSP transgenic tobacco and endogenous Cytochrome C oxidase were also used for another *in vitro* assay. The mitochondria fraction from MT-sHSP transgenic tobacco showed much higher Cytochrome C oxidase activity than mitochondria fraction from control tobacco under higher temperatures.

Heat-stress response of MT-sHSP in transgenic tobacco

Successful pollination and fertilization are absolute requirements for sexual reproduction in higher plants

(Wolters-Arts et al. 1998). Heat stress affects plant reproduction by affecting pollen fertility (Weever et al. 1985, Suzuki et al. 1999) and viability (Weever and Timm 1989, Shivana and Cresti 1989, Shivana et al. 1991). The effect of high temperature on pollen response has been reported in connection with the synthesis of heat shock proteins (Xio and Mascarenhas 1985, Frova et al. 1987, Herpen et al. 1988, Frankis and Grayson 1990). However, there is no report about the role of Mt-sHSP in pollen germination.

Western blotting analysis of leaf proteins showed a distinct protein band of MT-sHSP of 23 kDa molecular size in LeHSP23.8 transgenic lines MT-a, MT-d and MT-e but the band could not be detected in non-transgenic cultivar SR1 and vector transgenic pBI grown under favorable growth conditions (28/22°C, day/night). However, exposure of pBI tobacco to 32°C and 37°C for 48 hr induced MT-sHSP production. Much more expression of MT-sHSP was observed at 37°C (Fig. 6).

MT-sHSP was also expressed in both flowers and pollen of transgenic lines MT-a and MT-d at 28°C but could not be detected in pBI. The heat stress of 37°C for 48 hr was unable to induce MT-sHSP in pollen grains of pBI, which was overexpressed in the transgenic lines (Fig. 7), indicating a possible role of MT-sHSP in heat tolerance during plant reproduction. We confirmed this observation by testing pollen viability under *in vitro* and *in vivo* heat-stress conditions.

Tobacco flowers were collected from the plants cultivated in a greenhouse (28/22°C, day/night) and then treated to heat stress. Treatment of isolated flowers for one hour at 45°C did not affect *in vitro* pollen

Fig. 6. Heat induction of MT-sHSP in transgenic tobacco leaves was analyzed by western blotting. Lanes 1-5 were protein analysis in leaves collected from the greenhouse (28/22°C day/night temperature and natural sunlight). Plants of pBI and MT-a were treated at 25/25(T1), 32/25(T2) and 37/25(T3)C, day/night temperature with 14/10-hr day/night cycle for 48 hr.

germination both in MT-a and pBI at 25°C. Pollen germination was completely inhibited at 40°C and 45°C in pBI, although pollen from MT-a flowers showed some germinability (Table 1).

Fig. 7. Heat induction of MT-sHSP in transgenic tobacco pollen was analyzed by western blotting. Plants of pBI and MT-a were treated at 25/25(T1) or 37/25(T3)°C, day/night temperature with 14/10-hr day/night cycle for 48 hr.

Table 1

Effect of incubation temperature on pollen germination (PG, %), bursting (PB, %) and tube length (PTL, μm) in transgenic tobacco. The pollen samples were collected from heat-treated flowers for one hour at different temperatures. In the treatment column, the first figure indicates flower treatment temperature and the second figure denotes the incubation temperature

Plant type		Treatment (°C)			
		25-25	45-25	40-45	45-45
pBI	PG	83.2	83.5	0.0	0.0
	PB	3.4	7.3	39.7	89.9
	PTL	718.1	269.3	0.0	0.0
MT-a	PG	91.9	86.9	4.0	2.4
	PB	5.0	4.4	31.5	83.5
	PTL	652.8	338.6	18.5	30.6

We are also trying to analyze the *in vivo* function of MT-sHSP. Further studies exclusively on mitochondrial respiration and respiratory enzymes of transgenic tobacco flowers will be helpful for a better understanding of the role of MT-sHSP in plant sexual reproduction. The studies need to be extended to other commercial crops.

Summary

1. Full-length cDNA of mitochondria-located small heat shock protein (LeHSP23.8: accession number AB017134) was cloned from tomato (*Lycopersicon esculentum* Mill.). The deduced protein precursor with a calculated molecular weight of 23.8 kDa was predicted to target mitochondria.
2. MT-sHSP gene was the quickest responding gene among the sHSPs in flower. This finding suggests that mitochondria should be the most sensitive organelle to heat stress.
3. MT-sHSP showed the molecular chaperone activity *in vitro*. The recombinant LeHSP23.8 was able to protect citrate synthase from thermal inactivation and promoted the renaturation of thermally or chemically denatured citrate synthase. Overexpression of MT-sHSP in mitochondria made some enzymes there heat tolerant.
4. Both MT- and ER-sHSP were not expressed in pollen but in female organs under the heat stressed conditions. *In vitro* pollen germination was completely inhibited at 40°C and 45°C in control tobacco, although pollen germination of MT-sHSP overexpressed flowers was observed. Expression of MT-sHSP in pollen made pollen more tolerant to heat stress.
5. We plan to confirm the contribution of MT-sHSP to heat tolerance by *in vivo* experiments.

Abstract

Salinity stress negatively impacts agricultural yield throughout the world affecting production whether it is for subsistence or economic gain. The plant response to salinity consists of numerous processes that must function in coordination to alleviate both cellular hyperosmolarity and ion disequilibrium. In addition, crop plants must be capable of satisfactory biomass production in a saline environment (yield stability). Tolerance and yield stability are complex genetic traits that are difficult to establish in crops since salt stress may occur as a catastrophic episode, be imposed continuously or intermittently, or become gradually more severe, and at any stage during development. However, cell biology and molecular genetics research is providing new insight into the plant response to salinity and is identifying genetic determinants that effect salt tolerance. Recent confirmation that many salt tolerance determinants are ubiquitous in plants has led to the use of genetic models, like *Arabidopsis thaliana*, to further dissect the plant salt stress response. Since many of the most fundamental salt tolerance determinants are those that mediate cellular ion homeostasis, this review will focus primarily on the functional essentiality of ion homeostasis mechanisms in plant salt tolerance. The transport systems that facilitate cellular capacity to utilize Na^+ for osmotic adjustment and growth and the role of the Salt-Overly-Sensitive (SOS) signal transduction pathway in the regulation of ion homeostasis and salt tolerance will be particularly emphasized. A perspective will be presented that integrates cellular based stress signaling and ion homeostasis mechanisms into a functional paradigm for whole plants and defines biotechnology strategies for enhancing salt tolerance of crops.

Keywords: Salt adaptation, ion homeostasis, transport determinants, stress signaling

Introduction

Soil salinity is a major constraint to food production because it limits crop yield and restricts use of land previously uncultivated. The United Nations Environment Program estimates that approximately 20% of agricultural land and 50% of cropland in the world is salt-stressed (Flowers and Yeo, 1995). Natural boundaries imposed by soil salinity also limit the caloric and the nutritional potential of agricultural production. These constraints are most acute in areas of the world where food distribution is problematic because of insufficient infrastructure or political instability. Water and soil management practices have facilitated agricultural production on soils marginalized by salinity but additional gain by these approaches seems problematic. On the horizon are crop improvement strategies that are based on the use of molecular marker techniques and biotechnology, and can be used in

conjunction with traditional breeding efforts (Ribaut and Hoisington, 1998). DNA markers should enhance the recovery rate of the isogenic recurrent genome after hybridisation and facilitate the introgression of quantitative trait loci necessary to increase stress tolerance. Molecular marker techniques were used successfully to transfer alleles of interest from wild relatives into commercial cultivars (Tanksley and McCouch, 1997).

The basic resources for biotechnology are genetic determinants of salt tolerance and yield stability. Implementation of biotechnology strategies to achieve this goal requires that substantial research effort be focused to on identify salt tolerance effectors and the regulatory components that control these during the stress episode (Hasegawa et al., 2000b). Further knowledge obtained about these stress tolerance determinants will be additional resource information for the dissection of the plant response to salinity, which

will reveal how plants sense salt stress, transduce signals to mediate a defensive response and define the signal pathway outputs or effectors that accomplish the processes required for stress survival and alleviation, and steady-state growth in the saline environment. Molecular genetic and plant transformation advances have made it feasible to assess biotechnological strategies based on activated signal cascades, engineered biosynthetic pathways, targeted gene or protein expression or alteration of the natural stress responsiveness of genes for development of salt tolerant crops (Hasegawa et al., 2000b; Zhu, 2001).

The molecular identities of key ion transport systems that are fundamental to plant salt tolerance are now known (Hasegawa et al., 2000b). More recently, the SOS salt stress signalling pathway was determined to have a pivotal regulatory function in salt tolerance, fundamental of which is the control of ion homeostasis (Hasegawa et al., 2000b; Sanders, 2000; Zhu, 2000). This review will summarize research on plant ion homeostasis in saline environments and present a model that integrates current understanding of salt stress sensing, which leads to the activation of the SOS pathway and the regulation of ion transport systems that facilitate ion homeostasis.

Genetic Diversity for Salt Tolerance in Plants

The extensive genetic diversity for salt tolerance that exists in plant taxa is distributed over numerous genera (Flowers et al., 1986; Greenway and Munns, 1980). Most crops are salt sensitive or hypersensitive plants (glycophytes) in contrast to halophytes, which are native flora of saline environments. Some halophytes have the capacity to accommodate extreme salinity because of very special anatomical and morphological adaptations or avoidance mechanisms (Flowers et al., 1986). However, these are rather unique characteristics for which the genes are not likely to be introgressed easily into crop plants.

Research of recent decades has established that most halophytes and glycophytes tolerate salinity by rather similar strategies often using analogous tactical processes (Hasegawa et al., 2000b). The cytotoxic ions in saline environments, typically Na^+ and Cl^- , are compartmentalized into the vacuole and used as osmotic solutes (Blumwald et al., 2000; Niu et al., 1995). It follows then that many of the molecular entities that mediate ion homeostasis and salt stress signaling are similar in all plants (Hasegawa et al., 2000b). In the fact, the paradigm for ion homeostasis that facilitates plant salt tolerance resembles that described for yeast (Bressan et al., 1998; Serrano et al., 1999). The fact that cellular ion homeostasis is controlled and effected by common molecular entities made it feasible to use of

model genetic organismal systems for the dissection of the plant salt stress response (Bressan et al., 1998; Serrano et al., 1999; Hasegawa et al., 2000a; Sanders, 2000; Zhu, 2000; 2001). Research on the plant genetic model *Arabidopsis* has increased greatly our understanding of how cellular salt tolerance mechanisms are integrated and coordinated in an organismal context, and are linked to essential phenological adaptations. Since *Arabidopsis* is a glycophyte, a salt tolerant genetic model will be required to delineate if salt tolerance is affected most by form or function of genes or more by differences in the expression of common genes due either to transcriptional or post-transcriptional control (Zhu, 2001).

Cellular Mechanisms of Salt Stress Survival, Recovery and Growth

High salinity causes hyperosmotic stress and ion disequilibrium that produce secondary effects or pathologies (Hasegawa et al., 2000b; Zhu, 2001). Fundamentally, plants cope by either avoiding or tolerating salt stress. That is plants are either dormant during the salt episode or there must be cellular adjust to tolerate the saline environment. Tolerance mechanisms can be categorized as those that function to minimize osmotic stress or ion disequilibrium or alleviate the consequent secondary effects caused by these stresses. The chemical potential of the saline solution initially establishes a water potential imbalance between the apoplast and symplast that leads to turgor decrease, which if severe enough can cause growth reduction (Bohnert et al., 1995). Growth cessation occurs when turgor is reduced below the yield threshold of the cell wall. Cellular dehydration begins when the water potential difference is greater than can be compensated for by turgor loss (Taiz and Zeiger, 1998).

The cellular response to turgor reduction is osmotic adjustment. The cytosolic and organellar machinery of glycophytes and halophytes is equivalently Na^+ and Cl^- sensitive; so osmotic adjustment is achieved in these compartments by accumulation of compatible osmolytes and osmoprotectants (Bohnert, 1995; Bohnert and Jensen, 1996). However, Na^+ and Cl^- are energetically efficient osmolytes for osmotic adjustment and are compartmentalized into the vacuole to minimize cytotoxicity (Blumwald et al., 2000; Niu et al., 1995). Since plant cell growth occurs primarily because of directional expansion mediated by an increase in vacuolar volume, compartmentalization of Na^+ and Cl^- facilitates osmotic adjustment that is essential for cellular development.

Movement of ions into the vacuole might occur directly from the apoplast into the vacuole through

membrane vesiculation or a cytological process that juxtaposes the plasma membrane to the tonoplast (Hasegawa et al. 2000b). Then compartmentalization could be achieved with minimal or no exposure of the cytosol to toxic ions. However, it is not clear presently the extent to which processes like these contribute to vacuolar ion compartmentalization. The bulk of Na^+ and Cl^- movement from the apoplast to the vacuole likely is mediated through ion transport systems located in the plasma membrane and tonoplast. Presumably, tight coordinate regulation of these ion transport systems is required in order to control net influx across the plasma membrane and vacuolar compartmentalization. The SOS signal pathway is a pivotal regulator of, at least some, key transport systems required for ion homeostasis (Hasegawa et al., 2000a; Sanders, 2000; Zhu, 2000).

Osmolytes and Osmoprotectants

As indicated previously, salt tolerance requires that compatible solutes accumulate in the cytosol and organelles where these function in osmotic adjustment and osmoprotection (Rhodes and Hanson, 1993). Some compatible osmolytes are essential elemental ions, such as K^+ , but the majority are organic solutes. Compatible solute accumulation as a response to osmotic stress is an ubiquitous process in organisms as diverse as bacteria to plants and animals. However, the solutes that accumulate vary with the organism and even between plant species. A major category of organic osmotic solutes consists of simple sugars (mainly fructose and glucose), sugar alcohols (glycerol and methylated inositols) and complex sugars (trehalose, raffinose and fructans) (Bohnert and Jensen, 1996). Others include quaternary amino acid derivatives (proline, glycine betaine, β -alanine betaine, proline betaine), tertiary amines (1,4,5,6-tetrahydro-2-methyl-4-carboxyl pyrimidine), and sulfonium compounds (choline *o*-sulfate, dimethyl sulfonium propionate) (Nuccio et al., 1999). Many organic osmolytes are presumed to be osmoprotectants, as their levels of accumulation are insufficient to facilitate osmotic adjustment. Glycine betaine preserves thylakoid and plasma membrane integrity after exposure to saline solutions or to freezing or high temperatures (Rhodes and Hanson, 1993). Furthermore, many of the osmoprotectants enhance stress tolerance of plants when expressed as transgene products (Bohnert and Jensen, 1996; Zhu, 2001). An adaptive biochemical function of osmoprotectants is the scavenging of reactive oxygen species that are by-products of hyperosmotic and ionic stresses and cause membrane dysfunction and cell death (Bohnert and Jensen, 1996).

A common feature of compatible solutes is that these

compounds can accumulate to high levels without disturbing intracellular biochemistry (Bohnert and Jensen, 1996). Compatible solutes have the capacity to persevere the activity of enzymes that are in saline solutions. These compounds have minimal effect on pH or charge balance of the cytosol or lumenal compartments of organelles. The synthesis of compatible osmolytes is often achieved by diversion of basic intermediary metabolites into unique biochemical reactions. Often, stress triggers this metabolic diversion. For example, higher plants synthesize glycine betaine from choline by two reactions that are catalyzed in sequence by choline monooxygenase (CMO) and betaine aldehyde dehydrogenase (BADH) (Rhodes and Hanson, 1993). Pinitol is synthesized from myo-inositol by the sequential catalysis of inositol-*o*-methyltransferase and ononitol epimerase (Bohnert and Jensen, 1996).

Ion Homeostasis - Transport Determinants and Their Regulation

Since NaCl is the principal soil salinity stress, a research focus has been the transport systems that are involved in utilization of Na^+ as an osmotic solute (Blumwald et al., 2000; Hasegawa et al., 2000b; Niu et al., 1995). Research of more than 30 years previously, established that intracellular Na^+ homeostasis and salt tolerance are modulated by Ca^{2+} and high $[\text{Na}^+]_{\text{ext}}$ negatively affects K^+ acquisition (Rains and Epstein, 1967). Na^+ competes with K^+ for uptake through common transport systems and does this effectively since the $[\text{Na}^+]_{\text{ext}}$ in saline environments is usually considerably greater than $[\text{K}^+]_{\text{ext}}$. Ca^{2+} enhances K^+/Na^+ selective intracellular accumulation (Maathuis et al., 1996; Rains and Epstein, 1967).

Research of the last decade has defined many of the molecular entities that mediate Na^+ and K^+ homeostasis and given insight into the function of Ca^{2+} in the regulation of these transport systems. Recently, the SOS stress-signaling pathway was identified to be a pivotal regulator of plant ion homeostasis and salt tolerance (Hasegawa et al., 2000b; Sanders, 2000). This signaling pathway functionally resembles the yeast calcineurin cascade that controls Na^+ influx and efflux across the plasma membrane (Bressan et al., 1998). Expression of an activated form of calcineurin in yeast or plants enhances salt tolerance further implicating the functional similarity between the calcineurin and the SOS pathways (Mendoza et al., 1996; Pardo et al., 1998). A diagram of the relevant transporters and Ca^{2+} -dependent stress signaling pathway involved in Na^+ homeostasis is shown in Figure 1. Little is known about the mechanistic entities that are responsible for Cl^- transport or the regulation of Cl^- homeostasis (Hedrich, 1994).

Salt Stress Signaling that Mediates Na⁺ Homeostasis

Fig. 1. Salt stress-induced, Ca²⁺-dependent signalling that mediates Na⁺ homeostasis and salt tolerance.

SOS1, plasma membrane Na⁺/H⁺ antiporter; SOS2, serine/threonine kinase; SOS3, Ca²⁺ binding protein; AHA, plasma membrane H⁺-ATPase; ACA, plasma/tonoplast membrane Ca²⁺-ATPase; KUP1/TRH1, high-affinity K⁺-H⁺ co-transporter; AKT1, K_{in} channel; NSCC, non selective cation channel; CAX1 or 2, Ca²⁺/H⁺ antiporter; NHX1, 2 or 5, endomembrane Na⁺/H⁺ antiporter; red - positive regulation, blue - negative regulation, yellow - protein activation

Ion Transport Systems that Mediate Na⁺ Homeostasis

H⁺-Pumps. H⁺ pumps in the plasma membrane and tonoplast energize solute transport necessary to compartmentalize cytotoxic ions away from the cytoplasm and to facilitate the function of ions as signal determinants (Maeshima, 2000; Maeshima, 2001; Morsomme and Boutry, 2000; Ratajczak, 2000). That is these pumps provide the driving force (H⁺ electrochemical potential) for secondary active transport and function to establish membrane potential gradients that facilitate electrophoretic ion flux (Figure 1). The plasma membrane localized H⁺ pump is a P-type ATPase and is primarily responsible for the large (pH and membrane potential gradient across this membrane (Morsomme and Boutry, 2000). A vacuolar type H⁺-ATPase and a vacuolar pyrophosphatase generate the ΔpH and membrane potential across the tonoplast (Drozdowicz and Rea, 2001; Maeshima, 2001). The activity of these H⁺ pumps is increased by salt treatment and induced gene expression may account for some of the upregulation (Hasegawa et al., 2000b; Maeshima, 2001).

Recently, the plasma membrane H⁺-ATPase was confirmed as a salt tolerance determinant based on analyses of phenotypes caused by the semi-dominant *aha4-1* mutation (Vitart et al., 2001). The mutation to *AHA4*, which is expressed predominantly in the roots,

causes a reduction in root and shoot growth (relative to wild type) of plants that are grown on medium supplemented with 75 mM NaCl. Decreased root length of salt treated *aha4-1* plants is due to reduce cell length. In NaCl supplemented medium, leaves of *aha4-1* plants accumulate substantially more Na⁺ and less K⁺ than those of wild type. It is postulated that *AHA4* functions in the control of Na⁺ flux across the endodermis (Vitart et al., 2001).

Na⁺ Influx and Efflux Across the Plasma Membrane.

Recently, much insight has been gained about Na⁺ transport systems that are involved in net flux of the cation across the plasma membrane (Amtmann and Sanders, 1999; Blumwald et al., 2000; Hasegawa et al., 2000b). Transport systems with greater selectivity for K⁺ are presumed to facilitate Na⁺ "leakage" into cells. Specifically, Na⁺ is a competitor for uptake through plasma membrane K⁺ inward rectifying channels, such as those that are in the Shaker type family, e.g. AKT1 (Schachtman, 2000). K⁺ outward rectifying channels also may facilitate Na⁺ influx (Schachtman, 2000). The high affinity K transporter (HKT) from wheat and low affinity cation transporter (LCT) also may be responsible for Na⁺ influx across the plasma membrane (Schachtman, 2000; Amtmann and Sanders, 1999; Blumwald et al., 2000). Both HKT and LCT transport Na⁺ when expressed in heterologous systems, providing evidence of their function in Na⁺ uptake. Wheat HKT1 is a Na⁺-H⁺-dependent K⁺ transporter. Modifications to HKT1 that enhance K⁺ transport also reduce Na⁺ influx and enhance salt tolerance further establishing that Na⁺ conductance occurs through this protein (Rubio et al., 1999). Physiological data also implicate nonselective cation (NSC) channels in Na⁺ influx (Amtmann and Sanders, 1999).

Recently, the properties of HKT proteins from *Arabidopsis* (Kato et al., 2001; Uozumi et al., 2000), rice (Horie et al., 2001) and eucalyptus (Fairbairn et al., 2000) have been characterized. AtHKT1 is the only member of the *Arabidopsis* gene family while both rice and eucalyptus have at least two genes. AtHKT1 expression increases NaCl sensitivity of a yeast strain deleted for the plasma membrane Na⁺ efflux system (*ena1-4Δ*) but does not suppress the K⁺ deficiency of *trk1 trk2* mutant cells that have attenuated uptake of this essential cation. However, AtHKT1 expression does suppress the K⁺ deficient phenotype of an *E. coli* mutant for which acquisition of the cation is disrupted. Electrophysiological data indicate that AtHKT1 expressed in *Xenopus* oocytes specifically transports Na⁺ and conductance is K⁺, H⁺ and voltage independent (Uozumi et al., 2000).

The *in planta* function of AtHKT1 as an effector of Na⁺ influx has been confirmed recently (Rus et al., 2001). T-DNA insertional and deletion mutations of AtHKT1 were identified in a screen for suppressors of

NaCl sensitivity of the *sos3-1* mutant (Liu and Zhu, 1997; Rus et al., 2001). Suppression of *sos3-1* NaCl sensitivity is correlated with reduced cellular accumulation of Na⁺ and capacity to maintain [K⁺]_{int}. Together, these results establish that AtHKT1 controls Na⁺ influx into plants. It is likely that AtHKT1 is a Na⁺ influx system but its function as a regulator of Na⁺ and K⁺ influx systems cannot be precluded. Since the transcript is expressed predominantly in the roots, AtHKT1 most probably functions in the control of Na⁺ into the xylem for export to the shoot (Rus et al., 2001; Uozumi et al., 2000).

Rice (*Oryza sativa* L. Indica) OsHKT1 and OsHKT2 were identified based on sequence similarity with wheat HKT (Horie et al., 2001). *OsHKT1* and 2 transcripts accumulate in response to low K⁺ but their steady-state abundance is reduced by treatment with 30 mM NaCl. Yeast complementation and *Xenopus* oocyte expression data indicate that OsHKT1 functions as a Na⁺ influx system like AtHKT1 but OsHKT2 is a Na⁺/K⁺ symporter. The two *Eucalyptus camaldulensis* HKT1 (EcHKT1 and 2) orthologs have similar transport characteristics as the wheat protein (Fairbairn et al., 2000). Interestingly, activation of these proteins occurs in response to hypotonic treatment, implicating an osmosensing capacity.

The recent identification of *sos3-1 hkt1* double mutations in *Arabidopsis* has confirmed the existence of a Na⁺ entry system(s) different than HKT1 that functions *in planta*. Reduction in [Ca]_{ext} to μM concentrations abrogates the capacity for an *hkt1* knockout mutation to suppress Na⁺ sensitivity of *sos3-1*. These results indicate the presence of a Ca²⁺-inhibited Na⁺ influx system. For the last several years, physiological research has indicated the presence of Ca²⁺ insensitive and sensitive Na⁺ conductance in analysis of plant cell patches (Amtmann and Sanders, 1999). The Ca²⁺ sensitive component of Na⁺ uptake recently has been attributed to NSC channels (Davenport and Tester, 2000). The combined electrophysiological and *in planta* mutant dissection data indicate that there are least two Na⁺ influx systems, one whose activity is directly inhibited by Ca²⁺ and the other HKT, for which genetic evidence indicates may be regulated negatively by the SOS signal pathway (Figure 1).

Energy-dependent Na⁺ transport across the plasma membrane of plant cells is mediated by the secondary active Na⁺/H⁺ antiporter SOS1. Phylogenetically, SOS1 is similar to SOD2 of *Saccharomyces pombe*, NHA1 of *S. cerevisiae* and NhaA and NhaP of *Pseudomonas aeruginosa* (Shi et al., 2000). The SOS1 protein contains a large C-terminal domain (1162 amino acid) that distinguishes it from other members of the phylogenetic family. The SOS1 antiporter is distantly related to the plant endomembrane NHX type of antiporters. *SOS1* gene expression is upregulated by

NaCl stress and this is dependent on other components of the SOS signal pathway (see below).

Na⁺ Vacuolar Compartmentalization. A Na⁺/H⁺ antiporter that is energized by the ΔpH across the tonoplast facilitates vacuolar compartmentalization of the cation. The *Arabidopsis AtNHX1* was isolated by functional genetic complementation of a yeast mutant defected for the endosomal Na⁺/H⁺ antiporter yeast (ScNHX1) and has sequence similarity to mammalian NHE transporters (Apse et al., 1999; Gaxiola et al., 1999; Quintero et al., 2000). Transgenic *Arabidopsis* and tomato plants that over express AtNHX1 accumulate abundant quantities of the transporter in the tonoplast and exhibit substantially enhanced salt tolerance (Apse et al., 1999; Quintero et al., 2000; Zhang and Blumwald, 2001). These results implicate the pivotal function of the AtNHX family in vacuolar compartmentalization of Na⁺.

Predicted amino acid sequence and topological similarities to AtNHX1 led to the categorization of six loci in *Arabidopsis* as *AtNHX* gene family members (Yokoi et al., submitted). Phylogenetically, the proteins can be categorized into two subgroups, one containing four (AtNHX1-4) and the other two (AtNHX5 and 6) members. AtNHX2 and AtNHX5 expression suppresses the Na⁺/Li⁺ sensitive phenotype of a salt sensitive yeast mutant (*enal-4 nha1 nhx1Δ*) indicating that both AtNHX2 and AtNHX5 are orthologous to yeast ScNHX1 and AtNHX1. AtNHX2 suppresses the Na⁺/Li⁺ sensitive phenotype of the yeast mutant to a greater extent than *AtNHX1*. *AtNHX1* and *AtNHX2* are expressed constitutively in shoot and roots. Transcript abundance of *AtNHX1* and *AtNHX2* is induced by hyperosmotic stress (NaCl, sorbitol) and this osmotic response is dependent on the hormone abscisic acid (ABA). NaCl but not ABA induces *AtNHX5* transcript abundance (Yokoi et al., submitted). Steady-state transcript abundance of *AtNHX1*, 2 and 5 is greater in *sos* mutants than wild type Col-0 *gll* indicating that the SOS pathway negatively regulates transcriptional expression of these Na⁺/H⁺ antiporters genes. Yeast complementation and expression profiling data indicate that AtNHX2 and 5, like AtNHX1, are functional salt tolerance determinants. A common hyperosmotic stress signal pathways regulates the expression of *AtNHX1* and 2 but a different cascade controls *AtNHX5* expression. Post-transcriptional mechanisms that control AtNHX antiporter activation are still not known.

Ca²⁺ Signaling and the Activation of the Salt Overly Sensitive (SOS) Signal Transduction Pathway

Jian-Kang Zhu and co-workers identified three genetically linked *Arabidopsis* loci (*SOS1*, *SOS2* and *SOS3*), which are components of a stress-signaling

pathway that controls ion homeostasis and salt tolerance (Hasegawa et al. 2000a; Sanders, 2000; Zhu, 2000; 2001). Genetic analysis of Na^+/Li^+ sensitivity established that *sos1* is epistatic to *sos2* and *sos3* (Zhu, 2000). These *sos* mutants also exhibit a K^+ deficient phenotype in medium supplemented with μM $[\text{K}^+]_{\text{ext}}$ and $[\text{Ca}^{2+}]_{\text{ext}}$. Na^+ and K^+ deficiency of *sos2* and *sos3* is suppressed with mM $[\text{Ca}^{2+}]_{\text{ext}}$ (Zhu et al., 1998). *sos1* exhibits hyperosmotic sensitivity unlike *sos3* and *sos2*. Together, these results indicate that the SOS signaling pathway regulates Na^+ and K^+ homeostasis and is Ca^{2+} activated.

SOS3 encodes a Ca^{2+} binding protein with sequence similarity to the regulatory B subunit of calcineurin (protein phosphatase 2B) and neuronal Ca^{2+} sensors (Ishitani et al., 2000; Liu and Zhu, 1998). Interaction of SOS3 with the SOS2 kinase (Liu et al., 2000) and SOS2 activation is Ca^{2+} dependent (Halfter et al., 2000). The *in planta* function of SOS3 as a salt tolerance determinant is dependent on Ca^{2+} binding and N-myristoylation (Ishitani et al., 2000).

The SOS2 serine/threonine kinase (446 amino acids) has a 267 amino acid N-terminal catalytic domain that is similar in sequence to yeast SNF1 (sucrose nonfermenting) kinase and the mammalian AMPK (AMP-activated protein kinase) (Liu et al., 2000; Zhu, 2000). The kinase activity of SOS2 is essential for its salt tolerance determinant function (Zhu, 2000). The SOS2 C-terminal regulatory domain interacts with the kinase domain to cause autoinhibition. A 21 amino acid motif in the regulatory domain of SOS2 is the site where SOS3 interacts with the kinase and is the autoinhibitory domain of the kinase (Guo et al., 2001). Binding of SOS3 to this motif blocks autoinhibition of SOS2 kinase activity. Deletion of the autoinhibitory domain results in constitutive SOS2 activation, independent of SOS3. Also, a Thr¹⁶⁸ to Asp mutation in the activation loop of the kinase domain constitutively activates SOS2.

Genetic and biochemical evidence indicates that components of the SOS signal pathway function in the hierarchical sequence outlined in Figure 1 (Hasegawa et al., 2000b; Sanders, 2000; Zhu, 2001). Ca^{2+} binds to SOS3, which leads to interaction with SOS2 and activation of the kinase. Among the SOS signal pathway outputs are transport systems that facilitate ion homeostasis. The plasma membrane sited Na^+/H^+ antiporter SOS1 is controlled by the SOS pathway at the transcriptional and post-transcriptional level (Guo et al., 2001; Zhu, 2001). Recently, functional disruption of *AtHKT1* was shown to suppress the salt sensitive phenotype of *sos3-1*, indicating that the SOS pathway negatively controls this Na^+ influx system (Rus et al., 2001). Also, the SOS pathway negatively controls expression of *AtNHX* family members that are implicated as determinants in the salt stress response (Yokoi et al., submitted).

$[\text{Ca}^{2+}]_{\text{ext}}$ enhances salt tolerance and salinity stress elicits a transient $[\text{Ca}^{2+}]_{\text{cyt}}$ increase, from either an internal or external source, that has been implicated in adaptation (Knight et al., 1997, Lauchli, 1990). Data from recent experiments with yeast has provided insight into Ca^{2+} activation of salt stress signaling that controls ion homeostasis and tolerance (Matsumoto et al., 2001). The hyperosmotic component of high salinity induces a short duration (1 min) rise in $[\text{Ca}^{2+}]_{\text{cyt}}$ that is due substantially to influx across the plasma membrane through the Cch1p and Mid1p Ca^{2+} transport system. The transient increase in $[\text{Ca}^{2+}]_{\text{cyt}}$ activates the PP2B phosphatase calcineurin (a key intermediate in salt stress signaling controlling ion homeostasis) leading to the transcription of *ENA1*, which encodes the P-type ATPase that is primarily responsible for Na^+ efflux across the plasma membrane (Nakamura et al., 1993; Mendoza et al., 1994; Matsumoto et al., submitted). The model proposes that the hyperosmotically-induced localized $[\text{Ca}^{2+}]_{\text{cyt}}$ transient activates calmodulin that is tethered to Cch1p-Midp (Elhers et al., 1999; Sanders et al., 1999; Matsumoto et al., submitted). Calmodulin in turn activates signaling through the calcineurin pathway, which mediates ion homeostasis and salt tolerance (Matsumoto et al., submitted). From these results, a paradigm for salt-induced Ca^{2+} signaling and the activation of the SOS pathway can be suggested (Figure 1). Components of the SOS pathway, either SOS3 or upstream elements, might be associated with an osmotically responsive channel through which Ca^{2+} influx could initiate signaling through the pathway.

It is notable that a new elevated $[\text{Ca}^{2+}]_{\text{cyt}}$ steady state is established in yeast cells, that are maintained in medium supplemented with NaCl, after the hyperosmotic induction of the short duration $[\text{Ca}^{2+}]_{\text{cyt}}$ transient (Matsumoto et al., submitted). It is likely that the newly established $[\text{Ca}^{2+}]_{\text{cyt}}$ contributes to cellular capacity for growth in salinity. The vacuolar membrane $\text{H}^+/\text{Ca}^{2+}$ antiporter Vcx1p and endomembrane localized Ca^{2+} -ATPases are pivotal effectors that regulate the amplitude and duration of the $[\text{Ca}^{2+}]_{\text{cyt}}$ transient (Miseta et al., 1999). The $[\text{Ca}^{2+}]_{\text{cyt}}$ steady state established in salt containing medium presumably also involves coordination of channel activation that facilitates influx from external and internal sources and energy dependent transport systems that compartmentalize the divalent cation. It is reasonable to assume that the salt induced $[\text{Ca}^{2+}]_{\text{cyt}}$ transient detected in plant cells (Knight, 1996) and, perhaps, a new $[\text{Ca}^{2+}]_{\text{cyt}}$ steady-state are controlled by the ECA and ACA Ca^{2+} -ATPases and CAX1 and 2 transporters which are orthologs of Vcx1p (Sze et al., 2000). Nevertheless, Ca^{2+} has at least two roles in salt tolerance, a pivotal signaling function in the salt stress response leading to adaptation and a direct inhibitory effect on a Na^+ entry system.

Perspectives

Database analysis indicates that there are at least seven additional SOS2 isoforms (PKS:Protein Kinase S) and six SOS3 isoforms (SCaBPs:SOS3-like Calcium Binding Proteins) of SOS3. Whether these isoforms also are salt tolerance determinants has yet to be elucidated. One can speculate that these proteins have similar signalling intermediate functions as the prototype proteins but in different cell types or at unique stages of development. Perhaps these isoforms are constituents of signal pathways that respond to different inducers but are still components of the plant response to salt stress. Notwithstanding, it is likely that these proteins have both unique and overlapping functions. It is plausible also that some of these isoforms act as negative regulators of SOS signal transduction by physical interaction with the positive effector or competition for substrates required for signalling. Such positive and negative regulation of signal modulation may constitute a "fine tuning" necessary to achieve the appropriate plant response for stress adaptation and yield stability. Further insight regarding these suggestions may establish how the plant salt stress response is coordinated through gene families. The control system probably is even more complicated since other SOS signal pathway intermediates and outputs and other signalling cascades necessary for salt tolerance may exist.

Recent progress in the elucidation of salt stress signalling and effector output determinants that mediate ion homeostasis has uncovered some potential biotechnology tactics that may be used to obtain salt tolerant crop plants, i.e. enhance the yield stability under salinity. Two basic strategies are feasible; regulate the salt stress signal pathway that controls tolerance effectors or modulate effector activity or efficacy. The recent demonstration that a constitutively activated SOS2 kinase can be achieved by deletion of the auto inhibitory domain or by site-specific modifications to the catalytic domain of the protein kinase (Guo et al., 2001) offers an approach to regulate stress signaling that controls ion homeostasis. Constitutive activation of yeast calcineurin in the host or in plants increases salt tolerance by predisposing the plants to survive the stress episode (Mendoza et al., 1996; Pardo et al., 1998). Furthermore, overexpression of AtNHX1 enhances plant salt tolerance, presumably by increasing vacuolar Na⁺ compartmentalization that minimizes the toxic accumulation of the ion in the cytosol and facilitates growth in the saline environment (Apse et al., 1999; Zhang and Blumwald, 2001). Perhaps regulating net Na⁺ influx across the plasma membrane would enhance salt tolerance efficacy achieved by overexpressing the vacuolar antiporter. Control of net Na⁺ flux across the plasma membrane should be achieved by modulating the expression or

activation of SOS1 (Na⁺ efflux) and/or HKT1 (Na⁺ influx). Or, by expressing more efficacious forms of the Na⁺ transport proteins. For example, mutant variant forms of HKT1 transport more K⁺ at the expense of Na⁺ and render greater salt tolerance (Rubio et al., 1999). Promoters that direct tissue and inducer specific regulation of the target genes can condition the expression of the signal intermediates and the effectors. Thus regulation of the numerous salt tolerance determinants can be coordinated for an effective plant response but many of the costs associated with salt tolerance in nature might be minimized because some essential evolutionary necessities can be compensated for by agricultural practices.

Development of transformation methods toward producing transgenic plants with abiotic stress tolerance

Francisco J. L. Aragão

Embrapa Recursos Genéticos e Biotecnologia
PqEB Av. W5 Norte, 70070-900 Brasília, DF, Brazil

Abstract

Several methods have been developed for inserting genetic information into plant cells, such as *Agrobacterium*-mediated systems, direct DNA uptake into protoplasts and particle bombardment (biolistic). Several methodologies are available to transform almost all important crops. However, some systems are still not a routine and do not achieve the frequency of transformation required for obtaining genetically modified plants containing useful traits, such as abiotic stress tolerance. Considerable advances have been made in the methodologies to transform plants, mainly using *Agrobacterium* and the biolistic process. The biolistic process has been responsible for producing the majority of the new transgenic varieties that have reached the market. The apical region of embryonic axes has been an obvious target for the development of systems, by particle bombardment of meristematic cells. Based on the introduction of genes into the meristematic cells by particle bombardment, we developed an efficient and reproducible system to achieve routinely transgenic plants of several species, such as dry bean, soybean and cotton.

Keywords: transgenic plants, genetic engineering, soybean, dry bean, cotton, plant transformation

Introduction

The use of genetic engineering techniques for introducing genes responsible for agronomic characteristics may facilitate the development of new varieties. In fact, the last two decades have seen significant developments in plant transformation technology, and many transgenic crop plants have now been released for commercial production. Advances in the technology have been due to the development of a range of *Agrobacterium*-mediated and direct DNA delivery techniques, along with appropriate tissue culture techniques for regenerating whole plants from plant cells or tissues in a large number of species.

To obtain a transgenic plant, methods of introducing the exogenous DNA into the vegetable tissue and regenerating the whole plant from such genetically transformed tissue are required. Depending upon the species to be transformed, various types of tissue have been used. The meristematic tissue has been preferably employed in various transformation processes, primarily

due to the ease of regeneration of a plant from this type of tissue. Several methods have been developed for inserting genetic information into plant cells, such as *Agrobacterium*-mediated systems, direct DNA uptake into protoplasts and particle bombardment (biolistic). However, although it was assumed that advances in the methodologies for gene delivery and plant tissue culture would make plant transformation routine for most important crops, some species have proved very difficult to transform. Several methodologies are available to transform almost all important crops, however, some systems are still not routine and do not achieve the frequency of transformation required for obtaining genetically modified plants containing useful traits, such as abiotic stress tolerance.

Particle bombardment and plant transformation

Since the development of the biolistic process for the direct introduction of genes into vegetable cells at the

end of the 1980s, a great number of transgenic plants of several species have been obtained, including those species that were considered difficult to transform by other methods. This is due to the fact that it has become possible to introduce and express exogenous genes in any kind of vegetable tissue. Thus, any type of tissue having the potential to regenerate a completely fertile plant is suitable for transformation (Sanford et al. 1987).

The biolistic process has also been called the microprojectile bombardment method, "gene gun" method, and particle acceleration method, among others. Different systems have been developed and constructed which are capable of accelerating microparticles (made of tungsten or gold), coated with nucleic acid sequences, at speeds exceeding 1,500 km/h. All these systems are based on the generation of a shock wave with enough energy to displace microparticles coated with DNA. The shock wave can be generated by a chemical explosion (dry powder gun), a discharge of helium gas under high pressure, or vaporization of a drop of water through an electric discharge at high voltage and low capacitance or at low voltage and high capacitance. Those systems that use helium gas under high pressure and electric discharge have shown a broad range of uses. The accelerated particles penetrate the cellular wall and membrane in a non-lethal way, locating themselves randomly in the cellular organelles. Then the DNA is dissociated from the microparticles by the action of the cellular liquid, and the process of integrating the exogenous DNA in the genome of the organism to be modified takes place (Yamashita et al. 1991). In spite of the efficiency and universality of utilization of the biolistic process, it requires the optimization of various biological parameters, related to tissue culture, allowing regeneration of transgenic plants from genetically modified tissues.

Several protocols have been developed to *de novo* regenerate the most important crops. However, genetic modification of some of them is still not routine, with low frequency of transformation, or limited to some specific varieties. Consequently, the apical region of embryonic axes is an obvious target for the development of systems based on the bombardment of meristematic cells. Based on the introduction of genes into the apical meristematic cells, by particle bombardment we developed an efficient and reproducible system to achieve routinely transgenic plants of several species, such as soybean, dry bean and cotton.

The ability to recover a high number of fertile transgenic plants may facilitate the detection of the "key event(s)" that could be integrated into plant breeding programs for the development of transgenic crops that will be introduced into the market. The high frequency of transformation achieved allowed our group to introduce agronomically important traits into these crops: resistance to viruses, fungi and insects, herbicide

tolerance, expression of methionine-rich proteins, human growth factor and insulin. Molecular analyses and progeny tests of several generations of transgenic lines revealed the presence of a small number of integrated copies of the foreign genes and segregation in a Medelian fashion in most of them. This is extremely important, in order to accelerate the introduction of these plants in a breeding program as well as the production of transgenic commercial varieties. Embrapa's groups and others are utilizing these systems in order to introduce genes for abiotic stress in important crops such as bean and soybean, namely drought and cold tolerance.

Dry bean transformation

The common bean (*Phaseolus vulgaris* L.) is one of the most important food legumes in the developing world. In Latin America, beans are a very important source of protein and calories. However, the production growth rates have been declining in Brazil and the Andean regions, mainly due to diseases, insects, nutritional deficiencies, and drought. Consequently, there is considerable interest in the introduction of agronomically useful traits into beans by breeding and genetic engineering.

Several methods have been developed for inserting genetic information into plant cells, such as *Agrobacterium*-mediated systems, direct DNA uptake into protoplasts and particle bombardment. Early efforts to transform the bean demonstrated its susceptibility to *Agrobacterium*, and some transgenic tissues such as callus, leaves, meristems, cotyledon and hypocotyl have been achieved (Lippincott et al. 1968, McClean et al. 1991, Franklin et al. 1993, Becker et al. 1994, Lewis and Bliss 1994, Brasileiro et al. 1996, Nagl et al. 1997). Mariotti et al. (1989) reported the production of transgenic bean plants through the utilization of the *Agrobacterium* system. However, there was no molecular evidence for genetic transformation or progeny analysis. Transient gene expression using either electroporation or PEG-mediated protoplast transformation was demonstrated (Crepéy et al. 1986, Bustos 1991, Leon et al. 1991, Giovanazzo et al. 1993). Dillen et al. (1995) demonstrated the applicability of electroporation of intact tissue to introduce and express the *gus* gene in bean embryonic axes. Nevertheless, no transgenic bean plants were obtained due to the difficulties of regenerating plants.

The applicability of particle bombardment to introduce and transiently express genes into apical meristematic cells of dry beans was demonstrated in the early 1990s (Genga et al. 1991, Aragão et al. 1992, 1993). However, it was not known how deep the particles should penetrate in order to reach the cells that

could generate transgenic plants. The different parts of the meristem have been divided in layers (L1, L2 and L3) (Satina et al. 1940). Layer L1 is the most external and forms the epidermis of the differentiated regions. Layers L2 and L3 divide preferentially in the anticlinal and periclinal planes to form the organs. Several studies have demonstrated that the differentiated *de novo* shoots originate from the sub-epidermal layers (L2 and L3) of the apical meristem. However, the L1 layer could participate in their formation (McClellan and Grafton 1989, Franklin et al. 1991, Mohamed et al. 1992). These shoots are formed in the peripheral regions of the apical meristem (Aragão and Rech 1997). The bombardment of *P. vulgaris* meristematic cells showed that it was possible to efficiently reach these layers, demonstrating that it would be possible to achieve transgenic plants (Aragão et al. 1993). In 1993, Russel et al. were able to achieve transgenic navy bean (cv. Seafarer) plants using an electrical particle acceleration device. It was the first report of *P. vulgaris* transformation, presenting molecular evidences and progeny. However, the frequency of transgenic plants obtained was much lower (0.03%) and variety-limited. In addition, their tissue culture protocol was time consuming, involving several temperature treatments and medium transfers of the bombarded embryos before recovery of transgenic shoots. Kim and Minamikawa (1996) achieved transformation by bombarding embryonic axes, obtaining stable transformed bean plants (cv. Goldstar).

We developed an efficient and reproducible system to achieve routinely transgenic bean plants. The bean transformation system was also based upon the development of a tissue culture protocol of multiple shoot induction, shoot elongation and rooting. The average frequency of transformation (the total number of putative transgenic plants divided by the total number of bombarded embryonic axes) was 0.9% (Aragão et al. 1996, Aragão and Rech 1997). In addition, we have been able to transform several varieties of *P. vulgaris*, including those that were considered difficult to transform in previous studies.

It has been assumed that the use of particle bombardment to introduce genes into apical meristematic cells can be extended to any genotype or variety (Sanford 1990). However, we have found that the morphology of the explants utilized during the bombardment process may greatly influence the successful recuperation achievement of transgenic bean plants (Aragão and Rech 1997). In some cultivars, the embryonic axes revealed the apical meristematic region partially exposed, whereas only the central region could be visualized. The number of meristematic cells that could be reached by the microparticles coated with DNA will be drastically reduced. Consequently, the efficiency of transformation could also be reduced. Several studies have shown that *de novo* shoot

differentiation in embryos of bean cultivated on cytokinins appeared in the peripheral layers of the meristematic ring (Franklin et al. 1991, McClellan and Grafton 1989, Aragão and Rech 1997). Thus, based on these concepts, cultivars with a non-exposed apical meristematic region are not suitable for particle bombardment transformation, considering the fact that removal of the leaf primordia is not practical.

Our group first introduced an agronomically important gene into Phaseolus. Mature embryos were transformed in order to transiently express a methionine-rich albumin gene from Brazil nut (*be2s1* gene), which could be detected by Western blot and ELISA, twenty-four hours later (Aragão et al. 1992). Recently, we stably transformed bean with the *be2s1* gene in order to improve the methionine content in the seeds. In two of the five transgenic lines, the methionine content was significantly increased by 14% and 23% over the non-transgenic plants (Aragão et al. 1999).

Recently, we obtained transgenic plants containing the bar gene that confers resistance to the herbicide glufosinate ammonium (Lyberty, Aventis). The bar gene was found to confer strong resistance in transgenic bean to the herbicide in the greenhouse. A field trial was carried out and one line presented high tolerance up to 400 g/ha of glufosinate ammonium (Figure 1; Aragão et al. 2001).

Fig. 1. Field trial conducted with transgenic dry bean plants tolerant to the herbicide glufosinate ammonium.

In order to achieve bean plants resistant to the bean golden mosaic geminivirus, which is responsible for one of the most important diseases in this crop in Latin America, plants containing the mutated *AC1* viral gene were obtained. We have identified two lines that presented immunity against the virus. These lines were introduced into the breeding program from the Center of Rice and Bean of EMBRAPA.

The bean transformation system developed in our lab is now available to introduce genes for abiotic stress tolerance. Indeed, other groups in Mexico and Brazil are

using this technology to introduce genes for tolerance to cold, drought and shade environment.

Soybean transformation

The first two successful reports of soybean transformation involved the use of the *Agrobacterium* system to obtain plants regenerated from cotyledonary nodes and the biolistic system, which is based on acceleration of microparticles coated with DNA into the apical meristematic region of embryonic axes (Hinchee et al. 1988, McCabe et al. 1988). Since then, several groups have been actively involved in improving these systems by manipulating somatic embryogenesis and shoot morphogenesis (Chee et al. 1989, Finer et al. 1991, Barwale et al. 1986, Hooykaas and Schilperooort 1992, Hansen et al. 1994). However, the protocols published failed to produce a highly efficient system that would be easy to conduct and variety independent. In addition, an efficient selectable marker that would allow the regeneration of only transgenic material and increase the frequency of recovery of fertile transgenic plants is not available.

One important constraint in the transformation system based on the bombardment of meristematic tissue of embryonic axes was the difficulty of achieving efficient selection of transformed cells (Kantha et al. 1981, Aragão et al. 1996, 2000). In this case, only a few cells from the meristem are transformed, while the others, including those that are in contact with the culture medium and the selective agent, are not transformed. Antibiotics such as kanamycin have been used as selective agents, associated with the *nptII* gene (Aragão et al. 1996). However, this selection is not efficient. A soybean transformation technology that would allow the selection of transgenic meristematic cells and regeneration of fertile plants should facilitate the production of transgenic plants with improved agricultural characteristics.

To obtain transgenic soybean plants from the apical region of embryonic axes, there are two essential requirements: 1) introduction of exogenous genes with high frequencies into the cells of the apical regions, and integration of exogenous genes into the vegetable genome, and 2) regeneration and production of fertile transgenic plants from the resulting transformed cells. With the development of the biolistic process, the first requirement was achieved. However, one problem remained: it was difficult to select the transformed apical meristematic cells. To solve this problem, which is one of the most important limiting factors for achieving transgenic soybean with a high frequency, we have developed a novel system to select transgenic meristematic cells. The system is based on the use of the selective agent imazapyr, a herbicidal molecule of the

imidazolinone class, capable of systemically translocating and concentrating in the apical meristematic region of the plant. The mechanism of action of imazapyr is the inhibition of the enzymatic activity of acetohydroxyacid synthase (AHAS; acetolactate synthase, acetolactate pyruvate-lyase (carboxylating), EC 4.1.3.18), which catalyses the initial step in the biosynthesis of isoleucine, leucine and valine. The *ahas* selectable marker gene, previously isolated from *Arabidopsis thaliana*, contains a mutation at position 653 bp resulting in a serine to asparagine substitution that confers imidazolinone-specific resistance. This selectable marker system, combined with an improved multiple shooting induction protocol, resulted in a significant increase in the recovery of fertile, transgenic material (from 4 to 20%, number of transgenic plants related to number of embryonic axes bombarded) compared with the standard soybean transformation protocol (0.1%) (Aragão et al. 2000). Basically, mature seeds are surface sterilized and soaked in distilled water for 18-20 h. The embryonic axes are excised from seeds and the apical meristems are exposed by removing the primary leaves, and positioned for the bombardment. After bombardment, the embryonic axes are transferred and completely immersed in the induction medium (MS basal salts medium, supplemented with 22.2 μ M benzylaminopurine, 3% sucrose and 0.6% agar, Sigma, pH 5.7), for 16 h in the dark. After this period, the explants are transferred to MS medium containing 500 nM imazapyr. As soon as the embryonic axes-derived shoots are 2 to 3 cm in length, they are analyzed for the presence of foreign genes and individually transferred to a plastic pot and acclimated (Figure 2).

We also demonstrate that this technique is variety-independent. It was possible to transform several commercial cultivars, such as BR-16, Doko RC, BR-91, Guarany and Conquista. One line, from the cultivar BR-16, was tested under field conditions and presented very high tolerance to the herbicide imazapyr (Figure 2; Aragão et al. 2000).

We believe that this new technology should have significant applications for the introduction of genes for agronomic characteristics such as biotic and abiotic stress tolerance. In fact, this soybean transformation system will be used for the introduction and expression of the *DREB1A* gene identified in *Arabidopsis thaliana* and involved in the response of the plants to abiotic stress (Liu et al. 1998, Shinozaki and Yamaguchi-Shinozaki 2000).

Cotton Transformation

Cotton (*Gossypium hirsutum* L.) is considered a high value agricultural product, adapted for the industrial production of vegetable oil and mainly textile fiber. The

Fig. 2. Acclimated transgenic soybean plantlets in the greenhouse (above) and a field trial conducted with a transgenic soybean line tolerant to herbicide.

sharp increase in cotton consumption in the form of greater variety of products justifies the need to optimize the production and quality of this crop. Genetic engineering can help improve cotton breeding programs.

The first reports of cotton transformation, using *Agrobacterium tumefaciens*, were applicable to only a few varieties (Firoozabady et al. 1987, Umbeck et al. 1987, Finer et al. 1990, Cousins et al. 1991, Bayley et al., 1992). Most varieties of commercial interest proved difficult or impossible to regenerate into plants from the obligatory callus phase. Genes introduced into regenerable varieties could be bred into other lines but the process is lengthy and prone to somaclonal variation. Most of the varieties transformed by *Agrobacterium* systems are Coker and Coker-derived (Thomas et al. 1995, Rajasekaran et al. 1996, Agrawal et al. 1997). In this regard, we have been looking for an efficient system to transfer genes to elite cultivars, avoiding the need of many years of crossing and selection to reach new varieties.

Based on their experience with soybean, McCabe

and Martinell (1993) developed a variety-independent protocol for the production of transgenic cotton. However, its efficiency was very low, from 0.027 to 0.2%, which is not sufficient for practical purposes.

Stable integration and expression of the genes have been achieved with both *Agrobacterium* and the biolistic process, however when only the epidermal cortex cell layer of a plant is transformed, the progeny will not inherit the transgene. Germline transformants, on the other hand, pass on the transgenes to their progeny and are suitable for conventional commercial cultivation (Keller et al. 1997). The frequency of cotton transformation has been relatively high (0.2 to 1%); nevertheless, the frequency of germline transformation has been very low. This is the most important constraint for the achievement of a variety-independent system with high frequency of cotton transformation.

We have successfully adapted the selection system developed for soybean (Aragão et al. 2000) to increase the cotton germline frequency of transformation. Indeed, the frequency of germline transformation was raised to 0.5%, using the herbicide imazapyr to select the shoots and plantlets originated from the apical meristematic tissue bombarded with the *ahas* gene. In summary, seeds of cotton, varieties CNPA-7MH and 7H, are surface sterilized and soaked in distilled water for 16 h. The water is removed and the seeds are incubated in the dark for an additional period of 16 h. Then, the embryonic axes are excised from seeds and the apical meristems are exposed by removing the primary leaves, and positioned for the bombardment (Figure 3). After bombardment the embryonic axes are transferred to MS medium containing 900 nM imazapyr, 0.1% activated charcoal, 3 mg/L BAP and 3% glucose. As soon as the embryonic axes-derived shoots are 2 to 3 cm in length, they are analyzed for the presence of foreign genes and individually transferred to a plastic pot and acclimated (Figure 3). Most of the elongated shoots showed the presence of foreign genes. The developed process should allow the introduction and expression of different genes in elite varieties of commercial cotton, with a frequency of germline transformation superior to those protocols described so far.

Conclusion

Crop improvement through genetic engineering has become a reality (Dunwell 2000). For some crops, transformation is already routine. However, for other crops, despite the possibility of obtaining transgenic plants, the frequency is still not sufficient for practical purposes. In our experience, we have seen that for each 20 transgenic plants obtained, only one has the potential to be introduced in a breeding program to generate a commercial variety. Consequently, a transformation

technology has to be very efficient in order to allow the selection of events with a desirable expression level, without severe somaclonal variation and unexpected segregation. This is particularly true for introducing genes for abiotic stress tolerance, since either the number of candidate genes or that of individual plants to be tested should be large. In addition, research in plant transformation is concentrating now not so much on the introduction of DNA into plant cells, but rather on the problems associated with stable integration and reliable expression of the DNA once it has been integrated.

Studies of the behavior of transgenic plants under field conditions need to be conducted. These studies should assess the interactions of the transgenic plants with other plants in the agricultural and natural environment. Moreover, the stability of foreign genes and factors related to their interaction with the complex physiology of these plants submitted to natural stress in tropical areas should be evaluated.

Recent developments in transgenics for abiotic stress tolerance in rice

Swapan K. Datta

International Rice Research Institute
Plant Breeding, Genetics, and Biochemistry Division
DAPO Box 7777, Metro Manila, Philippines

Abstract

Abiotic stress is a major environmental constraint to rice production in non-irrigated rice areas. Genetic engineering aims at cross-talk between different stress-signaling pathways and is expected to unravel the roadmap of the bioengineering pathway leading to stress tolerance. Multidisciplinary collaboration involving molecular biologists, plant breeders, agronomists, physiologists, and biotechnologists could genetically improve this trait in rice. Osmotic adjustment (OA) is an effective component of abiotic stress (drought and salinity) tolerance in many plants, including rice. When the plant experiences water stress, OA contributes to turgor maintenance of both shoots and roots. Osmoprotectants (compatible solutes), which accumulate in the cytoplasm of water-stressed plants, are used for OA. Conventional breeding could not achieve OA in rice except for a few rice cultivars that are well adapted to water-stress conditions. Several stress-related genes have now been cloned and transferred into rice to enhance the osmolytes and some transgenic lines showed increased tolerance of osmotic stress. However, tolerance of water stress could require multigene families or a transcription factor regulating several genes, which has been shown in *Arabidopsis* (Shinozaki and Yamaguchi-Shinozaki, *Current Opinion in Plant Biology*, 2000, 3:217-223).

To better understand water-stress tolerance in rice and to develop transgenic rice which can survive for a critical period under water-stress conditions, the following strategies could be effectively deployed:

1) Switching on a transcription factor regulating the expression of several genes related to abiotic stress; 2) using a suitable root-specific promoter driving the target gene for an efficient and directed expression in roots and modification of roots; 3) understanding phenotyping and G X E in a given environment; 4) selecting a few adaptive rice cultivars suitable for drought and salinity-prone areas; 5) using microarray, proteomics, QTLs and marker-aided selection to expedite the cloning and characterization of stress-inducible genes; and, finally, 6) using an efficient transformation system to generate a large number of transgenic rice cultivars of different background that will eventually help in selecting a desirable phenotype with adequate OA. The genetic engineering approach for abiotic stress tolerance in rice will be highlighted and discussed.

Keywords: OA (osmotic adjustment), bioengineering, transcription factor, reactive oxygen species (ROS), osmoprotectants, oxidative stress-related genes, regulatory genes, phenotyping

Conclusions

Abiotic stress, particularly drought and salinity, is a complex phenotypic and physiological phenomenon in plants. The number of genes that regulate the process and how they coordinate it has yet to be unraveled. Nevertheless, adaptive cultivars that pyramid physiological traits using molecular markers/QTLs or

tools of functional genomics such as microarray or proteomics might help as the first step along the path to developing stress-tolerant cultivars. Once the regulatory gene(s) governing the stress-signaling pathways are available, selected transgenic rice lines in an adaptive background with adequate OA may lead us to desirable rice for abiotic stress tolerance.

Introduction

Asia produces 92% of the world's rice. India and China together produce 58%. Only 4-5% of world rice production enters the global market. Any shortfall in the major rice-growing countries could be a disaster for food security (Hossain et al. 2000). The rice genome is as dynamic as that of other crop plants, but it needs to be more amenable to the addition of new genes for further rice production growth in different ecosystems. The irrigated ecosystem accounts for 55% of the total rice area and contributes 75% of global rice production. The remaining 25% of rice comes from unfavorable rice-growing areas (45%): rainfed lowland (25%), upland (12%), and flood-prone areas (8%). Water stress is the single most severe limitation to the productivity of rice in the rainfed ecosystem (Widawsky and O'Toole, 1990). Table 1 summarizes the yield loss caused by

Table 1
Estimated yield loss caused by various abiotic factors

Country/ region	Yield loss (kg ha ⁻¹)				
	All technical constraints	Abiotic factors	Drought	Cold	Submergence
Southern India	468	117	17	4	0
Eastern India	658	306	144	18	24

various abiotic stresses in South and Southeast Asia countries. In general, screening methods and phenotypic characterization are inadequate for improving drought tolerance in rice breeding. Marker-aided selection (MAS) and QTL mapping may speed up the process. However, recent developments in genetic engineering and functional genomics, particularly gene discovery of candidate genes, may address many unsolved questions of crop design for abiotic stress tolerance in plants, with special reference to rice. I will discuss a few recent research activities and strategies to develop abiotic stress-tolerant rice.

Genomics and genetic engineering

Genomics involves DNA sequencing, the use of DNA microarray technology to analyze the gene expression profile at the mRNA level, and improved informatics tools to organize and analyze such data. Cultivated rice has evolved through domestication for

centuries, which has allowed a limited diversity of genetic resources. It is possible to combine the pyramiding of phenotype breeding and physiological traits and the further selection of germplasm may enhance crop improvement (Fig. 1). Genomics-based strategies for gene discovery, QTL/physical mapping, adaptive cultivars, MAS, and genetic engineering lead to the process of crop improvement as shown in Figure 2.

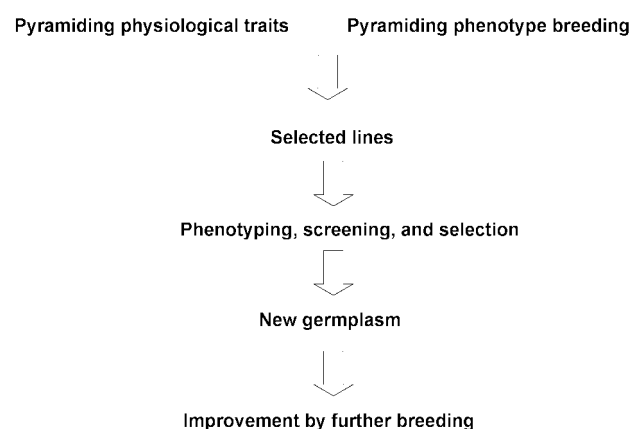

Fig. 1. Combining physiological traits and phenotype in breeding.

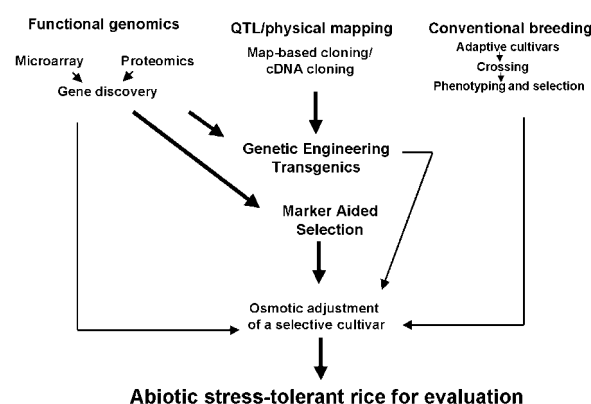

Fig. 2. Multidisciplinary approach for abiotic stress tolerance in rice.

Major crops such as rice, wheat, maize, cotton, soybean, sunflower, barley, canola, and sorghum have been transformed using various gene transfer technologies (Potrykus, 1991; James, 2000). However, the most reproducible and most unambiguous results have been obtained from protoplast, biolistic, and *Agrobacterium* methods as shown in Figure 3 (Datta et al. 1997; Datta, 2000).

Osmotic adjustment and genotypic variation

Osmotic adjustment (OA) is a major component of abiotic stress tolerance, particularly for water stress

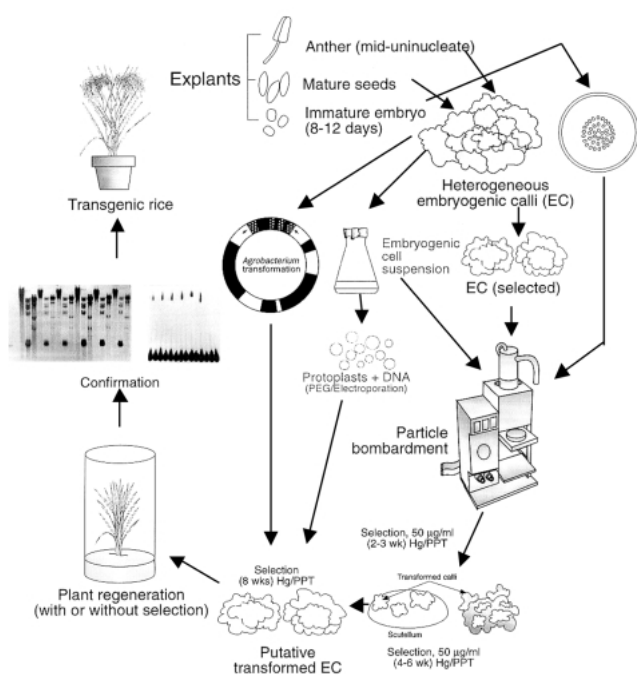

Fig. 3. Schematic protocol for production of transgenic rice plants using biolistic, protoplast, and *Agrobacterium* systems.

(either drought or salinity). Blum (1988) defined OA as follows: "As water is being removed from the plant cell, its osmotic potential (OP) is reduced due to the simple effect of solute concentration. However, if during the course of cellular water loss solutes are actively accumulated, OP would be reduced beyond the rate dictated by the mere effect of concentration. Such an active accumulation of solutes during the development of water deficit is termed OA". OA contributes to turgor maintenance of roots and shoots in response to water deficit. OA is reported to occur in rice under water deficit in the range of 0.4-0.6 MPa and it may extend to higher levels under prolonged stress in some rice cultivars, for example, up to 1.5 MPa in IR cultivars (Lilley and Ludlow, 1996). Lines with a japonica background showed poor dehydration tolerance and low OA, whereas indica lines had greater dehydration tolerance and higher OA. OA has been shown to be associated with yield and it has a positive influence on leaf rolling, tissue death, and retention of green leaf area in rice (Nguyen et al. 1997).

The biochemical mechanisms of action of solutes protecting plants are not known. Hence, several studies have focused on the physiological mechanisms of compatible solute action and ion homeostasis and water relations, C/N partitioning, reserve allocation and management of reducing power, and, finally, correlation of single or multiple functions of a single solute (Levitt, 1980; Bohnert et al. 1995, 2000).

A comprehensive study on transgenic plants

summarizing a correlation among solute amount, nature, and tolerance has been documented in Table 2 and particularly in rice in Table 3. The main solutes responsible for OA in response to water deficit in rice have not been characterized. Osmotic adjustment is time-dependent. Thus, a slow water deficit may allow the rice plant to accumulate solutes and may provide protection (Lilley and Ludlow, 1996; Nguyen et al. 1997).

Osmoticum, drought, and salinity

Water deficit is the key cause of abiotic stress in rice. However, a minor water deficit results in a reduction in photosynthesis, while major deficits lead to complete inhibition of photosynthesis and the production of reactive oxygen species (ROS) such as superoxides and peroxides. These intermediates affect membrane integrity and cause severe impairment of several physiological processes and biochemical reactions. Several reports show that transgenic plants can scavenge or protect themselves from ROS (Bohnert et al. 1995, 2000).

Transgenic plants accumulate osmoprotectants (e.g., glycine betaine) and osmolytes, which have been shown to accumulate in response to drought, salinity, and cold stress. Osmolytes are molecules with low molecular mass and they could be quaternary amines, amino acids, or sugar alcohol. Enhanced accumulation of these molecules is known to increase the osmotic potential of the cell, which could help in combating water stress. Eventually, they could stabilize membranes and other macromolecular structures. A few genes incorporated in transgenic plants leading to enhanced osmolytes or another kind of stress-related protection are summarized below.

Choline oxidase/glycine betaine

Glycine betaine is an important compatible solute widely distributed among plants. The *codA* (choline oxidase) gene isolated from the soil bacterium *Arthrobacter globiformis* converts choline to glycine betaine via betaine aldehyde (Desnium et al. 1995). Salt-tolerant transgenic *Arabidopsis thaliana* was reported to use the *codA* gene (Hayashi et al. 1997). The transformed plant could easily grow at 200 mM NaCl, whereas control wild-type plants did not grow. About 80% enhancement of salt tolerance was reported in transgenic tobacco expressing the *E. coli betA* gene (Lilius et al. 1996). Transgenic *Arabidopsis* carrying the *codA* gene showed tolerance for light stress and increased accumulation of H₂O₂ and several other stress-related chemicals (Alia et al. 1998). Rice does not accumulate glycine betaine unlike other plants (Ishitani et al. 1993). Sakamoto et al. (1998) reported transgenic

Progress in developing transgenic rice with genes conferring abiotic stress tolerance

Gene	Gene action	Phenotypic expression	Reference
<i>Adc</i>	Arginine decarboxylase	Reduced chlorophyll loss under drought stress	Capell et al. (1998)
<i>codA</i>	Choline oxidase (glycine betaine synthesis)	Increased tolerance of salinity and cold	Sakamoto et al. (1998)
<i>GS2</i>	Chloroplastic glutaminesynthetase	Increased salinity resistance and chilling tolerance	Hoshida et al. (2000)
<i>p5cs</i>	Pyrroline carboxylate synthetase (proline synthesis)	Increased biomass production under drought and salinity stress	Zhu et al. (1998)
<i>pdcl</i>	Pyruvate decarboxylase	Increased submergence tolerance	Quimio et al. (2000)
<i>HVA1</i>	Group 3 LEA protein gene	Increased tolerance of drought and salinity stress	Xu et al. (1996)
<i>OsCDPK7</i>	Transcription factor	Increased tolerance of cold, salinity, and drought	Saijo et al. (2000)
<i>wx</i>	Controls amylose synthesis	Increased amylose content at low temperature	Hirano and Sano (1998)
<i>TLP-D34</i>	Thaumatin-like protein (PR-5 member related to osmotin)	Enhanced fungal protection and osmotic adjustment	Datta et al. (2000)

rice expressing the *codA* gene in the chloroplast and the cytosol recovered to normal growth at a faster rate than the wild type after an initial growth inhibition under salt and low-temperature stress. This study demonstrated that the subcellular compartmentalization of the biosynthesis of glycine betaine was a critical step in attaining enhancement of tolerance for salinity and water stress.

Trehalose-6-phosphate synthetase gene (*TPS1*)

Trehalose, an osmoprotectant, non-reducing disaccharide, effectively stabilizes dehydrated enzymes and lipid membranes in some plants. Transgenic tobacco plants containing the yeast *trehalose-6-phosphate synthetase* gene (*TPS1*) producing trehalose exhibited multiple alteration and improved drought tolerance (Romero et al. 1997). Bacterial *trehalose-6-phosphate phosphatase* (*OtsB*) genes introduced in tobacco showed better growth under drought stress (Pilon-Smits et al. 1995). Transgenic plants also showed a better capacity to retain water and performed more efficient photosynthesis under stress.

Fructans

Fructans are polyfructose molecules produced by many plants and bacteria. About 45,000 plant species use fructans as their storage carbohydrates (Hendry 1993; Pilon-Smits et al. 1995). Fructans promote the process of root branching, thus increasing root surface and water uptake. Transgenic plants containing the *sacB* gene (producing fructans) showed a higher capacity for osmotic adjustment. The additional carbohydrates gained may lead to deeper rooting and greater water uptake (Sharp et al. 1996; Pilon-Smits et al. 1995; Schellenbaum et al. 1999).

Myo-inositol O-methyl transferase (IMT1)

Myo-inositol and its stereoisomers can be methylated to form a variety of products such as D-ononitol and D-pinitol, which resemble similar products associated with plants that grow in salt and drought conditions (Ishitani et al. 1997). Sheveleva et al. (1997, 2000) showed that transgenic tobacco plants containing the *IMT1* gene produced methylated inositol D-ononitol and had higher tolerance for drought and salt stresses. Transgenic plants also showed efficient photosynthesis using higher CO₂.

Δ^1 pyrroline-5-carboxylate synthetase

The potential value of proline accumulation during environmental stress has yet to be fully understood. Proline accumulation has been demonstrated to be associated with abiotic stress (Delauney and Verma, 1993). Overproduction of proline in transgenic tobacco (Kavi Kishor et al. 1995) and in rice with the P5CS (Δ^1 pyrroline-5-carboxylate synthetase) gene enhanced root biomass and flower development under water stress (Zhu et al. 1998). Further work on transgenic soybean plants transformed with the antisense *L- Δ^1 pyrroline-5-carboxylate reductase* (*P5CR*) gene showed additional evidence that proline accumulation is correlated with the tolerance of water stress (De Ronde et al. 2000).

Mannitol-1-phosphate dehydrogenase (mt1D)

It is reported that mannitol may play an important role in OA and provide enhanced tolerance in response to high salinity or water stress. Transgenic tobacco plants transformed with *E. coli mt1D* showed enhanced accumulation of mannitol, leading to increased tolerance of transgenic plants in response to salinity (Tarczynski et al. 1993). Enhanced mannitol

biosynthesis in the chloroplast of transgenic plants resulted in increased tolerance of oxidative stress (Shen et al. 1997).

Late embryogenesis abundant (LEA) proteins

Certain plant proteins such as late embryogenesis abundant (LEA) proteins accumulate during seed desiccation and in response to water stress (Dure, 1993). HVA1, a group 3 LEA protein from barley transferred to rice (japonica), showed tolerance of water deficit and salt stress (Xu et al. 1996). Transgenic rice showed enhanced accumulation of the HVA1 protein, which led to higher growth rates, delayed stress-related damage symptoms, and improved recovery from the removal of stress conditions (Xu et al. 1996). Transgenic wheat plants containing the *HVA1* gene showed constitutive expression of the transgene resulting in improvement of growth characteristics under water-deficient conditions, more biomass, and more efficient water use (Sivamani et al. 2000). However, the size of the HVA1 protein found in transgenic wheat differed from that of transgenic rice. The exact function of the group 3 LEA protein has still not been clearly characterized. More studies are needed using homozygous transgenic wheat and rice to demonstrate the exact function of this protein.

Oxidative stress-related genes

Several stresses such as high temperature, high light intensity, osmotic stresses, heavy metals, and several herbicides, and toxins lead to overproduction of reactive oxygen species (ROS), causing extensive cellular damage and inhibition of photosynthesis (Allen 1997). Plants have evolved systems to combat oxidative stress with a battery of gene products that aid in reducing the active oxygen species that damage membranes. Enzymes such as superoxide dismutase, glutathione reductase, glutathione- δ -transferase, catalase, glyoxalase, etc., are involved in such protective processes.

Transgenic tobacco plants containing oxidative stress-related genes showed elevated levels of glutathione reductase, superoxide dismutase, and ascorbate peroxidase, resulting in enhanced drought tolerance (Van Rensburg and Kruger 1994). However, the results are often not correlated with expectations as has been shown by Tepperman and Dunsmuir (1990) in transgenic tobacco and tomato with the Cu/Zn superoxide dismutase (*SOD*) gene, which failed to show any protection against superoxide toxicity. In contrast, constitutively overexpressed *Mn-SOD* in the chloroplast and mitochondria reduced cellular damage (Bowler et al. 1991). Overexpression of *Fe-SOD* in transgenic tobacco plants did not show any tolerance for the salt stress,

though expressing elevated levels of oxidative stress-related enzymes (Van Camp et al. 1996). However, *Arabidopsis Fe-SOD* in transgenic maize under the 35SP of CaMV + chloroplast targeting the transit peptide signal from pea Rubisco showed enhanced methyl biogenesis, resulting in higher growth rates at low temperature (Van Breusegem et al. 1999). Another report in transgenic tobacco containing the *Nt107* gene encoding glutathione- δ -transferase showed better seedling growth under cold and salt stress (Roxas et al. 1997).

Anaerobiosis/anoxia

Most plants, including rice, are highly sensitive to anoxia during submergence. Submergence caused by flooding ranks next to drought as the most serious abiotic constraint to rice yields in Asia. During anoxia, ATP and NAD are generated not in the Krebs cycle and the respiratory chain but via glycolysis and fermentation. In this anaerobic pathway, several genes, such as alcohol dehydrogenase (*adh*) and pyruvate decarboxylase (*pdh*), induced during anoxia have been cloned and characterized (Bucher and Kuhlemeier, 1993; Umeda and Uchimiya 1994; Hossain et al. 1996).

Rice cultivars FR13A and IR42 are known to be tolerant and sensitive, respectively, under submergence conditions. It has been shown that a few genes encoding glucosephosphate isomerase, phosphofructokinase, glyceraldehyde phosphate dehydrogenase, enolase, and aldehyde kinase are induced faster in FR13A (Umeda and Uchimiya, 1994; Kawai et al. 1993). Besides *adh* and *pdh* the question remains as to how many genes govern tolerance of flooding stress. The exact answer is not yet known but surely more than one is required to solve the problem. Xu and Mackill (1996) reported localizing *Sub (t)* in rice chromosome 9, which is associated with variation of the phenotype of submergence tolerance. Further study based on tightly linked AFLP markers showed that researchers were now very close to cloning the gene (Kenong et al. 1997).

IRRI reported developing transgenic rice with the *adh* and *pdh* genes in several cultivars (Quimio et al. 2000). Results on transgenic lines with the *adh* gene are inconclusive. The rice *pdh1* (reported by Hossain et al. 1996) gene coding for pyruvate decarboxylase (PDC) is one of the enzymes involved in alcohol fermentation. The overexpression of the *pdh* gene was used not only to assess the role of alcohol fermentation but also to produce lines with enhanced metabolic capacity and submergence tolerance. Tillers of confirmed T₀ transgenic lines showed higher *pdh* gene activities and ethanol production than the untransformed control. Consequently, ethanol production of tillers of T₀ transgenic plants was positively correlated with survival after submergence. However, the exact mechanism of

the beneficial effects of overexpression of the *pdh* gene requires further metabolic studies. For example, overexpression of the *pdh* may have induced the expression of other genes that control the rate of carbon flow through the glycolytic and ethanolic fermentation pathways under anaerobic conditions. Transgenic lines with overexpression of both the *adh* and *pdh* genes may provide more information regarding the importance or validity of the fermentation pathway for inducing flooding tolerance (Minhas and Grover 1999).

Adverse soils

About 11% of the world's land is currently used for cultivation and 24.4% of that is considered as potential cultivable or arable land (FAO 1991). Among the problems common to tropical regions, probably the most important is soil acidity, which constitutes about 3.95 billion hectares of land including 38% of tropical Asia. Nutrient deficiencies (P, Ca, Mg, K, and Fe) and acid soils caused by a combination of aluminum and manganese toxicity are major constraints to soil fertility and crop productivity. Aluminum toxicity problems are of enormous importance in the production of rice, maize, and sorghum in developing countries of Asia, Africa, and Latin America. Aluminum has a clear toxic effect on roots, disturbing plant metabolism by decreasing water absorption and mineral nutrition.

Besides aluminum toxicity, some essential elements such as P, Ca, Mg, and Fe form complexes with Al, resulting in their low availability and non-availability for root uptake. Several improved rice cultivars have been developed at IRRI that can survive partially under these adverse soil conditions (IRRI, 1999). The generation of transgenic metal-tolerant tobacco plants has been reported (Pan et al. 1994). Mexican scientists have developed transgenic rice conferring tolerance of a high concentration of aluminum (Conway and Toenniessen, 1999).

Osmotin

Osmotin is a cationic protein with a pI^2 value of >8.2 and it accounts for 10% to 12% of total cellular protein (Singh et al. 1987). Osmotin synthesis is regulated by abscisic acid but its accumulation is affected on adjustment of the cells, by NaCl or water stress (Singh et al. 1987). Osmotin strongly resembles the sweet protein thaumatin in its molecular amino acid composition, N-terminal sequence, and the presence of a signal peptide on the precursor protein (Singh et al. 1987). Transgenic rice containing the coding region of a thaumatin-like protein (TLP-D34), a member of the PR-5 group, has been shown to confer resistance against

sheath blight disease in rice (Datta et al. 1999). As this *tlp* gene has some sequence homologies with the osmotin gene, perhaps it would be worthwhile to evaluate the tolerance of homozygous transgenic plants in response to salinity.

Adaptation to adverse conditions, higher grain filling, and C₄ rice

It is well known that the ice plant responds to drought or salt stress by switching from C₃ to crassulacean acid metabolism (CAM), which allows the plant to fix CO₂ at night, thus reducing transpiratory water loss. The key enzyme of the C₄ pathway is phosphoenolpyruvate carboxylase (PEPc), which, along with other enzymes, is regulated by osmotic stress at the transcriptional and translation levels (Dhaliwal et al. 1998). Transgenic C₄ rice has already been reported in a model japonica rice background (Ku et al. 1999). Transgenic elite indica rice is being developed at IRRI, which eventually may address many questions regarding the efficient use of CO₂ and water as they are needed (Matsuoka et al. 2000; our unpublished data). Transgenic rice with the *ferritin* gene to enhance high iron storage can reduce ROS (Deak et al. 1999). We are working on developing transgenic adaptive elite varieties for comprehensive study.

Transcriptional activators and regulatory genes

For details, please see the chapter of Dr. Yamaguchi-Shinozaki in this volume. It has been reported (Fig. 4) that the dehydration response element (DRE) plays an important role in the response to drought stress in *Arabidopsis* (Shinozaki and Yamaguchi-Shinozaki 2000). It is also involved in low-temperature and salinity-related stress. The transcription factor DREB1A specifically interacts with DRE and induces

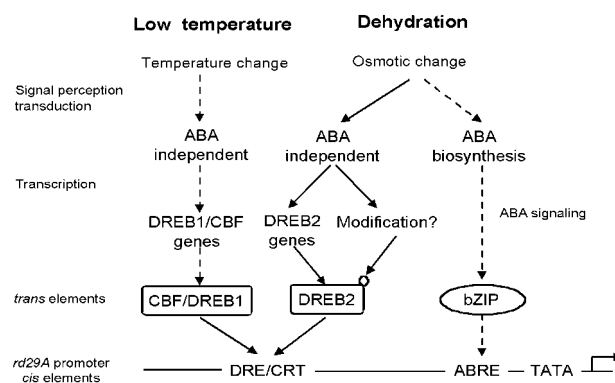

Fig. 4. Stepwise gene expression in molecular responses to dehydration and low temperature.

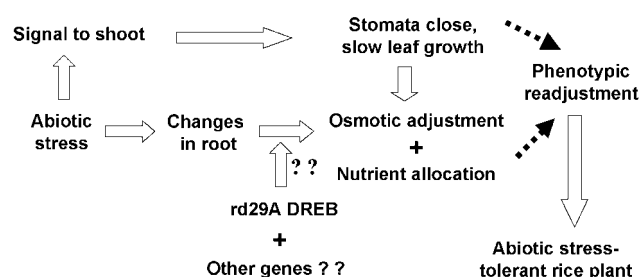

Fig. 5. Transgenic approach to abiotic stress-tolerant rice.

the expression of stress tolerance genes. Overexpression of DREB1A in transgenic *Arabidopsis* plants activated the expression of many of these stress tolerance genes and resulted in tolerance of freezing, salt loading, and drought (Liu et al. 1998; Kasuga et al. 1999; Seki et al. 2001; Urao et al. 1998, 2000). In collaboration with JIRCAS (Dr. Yamaguchi-Shinozaki's group), we are developing transgenic tropical rice with the *DRE* gene (along with rice homologous genes) driven by the stress-induced promoter *rd29A* (Fig. 5). Transgenic rice with a regulatory gene, such as the *DRE* gene, may help in understanding cross-talk between different stress-signaling pathways and is expected to unravel the roadmap of the bioengineering pathway leading to abiotic stress tolerance.

Acknowledgments

I am grateful to Dr. Masa Iwanaga (JIRCAS) for developing the collaborative research program on abiotic stress and to Dr. Y. Yamaguchi-Shinozaki (also from JIRCAS) for providing the genes *rd29A* and *DREB*. I thank several colleagues from IRRI, particularly Drs. Mahabub Hossain, Brigitte Courtois, and John Bennett, for their valuable discussions; Dr. Niranjan Baisakh, Ms. Emilie Fradin, Mr. Norman Oliva, Ms. Editha Abrigo, Ms. Lina Torrizo, and Dr. Karabi Datta for their help; Michelle Viray for typing; and Bill Hardy for editorial assistance.

Abstract

The overall objective of plant improvement can be defined as the accumulation of the maximum number of favorable alleles involved in the expression of target traits in a plant's genome. This task can be achieved through several approaches, including phenotypic and DNA marker selection or the introduction of new genes through genetic engineering. Regulation of plant responses to abiotic stresses is genetically complex due to the interaction between the environment and the plant genotype. Therefore, the major challenge when using genetic engineering for plant improvement of abiotic stress tolerance is to identify the nature and the number of genes that must be introduced to have a significant impact on the plant phenotype. Given that the number of genes that could be evaluated is large, the efficiency of the transformation system is a key issue. At CIMMYT, after an intensive germplasm screening, a 'Bobwhite' bread wheat line was selected for biolistic transformation work based on its transformation efficiency that exceeds 60%. In collaboration with other institutes, genes involved in abiotic stress tolerance have been identified and are being introduced into wheat. Our preliminary experiments conducted with the *DREB1A* gene demonstrated that when introduced into wheat, the transformed T₁ plants survived a short and intensive water stress at the plantlet stage, while the controls were completely desiccated. The next step is to test these plants under stress conditions that correspond more closely to field conditions, where water stress is a very slow and progressive phenomenon. The role of genetic engineering as a tool to better understand gene function under water-limited conditions and produce tolerant genotypes is discussed.

Constraints to breeding for drought conditions

The reduction in land resources available for agriculture is due to loss of land to industrialization, urbanization, erosion, declining fertility, salinization, compaction, and acidification from fertilizer use. While crop yields and the sustainability of cropping systems in temperate areas are generally stable, if not improving, the opposite is often true for tropical environments, where inputs are usually unavailable or uneconomical. Both types of environments are affected by the destabilizing effects of global warming, which are predicted to increase variability in temperatures and rainfall (Curry et al. 1995). Nowhere are drought and declining fertility more acute than in sub-Saharan Africa, where fertilizer use in 1997 was only 15 kg/ha,

versus 91 kg/ha at the global level (FAO 2000).

Quantitative estimates of yield losses due to individual abiotic stresses are essential for setting research priorities and most estimates are based on extrapolation from trial data, the frequency of occurrence of the stress, and/or expert experience. Like most abiotic stresses, drought can induce major changes in the growth and development of cultivated crops through complex modifications in physiological pathways. For example, Subbarao et al. (1995) suggest that production could be increased over present levels in chickpea, pigeonpea, and groundnut by 49%, 57%, and 29%, respectively, if water was not a limiting factor. Empirical estimates of losses from stress result in "best guesses" such as those for maize (Edmeades et al. 2000), in which water and nutrient deficits are thought

to incur the greatest losses. Water deficit is also the most important abiotic stress affecting rice production. In the Asian uplands, water deficit results in an estimated average annual loss of 190 kg/ha, or 17% of production (Edmeades et al. 2001). Irrigated rice loses 134 kg/ha due to shortages of water, or 9.9 million tons of grain annually in Asia alone. These losses are expected to increase in the future, as water scarcity in Asia becomes more severe. At least 60 million hectares of wheat are grown in marginal rainfed environments in developing countries. National average yields range from 0.8 to 1.5 t/ha, approximately 10-50 % of their theoretical irrigated potential (Morris et al. 1991).

Due to its unpredictable nature, breeding for drought tolerance is more challenging than for tolerances to other abiotic stresses. Selected materials should be outstanding not only under water-limited conditions but they should also perform well when water is adequate. Establishing optimal environments to select for improved performance under drought is complicated by environmental variation; there is generally only one drought-prone season per year in the tropics and conventional selection for drought tolerance requires careful irrigation management, which is a constraint for many breeding programs. In addition, there is clearly a yield barrier for any plant and under drought this yield barrier is highly related to water supply. Grain production requires a plant to support and produce the floral structure(s), but without a minimum of water, there is little or no plant development. Moreover, the global impact of water-limited conditions is not easy to evaluate, especially when drought is combined with insect or pathogen attack, or with non-optimal soil conditions. For example, coastal areas often suffer from both salinity and submergence, and acid soils generally exhibit P deficiency as well. These limitations make it difficult to predict the level of the yield barrier under drought conditions.

Like for other crops, breeding wheat for tolerance to water-limited environments is fraught with difficulties as the genetic control of drought tolerance is poorly understood. Genetic increases in yield over time have therefore been significantly lower in the drier wheat production environments of the world (Derera et al., 1982; Sayre et al., 1997). Furthermore, it is often difficult to separate genetic improvement in yield from increased adoption of moisture conservation practices. Most plant breeders, when confronted with the challenge of developing cultivars for these environments, have opted to select for those traits for which the genetic control is clearly understood. They have targeted improved root development through the manipulation of genes controlling resistance to root pathogens and tolerance to micronutrient imbalances (Trethowan and Pfeiffer, 2000). The manipulation of plant height and flowering time, both under strong genetic control, have

also allowed breeders to better tailor genotypes to the dominant stress patterns found in particular regions (Richards et al., 2001). Significant progress has been achieved through conventional breeding (Trethowan et al., 2001), and the potential for genetic improvement of wheat production under drought conditions is still large. However, conventional breeding for yield improvement remains time-consuming and laborious, because carefully managed field conditions are required. In addition, there is a decrease in the genetic variance and heritability of yield components that parallels an increase in environmental stress, thereby inducing some bias for selection conducted on plant phenotypes. Although challenging, biotechnology approaches that combine QTL studies, functional genomics and genetic engineering should provide useful information and tools to effectively complement conventional selection for drought-tolerance improvement.

The biotechnology approach

The development of molecular genetics and associated technologies has represented a quantum leap in our understanding of the underlying genetics of the traits sought through plant breeding. The usefulness of DNA markers for germplasm characterization, genetic dissection of target traits and marker-assisted selection has been well demonstrated (for a review, see the companion paper, Ribaut et al., in this volume). To date, the complete genome of *Arabidopsis* and rice have been sequenced and a large number of ESTs are available in public databases for other cereals. At the same time, several genes and pathways involved into the expression of morphological traits and physiological parameters involved in water-stress tolerance have been identified. Given this large volume of information, several candidate genes putatively involved in drought tolerance can be identified in the literature and gene databases (Skriver and Mundy 1990, Bray 1993, Ingram and Bartels 1996, Bohnert et al. 2000, Seki et al. 2001). The candidate genes potentially involved in the plant's response under water-limited conditions can be divided in three classes: (1) genes for which very strong evidence has already been published, which demonstrates their significant role under abiotic stresses conditions (Finkelstein and Lynch 2000); (2) genes that have been identified as being of interest, but which require further evaluation (Liu et al. 1998); and (3) those genes that have not been evaluated in a plant, and therefore still need to be confirmed under experimental conditions (Guiltinan et al. 1990).

Recent work has shown how different genes can provide new clues to understanding stress tolerance in plants (Shinozaki and Yamaguchi-Shinozaki 1996, Cushman and Bohnert 2000). They actively play a role

in the biosynthesis of various osmoprotectants (Tarczynski and Bohnert 1993), modification of cell membrane structure and sometimes code for enzymes that detoxify plant cells. Analyses of the expression of dehydration-induced genes have shown that at least four independent signal pathways function in response to dehydration. Two are abscisic acid (ABA) dependent (Abe et al. 1997, Chandler and Robertson 1994), and two are ABA-independent. Several stress-induced genes, such as *rd29A*, are induced through the ABA-independent pathway. The *rd29A* gene in particular is responsible for dehydration and cold-induced expression (Yamaguchi-Shinozaki and Shinozaki 1994). Expression of the *DREB1A* gene, under constitutive promoters such as CaMV 35S, leads to strong increases in tolerance to abiotic stresses; however, it also induces growth retardation under normal growth conditions (Liu et al. 1998), raising concerns about its possible use in plant breeding. However, plants produced using the stress regulated *rd29A* promoter demonstrated increased tolerance to freezing, salt and water limited stresses, without producing changes in the normal phenotype of the transformed plants. One way to validate these candidate genes is to introduce them into a genotype via genetic engineering and test if the plant's tolerance to water stress has been improved. This approach has been followed at CIMMYT to evaluate and characterize the effect of the *DREB1A* gene under water-limited conditions when introduced into wheat germplasm.

Genetic engineering and evaluation of *DREB1A* containing wheat

Two plasmids were used in our transformation experiments. The plasmid pACH25 contained the *gusA* reporter gene and the *bar* selectable marker (conferring resistance to PPT), with each gene under the control of the maize ubiquitin promoter (Christensen et al., 1992). The second construct contained the *DREB1A* cDNA under the control of the *rd29* promoter. Immature embryos (0.8-1.2 mm) from the wheat variety MPB-Bobwhite26, were excised, scutella transferred to an osmotic medium (MS plus 15% maltose) and dehydrated for 4 hr. Plasmid DNA was precipitated onto gold particles as described in several reports (Nehra et al. 1994; Vasil et al., 1992). After microprojectile-DNA precipitation, the particles were washed in 250 μ l ethanol and resuspended in 250 μ l ethanol. For each bombardment, 10 μ l of microparticle-DNA were placed on the macrocarrier. Over 20 independent transformation experiments (bombarded rings) were conducted at a distance of 5 cm. from the stopping plate using a PDS 1000/He microprojectile

gun (Bio-Rad) with a pressure of 900 ics (inches cm. square), as described by Pellegrineschi et al. (2001). Eight hours after bombardment, the embryos were placed on MS medium (Murashige and Skoog 1962), containing 2.5 mg/L 2,4-dichlorophenoxyacetic acid (2,4-D), 30 g/L sucrose, and 8 g/L Bacto-Agar for somatic embryo induction. Twenty days later, the treated embryos were evaluated for somatic embryo production and transferred to MS medium (Murashige and Skoog 1962) with 5 mg/L phosphinothricin (PPT). After 30 days, green regenerating shoots that survived the treatment were again transferred to the same medium for plantlet development. After 20 days, surviving plantlets were transferred to soil and grown in a biosafety greenhouse. Twenty days later, when the plants were at the 5-6 leaf stage, they were sprayed with 0.3% w/v Bast™ herbicide, and the surviving plants were selected for molecular characterization (PCR and Southern blot analyses). All plants containing *bar* and *DREB1A* genes were selfed pollinated to produced seeds.

Twenty seeds from T₀ plants that were positive for the *bar* and DREB genes were planted in small square pots (5 \times 5 cm) and grown in CIMMYT's Biosafety Greenhouse until the 4-leaf stage. Water-limited conditions were generated by withholding water for up to 15 days. These conditions were determined by subjecting control plants to various periods of water deficit. Withholding water for 15 days gave the best discrimination.

After sowing the T₁ progeny, a retardation of germination was observed in the transgenic individuals. Control plants started to germinate after 2-3 days, while the DREB lines showed irregular germination. After germination, no significant differences in plant development were observed between the transgenic and control lines. At the 4-leaf stage, the plants were subjected to water-limited stress by withholding water. The wheat lines started to show differences in the wilting of the leaves after 10 days without water. Table 1 summarizes the water-limited stress development on transgenic and control plants. Controls started to show water-limited symptoms (loss of turgor and bleaching of the leaves) after 10 days of stress, and severe symptoms (e.g., senescence of all leaf tissue) were evident in the control samples after 15 days without water, while the transgenic plants either showed no or reduced symptoms (Fig. 1). These preliminary results suggest that the *rd26::DREB1A* gene has a general effect on tolerance to water-limited conditions. Whether this tolerance is attributable to reduced evapotranspiration of the transgenic plants or differential regulation of the water status in the cell (e.g., osmotic adjustment) clearly needs to be determined through future physiological measurements on both the control and the transgenic plants.

Table 1

Phenotypes of control and transgenic lines under water stress conditions

Genotype	Phenotype observed after 5 days withholding water	Phenotype observed after 10 days withholding water	Phenotype observed after 15 days withholding water
Transgenic	Normal	Plants showing bleaching, loss of turgor in young leaves, some leaves dead.	Plants showing reduced turgor in the leaves.
Control	Normal	Old leaves bleached, loss of turgor in young leaves, some leaves dead.	All plants dead.

Fig. 1. *rd29::ADREB1A* plants and control plants after 15 days drought stress. The stress treatment was performed as described in the text. After the stress treatment, the controls were placed in the same tray to show the different responses to the stress with respect to the transgenic plants.

The next characterization phase

Like in other studies reporting gene characterization under abiotic stresses (e.g., Shannon 1998, Liu et al. 1998, de la Fuente-Martinez and Herrera-Estrella 1999, Kasuga et al. 1999) our phenotypic evaluation at the T₁ stage has been designed to test the survival of different genotypes at the plantlet stage. Although it has been noted that traits that enhance survival have greater relative value when the crop is young, our focus at CIMMYT is to test the general mechanisms by which crop plants cope with stress and identify genes that favor productivity rather than survival. In this regard, the experiments described in this paper for testing the *rd29DREB1A* gene in T₁ plants represent only the first step of our study. In the next generation (T₂), promising transformed wheat plants selected from T₁ families will be grown in large pots. The strategy will be to flood the pots when the plants are at the 4-5 leaf stage and then stop irrigation for the following two months. These experimental conditions should mimic, to some extent, stress conditions in the field by inducing a "long-term" stress, while the large soil capacity of the pots should

provide sufficient water for the most adapted genotypes to survive. This is a key validation step to test the impact of a transgene on plant performance under target conditions. Concomitant with this phenotypic testing, leaf tissue from the plants will be harvested at different stages of the stress to determine their relative water content, osmotic adjustment, and ABA content. This should help us better understand the effect of the transgene at the physiological level. In addition, the expression of the *DREB1A* gene will be characterized for the different families. Finally, to further understand the role of the *DREB* genes in drought tolerance, two different "rice versions" (*OsDREB1A* and *OsDREB1B*) will be evaluated, following the same protocol as for the *AtDREB1A*. These genes will be tested for their performance with stress-specific and constitutive promoters.

It is generally accepted that independent metabolic pathways control tolerance to different abiotic stresses in wheat. Therefore, improvement in tolerance to one stress does not necessarily lead to improvement in tolerance to secondary stresses (Gusta and Chen, 1987). However, due to spillover effects, improved field performance of a transgenic plant selected for drought tolerance might be expected under various abiotic stress (e.g., heat stress, salinity stress, or low nitrogen fertility). For that reason, the *DREB* transgenic wheat plants will be evaluated under diverse stress conditions in the field.

Conclusions

Continued genetic progress in cultivar development for dry regions will depend upon a number of factors. First, the prevailing stresses, other than moisture availability, must be better understood. Second, our understanding of the genetic control of drought tolerance needs to be improved. Third, the selection methods used to screen for drought tolerance must be refined, and finally, new genetic variability for improved water-use efficiency must be found and exploited. Considering the limitations imposed by phenotypic selection, alternatives that take advantage of the explosion of new molecular technologies such as, functional genomics and genetic engineering, should be explored to efficiently complement phenotypic selection. Within this broad scope, genetic engineering is undoubtedly a very suitable approach to (1) confirm a gene's function *in planta*, (2) improve germplasm performance by introducing a new gene and/or changing the gene expression with suitable promoters, and (3) identify new genotypes by screening plants transformed with a large number of candidate genes under different stress conditions. Considering the complexity of abiotic stresses that vary in intensity and timing of the stress,

the introduction of one or a few genes may have only limited impact on productivity under abiotic stress conditions. However, it can be reasonably proposed that a genotype that performs well under a wide spectrum of stress intensities might combine properly-regulated transgenes with elite alleles at key genes, which have been selected through the use of DNA markers.

Recent developments in transgenics for abiotic stress in legumes of the semi-arid tropics

Kiran K. Sharma and M. Lavanya

Genetic Transformation Laboratory

International Crops Research Institute for the Semi-Arid Tropics (ICRISAT)

Patancheru, Andhra Pradesh 502 324, India.

Abstract

The semi-arid tropics (SAT) are characterized by unpredictable weather, limited and erratic rainfall and nutrient poor soils and suffer from a host of agricultural constraints. Several biotic and abiotic stresses affect crop productivity. Mandated crops of ICRISAT that include groundnut, pigeonpea, chickpea, sorghum, and pearl millet are the main staple foods for nearly one billion people in the SAT. Judicious application of biotechnological tools holds great potential in alleviating some of the major constraints to productivity of these crops. Gains in crop productivity through research advances in genetic enhancement will help to achieve sustainable food security, poverty alleviation, and environmental protection in the SAT. ICRISAT has a commitment to transfer the benefits of plant biotechnology to the developing world, as genes relevant to their crops and environment become available. Genetic transformation provides a complimentary means for the genetic betterment of the genome of these crops. Therefore, the research in transgenic crops offers a new means to achieve ICRISAT's mission, i.e., applying science to improve agriculture in areas of the world where sub-optimal rainfall and biotic stresses are the major constraints for crop productivity. In this pursuit, efficient protocols for the genetic transformation of the important legumes of the SAT including groundnut, pigeonpea and chickpea have recently been developed at ICRISAT. More recently, in collaboration with our partners, we have initiated work on the development of transgenic plants for major abiotic stresses that include drought, salinity and low temperatures. Several gene transfer approaches have been shown to improve the stress tolerance of crop plants. The transferred genes include those encoding for enzymes required for the biosynthesis of various osmoprotectants, or those encoding enzymes for modifying membrane lipids, LEA proteins, detoxification enzyme, and stress-inducible transcription factors have been demonstrated to have great potential. This paper reviews the current status of transformation technology for the genetic improvement of legumes of the SAT and it's possible application for developing transgenic plants with enhanced tolerance/resistance to abiotic stresses.

Keywords: Abiotic stress; chickpea; drought; groundnut; pigeonpea; semi-arid tropics; transgenic plants

Introduction

Abiotic stresses like drought, low temperature, and high salinity are environmental factors that dramatically limit plant growth and crop productivity (Boyer, 1982). It has been estimated that 10% of the arable land can be classified under the non-stress category, which implies that the crops grown under the 90% of arable land experience different environmental stresses, singly or in combination. The prediction is that the water deficits will continue to be the major single abiotic factor likely to affect crop yields globally.

The semi-arid tropics (SAT) are prone to hot summers and erratic rainfall having the season length of less than 100 days (Virmani and Singh, 1986). Agriculture in these environments means growing marginal crops on marginal lands with marginal resources. The productivity of crops in these regions is severely affected by drought besides several biotic constraints (Sharma and Ortiz, 2000). Some of the most important crops of this region include groundnut, chickpea, pigeonpea, sorghum, and pearl millet that are the mandated crops of ICRISAT and are the main staple food for nearly one billion people in the SAT. Amongst

these groundnut, chickpea and pigeonpea are legumes that are significant groups of agriculturally important crops and have been the subject of widespread efforts to improve desirable traits. Though, quantitative estimates of yield losses due to drought in tropics are scarce and imprecise, according to some predictions (Subbarao et al., 1995), the productivity could be increased over the present levels in groundnut, chickpea and pigeonpea by 29%, 49%, and 57% respectively, if water was not limiting. However, in rainfed agriculture, there seem to be very few options to increase the area under irrigation and the only option is to improve the realizable yields under water deficit conditions. Although drought management has been an option to increase realizable yields, it is now increasingly being realized that the genetic improvement of drought tolerance is more rewarding (Udaya Kumar et al., 1998; Saxena, 2001). The seed-based technology seems to be easier to transfer to farmers than the more complex knowledge-based agronomic practices. As irrigation water sources become more scarce, development of crop cultivars with improved adaptation to drought is a major goal in many crop breeding programmes. Although, in the last two decades very encouraging progress has been made in assessing the stress responses of several plants (Blum, 1985; Boyer, 1996; Ludlow, 1993; Edmeades et al., 1996), the progress in developing genotypes with enhanced tolerance to abiotic stress has been very slow. Due to the complexity in the physiological, biochemical, and genetic traits involved in drought tolerance, an imperfect understanding of nature of drought, and using yield as an empirical selection criteria, no single strategy may suffice to develop stress tolerant genotypes. It has been recognized that genetic improvement is one of the major components of an integrated approach to stabilizing and improving crop production in drought environments (Subbarao et al., 1995). New tool of biotechnology offer impressive options to supplement the ongoing efforts on developing genetically enhanced germplasm for achieving sustainable food production in the SAT. Drought tolerance breeding might be facilitated by marker-assisted selection in the near future based on the development of molecular linkage maps for crop species (Ribaut et al., 1996, 1997; Nguyen et al., 1997; Zhang et al., 1999; Forster et al., 2000). In addition to classical and molecular breeding approaches (see Fig. 1), genetic transformation to introduce novel genes into plants for better tolerance to water deficit offers an attractive option (Tarczynski et al., 1993; Pilon-Smits et al., 1995; Xu et al., 1996; Sivamani et al., 2000). In fact, the genetic engineering approaches have been shown to be relatively fast and precise means of achieving improved stress tolerance (Hanson and Burnet, 1994; Bohnert and Jensen, 1996; Bohnert and Shen, 1999; Kasuga et al., 1999).

Biotech Approaches for enhancing drought tolerance

Fig. 1. A schematic representation of an integrated approach employing biotechnological tools and traditional plant breeding to develop abiotic stress tolerant crops.

Drought as a major abiotic constraint to productivity of legumes in the SAT

Drought though a broad term can be defined as a meteorological event which implies the absence of rainfall for a period of time long enough to cause moisture depletion in soil and water deficit with a decrease of water potential in plant tissues (Kramer, 1980). It prevents the crops from reaching the determined and expected yield and drastically lowers the production thus affecting the economy of a country. In an agronomic sense, drought stress has been defined as a reduction in grain yield attributable to plant water deficit (Subbarao et al., 1995). Further, the grain legumes dependent on current rainfall are prone to intermittent drought stress during the vegetative or reproductive growth period; the crop recovery from the drought is determined by subsequent rainfall. Terminal drought stress, which occurs during the pod-filling phase of crops, is common and a major yield reducer for crops growing with current rainfall (Nageshwara Rao et al., 1985a,b). This is even more critical for crops grown during a post-rainy season and reliant on stored soil moisture. Groundnut, chickpea, and pigeonpea that are major crops in SAT are very sensitive to high temperatures and water deficits during the flowering stage and seed/pod development stage resulting in heavy loss to productivity.

Groundnut. Groundnut (*Arachis hypogaea* L.) is a major oilseed legume native to south America and forms an important legume in Asia and Africa. It is mainly grown under rainfed, irrigated, and residual moisture conditions. The crop is cultivated on 24.8 million hectares with an average productivity of 1.32 t^{ha}. About 93.8% of the world's production of groundnut is grown by resource-poor, small farmers in 96.9% of world's groundnut area in developing countries where scanty and unseasonal and unpredictable rainfall is

observed (Nageshwara Rao and Nigam, 2001). Asia accounts for 66.5% groundnut production on 56.8% area while Africa produces 24.7% on 38% area subjected to groundnut production. This also accounts for low average yields of 0.86 t ha in Africa and 1.55 t^{ha} in Asia as opposed to 2.5 t^{ha} in developed countries despite the potential to produce 10 t^{ha}. Poor yields in these countries is mainly due to the biotic and abiotic constraints like erratic rainfall, low residual moisture, lack of high yielding adapted cultivars, damage by pests and diseases, poor agronomic practices, and limited use of inputs (Nageshwara Rao and Nigam, 2001). In the event of end-of-season drought, which is common under rainfed and residual moisture conditions, the produce becomes vulnerable to aflatoxin contamination. The loss due to biotic factors that include various diseases caused by fungal pathogens, viruses, bacteria and nematodes is estimated to be US \$2 billion. (Sharma et al., 2001). Yield losses due to drought are highly variable in nature depending on timing, intensity, and duration coupled with other location-specific environmental stress factors such as high irradiance and temperature. An annual estimated loss in groundnut production equivalent to over US\$520 million are caused by drought. According to Johansen and Nigam (1994), almost half of it (US\$208 million) can be recovered through genetic enhancement for drought resistance with a benefit:cost ratio of 5:2.

Drought affects the calcium uptake by pods and nitrogen fixation in groundnut where the photosynthesis is also reduced. When the crop reaches the harvesting stage there is the possibility of high contamination of the seeds with aflatoxins which makes the seeds toxic and unfit for consumption by both humans and livestock. It has been suggested by Freeman et al. (1999) that in the medium-term groundnut production and consumption is likely to shift increasingly to developing countries; production will grow in all regions but most rapidly in Asia, slowly in sub-Saharan Africa, and decline in Latin America; and there would be a shift in the utilization of groundnut products from oil to confectionery products suggesting an urgent need and shift in research for exploring the available genetic resources for their traits to tolerate drought.

Chickpea. Chickpea (*Cicer arietinum* L.) is the world's second most important pulse crop that is cultivated in more than 41 countries covering more than 11 million hectares of land and producing around 8 million tons of high protein food grain (FAO, 1999). The mean protein content of chickpea is about 24% that serves as an important source of dietary nutrition to poor of the SAT. It also has tremendous beneficial effects on increasing the productivity of succeeding crops in rotation besides enhancing the sustainability and productivity of production systems (Kumar Rao et al., 1998).

It is predominantly a rainfed crop grown after the end of the rains in south Asia and eastern Africa. This makes the crop to complete its life cycle on stored and receding soil moisture where it is exposed to increasing drought (Saxena, 2001). Despite having the yield potential of 5 t ha, the average yield is only about 0.8 t ha due to poor management practices and diseases. The yield losses across the SAT and the west Asia and north Africa (WANA) regions range from 40-60%. Global yield losses due to drought in chickpea are estimated to be around 3.7 million t and around 2.1 million t of these can be recovered through crop improvement efforts (Johansen et al., 1993). The yield losses in chickpea can be completely overcome with irrigation. Although some of the drought effects can be alleviated through agronomic and genetic options that do not involve external input of irrigation, these options can be only partial solution to this problem since the yield will always be lower than what can be achieved with irrigation (Saxena, 2001). It was shown that the yield gap between the most drought tolerant variety ICC 4958 and many other varieties with irrigation was large where the yield of ICC 4958 was only 30% of the potential, irrigated yield of most of the varieties. Conventional plant breeding techniques to upgrade the quality of the variety to tolerate drought have not been successful in chickpea due to the unavailability of appropriate methods to screen and breed varieties tolerant to drought, and also the appropriate selection tools to select the tolerant varieties.

Pigeonpea. Pigeonpea [*Cajanus cajan* L. (Millsp.)] is an important grain legume crop of the SAT that has ability to withstand drought conditions to produce grain of high protein concentration and biomass products such as fuel wood and fodder (Nene et al., 1990). It ranks sixth in area and production in comparison to other legumes of developing countries. It is widely grown in India mainly by resource-poor farmers accounting for 90% of the world production. Other regions where pigeonpea is grown are south east Asia, Asia, Africa, and the Americas. Its seed has approximately 21% of the protein content and is known as poor man's meat. The crop is usually grown under rainfed conditions where intermittent and terminal drought stress are frequent. It can be exposed to intermittent drought stress during dry periods of the normal rainy season and to terminal drought stress in the post-rainy season. In recent years, the advent of shorter duration genotypes has widened the scope of pigeonpea cultivation in various, non-traditional cropping systems (Nam et al., 1993, 2000). Pigeonpea has an excellent deep and lateral rooted system that makes it salinity and alkalinity tolerant crop. Despite having such stress-tolerant traits in it, the yield and the productivity of pigeonpea, however, is very poor mainly due to the poor crop resource management (Lawn and Troedson, 1990).

While the traditional long duration pigeonpea can survive periods of drought stress during its growth cycle, the challenge is to improve the ability of the plant to produce under drought conditions. Studies in which irrigation has been given during the reproductive phase indicate that terminal drought usually reduces grain yield of landraces growing in their usual environment (Chauhan et al., 1992). A thorough characterization of the drought environments where pigeonpea is grown has not been adequately done so as to enable proper targeting of drought resistance traits (Johansen, 2001). There has been as yet no concerted breeding effort to enhance drought resistance of this crop due to the allocation of resources to other constraints like development of resistance to an important insect pest, *Helicoverpa armigera*.

Strategies to combat drought

Drought tolerance in plants is a complex trait and is mediated by many environmental adaptations that may involve many genes (Bohnert et al., 1995). A single strategy cannot confer drought tolerance in these plants. The problem of drought can best be tackled following a holistic approach integrating genetic resistance for drought, matching of genotypes to environments, and cultural methods that lead to better conservation and utilization of soil moisture. Further, efforts involving conventional and biotechnological approaches (see Figure 1) for genetic enhancement can certainly promise to induce and enhance the required drought tolerance in these important crop plants of SAT.

Conventional Approaches

a. Agronomic management options

Various aspects like providing supplementary irrigation, timing, method and intensity of irrigation would effect the yield of the crop (Wright and Nageshwara Rao 1994). Since in legumes the pod filling stage is very sensitive to drought, tackling the crop at such stage with proper care would increase the yield. The pod yield in groundnut can be increased by 13-19% if the crop is irrigated adequately during the pre-flowering phase (Nageshwara Rao et al., 1985b). The adaptive response of groundnut to drought can also be increased by exposing the crop to short duration drought during the vegetative phase which may enhance the root development and reduce transpirational losses by limiting the leaf area development allowing the plant to utilize the soil moisture from the deeper soil profile. This would reduce the impact of the second drought at the seedling stage by carefully selecting the cultivar, manipulating the sowing date, matching the water availability in the soil and intercropping with other

crops can enhance the productivity and can ameliorate the severe effects of drought on groundnut productivity.

In chickpea too similar practices would have a positive impact on the crop productivity. However, being a post rainy crop and more sensitive to drought than groundnut few other simple input management options like improving the plant stand by timely sowing, using the high quality seeds, sowing the seed at soil depths so that it utilizes available soil moisture from the deeper regions of the soil profile, and seed dressing with fungicide which would increase the stability of plant stand per unit area (Saxena, 2001). Generally, sowing is done in surface layers where there is not adequate soil moisture after preparatory land cultivation. Advancing planting dates into autumn instead of traditional spring planting in WANA, and coinciding with late summer rains in south Asia and east Africa with disease tolerant varieties would allow plant to access to additional water concurrent with rainfall. Since the temperatures are low and evaporation is less during that rainy period, the evapotranspirational loss of water is reduced.

b. Plant breeding

In conjunction with the agronomic management, genetic management options in these crops can prove to be a better long-term strategy to improve the yield and performance of the crop in water limited and drought prone regions. At ICRISAT, genetic management approaches like developing short duration genotypes that can escape end-of-season drought, has resulted in 23% to 411% superior pod yield over the control varieties of groundnut (Nageshwara Rao and Nigam, 2001). Selecting the genotypes based on their fit to the historical weather and soil data of target location can also improve the overall efficiency of the crop. Alternatively genotypes which thrive well under limited moisture conditions show 12% to 144% pod yield superiority (see Nageshwara Rao and Nigam, 2001). Screening groundnut genotypes for better vegetative growth and pod yield under severe end-of-season and mid season drought has been an option. Genotypic variation for deep root system (Ketering 1984; Wright et al., 1991; Wright and Nageshwara Rao 1994), genotypes with lower mean SLA (surface leaf area) which have higher transcription efficiency has also been observed (Nageshwara Rao and Wright, 1994). Another way is to evaluate wild species for physiological traits associated with drought and aflatoxin resistance and identify suitable DNA markers for drought resistance gene[s] for use in inter-specific breeding to develop drought resistant lines (Nageshwara Rao and Nigam, 2001).

Conventional plant breeding with better agricultural management practices described above can promise to improve drought tolerance in the legume crops, however the major draw back of such conventional methods is that the available drought tolerant traits in the natural

system may not be readily amenable for breeding strategies due to species barrier and also the lacking of proper methods and techniques for screening the drought tolerant traits in the segregating populations thus obtained.

Biotechnological Approaches

Plant biotechnology offers new ideas and techniques applicable to agriculture. It uses the conceptual framework and technical approaches of plant tissue culture and molecular biology to develop commercial processes and products. These techniques enable the selection of successful genotypes, better isolation and cloning of favourable traits, and the creation of transgenic crops of importance to agriculture. This ability has moved agriculture from a resource-based to a science-based industry (Sharma and Ortiz, 2000). Together, these generic techniques are both an extension and an integral part of classical breeding, contributing successfully to shortening breeding and selection cycles (see Sharma et al., 2002). New bio-techniques, in addition to conventional plant breeding, are necessary to boost yields of the crops that feed the world (Borlaug, 1997), thereby contributing to food security by helping to promote sustainable agriculture centered on small-holder farmers in developing countries (Serageldin, 1999; Sharma and Ortiz, 2000). Although more difficult to control and engineer than the usually monogenic traits of resistance to biotic stresses, the genetically complex response to abiotic stress is globally and regionally far more important. Judicious application of biotechnological tools holds great potential in alleviating some of the major constraints to productivity of crops grown in the SAT. Schematic representation of the application of tools of biotechnology to address complex issues in agriculture such as drought stress is shown in Figure 1.

a. Molecular markers and marker-assisted selection

Many of the agronomic traits in plants are quantitative in nature. The process of domestication and selection have resulted in a drastic narrowing of the genetic variation of crop species (Tanksley and McCouch, 1997). The genetic/ physiology interaction provides a potential means of identifying candidate genes/ mechanisms (Forster et al., 2000). It is possible to identify and map the factors controlling characters as intransigent as yield (Thoday, 1961). Few loci in crops and their allelic forms account for a significant genetic variation in traits. Such loci can be mapped using molecular markers based on random amplified polymorphic DNA (RAPD), restriction fragment length polymorphism (RFLP), amplified fragment length polymorphism (AFLP), DNA amplification polymorphism (DAF), sequence characterized amplified

regions (SCAR's), sequence-tagged sites (STS), expressed sequence tags (EST's), and amplicon length polymorphisms (ALPs) as long as polymorphism is observed in the segregating populations, the molecular marker is tightly linked to the trait of interest, and the phenotypic information on the population is available. Molecular markers have several advantages over the traditional phenotypic markers that were previously available to plant breeders. They offer great scope for improving the efficiency of conventional plant breeding by carrying out selection not directly on the trait of interest but on molecular markers linked to that trait. Moreover, these markers are not environmentally regulated and are, therefore, unaffected by the conditions in which the plants are grown and are detectable in all stages of plant growth (Mohan et al., 1997).

Although polymorphic variation in DNA has been detected in groundnut germplasm, the levels of genetic polymorphism have been very low (Bhagwat et al., 1997; He and Prakash, 1997; Hopkins et al., 1999; Subramanian et al., 2000). However, abundant polymorphism has been detected between related wild species in the section *Arachis* (Halward et al., 1991, 1992; Lanham et al., 1992; Paik-Ro et al., 1992). The information on biochemical and molecular basis for variation among the genotypes for drought resistance is very limited (Nageshwara Rao, et al., 1995). More recently, 43 drought-responsive mRNA transcripts (peanut transcripts responsive to drought; PTRD) that are up- or down-regulated following water stress have been identified in *Arachis hypogaea* (Jain et al., 2001). Amongst these 12 PTRD were completely suppressed due to prolonged drought while two were down-regulated, and two were up-regulated. Once the information is known, linkages can be developed between the drought resistance traits and the molecular markers to deploy the molecular tools to accelerate the plant breeding process for drought tolerant varieties.

The progress in genetic enhancement of chickpea and pigeonpea for drought tolerance is expected to progress faster with MAS for drought tolerance traits that would enhance the efficiency of breeding for this complex trait. According to Saxena (2001), the drought tolerant chickpea varieties already developed at ICRISAT and the segregating populations available for drought tolerant traits could be used to initiate such programs and build upon the information and material already available. However, genetic analysis particularly of quantitative traits associated with abiotic stress tolerance have associated errors. The detection of the loci involved is based on the probabilities and can be crude (Hay and Ellis, 1998), with different results in different environments. This approach may be limited to a few selective traits considering the practical difficulties involved in developing these genetic

markers for a given physiological trait and also the limitations associated with generating large numbers of early segregating materials to get a desired level of recombination if one has to handle several traits simultaneously in a breeding programme (Marshall, 1991; Subbarao et al., 1995). The application of molecular markers can promise more rigor when both the genetic and physiological analyses point to the same gene function, allowing greater confidence in identifying a candidate gene (Forster et al., 2000).

b. Transgenic technology and genes for drought tolerance

Genetic transformation provides a complementary means for the genetic betterment of the genome of field crops thus promising for alleviating some of the major constraints to crop productivity in developing countries (Sharma and Ortiz, 2000). The technology required for engineering transgenic plants is considerably more sophisticated than that required for production of hybrid plants by cross-fertilization (Goodman et al., 1987; Kung, 1993; Birch, 1997). Novel genes can be accessed from exotic sources-plants, animals, bacterial, even viral and introduced into a crop either physically through biolistics or by using binary vectors based in *Agrobacterium tumefaciens*. Further, it is possible to control the timing, tissue-specificity, and expression level of transferred genes for their optimal function. There are several traits whose correlative association with resistance has been tested in transgenic plants. The results of transgenic modifications of biosynthetic and metabolic pathways indicate that higher stress tolerance can be achieved by engineering, that tolerance is only marginally increased by the transfer of a single trait, and that multiple mechanisms to engineer water stress tolerance must be utilized (Bohnert et al., 1995).

Crops can be tailored to tolerate stress if only one knows the amount of damage that occurs to the plant at the physiological and cellular level. The physiological response to stress usually arises out of change in the cellular gene expression (Nanjo et al., 1999a). As a result changes in the integrity of the cellular membrane, imbalance in the homeostatic conditions and finally decline in the growth or death of the plant are usually noticed (Zhu, 2001). Such alteration in the gene expression is always involved in preparing the plant to thrive under stress. The distribution and occurrence of naturally stress-adapted plants in many different families like *Hydrilla verticillata*, *Najas indica*, *Najas graminia* belonging to submerged macrophytes (Rout and Shaw, 2001), the occurrence of stress-tolerant relatives in many glycophytic species like *Arabidopsis thaliana* (Zhu, 2001), and the occurrence of genetic variability in stress tolerance of crop plants per se makes the mechanisms that control the stress perception and the gene expression after the stress, universal in

plant kingdom (Bohnert et al., 1995).

Certain genes are expressed at elevated levels when a plant encounters stress (Bray, 1993). Hence, several gene transfer approaches have been employed to improve the stress tolerance of plants (Holmberg and Bulow, 1998; see also Fig. 1). These can be a product of single gene or a product of a regulatory gene that activates the whole cascade of other gene products in the plant in response to stress. Genetically engineered plants for single gene products include those encoding for enzymes required for the biosynthesis of osmoprotectants (Tarczynski et al., 1993; Kavikishore et al., 1995; Hayashi et al., 1997), or modifying membrane lipids (Kodama et al., 1994; Ishizaki-Nishizawa et al., 1996), LEA protein (Xu et al., 1996), and detoxification enzyme (McKersie et al., 1996). Similarly, many genes involved in stress response can be simultaneously regulated by using a single gene encoding stress-inducible transcription factor (Kasuga et al., 1999), thus offering possibility of enhancing tolerance towards multiple stresses including drought, salinity, and freezing. In general, very little attention has been given to genetic improvement to cope with intermittent drought (N.P. Saxena personal communication). It is believed that osmoregulation would be the best strategy for this kind of drought, especially if osmoregulatory genes could be triggered in response to drought. Some of the key strategies that have successfully been used in developing transgenic plants with some level of tolerance to abiotic stress are as follows:

Osmoprotectants: The maintenance of total water potential during water deficit can be achieved by osmotic adjustment. A reduction in cellular water potential below the external water potential, resulting from a decrease in osmotic potential, allows water to move into the cell. The osmotic potential inside the cell is lowered by the accumulation of osmoprotectants (compatible solutes) in the cytoplasm due to the induction of several genes (Bray et al., 1993). These are highly soluble compounds that carry no net charge at physiological pH and are non-toxic at high concentrations. Chemically, there are three types: betaines and allied compounds, polyols and sugars (e.g., betaines and trehalose), and amino acids such as proline (Pro) (Delauney and Verma, 1993; Stoop et al., 1996; McNeil et al., 1999). The first strategy involved in obtaining stress tolerant transgenic plants is to engineer such genes that encode enzymes for steps in the synthesis of these osmolytes. Various strategies are being pursued to genetically engineer increased osmoprotection in plants. Many osmoprotectants like glycine-betaine (Ishitani et al., 1995; McNeil et al., 2001), proline (Delauney and Verma, 1993; Nanjo et al., 1999a), choline oxidase (Sakamoto et al., 2000), glutamine synthetase (Hoshida et al., 2000), arginine decarboxylase (Roy and Wu, 2001), mannitol,

nonnitrol, fructans, ectoine, and other gene products have been studied which play a role in osmoregulation thereby protecting the membrane and protein complexes (Yang et al., 1996). Although improved stress tolerance has not been achieved when native stress-induced genes are expressed, transgenic tobacco plants expressing a foreign gene leading to mannitol accumulation (Tarczynski et al., 1993) does improve stress tolerance. Free Pro is regarded as having multiple roles in stress tolerance in plants such as mediator of osmotic adjustment (Handa et al., 1986), a stabilizer of subcellular structures (Schobert and Tschesche, 1978), a scavenger of free radicals (Pardha Saradhi et al., 1995), a buffer in cellular redox potential and a major constituent of cell wall structural proteins that may provide mechanical support for cells (Nanjo et al., 1999b).

More recently, a positive correlation between Pro accumulation and stress tolerance in *Arabidopsis thaliana* has been shown by Nanjo et al. (1999a) by using antisense proline dehydrogenase (*AtProDH*). Significant tolerance to drought stress has been observed in potato by using trehalose-6-phosphate synthase (TPS1) gene (Yeo et al., 2000). An improved protection of the photosynthetic apparatus was thought to be associated with the increased stress tolerance due to the introduced expression of *betA* gene that results in the production of glycine-betaine (Holmstrom et al., 2000).

Amongst the several groups of LEA proteins those belonging to the D-7 family are predicted to play a role in the sequestration of ions that are concentrated during cellular dehydration. These proteins have 11-mer amino acid motif with the consensus sequence TAQAAKEKAGE repeated as many as 13-times (Dure, 1993a). The D-19 family LEA proteins are predicted to have enhanced water-binding capacity, while the D-29 family is supposed to sequester ions during water loss. At least 30 different genes have been identified as members of lea group 2 (D-11 family) whose possible functions include a chaperone function or one that preserves protein structure (Dure, 1993b). However, further investigations combining physiological and genetic studies are needed to evaluate the role of water-deficit-induced genes and any adverse metabolic cost associated with osmoprotection.

Ion-Compartmentalization: Second strategy involves in protecting the crop against abiotic stress mainly salinity and water stress by regulating the ion uptake and compartmentalization of ions (Adams et al., 1992). These salts have detrimental effects on the biochemical processes of a plant resulting in the osmotic stress. Numerous metabolic changes occur in different salt sensitive plants which are subjected to ionic stress. The Na^+/H^+ exchange across the membrane is activated so that K^+ can be pumped across the cell membrane. Structurally plant cells are well suited for the

sequestration of ions because of the presence of the membrane-bound vacuoles. Many halophytes have a mechanism in them to compartmentalize Na^+ into vacuoles through a vacuolar Na^+/H^+ antiport. Such vacuolar Na^+/H^+ antiport activity was first reported in tonoplast vesicles from red beet storage tissue (Blumwald and Poole, 1985), and also in various halophytes and salt tolerant glycophytic species (Barkla and Pantoja, 1996). In *Arabidopsis* a vacuolar chloride channel, *AtCLC*d gene was cloned which involves in cation detoxification and more recently in *Arabidopsis* *AtNHX1* gene which is homologous to *Nhx1* gene in yeast has been cloned and over expressed in *Arabidopsis* which confers salt tolerance by compartmentalizing the Na^+ ions in the vacuoles. SOS1 (Salt Overly Sensitive 1) locus is one such locus in *Arabidopsis thaliana* which is similar to plasma membrane Na^+/H^+ antiport from bacteria and fungi and encodes a putative Na^+/H^+ antiporter that was cloned and over expressed using a CAMV35S promoter. *SOS1* gene expression in plants was up-regulated in response to salt tolerance (Shi et al., 2000).

Regulatory genes: Abiotic stress is a broad term which includes multiple stresses like heat, chilling, excessive light, drought, wounding, ozone exposure, UV-B irradiation, osmotic shock, where various cellular functions are disturbed. In order to restore the cellular function and make plant more tolerant to stress, transferring of a single gene encoding a single specific stress protein may not possibly show the required tolerance levels. To overcome such constraint enhancing tolerance towards multiple stress by a gene encoding a stress inducible cis-acting or trans-acting transcription factors that regulate a number of genes down stream or upstream of it thus activating a cascade of genes that act together in enhancing the tolerance towards the multiple stresses will prove to be a promising technology (Yamaguchi-Shinozaki et al., 1994; Kasuga et al., 1999). Both DREB1A cDNA and the *rd29A* promoter can be used to improve the dehydration, salt, and freezing tolerance of crops by gene transfer (Kasuga et al., 1999). Many genes respond to multiple stresses like dehydration and low temperature at the transcriptional level are also induced by ABA (Mundy and Chua, 1998) which protect the cell from dehydration. (Dure et al., 1989; Skriver and Mundy, 1990). Dehydration appears to trigger the production of ABA, which in turn induces expression of various genes (Ingram and Bartels, 1996; Shinozaki and Yamaguchi-Shinozaki, 1997). Transcription factors acting both *cis* as well as *trans* have been analyzed and a conserved sequence PyACGTGGC has been reported to function as ABA-responsive element (ABRE) (Marcotte et al., 1989). Genes which respond to these transcription factors or elements mostly have a basic domain and a leucine zipper structure (Guiltingan et al.,

1990; Oeda et al., 1991). Transgenic tobacco thus obtained by transferring the tetramer of a synthetic element conferred enhanced response to water stress (Lam and Chua, 1991).

There are other cis acting elements or factors of genes that have ABA independent expression (Yamaguchi-Shinozaki et al., 1992). A cis-acting element designated as dehydration responsive element (DRE) having the sequence TACCGACAT is known to be involve in ABA-independent gene expression under drought, high salt, and low temperature conditions in many dehydration responsive genes like *rd29A* that is responsible for dehydration- and cold-induced expression. The cDNAs encoding the DRE-binding proteins, DREB1A and DREB2A, have been isolated and the proteins shown to specifically bind and activate transcription of genes (*rd29A*) containing the DRE sequence in *Arabidopsis* (Liu et al., 1998). For detail discussion on these regulatory genes and sequences see chapter by Shinozaki-Yamaguchi et al. in this report. Transforming such drought responsive elements and transcription factors such as DREB1A cDNA and *rd29A* promoter into crops like groundnut and chickpea using genetic transformation either by *Agrobacterium*-mediated transformation or by using a Biolistic approach, can be an effective strategy for the development of crops having improved tolerance to abiotic stress.

Current Status of legume transgenics at ICRISAT

Genetic engineering of plants makes it feasible to transfer genes from totally unrelated organisms thus breaking the species barrier which is otherwise not possible by conventional plant breeding. Gene transfer technologies have widened the scope for agriculture in modifying the crops to increase the yield, to impart resistance against various diseases, increase the nutritional content, and enhance resistance against drought. The application of this technology for the improvement of important crops of the SAT has been shown to hold great potential (Sharma and Ortiz, 2000). However, for the successful genetic modification by the production of transgenic plants, effective regeneration and transformation systems are imperative. Transformation of crops involves the stable introduction of DNA sequences into the nuclear genome of cells capable of giving rise to a whole transformed plant (Sharma and Ortiz, 2000). At ICRISAT, these barriers have recently been overcome and efficient transformation and regeneration of transgenic plants of the mandate legumes including groundnut, pigeonpea and chickpea is now routinely possible for various biotic and abiotic constraints (Sharma, 1999; Sharma and Anjaiah, 2000a,b).

Groundnut: The method for genetic transformation of groundnut (Sharma and Anjaiah, 2000b) reported from ICRISAT is a significant improvement over the previously reported results where at least 55% of the treated explants resulted in one or more independently transformed shoots. Multiple shoots originating from a single explant (Fig. 2A) showed different integration patterns suggesting that the transformation frequency in fact is higher. The transformation procedure utilizing cotyledon explants is highly susceptible to *Agrobacterium*-mediated gene transfer, and also displays very high regeneration rates across a wide range of *Arachis hypogaea* varieties of both Spanish and Virginia type peanuts. A key feature of this procedure is the regenerability of the cells wounded during excision of the cotyledons at the time of culture initiation and *Agro*-infection, and these cells being mainly surface cells are readily accessible to the *Agrobacterium*. Shoot regeneration in this system is quite rapid and prolific, and a large proportion (>98%) of these shoots develop into phenotypically normal fertile plants where the transgene function is normal at transcriptional and translational levels. This system has been successfully utilized for the introduction of several genes such as those encoding for viral coat protein of Indian peanut clump virus (IPCV) and groundnut rosette assistor virus (GRAV), replicase of IPCV, *Bt CryIA(b)*, and chitinase from rice. A new initiative with JIRCAS is being developed to utilize their constructs (*rd29A:DREB1A*) carrying DRE of *Arabidopsis* into *Arachis* for inducing drought resistance in groundnut. Putative transformants obtained in *Agrobacterium*-mediated transformation are being characterized for presence and expression of the introduced genes. The confirmed transgenic groundnut plants will be characterized for their phenotype and physiologically under normal and drought stress conditions to study their drought tolerance potential. The drought tolerance trait can eventually be transferred to selected genotypes with specific adaptations by conventional plant breeding by using the introduced genes as molecular markers. This protocol provides a transformation scheme that allows cost-effective, routine, and highly reproducible use of peanut transformation as part of both basic and applied studies in gene expression, transgenics, and functional genomics.

Pigeonpea: Efficient systems for the tissue culture regeneration of pigeonpea have been developed by using the axillary tissue (Fig. 2B; Sharma and Anjaiah, 2000a) and leaflet explants (Dayal and Sharma, unpublished results). A transformation protocol for pigeonpea to incorporate novel genes is in the final stages of development. A large number of putative transformants of pigeonpea have been successfully transferred to glasshouse and preliminary evidence suggests the presence of introduced genes like *Bt Cry IA(b)*, soybean trypsin inhibitor (*SBTI*), and rice

Fig. 2A-C. Tissue culture systems in legumes for use in developing abiotic stress tolerance. A. Regeneration of multiple shoots from cotyledon explants of *Arachis hypogaea*; B. Regeneration of multiple shoots from axillary meristems of *Cajanus cajan*; C. Regeneration of multiple shoots from axillary meristem explants of *Cicer arietinum*.

chitinase. Insect bioassays with tobacco transgenics having insecticidal genes have shown the potential of the available *Bt CryIA(b)* and *SBTI* genes for insect control. Further work on developing resistance to fungal pathogens of pigeonpea is ongoing. These systems can be effectively used for developing drought resistant transgenics by employing the several strategies listed above.

Chickpea: A tissue culture system for chickpea has been optimized by using the embryo axis explants that produce multiple shoots (Fig. 2C). The axillary meristem tissues from embryo axis explants have been optimized to obtain a high frequency of shoots. Successful rooting and transplantation of these shoots is now possible with over 90% success rates. Putative transformants containing *Bt Cry IA(b)* and (*SBTI*) genes have been obtained. Recently, this system is being employed to introduce genes for abiotic stress tolerance such as *codA* (Alia et al., 1999), *P5CSF:129A*, (Kavi Kishore et al., 1995), *mtld* (Tarczynski et al., 1993) and *annexin* (Gidrol et al., 1996). The putative transgenics are being analyzed at the molecular level.

Summary

Significant progress has been made in the field of agriculture to successfully enhance the drought tolerance in various plants using several strategies. The discovery of genes involved in osmoregulation, ion compartmentalization, and regulatory elements that are responsive to drought have opened up new avenues for developing crop plants with enhanced drought tolerance. Further research must be carried out in finding out the availability of stress responsive genes and transcripts in groundnut and chickpea and their expression under different environmental conditions. Wild species, due to their better adaptability offer unique opportunities for identifying and cloning new

genes and promoters that can be employed for developing stress tolerance by using an integrated approach as outlined in Figure 1. Gains in crop productivity through research advances in genetic enhancement will help to achieve sustainable food security, poverty alleviation, and environmental protection in the SAT. ICRISAT has a commitment to transfer the benefits of plant biotechnology to the developing world, as genes relevant to their crops and environment become available. Therefore, the research in transgenic crops offers a new means to achieve ICRISAT's mission, i.e., applying science to improve agriculture in areas of the world where sub-optimal rainfall and biotic stresses are the major constraints to crop productivity.

Acknowledgements

We thank Dr. N.P. Saxena for his valuable comments and suggestions on the manuscript, and Dr. Masaru Ivanaga for his encouragement on the research related to groundnut transgenics for drought tolerance. The financial assistance from Indo-Swiss Collaboration in Biotechnology (ISCB) on work related to chickpea is gratefully acknowledged.

Challenges in biotechnology for abiotic stress tolerance on roots and tubers

Kazuo N. Watanabe

Gene Research Center & Institute of Biological Sciences, University of Tsukuba,
1-1-1 Tennoudai, Tsukuba, Ibaraki, 305-8572, Japan

Abstract

Roots and tuber crops such as potato, sweetpotato, cassava, yam and taro, could have a large impact as food, feed and industrial materials with far smaller investment than what have been made to cereals and pulses. Although the social status of these crops are regarded somewhat low, the contribution as staple crops should not be under-estimated to the subsistent farmers and to the production at the marginal lands and/or at a harsh climatic condition.

These root and tuber crops are vegetatively propagated and diverse biological constraints are encumbered with their crop reproductive nature. Furthermore, the crops get damages by series of the environmental stresses during the development of roots or tubers, and also at the storage. The importance of these environmental constraints varies with agroecology and by crop species. Principle environmental stresses of global and ecoregional concerns are drought, excess soil moisture and cold. High soil salinity is the upcoming issue where irrigation is practiced at marginal lands and/or at areas with rapid desertification. Improvement in the storage quality is another important aspect, and keeping moisture and longer dormancy in the storage organs are one of the key subjects for storing the foodstuff and for the wide application to industrial uses.

Progress should yet be expected on transgenic research on root and tuber crops. Many root and tuber crops have not been examined even for feasibility of biotechnology applications for alleviating their pitfalls in production and uses, and challenges should be made in exploiting these regionally important crops and seeking the potential by the biotechnological tools.

Key words: root and tuber crops, biotechnology, diagnostics, genetic engineering, pathogen-free propagules, environmental stresses

Introduction

Root and tuber crops are important staple crops in many developing countries and also important industrial materials in developed nations (CIP 2001; Scott et al. 2000; Wheatley et al. 1995). Examples of the root and tuber crops are potato, sweetpotato, cassava, yam and taro, and many other locally important crop species are present and rather under-utilized (Hermann and Heller 1997; NRC 1989; NRC 1993; Watanabe and Arbizu 1997).

Common biological features of the root and tuber crops such as, would be: 1) vegetatively propagated; 2) genetically heterozygous, 3) outcrossing; 4) polyploids or polyploidization origin; 5) storage parts being underground; and 6) foliage could also be used for food and feed. General breeding objectives are on: 1) resistances against disease, insect and nematode pests,

especially vegetative organ born problems; 2) abiotic tolerances to drought, excess soil moisture, frost and freezing, and salinity; 3) general productivity and earliness. Improvements in the storage and in the processing quality are another important aspects in the root and tuber crops. Particularly keeping moisture without biological and abiotic stresses and longer dormancy in the storage organs are some of the key subjects for storing the food materials and for the wide application to industrial uses. However, this paper should focus on the general issues on the biotechnology application to the root and tuber crops.

Based on the biology of the root and tuber crops, crop protection and improvement for productivity and sustainability should be considered. A diverse range of biotechnology can be applied for the root and tuber crops. The examples are: tissue culture for germplasm

conservation and mass propagation of planting materials; diagnostic tools such as ELISA and NASH for crop health and quarantine, molecular markers for genebank management, cultivar identification and breeding; genetic engineering for alleviating the pitfalls that conventional breeding approaches could not overcome etc.

Major genetic resources on the root and tuber crops are conserved *ex situ* at national or international genebanks such as international agricultural research centers under CGIAR (Consultative group on International Agricultural Research) (NRC 1993). It should be noted that the total number of accessions on these root and tuber crops occupy only 4% of the entire PGR collections under CGIAR, and the figure must support breeding and crop production efforts for around one fifth of world population who mainly depending on the root and tuber crops are their major food and/or cash making materials (CIP 2001). Especially at marginal lands or at regions with harsh cropping conditions, root and tuber crops have far advantages to cereals and pulses as vegetative organs have less damage from the abiotic stresses under such difficult conditions, thus more possibility to provide food materials. Besides the discussion on the biotechnology applications, consideration should be relevantly made on the conservation and uses of the genetic resources on the root and tuber crops.

Potatoes

The common potato (*Solanum tuberosum*) has been widely grown over the world and it has the fourth place as the important staple crops after rice, maize and wheat. Potatoes are unique over these cereals. The edible parts of cereals are botanical seeds that is specifically endosperms, in contrast, the edible part of the potato is the tuber that is underground stem. Thus its physiology is unique and tuberization and its physiology have been the major topics in potato science (Li 1985). Also due to its vegetative reproductive nature by tubers, potato can be damaged by many different biological stresses (Hooker 1981). Potatoes have many enemies in fields, and over five hundred species of pathogens and pests could infest or damage the crops and a series of environmental stresses such as low temperature at the early growing stage and drought at the tuberization period, could result in nil yield (Harris 1978).

Potatoes are cross-pollinating tetrasomic tetraploid and its genetics is far more complicated than self-pollinating diploid such as rice (Watanabe et al. 1997). Many of the breeding targets on potatoes are quantitatively inherited and gain in one generation of selection even on a single trait, is not efficient by

conventional breeding. Heritability varies among such quantitative traits, however, in general, breeding on multiple traits by phenotype evaluation has been cumbersome and only individual experiences by breeders could handle the pitfalls in making slow progresses, and more subjective and sophisticated methods have been desired to make efficiency in breeding.

Potatoes have approximately two hundred species of wild and cultivated relatives which consists of diploid to hexaploid. These species have been the abundant sources for breeding for biotic and abiotic stresses: important traits found in the wild species include resistance and/or tolerance to major biotic and abiotic stresses such as viruses, viroids, insects, nematodes, fungi, bacteria, heat and frost. However, due to the complication of the tetraploid genetics and quantitative nature of the breeding targets, it has been challenging to use especially the wild species into potato breeding. For example, it took several decades to use a single gene control trait on PVY resistance from a tetraploid species *S. stoloniferum* into potato cultivars (Ross 1986 In Watanabe et al. 1995a). Thus, to cope with the constraints in use of the valuable genetic resources, molecular markers have been studied and gradually employed in germplasm enhancement with potato species (Watanabe and Watanabe 2000).

Since also the most of the cultivated potatoes are tetraploid ($2n = 4x = 48$), while approximately seventy percent of the wild relatives are diploid ($2n = 2x = 24$). Ploidy manipulation is essential to introgress desirable traits from the diploid wild species into the high yielding tetraploid cultivated cultivars. Cell fusion and $2n$ gametes have been considered as the tools to transfer the valuable traits from the breeding lines at diploids and substantial successes have been demonstrated in the ploidy manipulation for the potato breeding (Bradshaw and Mackay 1994; Watanabe et al. 1995a).

Adoption of Old Biotechnology

Biotechnological tools have been employed to enhance potato production both in developed and developing countries. Since potatoes are usually propagated as tubers, disease and pest free tubers are important in making high yield and sustainable production. *In vitro* pathogen clean-up process by meristem culture has been established and this has been used widely in many countries. Diagnostic tools also followed after the clean-up processes, and a series of detection methods to viral, bacterial and fungal pathogens, insects, mites and nematodes are available at commercial basis. Among these technologies, NASH (Nucleic acid spot hybridization) method has been applied effectively to eliminate PSTVd (potato spindle tuber viroid) and common viruses such as PVX, PVY and PLRV from the germplasm and seed potatoes. A wide availability of ELISA methods using monoclonal

or polyclonal antibodies also helped monitoring the crop health at field and also a mass scale production of seed potatoes in many developing countries (Watanabe et al. 1995a,b, Watanabe et al. 1997).

Tissue and cell culture system on potato is a model for educational training and industrial applications. Tissue culture derived tubers have been used as the clean nuclear seeds for propagating the production seeds for decades and this accelerated the increasing the yield and cash income in many countries. Even in many developing countries, seed potatoes production by the tissue culture has been conducted, and the technology has been further adapted to small farm-family level: even with a small kitchen and net-house facility in backyard, the seed potatoes are produced in Southeast Asian countries. This is a successful example on low profile biotechnology application and technology acceptance by the endusers. Consequently the recipients of the technology could get cash income and the local community has received benefits (Watanabe et al. 1997).

Genetic Markers for Potato Germplasm Management and Breeding

Although conventional potato breeding has demonstrably resulted in improving potato crops, there are several key bottlenecks. 1) The most important cultivated potato is a tetraploid with tetrasomic inheritance; thus segregation is more complicated than disomic inheritance, and selection even for simply inherited characters is sometimes laborious and less cost-effective compared with that in diploids. 2) Major breeding targets tend to be quantitatively inherited, for example, resistances to bacterial wilt caused by *Pseudomonas solanacearum*; potato leaf roll virus; potato tuber moth; and root-knot nematodes, as well as tuber quality traits and yield components. 3) "Genotype by environment" interactions complicate the expression of the characters. 4) Identification of individual chromosomes by conventional cytogenetical methods is very difficult and it is very hard to monitor introgression in hybridization from wild species which are valuable sources of resistances to major diseases and pests (Watanabe and Watanabe 2000).

A major problem is the difficulty in monitoring introgression of target genes and elimination of undesirable characters, especially from wild species. Furthermore, confirmation of transmission of resistance(s) from progenitors by progeny testing is time-consuming but essential since several genetic factors such as cytoplasmic effects and female by male interactions influence the expression of resistance in progenies. However, molecular markers such as AFLP, RFLP and RAPD markers are actual DNA, thus use of these markers could alleviate these bottlenecks drastically (Watanabe and Watanabe 2000).

The cost of employing DNA markers is, however, an

impediment to their use. Compared with the inherent difficulty in screening and selection for many target characters in potato breeding, the cost of DNA markers may however prove to be reasonably competitive. For example, present phenotypic screening for bacterial wilt resistance requires preparation of much plant materials either by generation of seedlings or cuttings, and an incubation period of at least two weeks. It also requires repeated testing and progeny testing to identify target genotypes. Thus, these procedures require enormous labor, materials and time. On the other hand, linked DNA markers would require several days maximum to identify the genotypes of interest once small amounts of plant tissue are available. Cost reductions would be made by simplifying several procedures in the utilization of DNA markers. Sample preparation is one step which can be simplified. The employment of PCR based markers can also facilitate the screening and selection procedures and increase efficiency in labour, cost and time.

Genetic Engineering Applications to Potatoes

Molecular biology studies and genetic engineering also have been conducted on potato science and industrial uses. A wide range of transgenic research has been made with potatoes for elucidating questions on its physiology and genetics (Belknap et al. 1994; Bradsahw and Mackay 1994; Watanabe et al. 1997), and industrial applications have been demonstrated by the release of transgenic cultivars in North America as well known in common newsmedia.

Transgenic potatoes on biological stresses:

Transgenic research on potatoes have been widely conducted and a series of transgenic potatoes with abiotic tolerance have been reported (Watanabe and Watanabe 2000). Coleoptera insect resistances with a series of BT endotoxins, particularly against Colorado potato beetles, have been developed and commercial cultivars have been released in North America. Viral protection using the viral genes has been employed and coat protein based protection has been widely used in cultivar development. Some technology transfer has been implemented from the developed countries to modestly developed countries such as Mexico and South Africa, and extended field trials have been implemented on these transgenic potatoes (Watanabe et al. 1997).

Carbohydrate synthesis:

Industry supports the research on the carbohydrate biosynthesis on potatoes since decades ago, and knowledge has been accumulated on the area. Molecular biology has been focused on the tuberization and carbohydrate biosynthesis and various studies had been conducted on altering the metabolism associated with

starch accumulation (Belknap et al. 1994). However, no commercial cultivar has been released for supporting industrial uses such as increased processing efficiency in chipping and polylactic acid processing for biodegradable plastic materials yet.

Production of functional substances for pharmaceutical uses:

Since potato tubers can be mass-produced *in vitro*, the tubers have been regarded as the plant factory which could produce rare substances such for pharmaceutical uses (Galun and Galun 2001).

Potato genetic engineering against environmental stresses:

Specific environmental constraints for potatoes are: heat at tropics, low soil moisture / drought, cold, frost and salinity, and indeed, potato yield can be affected by any abiotic stresses. At an early growing stage, the potato buds are sensitive to the change in temperature and both low and high temperatures could sharply influence the successive growth and sometimes a severe damage could result in death of potato plants. Since potatoes can be growing highlands such at Andes, hill sides of East Africa and Central Asia, the drastic change in the night temperature, frost and freezing are also important matters for the crop success over the growing period. While tubers contain high amount of water, the low soil moisture at the early growing and tuberization stages lower the yield and drought at the tuberization period would damage severely on the crops as substantial amount of water is required for tuberization and development of the organs. Since potatoes are often grown at marginal lands such as dry areas, salinity is also another concern on the crop which is rather weak at high level of salt in the field and irrigated water (Harris 1978).

A series of basic research on potato molecular biology for the abiotic stresses have been conducted widely, particularly wounding associated gene expression (Vayda and Morelli 1994 in Belknap et al. 1994), however, the attempt to create tolerances against environmental stresses have not been demonstrated much for practical applications. This is a typical case that lab-based research does not have close-interdisciplinary association with field-oriented research problems and agriculture practice.

We have been employed for generating transgenic potatoes with the transcription factors, *DREB* genes and associated gene components (Kasuga et al. 1999). Our joint effort with JIRCAS, Japan International Research Center for Agricultural Sciences, demonstrates the provisional result on the performance of transgenic potatoes with multiple tolerance to abiotic constraints: drought, salinity and freezing. However, a downstream

research should be conducted to determine the appropriateness of the use of these genetic components and breeding shall be followed up with the finding to create the transgenic potato cultivars with multiple abiotic stresses.

Sweetpotatoes (*Ipomoea batatas*):

Sweetpotatoes are hexaploid and it is regarded as polysomic polyploid (Rao 1996). Thus, due to its polysomic genetics in many traits, even with a single dominant gene control, breeding effort has been very challenging. Furthermore, due to the presence of cross incompatibility genes and low seed set per pollination, production of botanical seeds for breeding has been a limiting factor to generate a large population (KNEAS 1997).

The same as potato, sweetpotato can be infested by various pathogens and pests, and also can be damaged by environmental stresses. The major biological constraints are viruses such as sweetpotato feathery mottle virus and sweetpotato weevils. Cold tolerance should be of critical on sweetpotato at Irian Jaya, Papua New Guinea and Hillside of Eastern Africa, and for the longer cultivation period in Inner Mongolia, winter cultivation in Southern China and Northern Vietnam (Clark and Moyer 1988; KNEAS 1997). By alleviating these constraints, the production shall be boosted up, but due to the low interest both at developed and developing countries, consequently, not much investment on the research has been made to break through the pitfalls in sweetpotato production.

Biotechnology applications have been, however, demonstrated on sweetpotatoes in tissue culture, diagnostics and some molecular marker as well as effort on genetic engineering (KNEAS 1997 and KNEAS 2000).

While extensive studies have been made on regeneration of the sweetpotatoes (Dhir et al. 1998; Gusukonda et al. 1995; Otani and Shimada 1996; Sihachakr et al. 1997; Zheng et al. 1996), there had not been substantial success on inventing a genotype-independent transgenic method. *Agrobacterium tumefaciens*-mediated transformation has been the most common and relatively successful approach (Gama et al. 1996; Otani et al. 1998; Watanabe et al. 1998), while particle-bombardment (Prakash and Varadarajan 1992), electroporation (Mitchell et al. 1998) and *A. ryzogenes* (Espinoza et al. 1987) had been also employed as the transformation methods. Overall yet no genotype-independent transgenic method for sweetpotato has been made in public.

We made a progress on improving efficiency in sweetpotato transformation system with genotype-

independence and some success has been shown to make transgenic sweetpotatoes with potential uses for bioremediation (Watanabe and Watanabe 2001, JPS 2001-223606; Watanabe et al. 2002 In reparation). Using the genotype independent method and some unique gene constructs provided by the collaborators, we shall be demonstrating in future on generating transgenic sweetpotatoes with multiple abiotic stress tolerances.

Cassava (*Manihot esculenta*)

Cassava is the important crop in developing regions in tropical and subtropical climates. While to harvest the crops, it could take more than five months, the maximum yield could be over 100 ton / hectare with 10 months cultivation in some Southeast Asian region. Also there is no major requirement on crop care after planting except water at storage root formation, this crop is highly suitable for the rustic cultivation condition at a marginal land. On the other hand, the crops often contain a high amount of cyanoids which causes serious illness or death to consumers, thus, breeding effort is needed for low cyanoids quantity crops as one of major objectives in the crop improvement (Wheatley et al. 1995).

Tissue culture and micropropagation systems have been established by the support of international agricultural research centers, that are CIAT (Centro Internacional Agripecuraria Tropical and IITA (International Institute for Tropical Agriculture) and some strong national programs such as Brazil and Cuba (CIAT 2001).

Transgenic cassavas have been generated and international agriculture centers declare that genotype independent methods can be employed for the practical applications for specific molecular breeding purposes. (Li et al. 1996; Schopke et al. 1996; Vasil 1996). Specific efforts to reduce cyanogens by transgenic approach have been also supported by CIAT and IITA that stimulate networking South-North collaboration (Anderson et al. 2000; Zhang et al. 2000).

Furthermore, studies on cassava viruses and transgenic cassava have been indicated possibility of alleviating the viral infection and productivity pitfalls due to the biotic stresses (Frey et al. 2001).

However, no specific report on transgenic attempt has been made as substantial progress on the environmental stresses on Cassava, while the crop has to cope with drought and cold damages, and the low temperature tolerance on the storage roots is also of challenge.

Taro and yam

Tissue culture systems have been developed both on taro (*Colocasia and Xanthosoma* spp.) and yam (*Dioscorea* spp.) for conservation and pathogen-cleaning processes at genebanks (Zu et al. 2000). But even the mass propagation of clean propagules based on tissue culture has not been disseminated to small farmers who can often get the severely pathogen-pest infested vegetatively maintained propagules for their crop production. Some useful information on the tissue culture is available in the local languages such in Japan and China, these shall be introduced by a review article and some reffort is in progress (M. Akita, personal communication, akita@bio.waka.kindai.ac.jp).

Taro: Some specific studies have been conducted on the storage protein components, such as tarin in the corms of taro that may be associated with the defense responses (Bezerra et al. 1995, de Castro et al. 1992; Monte-Neshich et al. 1995). However, a little knowledge has been obtained yet on the storage protein, and the function of the gene family which encode the isoforms of tarin that the major soluble proteins in taro corms (Guimaraes et al. 2001), should be elucidated further for practical application for creating stress tolerance into taro crops.

Yam: Only localized importance exists in the case of yam as a major crop in the West Africa particularly in Nigeria, while many subsistent farmers in tropical and temperate zones use the crops as basic nutritional sources (Orkwor et al. 1998). As previously mentioned, tissue culture system is available for the dissemination of biotechnology, however, no trial has been made with molecular biological approaches for crop improvement. On the other hand, pharmaceutical industry has been working on diosgenin in some *Dioscorea* species. Diosgenin is an effective medicinal substance against uterus cancer, and cellular, biochemical and moleculare biology studies have been conducted immensely for product development (Haraguchi et al. 1994, Savikin-Fodulovic et al. 1998). A small investment from such a wealthy industry shall improve the yam crops for food together with increased value as preventive medicine.

Overall, no major effort has been made widely on taro and yam for the agricultural application of the modern biotechnology. Basic tissue culture, embryogenesis and transformation methods should be enhanced on yam and taro. Pitfall studies on production and post harvest processing should be conducted to identify the major constraints whether application of the modern biotechnology such as transgenic approach could be desirable or not for the abiotic stresses.

Challenges with locally important root and tuber crops: Examples on andean root and tuber crops

First of all, this section is revised after Watanabe and Arbizu (1997). There are many locally-important plant species in Andean region which must be protected and improved in the region, and they could be employed in other part of the world. These examples are: oca (*Oxalis tuberosa*), ulluco (*Ullucus tuberosus*), maswa (*Tropaeolum tuberosum*), yacon (*Polymia sonchifolia*), maca (*Lepidium meyenii*) and arracacha (*Arracacia xanthorrhiza*) in Andean region (Hermann and Heller 1997; NRC 1989). Four areas of biotechnology could assist in genetic resources management and utilization of under-exploited Andean domestic crops: a) in vitro germplasm conservation with tissue culture and cryoconservation, b) genetic fingerprinting of collections and monitoring genetic diversity with molecular markers, c) diagnosis of plant diseases and clean-seed propagation; and d) potentially on the application of genetic engineering. Among the diverse crops from the Andean regions, Andean root and tuber crops (ARTC) are focused in this chapter and a brief idea of other important plant species is discussed.

Features and Constraints in ARTC

Plant biotechnology tools assist in the management and utilization of potato and sweetpotato genetic resources. These biotechnology tools and their strategies for applications, could also be useful in managing at least nine species of Andean root and tuber crops, listed according to their economic importance on Andean region. These crops have comparatively balanced nutritional values as potatoes have, however, due to its social status as poor men's food, somehow the uses of the crops have been limited for harsh conditions.

Ulluco, oca, and mashua have been important components of potato-based farming systems for more than five thousand years in the tuber-growing areas of the Andes. Arracacha, yacón, achira, mauka, and ahipa have also been grown in the quechua zone of the warm Andean valleys as one of the main components of maize-based farming systems for thousands of years. Along with bitter potatoes, maca has played a major role in the herding-based economy of farmers living in the Puna zone of Peru above 4,000 m. Whereas maca and ahipa are seed-propagated crops, the others are vegetatively propagated.

Biotechnology Applications to ARTC

a. Genetic Resources Conservation and Micropropagation on ARTC

Ex situ conservation of the genetic resources of the nine species mentioned above has been attempted by 10 scientific institutes working in South America. In July,

1995, some 2,034 accessions of ulluco, 3,282 of oca, 725 of mashua, 921 of arracacha, 105 of yacón, 108 of achira, 48 of maca, 2 of mauka, and 2 of ahipa were being maintained by germplasm banks working with Andean root and tuber crops (Arbizu and Holle, unpublished data).

The in vitro conservation of ulluco, oca, and mashua tubers has been carried out for about 10 years by several Andean genebanks, and as a result, more than 60% of the ullucos, oca, and mashuas are being maintained in vitro. In the past three years, evidence has shown that more than 90% of maukas and 50% of yacóns have also been maintained in vitro. The entire collection of arracacha and achira, however, along with about 50% of yacóns, 40% of ullucos, oca, and mashuas, and 10% of maukas appear not to have been introduced in vitro yet. They have been maintained as field collections. Insufficient funding and biotic and abiotic stresses are the main constraints to their conservation under field conditions. The International Potato Center (CIP) has been playing a major role in the conservation of the genetic resources of Andean root and tuber crops in cooperation with nine South American National Agriculture Research Systems (NARS) working with this material. However, more logistic support is still needed to optimize their conservation, and fulfill their economic potentials.

Cryoconservation is an alternative for in vitro conservation of clonal germplasm. Technically speaking, many root and tuber crops, including common potatoes, can be maintained by cryoconservation, but no major genebank has employed the system as the principal conservation system. Cost is one of the key issues for the acceptance of this technology. For example, in the case of potatoes, an initial introduction of 5,000 in vitro clonal accessions into cryoconservation could cost US \$ 20,000, with annual maintenance costs of US \$ 3,000. A tissue culture-based sub-culturing system could cost US \$ 30,000 annually for the conservation of the same number of accessions. Further sub-cultures could cause mislabeling of accessions and contamination. But this is significantly reduced by cryoconservation. The current recovery rate of shoot tips after cryoconservation is very high in potato--more than 90% (Steponkus, personal communication), but no long-term and large-scale testing has been done for root and tuber crops in general, which could hamper the use of the cryoconservation technology.

b. Monitoring Genetic Variation and Fingerprinting in ARTC

The organization of a germplasm collection is often cumbersome, as the clonal accessions have to be evaluated for duplicate identification, as well as evaluation of genetic diversity in the collections. Molecular markers can assist in these tedious activities for more efficient

establishment of core collections. Furthermore, these same tools can be used for biosystematic studies and in situ management of the germplasm.

The genetic diversity of Andean root and tuber crops is not well known, while distinct phenotypic groups are recognized, as for root and tuber color and shape. Because Andean root and tuber crops are underexploited, a rapid assessment of genetic variation in nature, farmers' fields, and known collections and varieties is needed. The goal is: 1) to maintain genetic diversity, 2) to identify cultivars, and 3) to establish a comprehensive core collection. Evaluations are conducted using isozymes and protein-gel electrophoresis in many national genetic resources programs, in collaboration with international genebanks. The use of DNA marker-based tools such as RFLP and PCR-based RAPD, STS, DAF, and SSR is widely recommended for many crop genera, but simple tools could be applied initially with these Andean root and tuber crops for cost-effectiveness and because fewer skills are required for operations in resource-limited Andean genebanks.

c. Plant Quarantine and Seeds

Although pests and diseases of Andean root and tuber crops have not been well surveyed, some virus-like diseases are seen in crops such as ulluco, oca, and arracacha. A general assessment of pests is also essential to maintain and improve crop productivity and genetic resources. In order to enhance productivity, we need to diagnose plant diseases and produce clean propagules efficiently.

For example, for diseases caused by viruses and viroids, an ELISA (enzyme-linked immunosorbent assay) or NASH (nucleic acid spot hybridization) test should be effective, while identification and characterization of viruses causing diseases shall be enhanced and a service system should be established to provide antisera for ELISA and labeled probing for NASH, as widely demonstrated with common potatoes by CIP. A PCR-based detection system for fungal and bacterial diseases could be also an effective tool. But basic technology should previously be well established and widely distributed for diseases.

Seed production of the vegetatively propagated species using micropropagation can be enhanced and following production can be boosted by the assistance of plant disease diagnostics. Some knowledge has been accumulated on that virus detection and irradiation are of importance for these vegetatively propagated species; e.g. oca yield can be improved by using virus free seeds up to several folds and could avoid secondary infection to other crops at the same farms or in rotation.

d. Potential for Genetic Engineering on ARTC

Although the main constraints to the cultivation of Andean root and tuber crops have been pointed out, the

traits to be improved have not been indicated in detail. Therefore, more surveys on biotic and abiotic constraints should be conducted to see whether a plant quarantine and seed program in conjunction with efforts on integrated pest management and crop management could improve crop production or whether genetic improvement of crops is essential for increasing productivity and sustainability.

Potential areas for genetic studies would be: 1) improvement of the quantity and quality of nutritional traits, and a reduction in toxic substances, 2) day-length adaptation, and 3) dormancy. As the basic reproductive biology of these root and tuber crops is not understood well, and a true seed production system has not been established for many of them, the conventional breeding approach may be inappropriate. Furthermore, many of these root and tuber crops are known as polyploids with an outcrossing nature, so that a complicated segregation of the trait of interest could occur. This would be a disadvantage in conventional breeding, as demonstrated in potatoes and sweetpotatoes, but wild relatives and closely related crop genera are available for Andean root and tuber crops, and molecular marker-assisted germplasm enhancement may be an approach to improve these crops and make them available to farmers.

Genetic engineering could facilitate the improvement of Andean root and tuber crops. Two specific areas are given in the following.

1) Glucosinolate content appear to be high in mashua and may cause goiter, on the other hand, glucosinolates and their biologically active metabolites may be responsible for medicinal uses of this particular Andean tuber. These compounds and others may also provide variation in resistances to insects, nematodes and diseases so that genetic engineering could provide a specific change to get rid of the goitrogenic effects of glucosinolates. Now, using genetic engineering, manipulation of specific biochemical pathways would be becoming doable, so that control of specific fractions on toxic substances, but increase of the useful components could be simultaneously achieved. This can be applied to other crops such as oca to reduce unpleasant tastes that could come from oxalic acids and glycoalkaloids.

2) Yacon has been studied to use its fructose for diet food for diabetes. Also the high molecular weight carbohydrates could meet specific industrial needs. Due to these specific characteristics of sugar, the crops have been adopted to non-conventional regions such as New Zealand, Japan, and Italy.

Conclusion

The role of root and tuber crops in this century will be more important and further investment by public is essential for the crop improvement and integration of all

scientific knowledge for crop production (Scott 2000). Besides supporting the major root and tuber crops such as potato, sweetpotato and cassava, emphasis should be made conservation and enhancement of the use of regional important root and tuber crops such as oca, ulluco, maswa, yacon, maca and arracacha in Andean region (Hermann and Heller 1997; NRC 1989; Watanabe and Arbizu 1997); edible canna (*Canna edulis*), arrow heads (*Sagittaria torifolia*) and aroids (principally taro) in Asia and Africa (Scott 2000). While biotechnology application could be one of the methods for the purpose, however, in-depth analyses of the pitfalls in production and storage / processing and of demands should be conducted carefully point out the target of the research and development activities.

Acknowledgments

Author would like to thank Japan Society for the Promotion of Sciences, Research for Future Program (JSPS-RFTF-96-L603 and JSPS-RFTF-00-L0162) on its financial aids to carry out the part of research introduced in this paper. Author also thank JIRCAS and Dr. K. Yamaguchi-Shinozaki, Biological Resources Division, Japan International Research Center for Agricultural Sciences (JIRCAS), Tsukuba, Japan for providing a set of precious gene constructs to generate abiotic-stress tolerant transgenic potatoes.

Genetic dissection and plant improvement under abiotic stress conditions: drought tolerance in maize as an example

J.-M. Ribaut, M. Banziger, and D. Hoisington

Int. Maize and Wheat Improvement Center (CIMMYT)

Abstract

Among abiotic stresses found in developing countries, drought and low soil fertility are paramount. Because of its genetic complexity, drought tolerance is probably the most difficult trait to improve through conventional plant breeding. The challenge is even greater for developing drought tolerant plants for water-limited environments where the occurrence, timing, and severity of drought may fluctuate from year to year. CIMMYT has devoted considerable effort during the past three decades to improving drought tolerance in maize. Extensive research has been conducted in the areas of breeding, physiology, agronomy, and most recently, biotechnology. The biotechnology work has focused on the genetic dissection of drought tolerance through the identification of quantitative trait loci (QTL) associated with yield components, secondary morphological traits of interest (e.g., anthesis-silking interval), and more recently, physiological parameters. To date, the genetic dissection of yield components and secondary traits of interest has been conducted in four different segregating crosses, under diverse water regimes and in several environments. In addition, to identify the QTLs for key physiological components (e.g., hormones, proteins, etc.) a recombinant inbred line (RIL) population has been developed by single seed descent from F_3 families obtained by crossing one of the four crosses mentioned above. The same morphological traits measured in the F_3 families have been evaluated in this RIL population. Based on these QTL results, several MAS experiments based on back crosses and new breeding approaches such as the Single Large-Scale MAS (SLS-MAS) have been successfully conducted, and will be presented in detail. However, based on our experience, we now recognize that germplasm improvement restricted to QTL manipulation presents several limitations, the most critical being the inability to predict the phenotype of any given genotype based on the allelic constitution. To overcome these limitations, improve the understanding of the genetic basis of drought tolerance, and develop the most efficient MAS strategies, future efforts at CIMMYT will concentrate on two main activities: (1) the construction of a consensus map that combines information related to QTL characterization and gene expression, and (2) the identification of key genes/pathways involved in maize drought response. The map and knowledge of key pathways will be used as selection tools in breeding programs. Concomitant with our QTL identification and manipulation efforts are several ongoing experiments based on functional genomics. We are convinced that emerging technologies based on gene expression have the potential to provide complementary information that will promote more efficient germplasm improvement. Indeed, understanding the genetic basis of the essential physiological parameters of drought tolerance in maize, together with the data generated by profiling experiments, should allow the identification of the key pathways involved in drought stress and further our understanding of how they interact. This, in turn, will lead to develop strategies to improve the tolerance of maize and other crops to water-limited conditions.

Abiotic stresses: Focus on drought

Plants vary tremendously in their ability to withstand abiotic stresses, both between species and within populations of a single species. Abiotic stresses limit crop productivity in every season and in every crop worldwide, yet the nature of tolerance is not well

characterized. Understanding the mechanisms of tolerance will have a significant impact on crop productivity (Boyer 1982). In general, tolerance to abiotic stresses is associated with a host of morphological and physiological traits; these include root morphology and depth, plant architecture, variation in leaf cuticle thickness, stomatal regulation, osmotic

adjustment, antioxidant capacity, hormonal regulation, desiccation tolerance (membrane and protein stability), maintenance of photosynthesis, and the timing of events during reproduction (Bohnert et al. 1995, Shinozaki and Yamaguchi-Shinozaki 1996, Bray 1997, Nguyen et al. 1997, Edmeades et al. 2001). The complexity of these responses is not surprising, because under stress conditions plants must be able to tolerate significant variations in soil composition, temperature and water potential during development. One of the most challenging traits for which to breed for is drought tolerance, due in large part to its unpredictable nature. Selected materials need to perform well under both water-limited and well watered conditions. In addition, establishing optimal environments to select for improved performance under drought is complicated by environmental variation.

Loss to drought in the tropics alone is thought to exceed 20 million tons of grain per year, or around 17% of well-watered production (Edmeades et al. 1992), reaching up to 60% in severely affected regions such as southern Africa in 1991-92. The magnitude of these losses has made breeding for drought tolerance a major focus of the International Maize and Wheat Improvement Center, known by its Spanish acronym as CIMMYT (for review, see Heisey and Edmeades 1999). Drought and soil infertility are the major causes of grain yield reduction in developing countries (Beck et al. 1996), and considering ongoing climatic changes attributable primarily to global warming (Curry et al. 1995), the pressure on food production in water-limited environments will probably increase in the future. Impressive progress has been achieved through conventional breeding (for review, see Heisey and Edmeades 1999), and the potential for genetic improvement of maize production under drought conditions remains large. But it should be kept in mind that conventional breeding for yield improvement remains time consuming and laborious, because carefully managed field conditions are required. In addition, there is a decrease in the genetic variance and heritability of yield components that parallels an increase in environmental stress (Ribaut et al. 1997). Considering these limitations to efficient selection, and that only one relatively rainfree crop season per year is available for selection in most tropical countries, the use of molecular markers could provide a useful tool to complement phenotypic selection.

Target traits and QTL identification under water-limited conditions

During the past two decades, molecular tools have aided tremendously in identifying, mapping, and

isolating quantitative trait loci (QTL) and genes in a wide range of crop species. The vast knowledge generated through the application of molecular markers has enabled scientists to analyze the plant genome and gain insight on how genes and pathways controlling important biochemical and physiological parameters are regulated. Three areas of biotechnology that have had significant impact are the application of molecular markers, tissue culture, and genetic transformation. The availability of molecular markers has enabled the identification of genes or genomic regions associated with the expression of an array of qualitative and quantitative traits, and made the manipulation of such genomic regions feasible through marker-assisted selection (MAS) processes. MAS for single gene, or few major genes, transfer has been well demonstrated. However, when several genomic regions must be manipulated, MAS turned out less convincing. The efficient and effective application of MAS for polygenic trait improvement certainly needs new technologies, but more importantly, it requires the development of innovative strategies that bypass the conceptual bottlenecks imposed by current approaches (Ribaut and Hoisington 1998). Molecular-marker applications have also helped us better understand the physiological parameters that control plant responses to abiotic stress factors, and, more generally, to those involved in plant structural development. Understanding these pathways has been one of the biggest challenges in plant improvement, because an observed plant phenotype is the result of the expression of many diverse plant physiological and biochemical pathways. Given that most physiological tests cannot be applied routinely in a breeding program, because their protocols are generally too complex or time consuming, the genetic dissection of target traits and physiological parameters is of primary importance for plant breeding.

Depending on the crop, different key secondary traits of interest involved in the plant response under water-limited environment have been identified. A suitable secondary trait is one that is (i) genetically associated with grain yield under drought; (ii) highly heritable; (iii) inexpensive and quick to measure; (iv) stable over the measurement period; (v) observed at or before flowering; and (vi) not associated with yield loss under unstressed conditions (Edmeades et al. 2001). In maize, when drought stress occurs just before and during the flowering period, a delay in silking is observed resulting in an increase in the length of the anthesis-silking interval (ASI) (Hall et al. 1982, Westgate and Bassetti 1990, Bolaños and Edmeades 1993). This asynchrony between male and female flowering has been associated with grain yield decrease under drought (Westgate and Boyer 1986,

Edmeades et al. 2000), is easy to measure in the field, and presents a high heritability under stress conditions. In sorghum, the term "stay green" is associated to a tolerance mechanism characterized by maintenance of green stems and upper leaves when water is limiting during grain filling. This post-flowering tolerance is especially important because of the negative impact of drought on yield at this stage. Yield reduction can result from reduced seed size as well as from factors associated with premature senescence, stalk rot, charcoal rot, and lodging of susceptible cultivars. Stay green genotypes maintain more photosynthetically active leaves than genotypes not possessing this trait (Rosenow et al. 1983) and produce significantly higher levels of sucrose, glucose, fructose, and starch, particularly in the stem (McBee and Miller 1982, McBee 1984, Duncan 1984). Since photosynthesis is maintained longer in stay green types, this may partly account for their higher yield in crops where carbohydrate is a main harvest component (Thomas and Smart 1993). In rice, scientists looking into drought tolerance focused more on the root structure and characteristics, as well as on osmotic adjustment (OA) in roots (Zhang et al. 2001). The rationale for selecting OA and root traits is that a well-developed deep root system can facilitate water uptake from lower soil layers, and OA can help maintain the turgor of both shoots and roots as plants experience water deficits (Nguyen et al. 1997, Zhang et al. 1999). Populations that segregate under water-limited conditions have been developed and QTLs involved in the expression of the target trait have been identified in all major crops (for review, see Ribaut and Poland 2000). However, the nature of QTLs at the gene level remains unclear, hence our understanding of the complexity of plant responses to drought stress continues to be incomplete. One of the weaknesses of the quantitative genetic approach that limits its use in plant breeding is that it provides very little information about the mechanisms and pathways involved in drought tolerance or about the multitude of genes involved in the plant's response. Recent developments in functional genomics should help overcome this problem, because these new approaches allow the simultaneous study of the expression of several thousand genes. Results produced by functional genomics studies, combined with QTL results, offer us a powerful approach to identify and characterize the key physiological/biochemical pathways involved in drought tolerance. The characterization of QTLs for yield that are correlated with secondary traits of interest and ultimately with QTL involved in the expression of key physiological parameters should allow us to bridge the gap between gene function and plant phenotype (Figure 1).

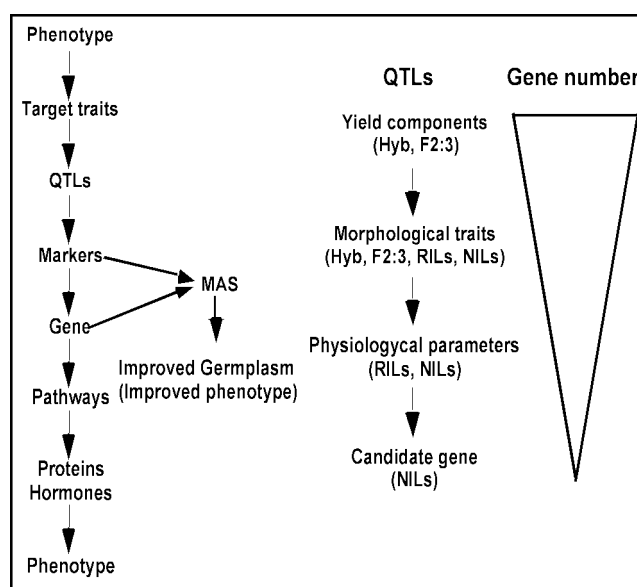

Fig. 1. Different regulatory levels involved into the plant phenotype (left side of the scheme). Depending on the nature of the target traits, the QTL identification involved in the expression of those traits requires different kind of segregating populations and present different levels of genetic complexity, the largest number of genes being involved in the expression of the yield components (right side of the scheme).

Genetic dissection of a maize plant's response under a water-limited environment at CIMMYT

The construction of QTL linkage maps using segregating populations is routine at CIMMYT. During the past seven years, major efforts have been dedicated to the genetic dissection of drought tolerance components in maize under water-stress, before, during, and after flowering. These efforts resulted in the identification of QTLs involved in the expression of yield components and secondary morphological traits of interest, such as ASI. As presented earlier, of primary interest are secondary traits that are correlated with yield and demonstrate segregation with high heritability under water-limited conditions. To date, genetic dissection has been conducted in four different crosses, at different inbreeding levels (hybrids, F2:3 families, and RILs), under different water regimes (well-watered conditions (WW), intermediate stress (IS), and severe stress conditions (SS)) and in several environments (Kenya, Mexico, and Zimbabwe) (Table 1).

Much of our past QTL identification has focused on yield components and secondary traits of interest, each important measures for drought tolerance in maize but complex polygenic traits (Ribaut et al. 1996, 1997). To more deeply explore, at the genetic level, the maize plant's response under water-limited conditions, it is necessary to identify the QTL involved in the

differential expression of the key physiological pathways that induce the drought tolerance phenotype. To achieve this objective, a RIL population was developed by single seed descent from F₃ families obtained by crossing Ac7643 with Ac7729/TZSRW (Table 1). The same morphological traits measured with the F₃ families have also been evaluated in this RIL population. RIL families are more suitable than F₃ families for physiological measurements because they are genetically fixed; on the other hand, they are poor material for evaluation of yield components because they usually demonstrate high inbreeding depression. In addition to the physiological parameters measured in-

house, such as relative water content, osmotic adjustment, and chlorophyll content, collaborations with other research groups allowed us to evaluate root growth under hydroponics (Roberto Tuberosa, Bologna University), quantify the ABA content in the ear leaf, the ear and the silks at the flowering stage (Tim Setter, Cornell University), and evaluate the photosynthetic apparatus and dehydration phenomena under low temperature conditions (Yvan Fracheboud, Institute of Plant Sciences ETH, Zurich). Although most of these physiological traits are not useful for routine screening purposes because they are too time consuming (the osmotic adjustment measurement being a typical example) once DNA markers closely linked to the QTL involved in the expression of a physiological trait are identified, they can be used efficiently in MAS experiments. Identification at the same genomic location of QTL related to physiological and morphological traits should be expected, given that changes in physiological pathways have an impact on the plant phenotype. As an example from our first field evaluation, a QTL for chlorophyll content was identified on chromosome 2, near a QTL for ASI (under IS and SS) and grain yield (under IS only). This QTL for chlorophyll content was consistent when measurements were conducted on the ear leaf and on a young leaf close to the tassel. On chromosome 6, a QTL for relative water content corresponds exactly to a QTL for ASI (under IS and SS) and grain yield (under IS and SS). At the same chromosomal region, the identification of a dehydrin gene (*dhn1*) has also been reported (Campbell and Close 1997). Since several physiological pathways involved in the drought tolerance mechanism are well known (e.g., ABA biosynthesis), the characterization of the gene(s) corresponding to identified QTL can be achieved, making the candidate gene approach an attractive option.

MAS for maize line improvement under drought

Based on the QTL and mapping information described earlier, a backcross marker-assisted selection (BC-MAS) project was initiated in 1994. The line P₁ (Ac7643) was used as the drought-tolerant donor line and CML247 was used as the recurrent parent. CML247 is an elite tropical inbred line developed by CIMMYT, with outstanding combining ability and good yield per se under well-watered conditions. It is susceptible to drought, in part because its ASI is large under drought. Genetic data from a segregating F₂ population derived from the P₁ × CML247 cross were combined with F₃ evaluations in the field under different water regimes to identify QTLs for traits of interest. The QTLs for ASI identified in this cross were quite consistent with those in the original P₁ × P₂ cross. Of the five QTLs originally

identified from P₁ that conferred a short ASI, only the QTL on chromosome 6 was not detected in the second cross. The QTL on the short arm of chromosome 1 was shifted by 40 cM in the new cross, and the three other QTLs on chromosomes 2, 8, and 10 were in similar positions in both. A new QTL for ASI was detected on the short arm of chromosome 3. These results demonstrate the need to make a new genetic map when the recurrent line is changed in BC-MAS schemes. A single good-quality trial under drought conditions, however, might be sufficient for identifying QTLs of interest, providing QTL identification has been previously carried out in another cross involving the donor line.

Five genomic regions involved in the expression of a short ASI were selected to be transferred from P₁ into CML247 genome. The screening of large populations (about 2,000 plants) at each selection cycle during backcrossing has been possible because of the development of reliable PCR-based markers, used here as preselection tools. After two BCs and two self-pollinations, the best genotype was fixed from the donor line for the five target regions (12% of the genome), as well as for 7% of the genome lying outside the QTL regions (Fig. 2). The 70 best BC₂F₃ (i.e., S₂ lines) were identified and crossed with two CIMMYT tester inbreds, CML254 and CML274. These hybrids, as well as the BC₂F₄ families (S₃ lines) derived from the selected BC₂F₃ plants, were evaluated in 1998, 1999, and 2000 under several water regimes. Results show that under stress conditions that induce a yield reduction of at least 80%, the mean of the 70 selected genotypes performed better than the control crossed with CML254 and CML274. In addition, the best genotype among the 70 selected (BC₂F₃ × testers) performed two to four times better than the control. This difference became less marked when the intensity of stress decreased; for a stress inducing less than 40% yield reduction, hybrids resulting from the MAS or developed with the "original" version of CML247 performed the same. Although which genotypes performed best depended on the stress intensity, few of the genotypes always performed significantly better than the controls across the six water-limited trials. Because the genotype performance is dependent to the environment or the stress level, those results demonstrate that different sets of gene might be involved in the plant response depending on the stress intensity. No yield reduction was observed under well-watered conditions.

MAS strategies and consensus map

For approximately 15 years, genetic dissection of polygenic traits has been hailed as a promising

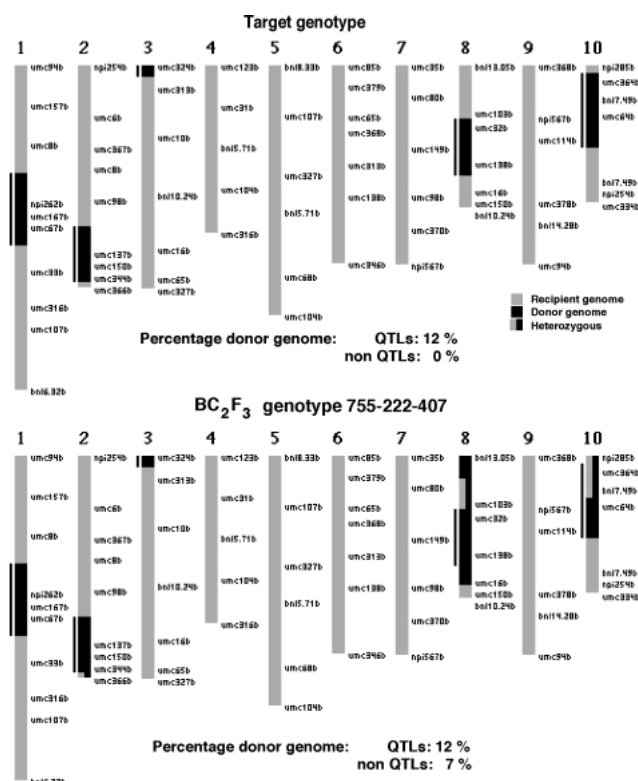

Fig. 2. With five selected regions, the target genotype of the BC-MAS for drought improvement conducted at CIMMYT is presented at the top of the figure. Those five regions, at which fixed donor genome contribution is expected, represent 12% of the mapped genome (70 loci/RFLP probes) and are presented in black. At the bottom of the figure is presented the best genotype identified after 4 cycles of MAS (2 BCs and 2 self-pollinations). For this genotype the remnant donor genome contribution outside the target regions represents about 7% of the mapped genome.

application of DNA markers, resulting in extensive mapping experiments aimed toward the development of MAS (Lee 1995). However, few concrete MAS results have been published that would justify the initial enthusiasm (Mohan et al. 1997, Ribaut and Hoisington 1998) because of the limited number of QTLs identified per trait, the reduced amount of phenotypic variance that they generally express individually, their interaction with the environment, plus the difficulty of epistasis evaluation. Until recently, a clear technical limitation has been the restricted population sizes that can be handled, limiting the flexibility and the power of selection. With the development of reliable PCR-based markers, a substantial increase in segregating population size that can be screened is now feasible. Another limitation was certainly the reduced flexibility of the "good by bad" concept, the transfer of genomic segments from a donor to a recipient elite genome through BC, which presents time and cost constraints, as

we came to realize in our BC-MAS for drought tolerance described in the previous section. However, when this project was initiated seven years ago, it then appeared to be an attractive option, given the limited amount of available information about elite line performance under drought. Today, the situation has evolved at both the germplasm and technology levels. New MAS strategies can be considered for the improvement of drought tolerance; some of these strategies are already being employed at CIMMYT. If the suitable germplasm is available, the pyramiding of favorable alleles through DNA markers in new germplasm by crossing two elite lines that perform well under the target environment conditions, "good by good," should open new doors for MAS (Ribaut and Betran 1999).

Another alternative is conducting MAS experiments based on "universal drought QTLs" identified on a consensus map that incorporates (1) QTL information for yield components, morphological traits and physiological parameters, (2) candidate genes and pathways, and (3) information provided by gene expression. The underlying rationale for this approach is that genes involved in drought response are most likely located at the same position in the maize genome, independently of the germplasm performance, and that phenotypic differences across germplasm is created by the nature/quality of the alleles at those genes. An accumulation of elite alleles at several genes will confer good drought tolerance, while poor alleles will induce susceptibility to drought. When a QTL is identified in a segregating population for a given trait, it means that the difference of the contribution between the two alleles coming from the two parental lines is significant at a certain genomic position. If in another segregating population the difference between the two alleles is not significant (e.g., they are both good or bad), although the gene(s) are still at the same location, no QTL will be identified. For this reason, the results of QTL identification for a given trait are cross dependent, making the extrapolation of this information questionable. However, one can postulate that if a QTL identification is conducted on various segregating populations for a target trait, the same key QTLs should be identified in more than one cross, thereby clearly demonstrating the importance of these genomic regions for the expression of the target trait.

To achieve this objective, a unique linkage map should be constructed, using the loci that are common for the four crosses as anchor markers. In a second phase, all of the QTL information available for each cross should be compiled on the consensus map (see Table 1), assigning a "weight" to each QTL. This weight will have two major components: (1) the nature of the trait and (2) the threshold value of the QTL identified

under a specific environment (likelihood ratio, LR). The highest weight will be attributed to yield components. For secondary traits, consideration should be given to the phenotypic correlation between the trait and yield components (mainly grain yield and ear per plant). The heritability of the trait might also be considered as a third component. With all the QTL information integrated into a single consensus map, outstanding regions involved in the expression of the same trait (different crosses or environments) or different target traits (same cross and/or different crosses or environments) should be identified. If such "universal" drought genomic regions are identified, the objective should be to conduct MAS experiments on those regions for new crosses (good by good lines with different genetic background), without making a QTL identification in each target cross.

Functional genomics

The recent development of genomic technologies that provide structural and functional information, gene characterization (i.e., the localization, sequence, and expression framework of a gene) has received a significant boost during the last few years. To date, if one tries to establish a list of candidate genes for drought tolerance based on gene function, hundreds of genes can easily be listed (Skriver and Mundy 1990, Bray 1993, Ingram and Bartels 1996, Bohnert et al. 2000). The questions now are how to prioritize research aimed at characterizing the genes involved in the drought-tolerance process, and once those genes are characterized, how to identify and efficiently manipulate the elite alleles at those target loci to improve a given variety. The first question must be addressed principally by the research groups conducting basic genomic research. Of course, establishing such priorities is more or less a function of the available resources and research objectives of a group. The recent discovery of promoter regulatory elements, like DRE (dehydration-responsive element) or ABRE (ABA-responsive element) involved in both dehydration- and low-temperature-induced gene expression in *Arabidopsis* (Shinozaki and Yamaguchi-Shinozaki 1997), as well as the identification of transcriptional factors interacting with those promoters (Liu et al. 1998), are exciting developments. The characterization of the genes involved in the initiation phase of the stress response (e.g., genes encoding for stress-induced transcription factors) should be a logical priority, since they represent the "upstream keys" to global genomic responses that might involve hundreds of genes. Moreover, once they have been identified, expression of these key genes should serve as a "timing reference" to identify expression products

from downstream genes involved in stress responses. This can be achieved using microarray technology, as described by Chu (1998).

The new field of functional genomics will provide useful information through profiling experiments (Seki et al. 2001) and/or through the candidate gene approach based on genomic location or function of interest. The candidate gene approach is facilitated by looking at the large number of sequences and freely available gene information found in plant genetic databases (maize, *Arabidopsis*, rice, etc.) to identify potential candidate genes and pathways involved in drought tolerance. The expression profile of the candidate genes defined under "in house" experimental conditions will provide important information for evaluating the role of potential pathways in target germplasm. The correlation on a linkage map between a differentially expressed EST and a QTL related to the same physiological parameter will be a key step in the validation process of a candidate gene. The gene expression response, together with the phenotypic characterization and additional QTL information about a plant, serve as the basis of an integrated approach for better understanding the maize response to a water-limited environment. Indeed, these three sources of information are complementary because the QTL characterization, which defines the genetic basis of the key physiological parameters, represents the link between the differential gene expression mechanisms and the morphological plant response.

Conclusion

It is clear that a multidisciplinary approach—including breeding, physiology, and biotechnology—is required for efficient germplasm improvement for greater drought tolerance in maize. The QTL characterization effort initiated at CIMMYT several years ago will continue, with particular emphasis given to the genetic dissection of physiological drought-adaptive traits. At the same time, we will explore the potential of functional genomics, which should provide useful information at the gene regulation level. Understanding the genetic basis (QTL characterization) of the essential physiological parameters of drought tolerance in maize, together with the data generated by profiling experiments, should allow the identification of the key pathways involved in drought stress and how they interact. The emergence of molecular genetics and associated technologies represents a major new breeding tool; the current challenge is to integrate this tool and the information it generates into breeding schemes to further the development of efficient MAS strategies. This, in turn, should lead to improved morphological maize response to water-limited conditions.

Abstract

We have embarked on a large-scale functional genomics using the microarray system in order to obtain a global expression profile of rice genes. More than 11,000 partial cDNA sequences corresponding to unique genes have been identified at the Rice Genome Research Program (RGP). From these sequences, microarrays were constructed using 1265 cDNA clones (phase I) and 8978 clones (phase II) as probes. Both the full insert and the gene-specific portions (3'-UTR) of the cDNA clones were spotted on the glass slides using a high-speed robotic arrayer. About one third of the genes have the annotation from the sequence homology search with the public Data Bases such as NCBI Genbank.

These were used as probes to hybridize target RNAs prepared from normally grown rice tissues (as control) and some stress treated tissues, such as some low temperature conditions, a high salt condition, some nutrient deficient conditions, oxidative stress treatment such as UV-B and Gamma irradiation and the treatment with Hydrogen peroxide, the additions of excess hormones and the treatment with hormone biosynthesis inhibitors and so on. Normalized data among several experiments are summarized in Data Base and the expression profiles of the genes are compared. According to the reproducibility of the microarray data, change of the gene expression was focused more than three-fold difference. Genes can be clustered into some groups such as "commonly up regulated and commonly down regulated responsible for some stress conditions and in some stresses up regulated and in other stresses down regulated genes.

Summarizing the expression data from the microarray analyses, the full-length sequence data of cDNA clones, gene annotation data from the homology search (especially from the mapping data on the chromosomes) and the genomic sequence data from the Rice Genome Sequence Project, it is possible to assign the promoter sequences of the genes which show common profile in stress responsible expression.

Introduction

The Rice Genome Research Program (RGP) has undertaken an extensive rice genome analysis since its initial launching in 1991 that has resulted in the

establishment of a catalog of rice genes,¹ a high-density linkage map,² and a YAC-based physical map.³⁻¹⁰ An enormous collection of ESTs was generated from large-scale cDNA sequencing using cDNA libraries derived from rice callus cultured in different medium and tissues

such as root, shoot, leaf and panicle.¹¹ As of today, more than 40,000 ESTs are analysed thus far, approximately more than 11,000 partial cDNA sequences corresponding to unique genes have been identified. Based on the results of large scale cDNA analysis, microarray can be used to monitor gene expression profiles and to initiate functional analysis of the rice genome. The use of microarray for measuring gene expression level is advantageous over other established techniques such as Northern blots and RT-PCR because it facilitates analysis of a large number of genes simultaneously.¹² It will therefore provide a fast and efficient method of monitoring the expression profiles of thousands of genes that comprise the genome. In many systems such as human,^{13,14} yeast,¹⁵⁻¹⁷ *Drosophila*,¹⁸ microarray is already a widely used tool for functional analysis. In *Arabidopsis*, a microarray system has also been established.¹⁹ Although the use of plant microarrays is only at its beginning, this approach will soon be a standard investigative approach in plant biology as well.²⁰⁻²²

We initiated a rice cDNA microarray project beginning in April 1999 that aims to elucidate the function of all genes in rice using a gene expression monitoring system. The National Institute of Agrobiological Sciences (NIAS) and the Institute of the Society for Techno-innovation of Agriculture, Forestry and Fisheries (STAFF) are jointly conducting this project in collaboration with 64 research institutions all over Japan. We have constructed 1265 probes (phase I) and 8987 probes (phase II) microarrays and we have embarked on a rice functional genomics using the various target RNAs.²³ Sequence data and the homology search results of the probe clones are shown in our WEB site <http://microarray.rice.dna.affrc.go.jp>. In this manuscript, we have focused on the expression profiles of the genes which altered transcription pattern after UV-B and gamma irradiation. Comparing which genes are up- and down regulated we have discussed the similarity of the different stress treatments.

Material and Methods

Rice cDNA clones as probes for microarray

All cDNA clones were generated by large-scale cDNA analysis at RGP (Yamamoto et al. 1997). Gene clustering to obtain the unique clones was performed by BLASTN. Sequence homology search (BLASTN and BLASTX) was performed with the representative clones of the clusters as queries, the results are shown in our WEB site <http://microarray.rice.dna.affrc.go.jp>.

Amplification of cDNA insert

The vectors used for the cDNA library constructions were λ ZAPII. Insert cDNA clones were amplified by

PCR using M13 as primer (TAKARA, Shiga, Japan); M4 (5'-GTTTTCCCAGTCACGAC) and RV (5'-CAGGAAACAGCTATGAC) were complementary to vector sequences flanking both sides of the cDNA insert. Plasmid template (1-2 ng) was added to 50 μ l PCR mixture containing 0.2 μ M of each nucleotide, 0.4 μ M of each primer, 2.5 mM of Mg²⁺ and 1.25 units of Taq polymerase. Inserts were amplified by PCR with 30 cycles of 94°C for 1 min, 60°C for 2 min, 72°C for 2 min, an initial denaturation at 94°C for 1 min and final extension at 72°C for 10 min. The 3'-UTR of the cDNA clones were amplified using each specific primer complementary to the specific region of each cDNA clone. The PCR was carried out in same condition as the cDNA full insert amplification. Both PCR products were purified using QIAquick 96-column (QIAGEN, Tsukuba, Japan), and mixed with water and reagent D (Amersham Pharmacia, Tokyo, Japan) for microarray fabrication. In general, the total quantity of each PCR product was greater than 1 μ g. The average size of full inserts and 3'-UTR in the cDNA clone was about 1000 and 200 bp, respectively.

Spotting

We spotted cDNA probes in duplicate on aluminum-coated and DMSO optimized glass slide (1" \times 3") using an Array Spotter Generation III (Amersham Pharmacia, Tokyo, Japan). The spot density is 4,608 spots of clones stored in twelve of 384-well microtiter plates are duplicated on the 20mm \times 60 mm area. The spotter was maintained at 55% humidity. After spotting the slides were dried for about 1 hr under the same condition and exposed to UV for cross linking.

Plant materials and RNA isolation

Mainly *Oryza sativa* L. cv. Nipponbare was used for RNA extraction and target preparation. Leaf and root tissues were collected from laboratory-cultured plants at several days post germination. Callus was induced from seeds cultured in MS medium supplemented with 2, 4-dichlorophenoxy acetic acid at 25°C for 20 days. Flower buds were collected at day one of developing stage. Stress treatments were performed to these tissues by several ways. Then the plants and calli were grown side by side and at some time points samples were taken.

Condition of UV-B and Gamma irradiation is as follows. Two week-old seedlings of *O. sativa* L. Nipponbare were irradiated with UV-B and Gamma rays from ⁶⁰Co. Dosage of UV-B is 3.8J/m² sec for 0.6 min. to 4.8 min and irradiated with Gamma rays from ⁶⁰Co (9.2 Gy /min) for 1.3 min to 8.5 min. Sampling was made at time 0 and 8hr to 3 days after irradiation.

Tissue samples for RNA preparation were quick-frozen in liquid nitrogen. Total RNA was prepared using the method of Chirgwin et al. (1979). Poly (A)+ RNA

was purified using Oligotex-dT super (TAKARA, Shiga, Japan) from 200 µg of total RNA.

Labeling and Hybridization

Each poly (A)+RNA was labelled by reverse transcript reaction with Cy-5 (Amersham Pharmacia, Tokyo, Japan). The reverse transcript reaction mixture was composed of 1µg poly(A)+RNA, oligo-(dT)25, random nonamer, control cRNA, 1xSSII reaction buffer, DTT, dATP 2mM, dGTP 2mM, dTTP 2mM, dCTP 1mM, Cy-5dCTP 1mM and SSII reverse transcriptase. The control cRNAs were synthesized by *in vitro* transcription from mouse platelet-derived growth factor receptor gene and *Homo sapiens* c-kit proto onco gene. These cRNAs were used as quantitative controls at 1 ng, 0.5 ng, 0.1 ng and 50 pg. The ratios of the control cRNA were 100:100 000, 50:100 000, 10:100 000 and 5:100 000. After incubation at 42°C for 2.5 hr, the reaction mixture was denatured at 94°C for 3 min and RNA was degraded by 2 µl 2N NaOH at 37°C for 15min. Following degradation, the mixture was treated with 10 µl 2M HEPES for neutralization. The labelled targets were purified with Qiaquick PCR Purification Kit (QIAGEN, Tsukuba, Japan) and dried using a vacuum concentrator. The dried targets were resuspended in a 6 µl water and denatured at 95°C for 4 min. A 1.5 µl Oligo A80 (1mg/ml) was added to the re-suspended targets and 7.5 µl 4 × hybridization buffer containing SSC, SDS, Denhardt's solution, salmon sperm DNA, formamide, 15 µl formamide. A final volume of 30 µl was used for hybridization.

Washing, Scanning and Data analysis

After 16 hr of hybridization, the glass slides were washed in 1 × SSC / 0.2% SDS for 10 min at 55°C under dark condition, then in 0.1 × SSC / 0.2% SDS for 10 min at 55°C twice in the dark condition and finally, in 0.1 × SSC for 1 min at room temperature twice. After the final wash, the slides were briefly rinsed with distilled water and air dried using air duster in a dust free environment. The hybridized and washed microarrays were scanned using an Array Scanner (Fujifilm FLA8000). Scanned spot data are indicated in Figure 1. A computer software, Array Gauge from Fujifilm was used to locate and delineate every spot in the array and to integrate spot intensities and volumes for each individual spot.

Volume detection

The control cRNA (1 ng, 0.5 ng, 0.1 ng and 50 pg) was added to 1 µg sample mRNA, thereby resulting in control cRNA to sample mRNA ratios of 100:100 000, 50:100 000, 10:100 000 and 5:100 000. The control cRNA and sample mRNA mixtures were reverse-transcribed in the presence of Cy-5dCTP into the first cDNA strand, and hybridized to complementary DNA elements on the microarray.

Fig. 1. Scanning pattern of Microarray slides

In this figure, five duplicated fields are shown. One field consists of 12 rows and 32 columns. Target RNAs were labelled with Cy3 and Cy5.

Results and Discussion

Reproducibility of the array data

At first for the microarray analysis, the reproducibility of the spot signal data is very important. We have performed two types experiments to check the reproducibility. One is to check the signal reproducibility of the duplicated spot data. The other is that the same target RNA labelled at the same time was hybridized with the different glasses. In both cases, scattered plots of the spot signals were drawn as indicated in Figure 2. Distribution of the spots were from 2 ($\log_2 X=1$) to 32768 ($\log_2 Y =15$). Then the threshold intensity is about 11 ($\log_2 Z = 3.5$ indicated with a dotted line in Figure 2).

Almost all the spots, which have the intensity more than threshold, located within the three fold lines (the region between two green lines in Figure 2). Therefore we have determined to focus the genes which show the change of expression more than three times.

Gene expression profiles of UV-B irradiation and Gamma irradiation

In our data analysis rule, the spots which show irreproducible signal between the duplicated spots data

Fig. 2. Scattered plot of the experiment checking the reproducibility of the micro array data

To check the reproducibility with the signal of duplicated spot data, each spot signal data are plotted. Dotted lines indicate the threshold line of signal intensity. Green lines are \log_3 and $\log_{1/3}$ lines, blue lines are $\log_{2.5}$ and $\log_{1/2.5}$ lines, and red lines are \log_2 and $\log_{1/2}$ lines. Spots locate between the lines show the difference of signals are with the indicated folds.

are removed, then the genes which show the change of the spot intensity more than three folds after irradiation are listed. As shown in Table 1, about 1% of the genes show up-regulated gene expression pattern one day after UV-B irradiation, and 0.5% to 1% genes show down-regulation expression pattern in the same targets. On the other hand, three days after UV-B irradiation, number of the genes showing similar pattern increases, however the common genes listed in 1 day and 3 days after irradiation are few (Table 2). Only seven genes are commonly up-regulated and seven genes are commonly down-regulated in the case of low dosage condition (136.8 J/m^2). Methalothionein-like protein gene and alpha 1 tubulin gene are the member of commonly up-regulated genes. The gene which has an annotation of Brassica napus mRNA for CTP: phosphocholine cytidyltransferase and the other gene with *Glycine max* seed maturation protein PM36 are the member of commonly down-regulated genes. The same pattern is also observed in the high dosage (1094.4 J/m^2) condition. Among 22 commonly up-regulated genes, acidic class III chitinase OsChib3a, pathogenesis-related thaumatin-like protein, Methalothionein-like protein, Putative peroxidase are

involved. These data suggest that although some stress-related genes are listed up, however, the groups of the genes which show early response after UV-B irradiation (1day) and late response after UV-B irradiation (3 days) are different. Further analyses, such as the time course experiments, are needed.

In the case of Gamma irradiation similar patterns are observed. Eight hours after irradiation 173 and 569 genes are listed as up-regulators in low (11.96Gy) and high (78.2Gy) dosage conditions, respectively, and the number increased in the case of 24 hours after irradiation in low dosage condition (450 and 541). Down-regulators show the similar results (Table 3), however, the commonly regulated genes in both sampling times are very rare (Table 4). Among ten commonly up-regulated clones in low dosage condition, alcohol dehydrogenase I gene, beta tubulin gene, NADH-Ubiquinone oxidoreductase subunit and poly ubiquitin gene are involved. While in the high dosage condition, almost all members of 20 commonly up-regulated genes are unknown. These data also suggest that the groups of the genes which show early responses and late responses should be separated.

UV-B and Gamma irradiations are both the DNA damage stresses and induce the Active Oxygen Species then the radical scavengers such as ascorbic acids and many kinds of flavonoids are known to accumulate in plant. Though these two stimuli induce the similar physiological effects to the plant, however, our microarray data show very small number of the genes commonly induced by both stimuli. Those are the gene with the annotation of Citrus iyo gene for polygalacturonase inhibitor (PGIP), major intrinsic protein, beta tubulin, eukaryotic initiation factor, lipid transfer protein, and methalothionein-like protein.

Using these gene expression profiles as parameters for checking the similarity of the stimuli, we have compared the list of genes which show the alteration of expression after several stress treatments such as the elicitor treatment, nutrition stress, cold stress, salt stress and treatment with several phytohormones. At this moment, we have the feeling that the gene expression profiles between the UV-B irradiation and the elicitor treatment are similar. Gamma irradiation and low temperature treatment commonly list up the similar genes. To confirm these data, further analysis and the

intensive comparison with the several conditions are necessary.

Conclusion

At this moment we can conclude two advantageous points of Microarray technology. One is that Microarray technology is a powerful technology to obtain the genes which show the interesting expression pattern in target RNAs. The other point is that comparison of the expression profiles of the genes of different targets, it is possible to estimate the similarity or the difference of the compared stimuli.

Acknowledgements

We thank Ms. A. Endoh, H. Hattori, S. Iizumi, S. Kimura, C. Miyamoto, Y. Satoh, T. Shibata, K. Takeychi, Y. Yoshida for the technical assistance to the microarray analysis.

JIRCAS Visiting Research Fellowship Program at Tsukuba 2001

Japan International Research Center for Agricultural Sciences (JIRCAS) (formerly Tropical Agriculture Research Center) has implemented the “Visiting Research Fellowship Program at Tsukuba” since 1995.

The fellowship aims at the promotion of collaborative research to address various problems confronting the countries in developing regions on a global scale, including the critical situation of food production, the progression of desertification and the gradual disappearance of genetic resources.

JIRCAS which is located in Tsukuba Science City and is equipped with facilities for advanced research, is inviting young promising researchers from institutes in developing regions who will play a major role in the activities of these institutes in future to carry out collaborative research for the sustainable development or rapid progress of agriculture, forestry and fisheries compatible with the preservation of the natural environment.

Under the Fellowship Program, a total of ten (10) researchers will be invited, of which six (6) will undertake the JIRCAS type projects for a period of one (1) year and the other four (4) researchers will be engaged in the NIAR type projects for a period of five (5) months. The former six (6) will carry out collaborative research at JIRCAS HQ, while the latter four (4) will conduct research at the National Institute of Agrobiological Resources (NIAR) at Tsukuba.

Fellowship Qualifications

- (1) Applicants should be outstanding researchers who will play a major role in the activities of the respective institutes in future. After the completion of the Fellowship, they should continue to carry out research at the same institute.

- (2) Hold a Master's degree in a field relating to socio-economics and natural sciences and technology or equivalent qualifications in related fields. Be preferably less than 35 years of age.
- (3) Carry out research related to one of the themes listed under "Research Themes".
- (4) Should enjoy a good health.
- (5) Have an adequate command of English or Japanese language.

Tenure

In principle, starting from October 2001, the JIRCAS type projects will cover a period of one (1) year and the NIAR type projects will cover a period of five (5) months.

Fellowship Conditions

- (1) A round-trip airline ticket (economy class) will be available (except for dependents).
- (2) Living allowance: 260,000yen per month.
(including housing allowance)
- (3) Housing: International Guesthouse
2-1-2, Kan-nondai, Tsukuba (single room)
- (4) Fixed-rate insurance package (for injury, sickness and damage, etc.) will be offered under the JIRCAS Fellowship Program. (except for dependents)

Application Procedure (This year's application has come to a close.)

Applicants are required to submit the following documents to the Director General of JIRCAS.

(1) Application form

[pdf](#)

[Word 6.0/95\(*.doc\)](#)

(2) Copies of the most important articles (Up to 3)

Deadline for Application

March 15, 2001

Notification

JIRCAS will examine the application documents and notify the results of the selection to the successful applicants and their recommending authorities about three months after the deadline date for application.

Further information about the Visiting Research Fellowship Program can be obtained from the International Relation Section, Japan International Research Center for Agricultural Sciences, 1-2, Ohwashi, Tsukuba, Ibaraki, 305-8686 Japan.

Theme you wish to study [check the theme ()]

I. JIRCAS type (Period : One year)

1. JIRCAS Development Research Division

- () a. Changes in agriculture and rural structure using a mathematical model.
() b. Development of method of monitoring agricultural land use and crop production using remote sensing and GIS.
() c. Research strategies for increase in food production and rural development in African Countries.

2. JIRCAS Biological Resources Division

- a. Development of new types of crops with stress-tolerant traits by gene transformation.
- b. Development of molecular methods for the evaluation and utilization of rice, wheat, soybean and their wild relatives.

3. JIRCAS Crop Production and Environment Division

- a. Analysis and evaluation of climate and human impacts to natural resources cycles of nitrogen and related materials in agro-ecosystems.
- b. Geological and mineralogical characterization of salt accumulation in dry-land agriculture and restoration technology development with locally available resources.
- c. Physiological mechanism on nutrient acquisition of crops from low-fertility tropical soils.

4. JIRCAS Animal Production and Grassland Division

- a. Studies for physiology and ecology of endophytic micro-organisms (nitrogen-fixing bacteria, chitinase-producing bacteria, etc.) in plants.

5. JIRCAS Food Science and Technology Division

- a. Determination and analysis of natural antioxidants and antimutagens from indigenous plants to improve the economical value.
- b. Development of practical methods of utilizing natural materials as insecticides, fungicides and antibacterial agents for reducing the postharvest losses.
- c. Investigation of interaction of food components and developing a new food processing technology.
- d. Development of technologies for food preservation, distribution and processing.

6. JIRCAS Forestry Division

- a. Studies on material properties affecting pulp production of unused tropical lignocellulosic resources including oil palm.

7. JIRCAS Fisheries Division

- a. Physiological studies on aquaculture fish (prawns will be included).

II. NIAS type (Period : Five months)

- 1. Methods for the analysis and preservation of biodiversity.
- 2. Production of new biological resources through the application of biotechnological procedures.
- 3. Methods for the analysis and control of biological functions.

JIRCAS Visiting Research Fellowship Program at Okinawa 2001

Japan International Research Center for Agricultural Sciences (JIRCAS) (formerly Tropical Agriculture Research Center) has implemented the “Visiting Research Fellowship Program at Okinawa” since 1992.

The Fellowship emphasizes presently pioneer research on the conservation of the global environment and optimum utilization of bio-resources in the tropics and subtropics.

The successful candidates, the number of which will be about 10, will undertake relevant research pertaining to one of the four themes listed below. Research will be carried out at the Okinawa Subtropical Station of JIRCAS in Ishigaki City, Okinawa Prefecture which is located in the subtropical zone of Japan and is equipped with advanced facilities for research.

Research Themes

- (1) Development of techniques for environmental control by using plants and microorganisms specific to the tropics and subtropics.
- (2) Elucidation of the mechanism of heat tolerance of tropical and subtropical plants.
- (3) Identification and evaluation of salt-tolerant crops.
- (4) Evaluation and utilization of useful traits of plant genetic resources in the tropics and subtropics.

Fellowship Qualifications

- (1) Applicants should be nationals of developing countries, be currently employed in a research organization (institute or university, etc.) and be engaged in research relating to tropical or subtropical agriculture and forestry, in principle.
- (2) Hold a Ph. D. degree in a field relating to natural sciences and technology or equivalent qualifications in related fields.
- (3) Be a researcher who will take up research subjects related to one of the four themes listed in the forementioned "Research Themes".
- (4) Be preferably less than 45 years of age.
- (5) Should enjoy a good health.
- (6) Have an adequate command of English or Japanese language.
- (7) Be committed to pursuing research in fields related to tropical agriculture and forestry after the termination of the Fellowship.

Tenure

In principle, one year, starting from October 2001.

Fellowship Conditions

- (1) A round-trip airline ticket (economy class) will be available (except for dependents).

(2) Living allowance: 260,000yen per month.

(excluding housing allowance)

(3) Housing (cost borne by JIRCAS): Maison ICRS, 874 Maezato,

Ishigaki, Okinawa, 907-0002 JAPAN

(4) Fixed-rate insurance package (for injury, sickness and damage, etc.) will be offered under the JIRCAS Fellowship Program. (except for dependents)

Application Procedure (This year's application has come to a close.)

Applicants are required to submit the following documents to the Director General of JIRCAS.

Diurnal and Seasonal Changes in CO₂ Concentration and Flux in an Andisol and Simulation Based on Changes in CO₂ Production Rate and Gas Diffusivity

Seiko YOSHIKAWA* and Shuichi HASEGAWA

Abstract

Changes in the concentrations and fluxes of CO₂ were monitored to a depth of 100 cm in an Andisol, under both fallow and soybean crop for a period of one year. Gas flux was calculated by the diffusion equation. Diurnal concentrations at depths less than 40 cm followed a sinusoidal pattern similar to that of the soil temperature, with the highest value being recorded in the daytime. Heavy rainfall which closes air voids open to the atmosphere resulted in a higher CO₂ concentration in the shallow soil layers. The subsequent decrease in the concentration in the shallow layers by the recovery of diffusion paths to the atmosphere was accompanied by an increase in concentrations in the deeper soil layers. CO₂ concentration profile under soybean showed a peak at depths that increased gradually from 20 to 80 cm with the growth of the roots. Upward CO₂ fluxes decreased with depth in both fields, and the fluxes in the soil profile were high in summer and low in winter. CO₂ fluxes from the soil surface calculated by the diffusion equation and measured by the closed chamber method were fairly well correlated. Annual CO₂ fluxes were 3,522 g m⁻² under fallow and 4,975 g m⁻² under soybean. The CO₂ movement in soil was simulated by use of the diffusion first law combined with the mass conservation equation. This mechanistic model enabled to analyze phenomena occurring under field conditions, suggesting that soil aeration is controlled by gas diffusion.

Discipline: Soils, fertilizers and plant nutrition

Additional key words: carbon dioxide, gas diffusion

1)...13): [References](#)

(Received for publication, February 15, 1999)

Introduction

Carbon dioxide (CO₂), amounting to about 0.03% in the air, is referred to as "the greenhouse-effect gas" in the same way as methane, nitrous oxide, ozone, etc. because it absorbs infrared rays. Increase of the concentration of greenhouse-effect gases induces the warming-up of the earth which affects biological phenomena. According to the IPCC (Intergovernmental Panel on Climate Change) report, the contribution of CO₂ to the warming-up of the earth is estimated at about half or more of the whole. CO₂ concentration in the atmosphere is controlled by exchange processes between the atmosphere, and the ocean and land biosphere. Therefore soils, which are the main habitat of land organisms, also play an important role in the changes in the CO₂ dynamics.

Quantitative analysis of CO₂ movement in soil profiles is essential for analyzing the carbon circulation and CO₂ emission from lands. De Jong and Schappert⁴⁾ studied the CO₂ flux and respiration rate at various depths in a soil by applying the diffusion equation combined with the mass conservation equation. They measured the CO₂ concentration in a virgin prairie in Canada from May to November and recorded the highest surface CO₂ flux in June ($7.5 \times 10^{-4} \text{ g m}^{-2} \text{ s}^{-1}$) and the lowest one in November (almost zero). They observed that the highest CO₂ concentration shifted downward toward summer, and ascribed this phenomenon to the gradual increase in the soil temperature with depth as the season progressed, combined with a decrease in the moisture content due to evapotranspiration. Campbell and Frascarelli²⁾ measured CO₂ fluxes using sampling wells through which CO₂ was trapped by an absorbent solution. They showed that the CO₂ flux decreased with depth and increased throughout the profile about 2 weeks after the increase in the soil temperature.

However, CO₂ concentration profiles on an hourly basis and after rainfall events are poorly documented, and more data on the CO₂ flux from fallow and cultivated fields are needed for analyzing CO₂ emission from agricultural lands.

The objectives of the present study are to investigate the diurnal changes, rain-induced changes, and seasonal changes in CO₂ concentrations and fluxes, and to confirm that soil aeration is controlled by gas diffusion through the simulation of the characteristics in CO₂ concentration changes using a model based on the gas diffusion law.

Experimental procedures

1) Field experiment

Field experiments to analyze the CO₂ behavior in an Andisol were conducted throughout a year from June 24, 1991 to June 25, 1992, in fields of the National Institute of Agro-Environmental Sciences (latitude 36°01' N and longitude 140°07' E). The soil was a Hydric Hapludand¹⁾, which extended over a 200 cm depth.

The soil profile was divided into 6 layers, Ap1 (0 to 20 cm), Ap2 (20 to 37 cm), 2B1 (37 to 79 cm), 3B21 (79 to 108 cm), 4B22 (108 to 155 cm) and 5B23 (155 to 200 cm). The top 4 layers were used in this study. A fallow field and a field cultivated with soybean (*Glycine max* Merr. (cv. Tachinagaha)) were used for the experiments. They were adjacent and the area of each field was 150 m². Soybean was sown on May 8, 1991, at a seed spacing of 15 cm on 65 cm rows and harvested on December 2. Plant residues above the ground were removed from the fields. Winter wheat (*Triticum aestivum* L. (cv. Norin No.61)) had been cultivated previously in both fields from the autumn of 1990 to the spring of 1991.

The soil profile and depths where measurements and samplings were performed are shown in [Fig. 1](#). Triplicate soil air samples were withdrawn into 3 cm³ vial bottles with a rubber cap *in vacuo* from gas-sampling tubes installed at depths of 2.5, 5, 17.5, 22.5, 34.5, 39.5, 55, 76.5, 81.5 and 100 cm below the soil surface. The gas sampling tubes were installed in the fields at least at 30 cm intervals. In the soybean field, the sampling tubes were buried between rows. The tube consisted of a polyethylene filter (8 mm in diameter, 10 cm in length), a hollow needle, a capillary tube (0.5 mm in inside diameter) connecting the filter and the needle, and an acrylic tube (10 mm in outside diameter)²⁾. The gas sampling tubes were inserted into holes bored in advance with a soil auger 21 mm in diameter, and the gap between the gas sampling tube and the wall of the hole was deliberately filled up by soils. The open end of the hollow needle was stuck into a rubber tap except at the time of the measurements. The air sample at 0-2 cm above the soil surface was drawn into the vial bottle through a hollow needle that pierced the rubber cap. Concentrations of CO₂ in the vial bottles were analyzed within 1 h after sampling by injecting 0.3 cm³ of sample air into a gas chromatograph (Hitachi gas analyzer, model 263-70, FID with Ni catalyst) using Porapak Q columns and N₂ as a carrier.

Fig.1. Soil profile, measurements and sampling depths for air, water and temperature

2) Gas diffusivity

The relative gas diffusion coefficient D/D_0 was measured by the diffusion chamber method developed by Osozawa⁸. Undisturbed 100 cm³ soil cores sampled from individual layers were used for the measurement. D/D_0 was measured at several moisture contents adjusted by a pressure plate method. The diffusion coefficient of CO₂ in air, D_0 (cm² s⁻¹), was calculated from the equation $D_0 = 0.139 \times (T/273.2)^{1.75}$ ¹⁰, where T was the absolute temperature (K) of the soil that was measured in the fields with thermocouples.

When the soil gas was sampled, the soil moisture content in the profile was measured to determine the gas diffusion coefficients in each soil layer D , based on the D/D_0 -air-filled porosity curves. Duplicate soil samples were taken to a depth of 100 cm using a thin steel tube with a tip 27.5 mm in diameter and 110 cm long, and the soil water content profile was measured by the oven-dry method.

3) CO₂ flux from the soil surface

CO₂ fluxes from the soil surface were calculated by applying the diffusion equation (described in the next section) to the surface 0-2.5 cm layer. CO₂ concentration at 0 to 2 cm above the soil surface was considered to be the CO₂ concentration at the soil surface. The closed chamber method^{5,13} was also applied to evaluate the CO₂ flux from the soil surface.

The increase in the CO₂ concentration in the chambers placed on the soil surface was measured every 2 min for 10 min. Duplicate measurements were carried out in each field. The measurement time was set at only 10 min to avoid large changes in temperature in the chamber and a gradient of CO₂ concentration between soil and air in the chamber. Sunlight reaching directly the chamber was also avoided during the

measurements. As a result, the temperature changes in the chamber during the sampling were less than 3 °C. CO₂ fluxes were corrected for the temperature in the chamber.

4) Other experiments

Soil temperatures at 1, 5, 10, 20, 40 and 70 cm below the soil surface and atmospheric temperatures at 120 cm above the soil surface and in the closed chamber were measured with thermocouples.

After sampling on August 30, soybean roots were washed out from the duplicate soil blocks 15 x 10 cm in area to a depth of 80 cm. Root length was measured with a root scanner (Commonwealth Aircraft Co. Ltd.) .

Soil pH (H₂O) was measured using duplicate samples taken on July 4 from 12 depths for each field. Soil pH was measured after thorough stirring, with a soil: water ratio of 1 : 2.5.

Data about precipitation and evaporation were obtained from a weather station located at less than 500 m from the experimental fields.

Student's t test was conducted for testing the significance between data of CO₂ concentrations or CO₂ fluxes measured at different depths, fields, and times.

[TOP](#)

Calculation of CO₂ flux

Gas diffusion through soil water can be ignored because the value of the gas diffusion coefficient in water is about 1/10,000 of that in air, and the gradient of CO₂ concentrations in soil water is of the same order as that in soil air, assuming that the vapor-liquid equilibrium is attained. Thus, gas diffusion in soils can be written as:

$$q = -D \frac{dC_a}{dz} \dots \dots \dots (1)$$

where:

q = flux of gas, $\text{g cm}^{-2} \text{s}^{-1}$,

D = diffusion coefficient in soil, $\text{cm}^2 \text{s}^{-1}$,

C_a = concentration of gas in soil air, g cm^{-3} ,

z = depth, cm.

The mass conservation of a gas in soil is written as:

$$\frac{dG}{dt} = -dq/dz + p \dots \dots \dots (2)$$

where:

G = amount of gas in soil, g cm^{-3} ,

t = time, s,

p = evolution rate of gas in soil, $\text{g cm}^{-3} \text{s}^{-1}$.

The amount of a particular gas in soil is expressed by the following equation:

$$G = C_a V_a + C_w V_w \dots \dots \dots (3)$$

where:

C_a = concentration of gas in soil air, g cm^{-3} ,

V_a = air-filled porosity in soil, $\text{cm}^3 \text{cm}^{-3}$,

C_w = concentration of gas in soil water, g cm^{-3} ,

V_w = water-filled porosity in soil, $\text{cm}^3 \text{cm}^{-3}$.

CO₂ concentration in soil water is linearly related to that in soil air when the soil water pH is constant.

$$C_w = a C_a \dots \dots \dots (4)$$

where a is a constant.

Thus, Eq. (3) becomes:

$$G = C_a V_a + a C_a V_w = C_a (V_a + a V_w) \dots \dots \dots (5)$$

Substituting Eq. (5) for Eq. (2) gives,

$$\frac{dC_a}{dt} = 1/(V_a + a V_w) (-dq/dz + p) \dots \dots \dots (6)$$

In these calculations, the soil profile was divided into 10 layers whose boundaries were the soil surface (z_0) and the sampling depths of soil air (z_1, z_2, \dots, z_{10}) shown in Fig. 1. Gas flux in the n th layer, q_n , is written as $q_n = -D_n (C_n - C_{n-1}) / (z_n - z_{n-1})$, where D_n and C_n are the gas diffusion coefficient and CO₂ concentration in the n th layer, respectively.

Simulation model

A simulation for calculating flux and CO₂ concentration to analyze the above characteristics observed in the field experiments was carried out.

CO₂ concentration in water is identical with that in air, when the water pH is 5.81, on the assumption that

vapor-liquid equilibrium is attained.

Then, Eq. (6) becomes:

$$dC_a/dt = 1/V_p (-dq/dz + p) \dots \dots \dots (6')$$

where:

V_p = porosity in soil, $\text{cm}^3 \text{cm}^{-3}$.

When the gas diffusion can be considered to be a steady-state process, i.e. C_a is constant with time, Eq. (6') becomes :

$$dq/dz = p \dots \dots \dots (7)$$

Eqs. (1), (6') and (7) were used to simulate the changes of CO₂ concentrations in the soil profile. For simplification of these calculations, it was assumed that the soil pH was 5.81, and that the pore space was 0.75 throughout the profile. The assumptions were close to the field conditions as described later. The unit distance was 5 cm in vertical length, and the unit time was 10 min.

Results and discussion

1) *Physical and chemical properties of soil*

Total carbon content and profile descriptions of the fields are shown in [Table 1](#).

The order of relative gas diffusion coefficient in the range of low air-filled porosities was inversely related to the total carbon content. This result was similar to that obtained in a former study. The gas diffusion coefficients of humic soils were smaller than those of soils with a blocky structure at the same level of air-filled porosity⁸.

Soil pH was not appreciably different with depths and fields. Soil pH throughout the profile was 5.90 ± 0.14 under fallow and 6.06 ± 0.14 under soybean.

2) *CO₂ movement in soil*

(1) Diurnal changes in CO₂ concentration and flux

CO₂ concentration and soil temperature were measured 6 times on fine summer days from August 8 to 9, 1991. The mean atmospheric temperature was 24.2 and 23.6 for August 8 and 9, respectively. There had been a rainfall of 23 mm on August 7. At the beginning of the measurements, i.e. 11:00 a.m. on August 8, the air-filled porosities at the 6 cm depth were 0.30 (the soil matric potential was -13.5 kPa) under fallow and 0.29 (the soil matric potential was -11.6 kPa) under soybean.

[Fig. 2](#) shows that the CO₂ concentrations at depths less than 40 cm tended to be high in the daytime and low during the night. CO₂ concentrations at 5 and 17.5 cm depths at 2:00 p.m. on August 8 were significantly (5% level) higher compared with those at 0:00 a.m. and 5:00 a.m. on August 9, based on Student's t test. Diurnal soil temperatures at 1 and 5 cm depths also followed a similar trend. CO₂ concentrations at depths more than 40 cm were relatively stable throughout the day from August 8 to 9, presumably due to the stable soil temperatures. Thus, the fact that both the CO₂ concentration and the temperature at shallower depths under fallow changed with time may be ascribed to the respiration of microorganisms, which is closely related to the soil temperature.

A similar trend was observed in the soil under soybean cultivation. However, the CO₂ concentrations were less related to the soil temperatures than in the fallow field, presumably because the respiration of the roots also affected the CO₂ concentrations.

Diurnal changes in CO₂ fluxes from the soil surface followed a sinusoidal pattern⁹.

Comparison of the CO₂ fluxes calculated by the diffusion equation method and those measured by the closed chamber method showed that both fluxes followed similar patterns. The difference between the fluxes measured by the 2 methods was not statistically significant (5% level) based on Student's t test. The calculation based on the mean fluxes determined by the diffusion method showed that the total fluxes for 24 h were 9.68 g m⁻² in soil under fallow, and 22.2 g m⁻² in soil under soybean, a value about twice that observed under fallow in the daytime from August 8 to 9, 1991.

(2) Turn-over time of CO₂

To determine the turn-over time of CO₂ in soil during the 24 h period from August 8 to 9, 1991, the total amount of CO₂ in soil under fallow to 100 cm depth was calculated based on the data of CO₂ concentrations and water contents measured at 11:00 a.m. on August 8. The values of 1.65 g m⁻² in soil

air, and 6.03 g m^{-2} in soil water were obtained by assuming that the vapor-liquid equilibrium of CO_2 was attained and the soil water pH was 5.90, which was the average value of soil pH throughout the profile under fallow. The turn-over time, which is expressed as the total amount of CO_2 within 100 cm depth divided by the CO_2 flux from the soil surface was 0.57 day based on the CO_2 flux calculated by the diffusion equation. Under ordinary field conditions, CO_2 is considered to evolve rapidly into the atmosphere.

(3) Changes in CO_2 concentration after heavy rainfall

Heavy rainfall which intercepts the open-air void pathway to the atmosphere must affect significantly the CO_2 movement in soil. [Fig. 3](#) shows the changes in the CO_2 concentration profile in soil under fallow and under soybean after heavy rainfall of 79 mm on August 20 and 30 mm on August 21. The CO_2 peak under fallow appeared at 5 cm depth on August 22 but disappeared by August 23. However, the CO_2 concentrations in the deeper layers on August 23 were higher than on the previous day. Thereafter, the CO_2 concentration decreased markedly at shallow depths.

A more typical trend of CO_2 concentration profiles was observed under soybean crop. The CO_2 concentration at depths more than 55 cm was the highest on August 26, 5 days after the rainfall, although the CO_2 concentrations in the shallower layers had started to decrease.

Soil matric potential in the surface layer (6 cm in depth) increased to -1 to -2 kPa by rainfall on August 20, and such conditions persisted for almost 1 day. During this period, air-filled porosity in the surface layer estimated from the soil water characteristic curve was about 10%, at which the D/D_0 value was 0 based on laboratory experiments⁹.

Based on the above facts, the changes in the CO_2 concentration with time and depth after heavy rainfall may be ascribed to the following process. First, the CO_2 concentration increased in the shallow layers because of the lack of a continuous air-void pathway to the atmosphere. Second, with the progression of the drying process (drainage and evapotranspiration), CO_2 in the shallow layers started to diffuse both upwards and downwards, resulting in a decrease of the CO_2 concentration in the shallow layers and an increase in the deeper layers. Thereafter, the CO_2 concentration throughout the soil profile decreased almost in the same way as under the initial conditions.

(4) Rapid vapor-liquid equilibrium of CO_2 in the subsoil after heavy rainfall

The increase of the CO_2 concentration in the subsoil by downward diffusion which appeared after heavy rainfall was investigated on the basis of the vapor-liquid equilibrium of CO_2 in soil. The soil layer studied extended from the center of the 7th layer to that of the 10th layer, i.e. the depth between 47 and 91 cm under soybean, and gas fluxes in this layer were calculated from 12:00 a.m. on August 22 to 12:00 a.m. on August 23. The values of the 7th flux q_7 and the 10th flux q_{10} , which were the average values on August 22 and 23 corresponded to downward fluxes of $1.066 \times 10^{-5} \text{ g m}^{-2} \text{ s}^{-1}$ and $2.42 \times 10^{-6} \text{ g m}^{-2} \text{ s}^{-1}$, respectively. The value of the flux obtained by subtracting the value of q_{10} from the value of q_7 was $8.24 \times 10^{-6} \text{ g m}^{-2} \text{ s}^{-1}$ ($1.88 \times 10^{-7} \text{ mol m}^{-2} \text{ s}^{-1}$) which must have contributed to the increase of the CO_2 concentration both in the gaseous and liquid phases of the soil. The values of air and water volumes through the depth of 47 to 91 cm per 1 cm^2 cross-section were 4.6 cm^3 and 30.1 cm^3 , respectively on an average between August 22 and 23. Thus, the amount of downward CO_2 flux for 24 h must have increased the CO_2 concentration in the air phase by 0.091% ($3.81 \times 10^{-5} \text{ M}$) and in the dissolved state (H_2CO_3 , HCO_3^- , and CO_3^{2-}) by $4.80 \times 10^{-5} \text{ M}$. In addition to the vapor-liquid equilibrium, the above

calculations were conducted on the assumption that the soil temperature was 20 and that the soil water pH was 6.06, which corresponded to the average value of the soil pH throughout the profile under soybean.

Measured values showed that the CO₂ concentration in the air phase increased by 0.089% on an average in the 47 to 91 cm layer during the 24 h period from August 22 to 23. Thus, the calculation fitted well to the increase of the CO₂ concentration observed in the field.

If the second term on the right side of Eq. (3) is not considered, the increase in the CO₂ concentration in the soil air phase becomes 0.84%, which is much larger than the value observed in the experiment. Thus, the results suggested that CO₂ which flowed into a specific layer through the gaseous phase was distributed rapidly into both the gaseous and liquid phases. Based on Eq. (6), the increase in the CO₂ concentration in the subsoil layers after heavy rainfall could be mainly attributed to the downward flux rather than to the increase in the evolution rate in the subsoil.

(5) Seasonal changes in CO₂ concentration

Seasonal changes in the CO₂ concentration were measured once a month, except in the summer, in 1991. Only the data collected between 11:00 a.m. and 2:00 p.m. on the days with negligible rain effect were used.

The seasonal changes in the CO₂ concentration are shown in [Fig. 4](#). At the beginning of the experiment on June 24, 1991, the CO₂ concentration profiles under fallow and soybean were statistically nonsignificant (5% level) based on Student's t test. The CO₂ concentrations under fallow increased with depth throughout the year, and showed maximum values toward the end of July. Thereafter, the CO₂ concentration began to decrease. On the other hand, the CO₂ concentrations under soybean showed maximum values at depths that shifted downward gradually with soybean growth from 20 to 40 cm on July 11 to 40 to 80 cm on August 30, suggesting the effect of root elongation. CO₂ concentrations from the end of autumn to winter again increased with depth. The CO₂ concentrations under soybean were significantly (5% or 1% level) higher than those under fallow, except on June 24, 1991, based on Student's t test.

Although the root length density decreased with depth, some roots reached 80 cm depth on August 30, 1991. The main factor influencing the difference in the CO₂ concentrations between fields under fallow and those under soybean may be the respiration of roots and the microbial activity in the rhizosphere.

(6) Changes in CO₂ concentration in the subsoil layer and determining factors

CO₂ concentrations at the depth of 79 cm (the average of CO₂ concentrations at 76.5 cm and 81.5 cm depths) including those after rainfall, and daily-mean soil temperatures at depths of 10 cm and 70 cm are shown in [Fig. 5](#). Total precipitation during one year was 1,977 mm and 51% of it occurred from late August to October.

CO₂ concentrations at 79 cm depth under fallow seemed to coincide well with the temperatures at 10 cm depth compared with those at 70 cm depth. This phenomenon may be explained as follows. The CO₂ increase in the surface layers by enhanced microorganism respiration associated with the increase in the temperature suppressed the CO₂ upward flux from the deeper layers due to the decrease in the concentration gradient between the surface and deeper layers. As a result, the CO₂ concentration at 79 cm depth increased when the soil temperature at 10 cm depth was high. The decrease in the surface temperature resulted in an inverse effect on the CO₂ concentration at 79 cm depth. This assumption is

based on the fact that most of the microorganisms are distributed in the surface layer where the seasonal changes in temperature are highly conspicuous¹²).

On the other hand, CO₂ concentrations under soybean increased until the middle of September when the temperature was lower than the maximum. Root respiration in addition to microorganism respiration is likely to influence the CO₂ concentration at 79 cm depth. CO₂ concentrations under soybean were higher than those under fallow, and the difference became more pronounced until October and still persisted until June of the following year.

Heavy rainfall clearly reflected the increase in the CO₂ concentration during 1-2 days after rainfall, even though only 3 measurements in August and September supported this assumption.

(7) Seasonal changes in CO₂ flux

The seasonal changes in upward CO₂ fluxes in each layer are shown in [Fig. 6](#). Fluxes decreased with depth in both fields. Fluxes in the upper to middle parts of the profile were higher under soybean than under fallow. Fluxes increased until the end of July and then decreased in both fields. However, fluxes under soybean in August were still high compared with those under fallow.

The CO₂ fluxes at depths deeper than that at which the CO₂ peak was observed from July 11 to August 30 under soybean (cf. [Fig. 4](#)) showed negative values. The negative values were smaller by 2 to 3 orders compared with those of the fluxes in shallow layers because the diffusion coefficient decreased with depth.

The seasonal changes in the CO₂ flux from the soil surface calculated by the diffusion equation are shown in [Fig. 7](#). Data for a few days after heavy rainfall exceeding 100 mm on August 22 and 23 were not included, because the CO₂ concentration changed so much after heavy rainfall in comparison with the seasonal changes that the CO₂ concentrations on such days were not suitable for following the seasonal changes. The values of the fluxes were high in summer and low in winter, and CO₂ fluxes under soybean were higher than those under fallow, especially during the growing season. Even after harvest, the difference in the values of the CO₂ flux under fallow and under soybean was statistically significant (5% level) based on Student's t test, presumably because of the increase in the microbial activity in the rhizosphere. CO₂ fluxes from the surface in summer were about 10 times higher than those in winter in both fields. The characteristics of the seasonal changes and amplitude of the CO₂ fluxes from the surface were similar to those previously reported^{2,4}. CO₂ fluxes from the surface under soybean were about 2 times higher than those under fallow in summer.

CO₂ fluxes from the soil surface measured by the closed chamber method (X) and calculated by the diffusion equation (Y) were expressed by the equation for a straight line that coincides with the origin: Y (g m⁻² d⁻¹) = 0.894 X (R = 0.893, n = 58), except for the fluxes after heavy rainfall. The correlation coefficient (R) between fluxes calculated by the diffusion equation (Y) and fluxes estimated by the equation (Y'): $Y' = 1 X$ was 0.888 (n = 58). Therefore, the fluxes calculated by the chamber method and the diffusion method coincided relatively well.

(8) Estimation of annual respiration

Total CO₂ fluxes from the surface estimated from measurements throughout a year were 3,522 g m⁻² y⁻¹ under fallow and 4,975 g m⁻² y⁻¹ under soybean. De Jong and Schappert⁴ estimated that 2,300 g m⁻² of

CO₂ was emitted during the growing season from a virgin prairie in Canada. Tulaphitak et al.[11](#) estimated that 5,170 g m⁻² of CO₂ was emitted during a year from an upland cultivation field in Thailand. Our values were comparable to the published data.

Simulation model

1) Simulation of diurnal changes in CO₂ concentrations

In the field experiments, CO₂ concentrations at depths less than 40 cm from the soil surface followed a sinusoidal trend with the highest values observed in the daytime.

Simulation was conducted to analyze the diurnal changes in CO₂ concentrations. The initial conditions of CO₂ distribution and the diffusion coefficient in the profile were set to be approximately those recorded on August 8, 1991 as follows:

$$C_a = 8.0e10^{-6} + 2.7e10^{-7}eZ - 8.6e10^{-9}eZ^2 + 2.6e10^{-10}eZ^3 - 3.2e10^{-12}eZ^4 + 1.3e10^{-14}eZ^5,$$

$$D = 0.024 e^{-0.042 z} + 0.0012$$

where C_a = CO₂ concentration, g cm⁻³ of air, Z = depth, cm, D = CO₂ diffusion coefficient in soil, cm² s⁻¹. The CO₂ evolution in the steady-state was calculated from the initial conditions.

CO₂ evolution from soils has been reported to be 3 times as high with an increase of about 10 in the soil temperature between 15-40 [3,7](#). A simulation for the CO₂ diurnal changes was conducted based on the dependency of CO₂ evolution on the soil temperature, as shown in [Fig. 8](#). CO₂ concentration at a depth less than about 40 cm from the soil surface increased in the daytime and decreased in the night time, reflecting the characteristics of CO₂ changes in the field.

2) Simulation of changes in CO₂ concentrations induced by rain

In the field experiments, heavy rains (August 20-21) generated a CO₂ peak in the shallow layer at both sites. The peak gradually shifted downward with a decreasing magnitude accompanied with CO₂ accumulation in deeper layers. Soil matric potential in the surface layer (6 cm in depth) increased up to -1 ~ -2 kPa by rainfall. The value remained constant for almost 1 day. During this period, air-filled porosity in the surface layer estimated from the water retention curve was 10% , and the D/D_0 value obtained from the curve of D/D_0 - air-filled porosity was almost 0.

To reproduce the changes in the CO₂ distribution obtained in the field experiments, the simulation was carried out on the following assumptions: (1) The initial distribution of the CO₂ concentration and the gas diffusion coefficient were the same as those on August 8 (the nearest measurement day before August 20), (2) The gas diffusion coefficient of the surface layer was assumed to be 0 during the first day, namely the continuity of the air-filled porosity in the surface layer was intercepted by abundant water. Thereafter, the gas diffusivity was assumed to recover gradually for 2 days to the previous level.

The results of the simulation are shown in [Fig. 9](#). The CO₂ peak in the upper layer continued to increase along with the accumulation of CO₂ in deeper layers during 1 day while the continuity of the air pores was kept for interception. After the recovery of the continuity of air-filled pores, the CO₂ concentration in the upper layer began to decrease. On the other hand, the CO₂ concentration in the subsoil layers at 90 to 100 cm depths continued to increase from 1 day to about 4 days after the rain in spite of the disappearance of the maximum peak.

These simulations reproduced the typical characteristics of the changes in CO₂ concentration after a large amount of rain.

3) Simulation of seasonal changes in CO₂ concentrations

CO₂ concentrations throughout the profiles in the fallow and soybean fields increased toward

mid-summer and decreased toward winter. CO₂ distribution in the fallow field showed an almost monotonic increase with depth throughout the year, while that of the soybean site showed a distinct peak during the growing season from 20 to 80 cm depths.

Simulation was conducted to analyze the seasonal changes in CO₂ concentrations toward summer (from June 24 to July 31, 1991) by using the gas diffusion law. The initial conditions of CO₂ distribution and the diffusion coefficient in the profile corresponded approximately to those on June 24, 1991.

CO₂ evolution rates in the steady-state were calculated from the initial conditions. They were assumed to increase at constant rates corresponding to the changes in daily mean temperatures between June 24 and July 31, 1991. The changes in the CO₂ distribution based on these assumptions are shown in [Fig. 10](#).

The increase of the CO₂ concentration from shallow layers to deeper layers was attributed to the following factors: 1) Increase in the rates of CO₂ concentration in the upper layers was larger than that in the subsoil layers. 2) The upward CO₂ flux was suppressed by the decrease in the concentration gradient between the shallower layers and the deeper layers, and incidentally CO₂ accumulated in the deeper layers.

Conclusions

The objective of this study was to investigate the factors that determine the CO₂ distribution in the soil profile by using a simulation model based on the calculation of the CO₂ flux by the gas diffusion equation. To achieve this objective, diurnal, rain-induced, and seasonal changes in CO₂ concentration were monitored along with the soil moisture content and soil temperature under fallow and soybean cultivation. The results were as follows.

Diel concentrations of CO₂ at depths less than 40 cm followed a sinusoidal pattern similar to that of the soil temperature, with the highest value being recorded in the daytime.

Heavy rainfall interrupted the continuity of the air pathway to the atmosphere, which resulted in a high CO₂ concentration in shallow layers at first, and a decrease in the concentration from shallow depths accompanied by an increase in the concentration in deeper layers with the progression of drying for a few days.

CO₂ concentration throughout the profile was high in summer and low in winter. CO₂ concentration under soybean increased from shallow to deeper layers with the increase of the rooting depth.

CO₂ fluxes from the soil surface based on calculations from the diffusion equation corresponded relatively well to those measured by the chamber method.

CO₂ gas was found to move rapidly through air-filled pores and to be swiftly equilibrated between the air phase and liquid phase.

A model was devised for calculating the CO₂ flux and CO₂ concentration to analyze the CO₂ changes observed in field experiments. CO₂ flux was calculated by the diffusion equation combined with the equation of continuity. CO₂ concentration in the air phase in each layer was assumed to change by CO₂ evolution and/or dissolution from/into the liquid phase as well as by CO₂ influx and efflux through the air phase and by CO₂ production.

In the model, the CO₂ production rate changed with the soil temperature, and the diffusivity changed with the soil water content. The model enabled to analyze the changes in the CO₂ concentrations observed in the field experiments fairly well in the absence of root respiration. However, if the root respiration for each layer could be measured with time, and the data could be introduced into the model, it would be possible to analyze the CO₂ concentration changes under vegetation. These results indicated that the changes in the CO₂ concentrations in soil were significantly influenced by the following 2 factors: (1) microorganism respiration, which is closely related to the soil temperature, and root respiration, which is closely related to the stage of crop growth, (2) soil moisture, which mainly affects the gas diffusivity in soil.

Abstract

Behavioral responses of a generalist predatory stink bug, *Eocanthecona furcellata* towards larvae of several lepidopteran species were observed in order to analyze the role of semiochemicals in eliciting a prey-locating behavior in this bug. Extracts of *Spodoptera litura* larvae elicited approaching behavior in *E. furcellata*. A hexane-eluted fraction from silica gel chromatography of the larval extracts was also attractive to the bugs. The hexane fraction contained *n*-tetradecane, *n*-pentadecane, *n*-hepta- decane, *n*-heptacosane, *n*-nonacosane, *n*-hentriacontane and 2,6,10,15,19,23-hexamethyl-2,6,10,14,18,22-tetracosahexaene (squalene). Synthetic *n*-pentadecane was attractive to the bugs. On the other hand, a 15%-ether-in-hexane-eluted fraction from silica gel chromatography of the solvent extracts of *S. litura* stimulated bugs to display a proboscis-protruding behavior. (*E*)-3,7,11,15-Tetra- methyl-2-hexadecen-1-ol [(*E*)-phytol] was identified in this fraction, and synthetic (*E*)-phytol showed the same effect on the bugs as the fraction. (*E*)-Phytol content of larvae increased depending on the amount of chlorophyll in the diets. These results suggest that (*E*)-phytol in larvae, which is derived from chlorophyll in the prey diet, acts as an important cue in the prey-locating behavior of the generalist predatory stink bug, *E. furcellata*. In conclusion, the 2 different chemicals act as "kairomones" in the prey location for the predatory stink bug, *E. furcellata*.

Introduction

Many synthetic organic pesticides have contributed to the improvement of mass production of agricultural crops. However, unsuitable use for pest management has caused severe side-effects such as the development of pesticide resistance in pest insects, accumulation of residues in crops and agricultural environments. Under these circumstances, suitable use of natural enemies as one of the technical skills for the integrated pest management (IPM) is attracting worldwide attention.

Natural enemies of herbivorous insects use chemical, visual, acoustic and vibrational cues in foraging behavior. Especially, the importance of semiochemicals in foraging by parasitoids has been well documented⁶. Some studies have suggested the possibility of applying semiochemicals in pest management: by attracting and/or arresting the parasitoids in crop fields, or by enhancing the responses of parasitoids to hosts^{6,8,16}.

Some investigators have suggested that predators could be applied to pest management against various pest insects⁶. Since predators in general kill the pest insects immediately after catching them, an immediate effect of application of the predators in pest management is expected while parasitoids usually require a long period of time for killing pest insects. A few studies have revealed that chemicals related to prey insects are important cues in foraging for some predators. The eastern yellowjacket, *Vespula maculifrons*¹, the cylindrical bark beetle, *Lasconotus intricatus* Kraus², *Enoclerus lecontei* (Wolcott)⁹, *Temnochila chlorodia* Mannerheim¹⁵ and *Mederera bistriata* Parent¹⁸ are attracted to pheromone components of their respective preys. Lewis et al.⁷ reported that larvae of the green lacewing, *Chrysopa carnea*, use "kairomones" in scales of a moth, *Heliothis zea*. Hislop & Prokopy⁴ reported that acarine predators, *Amblyseius fallacis* and *Phytoseiulus macropilis*, respond to silk and feces of a prey mite, *Tetranychus urticae*. However, these studies deal with the relationships between a predator and its specific prey.

Fig.1
Nymphs of *Eocanthecona furcellata* feeding on larvae of *Spodoptera litura*

The predatory stink bug, *Eocanthecona furcellata* (Wolff) (Heteroptera: Pentatomidae)(Fig. 1), is a generalist predator that feeds on larvae of Lepidoptera, Coleoptera and Heteroptera and is distributed in India, Southeast Asia, the southern part of China, Taiwan and the Okinawa region of Japan^{3,5,10,13}. Takai & Yasuoka¹⁴ demonstrated that *E. furcellata* could be a good biological control agent against the noctuid *Spodoptera litura* (Fabricius) (Lepidoptera: Noctuidae) in greenhouses. The bugs can be easily reared on live larvae of *Pieris rapae*³ and frozen-preserved larvae of *S. litura*²².

Over the last several years, I conducted a series of studies on the prey-locating behavior of *E. furcellata*, and identified 2 chemical cues eliciting this behavior^{19,21,23}. In this report, I summarized the results of these studies.

Prey-locating behavior of *E. furcellata*

E. furcellata bugs were found to approach intact larvae of *S. litura*, and the bugs protruded their proboscis when they were in close vicinity to the larvae of *S. litura* and inserted it through the body surface of preys. This behavior was observed under contact illumination as well as under continuous darkness. A similar behavior was also elicited by dead larvae or solvent extracts of *S. litura* larvae. These findings indicated that odor, or chemical cue(s), from the prey apparently induced the prey-locating behavior of the predatory stink bug.

Fig.2. Linear track olfactometer

1) Approaching behavior

To evaluate the attractiveness of the larval extracts, a linear track olfactometer, which was designed according to Sakuma & Fukami¹¹ but with minor modifications²³, was used. The olfactometer consisted of a T-shaped wind tunnel and wire structures (Fig. 2). In this bioassay, test insects were made to climb up to a T-junction on the wire and choose a direction at one point. When a small piece of absorbent cotton impregnated with a crude extract of *S. litura* larvae (in 100- $\frac{1}{4}$ L acetone) was placed at one of the horizontal ends of the T-shaped wind tunnel (sample side) and a small piece of absorbent cotton impregnated with 100 $\frac{1}{4}$ L of acetone was placed at the other end (control side), 52 bugs chose the sample side and 15 bugs chose the control side. These results indicated that *E. furcellata* nymphs were apparently attracted to the crude extracts of *S. litura* larvae. *E. furcellata* nymphs were also found to be attracted to the ether-soluble layer of *S. litura* larvae (Fig. 3). When the ether-soluble layer of the larval extracts was fractionated on silica gel column chromatography, only the fraction eluted with hexane showed attractiveness.

When the hexane fraction was analyzed using GC-MS, one predominant peak and 6 minor peaks were observed. The predominant one corresponded to *n*-pentadecane (C₁₅)(2500 ng/larva). The minor peaks corresponded to *n*-tetradecane (C₁₄)(54 ng/larva), *n*-hepta-decane (C₁₇)(41 ng/larva), *n*-heptacosane (C₂₇)(61 ng/larva), *n*-nonacosane (C₂₉)(147 ng/larva), *n*-hentriacontane (C₃₁)(200 ng/larva) and 2,6,10,15,19,23-hexamethyl-2,6,10,14,18,22-tetracosahexaene (squalene)(323 ng/larva).

The approaching responses of *E. furcellata* nymphs in the linear olfactometer to the hexane fraction of *S. litura* larvae and synthetic hydrocarbons are shown in Fig. 4. The hexane fraction induced a significant approaching response in bugs at a dose of 0.4 larval equivalents (LE) containing ca. 1 $\frac{1}{4}$ g of C₁₅ in a linear track olfactometer. However, 1 $\frac{1}{4}$ g of synthetic C₁₅ did not induce a comparable response. More than 10 $\frac{1}{4}$ g of C₁₅ was necessary to attract *E. furcellata* nymphs, but no increasing effect was obtained by the addition of the other 6 components, C₁₄, C₁₇, C₂₇, C₂₉, C₃₁ and squalene, to C₁₅.

2) Proboscis-protruding behavior

In a preliminary observation, *E. furcellata* nymphs protruded their proboscis toward the crude extracts of *S. litura* larvae. However they did not protrude their proboscis when they were in close vicinity to a small piece of absorbent cotton impregnated with the hexane fraction or synthetic C₁₅. It seemed that any chemical(s) could elicit a proboscis-protruding behavior in the bugs.

A 15%-ether-in-hexane fraction from silica gel chromatography of the solvent extracts of *S. litura* larvae elicited the proboscis-protruding behavior in *E. furcellata* nymphs and a similar response was also observed with a neutral-layer fraction of the 15% fraction ([Fig. 5](#)).

Analysis of the neutral-layer fraction using GC-MS showed that it contained (*E*)-3,7,11,15-tetramethyl-2-hexadecen-1-ol [(*E*)-phytol]. Synthetic (*E*)-phytol elicited a proboscis-protruding response from the predators as well as the 15% fraction ([Fig. 6](#)).

BACK

Effect of prey diet on bug's prey-locating behavior

(*E*)-Phytol generally occurs in green plants as an alcoholic moiety of the chlorophyll molecule ([Fig. 7](#)¹²) and the amount of free (*E*)-phytol is usually small in plant tissues. However, this compound is obtained by hydrolysis of chlorophyll in the laboratory¹⁷. (*E*)-Phytol contents in larvae and in their feces were positively correlated with the chlorophyll content in the artificial diets ([Fig. 8](#)). Therefore, it is possible that food items for prey insects considerably influence the prey-locating behavior of the predatory stink bug, *E. furcellata*.

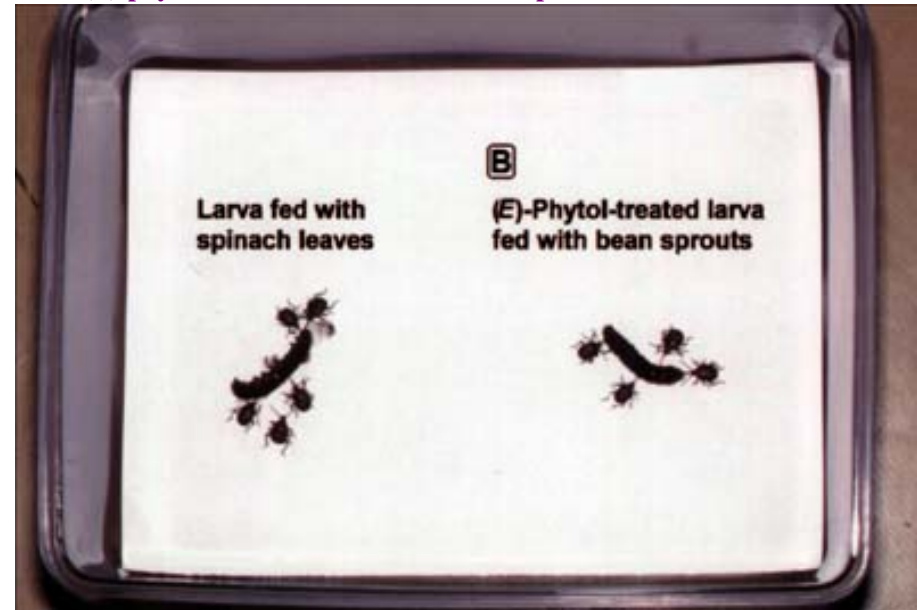

The bugs may prefer insects feeding on a chlorophyll-rich diet to those feeding on a chlorophyll-poor diet. When preference responses of *E. furcellata* nymphs to *S. litura* larvae fed with 2 food items, chlorophyll-rich spinach (*Spinacia oleracea*) leaves and bean sprouts (chlorophyll-poor seedlings of *Vigna radiata*), were observed, bugs preferred larvae fed with spinach leaves to those fed with bean sprouts ([Fig. 9A](#)): a total of 45 nymphs chose the former and 5 nymphs the latter. Solvent extracts of *S. litura* larvae given spinach leaves contained 9¼g/larva of (*E*)-phytol, but less than 0.001¼g/larva in those fed with bean sprouts. When a *S. litura* larva fed with bean sprouts was coated with 10 mg of (*E*)-phytol and presented to the bugs together with a larva fed with spinach leaves, almost the same number of *E. furcellata* bugs was located on these larvae ([Fig. 9B](#)): a total of 24 nymphs chose an (*E*)-phytol-treated larva fed with bean sprouts and 26 nymphs chose a larva fed with spinach leaves. The results indicated that (*E*)-phytol is utilized as a "kairomone" for prey-location by *E. furcellata* nymphs.

Fig.9. Feeding preference response of *Eocanthecona furcellata* nymphs to *Spodoptera litura* larva fed with spinach leaves (left) versus A and B (right)

A: a larva fed with bean sprouts.

B: an (*E*)-phytol-treated larva fed with bean sprouts.

(*E*)-Phytol was also detected in the extracts of larvae of the pellucid zygænid, *Pryeria sinica*, a giant silkworm, *Samia cynthia ricini*, an armyworm, *Pseudaletia separata*, the cabbage armyworm, *Mamestra brassicae*, which had been fed on diets containing chlorophyll. These extracts elicited the proboscis-protruding behavior of the bug, and the response depended directly on the (*E*)-phytol concentration in these larvae. Therefore, larvae of lepidopterans feeding on green plants could become potential preys for the generalist predatory stink bug, *E. furcellata*.

Conclusion

The present studies demonstrated that the generalist predatory stink bug, *E. furcellata*, uses 2 different chemical cues as "kairomones" to locate larvae of several lepidopterans. *n*-Pentadecane (C₁₅) acts as a long-range (relatively long) attractant for the bug. On the other hand, (*E*)-phytol induced a proboscis-protruding behavior within a short distance. (*E*)-Phytol could be a key chemical associated with herbivorous lepidopterans for the prey location of this generalist predator, since the chemical originating from chlorophyll in prey diets is found in lepidopteran larvae feeding on green plants and the bugs protruded their proboscis toward an object, even a glass rod, treated with (*E*)-phytol.

The behavioral manipulation for *E. furcellata* with the semiochemicals has not yet been evaluated in the field. However, some applications in pest management have been speculated. C₁₅ and (*E*)-phytol could be used as an attractant and an arrestant, respectively, to recruit *E. furcellata* bugs and/or prevent their dispersal from the crop fields. The current studies suggested that (*E*)-phytol may be an indicator of the effects on pest control using *E. furcellata*, if the contents of (*E*)-phytol in pest insects could be measured. (*E*)-Phytol could also be used as a feeding stimulant in artificial diets for mass rearing of *E. furcellata*. Further studies should be carried out for using these compounds for pest management with *E. furcellata* bugs.

Development of Fully Automatic Vegetable Transplanter

Konosuke TSUGA

Institute of Agricultural Machinery, Bio-oriented Technology Research Advancement Institution

(1-40-2, Nisshin, Ohmiya, Saitama, 331-8537 Japan)

Corresponding author: K. Tsuga (ktsuga@iam.brain.go.jp, fax +81-48-654-7130)

Abstract

We developed 3 models of riding-type, fully automatic vegetable transplanters. These prototypes are suitable for cell mold seedlings and pulp mold cell pot seedlings, mainly of leaf vegetables such as cabbage, Chinese cabbage, and lettuce. The prototypes enabled continuous transplanting work on 2 rows simultaneously, at a planting speed of 60 cells/row/min, with vegetable seedlings fed automatically. The transplanting accuracy, in terms of the rate of misplanted hills, was 3% or less, and the working capacity per worker was approximately 10 a/h. We estimated that the annual coverage area of this machine for cultivating cabbage is 53 ha/year, and the minimum economically suitable area for use is 8.2 ha. Based on these prototypes, transplanters have been put on the market by several companies and are now being used in various areas. In this study, we presented a draft of the standards for seedling trays, such as cell mold seedling trays and pulp mold cell pots (paper pots), for possible use of a fully automatic vegetable transplanter. At present, 4 million or more trays are supplied to the market.

Discipline: Agricultural machinery

Additional key words: transplanting, machine, seedlings, cabbage, lettuce

(Received for publication, February 25, 1999)

Introduction

Vegetable cultivation in Japan lags behind in terms of mechanization of transplanting and harvesting operations. Seeding and transplanting operations, in particular, are mainly performed manually, accounting for approximately 40% of total working hours. Recently, however, the mechanization of soil filling, seeding, germination, and the raising of seedlings has advanced, and mass raising of seedlings is performed now in production areas. Transplanters are presently used for leaf vegetables such as cabbage, Chinese cabbage, and lettuce.

Current vegetable transplanters are divided into 2 categories: fully automatic transplanters and semi-automatic transplanters. The semi-automatic transplanter has a limited operating speed due to the need for manual feeding of one seedling cell after another and is not suitable for continuous operation over a long period of time. The fully automatic transplanter allows for high-speed operation and labor-saving, because seedlings fed automatically by the machine itself can be planted. However, the fully automatic transplanters that have been developed so far can use only limited types of seedling trays and the working capacity is low because they are of the walking-type. There was a demand for fully automatic transplanters capable of higher speed and small labor load. Therefore, the Bio-oriented Research Technology Advancement Institution proposed standards for seedling trays of vegetables suitable for use with fully automatic transplanters in the "Urgent Development of Agricultural Machinery" implemented during the period from 1993 to 1995. The Institution also developed jointly with Iseki Noki Co., Ltd., Kubota Co., Ltd., and Yanmar Noki Co., Ltd. riding-type, fully automatic transplanters for vegetables.

In this paper, we will describe the transplanters, the kinds of seedlings, and the standards for trays (standardization), mainly for leaf vegetables, as well as introduce the outline of the riding-type, fully automatic transplanter that

achieved the highest performance in Japan.

Prototypes suitable for seedlings³⁾

Transplanters can be broadly divided into those to which seedlings are fed manually (semi-automatic transplanters) and those to which seedlings are fed automatically (fully automatic transplanters), as shown in [Table 1](#). These are further divided into the walking-type and the riding-type. In addition, the type of transplanter may vary depending on the seedlings to which it can adapt. Seedlings used for transplanting by a machine can be broadly divided into seedlings with soil and seedlings without soil (bare seedlings). Seedlings with soil can be further divided into cell mold seedlings, paper pot seedlings, kneaded nursery seedlings, and soil block seedlings. Recently, since the mechanization of seeding and that of transplantation are progressing in parallel, the use of seedlings with soil, adjustment of the properties of seedlings, and reduction in size of the seedlings are also making progress. In this study, we developed riding-type, fully automatic transplanters that are suitable for cell mold seedlings and pulp mold cell pot seedlings (a kind of paper pot seedlings).

Standardization of seedling trays

To transplant cell pot seedlings and paper pot seedlings, the fully automatic transplanter requires the use of seedling trays in which the arrangement of the seedlings is suitable for the seedling feeding device applied. Therefore, seedlings must be grown in trays that are suitable for the particular transplanter to be used, and the seedling form will differ from one kind of tray to another. If the same types of trays are used, the machine has to be adjusted to the number of cells per tray. Therefore, attempts were made to develop trays that were interchangeable among the seedlings from various seedling centers and among transplanters from different manufacturers. In this study, we prepared a draft of the standards for seedling trays, such as cell mold seedling trays and pulp mold cell pots, for possible use of a fully automatic vegetable transplanter ([Fig. 1](#)). As a result, the form and dimensions of these trays have been standardized, as shown in [Table 2](#).

Fig.1. Cell mold seedling trays and pulp mold cell pots (paper pots)

The cell mold seedling tray is made of flexible plastic, and there are 3 types of trays, containing 128, 200, or 288 cells, in which the arrangement of cells is 8 x 16, 10 x 20, and 12 x 24. The shape of the trays is that of an inverted pyramid.

The pulp mold cell pot is a kind of paper pot, in which the pulp mold is made of used paper, etc. Pot dimensions are 30 mm² (128 pots) and 25 mm² (200 pots), and the seedlings are arranged in the form of a pyramid. The

arrangement of cells is 8 x 8 and 10 x 10, and each pair of pots is arranged on an under-tray.

Both types of standard trays can use a rice seedling box as the under-tray. Four million or more of these standard trays had been supplied to the market as of 1998.

Development of riding-type, fully automatic transplanters^{1,5)}

1) Outline of fully automatic transplanter

We developed 3 models of riding-type, fully automatic transplanters that allow continuous transplanting work on 2 rows simultaneously at a planting speed of 60 cells/row/min, with vegetable seedlings fed automatically. The prototypes manufactured in 1995 consist of 2 models for cell mold seedlings (Type A in [Fig. 2](#), Type B in [Fig. 3](#)) and a model for pulp mold cell pot seedlings ([Fig. 4](#)). The outline of each model is described below.

(1) These machines handle mainly leaf vegetables such as cabbage, Chinese cabbage, and lettuce ([Fig. 5](#)), with cell mold seedlings and pulp mold cell pot seedlings. As the under-tray, a rice seedling box is used. Since the numbers of cells (pots) per tray are 128 and 200, standard trays can be used.

Fig.5. Chinese cabbage and lettuce seedlings

(2) The basic configuration of these machines is that of a small, riding-type machine consisting of a 2-row planting device mounted on the back of a vehicle. The planting device is composed of the seedling feeding and transplanting sections. The vehicle has a 4 wheel-drive system and is well adapted to slopes. The standard adjustment range of the tread (distance between the right and left wheels) is 90 to 120 cm. Although usually riding-type machines are very long and require a considerable area at the end of the field for turning, the current machine is a compact 4-wheel-drive vehicle, adapted to such use, and requiring only 3 to 4 m of headland for turning. This riding-type is suitable for relatively small fields.

(3) The models for cell mold seedlings (Types A and B) pull out seedlings one at a time from the tray using a seedling take-out claw of the holding type and discharge seedlings into the bill-type opener. The opener, which is interlocked with the claw, transplants the seedlings to the tamped surface of the ridge, and the tamping ring at the rear presses soil from the left and right to cover the seedlings. The automatic-planting-depth control unit and the ridge-following control unit allow stable transplanting with the use of hydraulic devices. Since the seedlings are independent cells, growth control is easy, growth rates are similar, and they display an outstanding initial rooting capacity after transplanting. The vehicle consists of a 4-wheel-drive system with either a diesel engine (Type A) or a gasoline engine (Type B).

(4) The model for pulp mold cell pot seedlings holds seedlings that are each wrapped by a paper pot (pulp mold) and transplants them continuously by separating them into individual hills. It allows the transplanting of seedlings with a wide range of sizes over a long period of time and is suitable for transplanting regardless of the degree of growth of the individual seedlings.

The model for pulp mold cell pot seedlings scratches off seedlings with the paper attached (pulp mold), after separating them into each hill with a transplanting claw, and transplants them in the hole opened by the arm. After transplanting, the soil is tamped. This transplanting claw consists of 2 blade-like claws and an extrusion arm. The blade-like claws scrape each seedling pot to separate it from the others and hold it, and the arm extrudes the seedling pot into the soil to plant it. Soil is pressed then from both sides of the planted seedling by the tamping ring to complete transplanting. The automatic-planting-depth control unit and ridge-following control unit allow stable transplanting with the use of hydraulic devices. The vehicle has a 4-wheel-drive system that allows maneuvering of both front and rear wheels.

(5) Planting conditions common to all the 3 models include an adaptable ridge height of 0 to 25 cm, a hill space of 25 to 50 cm, and a ridge space of 45 to 60 cm, in which the model for cell mold seedlings (Type A) allows zigzag planting on 2 rows.

2) Performance of the prototypes

(1) Working accuracy²⁾

Based on operation tests on the prototypes using seedlings of cabbage, Chinese cabbage, and lettuce, we confirmed that hill spacing, planting depth, and soil cover can be adjusted easily, a planting speed of 60 to 70 hills/row/min is possible, and the ratio of misplanted hills is 3% or less (excluding non-seeded hills in the tray). Lateral displacement of planting positions (rows), changes in hill spacing, and the ratio of slanted hills were also small. In the case of planting on slopes (maximum of 10°), number of misplanted hills and changes in hill spacing were small. [Table 3](#) shows the results of the planting accuracy test performed in Aichi Prefecture in 1994.

(2) Working capacity⁴⁾

We found that when 12 to 14 trays were mounted on the seedling tray and the auxiliary seedling tray, it was possible to transplant 2,400 or more hills without requiring the operator to get off the vehicle. Working time per 10 a per operator, including the planting time, seedling feeding time, turning time, etc., was approximately one hour. [Table 4](#) shows the results of the working capacity test performed in Aichi Prefecture in 1994, indicating that when one operator planted cabbage (at a hill spacing of 30 cm and row spacing of 60 cm), the working speed was 0.33 to 0.39 m/s, and all the 3 models showed a working capacity value of approximately 10 a/h. A similar value of working capacity of approximately 10 a/h was reported in a test on commercial machines.

3) Economic efficiency of the prototypes⁴⁾

(1) Maximum working area

We calculated the maximum transplanting working area per year achieved by these prototypes in the case of cabbage cultivation ([Table 5](#)). The time available for transplanting work was 2.8 h per day. This value was calculated on the assumption that half a day (4 h) can be used for transplanting work, to avoid other conflicting tasks and poor rooting conditions, as well as high temperatures in summer and low temperatures in early spring. Assuming that the actual working rate is 70%, the maximum working area per day was 0.29 ha/day, based on the time available for transplanting work and the working capacity of the machine. Next, the number of days available for working was 183, on the assumption that the ratio of days available for work is 75% because transplanting work is performed over a period of 8 months from April to November, including the days when rain prevents outdoor work. The maximum transplanting working area per year (cumulative working area per year) was 53.1 ha, based on the calculation of the maximum working area per day and the number of days available for working per year.

(2) Cost and economic efficiency

We calculated the cost of using these machines in the case of cabbage cultivation. The costs included fixed costs (expenses required for owning the machine) and variable costs (operating costs, including fuel, lubricating oil, and labor). [Fig. 6](#) shows the relationship between the area covered and the cost of the machine. To evaluate the economic efficiency, we calculated the minimum economical area for using this machine based on the work contract wage for manual transplanting. Based on that wage, the result was 8.21 ha. Since the maximum transplanting working area per year is 53.1 ha, and since this machine can cover an area 6.5 times as large, we consider that this machine is economically efficient.

Conclusion

We developed 3 models of small-sized, high speed, riding-type, and fully automatic vegetable transplanting machines for the first time in Japan. These machines feed vegetable seedlings automatically and enable continuous transplanting work on 2 ridges simultaneously at a planting speed of 60 hills/row/min. The machines can be used for cell mold seedlings and pulp mold cell pot seedlings. In Ogoori City, Fukuoka Prefecture, where the machine was put on the market and used, cabbage is cultivated over the year on a 15-ha field, using a transplanter model for cell mold seedlings (manufacturer, Yanmar Noki Co., Ltd.), as shown in [Fig. 7](#). This was part of a thorough mechanization system, including general-purpose use of this vehicle and the introduction of harvesters. [Fig. 8](#) shows another model for cell mold seedlings (manufacturer, Kubota Co., Ltd.), which is used for transplanting cabbage, etc., in a farm where cabbage, Chinese cabbage, and lettuce are cultivated (25 ha) in Takeda City, Kumamoto Prefecture. Six riding-type transplanters of the model for pulp mold cell pot seedlings (manufacturer, Iseki Noki Co., Ltd., [Fig. 9](#)) were used for a thorough mechanization system, including general-purpose use of this vehicle, in Kazuno City, Akita Prefecture, where a cabbage production center of 100 ha is being constructed. As a result, dozens of such riding-type, fully automatic transplanters have been introduced already in various areas and we anticipate that their use will be disseminated throughout the country.

We thank the Agricultural Experimental Stations of Iwate Prefecture and Aichi Prefecture for their cooperation during the field tests of the automatic transplanter.

Abstract

A new method for estimating crop transpiration and crop water stress index (*CWSI*) by using a temperature-related approach was developed and verified in this study. In the proposed method, 3 temperatures and a few meteorological variables (net radiation and humidity) are required. The 3 temperatures include sunlit leaf temperature, imitation leaf temperature, and air temperature. The imitation leaf refers to an artificial leaf without transpiration. The major advantage of the proposed method is that plant correction factors, empirical coefficients, and canopy and aerodynamic resistances are not required. Experiments for verification were conducted in a sandy field with sorghum crop and in a greenhouse with melon crop. Data obtained by the proposed method were compared with the amount of transpiration determined with lysimeters, soil water status determined by TDR, and *CWSI* estimated by Jackson's method. The calculated transpiration by the proposed method was consistent with the results obtained with lysimeters, with a regression coefficient $r^2=0.88$. Values of *CWSI* calculated by the proposed method were in agreement with Jackson's *CWSI*, with a regression coefficient approximately equal to 1. These results indicate that the proposed method can be applied to estimate crop transpiration and water stress index under both field and greenhouse conditions.

Discipline: Agro-meteorology

Introduction

Water management in modern agriculture requires the determination of the crop water requirement and irrigation time as accurately and quickly as possible. Transpiration (*T*) is the key factor to estimate crop water requirement and crop water stress index (*CWSI*) is the key factor to evaluate the time when irrigation should be applied. Among the methods of estimation of *T* and *CWSI*, a temperature-related approach can be adopted. As cited by Jackson¹³⁾ and Jackson et al.¹⁶⁾, research on foliage temperature was started in 1843. The literature on this topic was rather sparse until the 1920s when thermocouples became standard equipment. Many of these early studies focused on the leaf and air temperature

differences^{18,32}). Subsequently, research results showed that the soil moisture status, foliage temperature, and plant transpiration rates were closely related^{3,4,6-8,12,14,30}).

As a result, a temperature difference method was developed to estimate T ^{5,12,17,21,30,31}). Mitchell and Hanks¹⁹) derived an empirical equation to predict T based on the temperature difference between canopy and air. Hatfield⁵), O'Toole and Real²³), and Ben-Asher et al.^{1,2}) evaluated aerodynamic and canopy resistances by using air temperature, canopy temperature, and vapor pressure deficits. Due to the complexity in evaluating the aerodynamic resistance, the temperature difference method is mainly applied for estimating the aerodynamic resistance with an already known T , rather than for the direct estimation of T . No studies have been reported on the direct estimation of T by air and canopy temperature without the use of aerodynamic resistance or empirical coefficients.

CWSI is another key factor for agricultural water management. Although maximum yields of crops are achieved only under non-limiting water supply, it remains to be determined how early water shortage should be detected to avoid a significant decrease in productivity. The use of canopy temperatures to detect water stress in plants is based upon the assumption that, as water becomes limiting, transpiration is reduced and plant temperature increases. Canopy temperature is determined based on the water status of the plants and by ambient meteorological conditions. *CWSI* based on the determination of the canopy temperature is derived as: $CWSI=(T_c-T_{cl})/(T_{cu}-T_{cl})$, where T_c , T_{cl} , and T_{cu} are the canopy temperature, lower limiting canopy temperature, and upper limiting canopy temperature, respectively. The lower limiting canopy temperature can be reached when the crop transpires without water shortage. On the other hand, the upper limiting canopy temperature can be reached when plant transpiration is zero. O'Toole et al.²⁴) conducted a comprehensive comparison of 8 different measurement methods for assessing the plant water status and concluded that *CWSI* based on the determination of the canopy temperature was the best technique, stating that it was a significant advancement in assessing the water status of crop or natural plant communities. Two types of *CWSI* based on canopy temperature have been proposed to estimate the T_{cl} , an empirical approach reported by Idso⁹) and Idso et al.^{10,11}) and a theoretical approach reported by Jackson et al.^{15,16}). In the empirical method (Idso's *CWSI*), *CWSI* is estimated by determining "non-water-stressed baselines" for crops. In addition, estimation of T_{cu} is necessary. However, the non-water-stressed baselines change not only with the crop variety but also with the seasons¹⁶). Furthermore, the estimation of the upper limit of temperature is somewhat ambiguous. The third criticism has been that Idso's *CWSI* does not account for radiation and wind speed. In the theoretical method (Jackson's *CWSI*), *CWSI* is estimated based on the net radiation and an aerodynamic resistance factor, in addition to the temperature and vapor pressure terms required by the empirical method. Since these variables are site-specific, it is difficult to collect representative meteorological data for field practice in a small and heterogeneous crop area. Requirement of large uniform fields and local meteorological data is the main problem facing the application of Jackson's *CWSI*. Although Jackson's approach shows how the upper and lower limits can be evaluated, the complexity of the method precludes thorough field tests. Thus, there has been a long search for theoretically sound and simple procedures that would enable to overcome the shortcomings of the above methods.

The objectives of the current studies are: 1) to develop a method to assess T using temperatures and a few meteorological parameters without the requirement of crop correction factors, empirical coefficients, or canopy and aerodynamic resistances, 2) to verify the estimation accuracy of the proposed method by comparison with actual T obtained by a weighing lysimeter, and 3) to apply the developed theory to the

estimation of *CWSI* under both field and greenhouse conditions.

Theoretical development

Assuming that there is an imitation leaf canopy in the plant canopy with a relatively small volume, the temperature, humidity, wind speed, and other environmental parameters of the plant canopy are not significantly modified by the imitation leaf canopy. In other words, the imitation leaf canopy is one part of the plant canopy. It is assumed that temperatures of plant canopy and imitation leaf canopy are represented by temperatures of sunlit leaves and imitation leaves, respectively. Hereafter, we refer to the imitation leaf canopy as the imitation leaf and the temperature of the imitation leaf canopy as imitation leaf temperature. It is assumed that the radiation absorptive and albedo properties of these imitation leaves are similar to those of plant leaves. Transpiration does not occur from imitation leaves and the latent heat flux is zero.

The energy balance of the canopy is represented by the equation²²:

$$R = G + H + LE \dots\dots\dots(1)$$

where R_n is the net radiation of the canopy, G the heat flux to soil, H the sensible heat flux from canopy to air, and LE the latent heat flux to air. All the units are expressed in $W\ m^{-2}$. Since these variables can be positive or negative, depending on their direction, positive direction for R_n is toward the soil surface and positive directions for G , H , and LE are away from the soil surface.

It should be emphasized that we only focus on the energy balance of the canopy by using Eq. (1). The exposed soil portion of the partially covered canopy is separated by using canopy coverage. In the canopy-covered area, the incident radiation is intercepted by the canopy so that the partitioning of energy on the soil surface is relatively negligible²⁰. Thus evaporation from the canopy-shadowed soil is generally low and LE is often expressed as canopy transpiration (T).

In Eq. (1), the net radiation can be measured or estimated from solar radiation and temperature. Generally G is negligible for the canopy on a daily basis^{1,22}. Jackson¹³ expressed H by the following equation:

$$H = \frac{\dot{A}C_p (T_c - T_a)}{r_a} \dots\dots\dots(2)$$

where PC_p is the volumetric heat capacity ($J\ m^{-3}\ K^{-1}$), T_c the canopy temperature (K), T_a the air temperature (K), and r_a the aerodynamic resistance ($s\ m^{-1}$).

Since the imitation leaf is in the same canopy, the same value of r_a can be used for the imitation leaf^{25,26,28}. By assuming that the air temperature at reference height is the same everywhere and r_a of the canopy is approximately equal to the r_a of the imitation leaf, r_a can be expressed by the following equation:

$$r_a = \frac{\dot{A}C_p (T_p - T_a)}{R_{np}} \dots\dots\dots(3)$$

where T_p is the temperature of the imitation leaf surface (K) and R_{np} the net radiation of the imitation leaf ($W\ m^{-2}$).

Combining Eq. (3) with Eqs. (1) and (2), an equation to estimate transpiration from plant canopy can be derived:

$$LE = \frac{R_n - R_{np}}{T_p - T_a} \frac{T_c - T_a}{\gamma + 3} \dots\dots\dots(4)$$

On the basis of the above data, the plant transpiration can be estimated by Eq. (4). The necessary input parameters of Eq. (4) are the temperature (T_c , T_a , and T_p) and net radiation (R_n and R_{np}).

From the coupling of the energy balance equation to the transfer equations for both sensible and latent heat, assuming that the heat fluxes in soil are negligible, and defining γ as the slope of the saturated vapor pressure-temperature relation ($(e_c^* - e_a^*) / (T_c - T_a)$), an expression for the temperature difference between the canopy and air can be derived^{15,29}:

$$T_c - T_a = \frac{r_a R_n \gamma^3 (1 + (r_c / r_a))}{\gamma + 3} \frac{e_a^* - e_a}{\gamma + 3} \dots\dots\dots(5)$$

where r_c is the crop canopy resistance ($s\ m^{-1}$), e_c^* the saturated vapor pressure (mbar) at T_c , e_a^* the saturated air vapor pressure (mbar) at T_a , e_a the vapor pressure of air (mbar), and $\gamma = 0.66\ mbar\ ^\circ C^{-1}$ the psychrometric constant.

Eq. (5) relates the difference between the canopy and air temperature to the vapor pressure deficit of air ($e_a^* - e_a$), the net radiation, and the aerodynamic and crop resistances. Based on Eqs. (3) and (5), *CWSI* related to the canopy temperature will be analyzed.

The temperature of the imitation leaf T_p could be considered to be equivalent to the upper limiting canopy temperature T_{cu} . Therefore, the *CWSI* obtained by our approach can be expressed by the equation:

$$CWSI = \frac{T_c - T_{cl}}{T_p - T_{cl}} \dots\dots\dots(6)$$

The lower limiting canopy temperature (T_{cl}), determined by setting $r_c = r_{cp}$ in Eq. (5) and substituting Eq. (3) into Eq. (5) is:

$$T_{cl} = \frac{R_n (T_p - T_a)}{R_{np}} \frac{e_c^* - e_a}{\gamma + 3} \dots\dots\dots(7)$$

$$\gamma + 3 = \frac{r_{cp} R_{np}}{C_p (T_p - T_a)} \dots\dots\dots(8)$$

where r_{cp} is the canopy resistance without water shortage ($s\ m^{-1}$). The value of r_{cp} is likely to vary with the crops and crop varieties.

Theoretical development

On the basis of the above data, it is concluded that by introducing the imitation leaf temperature, *CWSI* defined by Eq. (6) can be determined from temperatures (canopy, imitation leaf, and air), net radiation, and the vapor pressure. The aerodynamic resistance is eliminated and accordingly the complexity of application is significantly reduced.

Verification experiments

1) Experiment in a sandy field with sorghum crop

A 1 ha flat field with coarse grain sand (95.8% of sand in the 0.25-2.00 mm range) at the Arid Land Research Center, Tottori University (Tottori, Japan) was used in this study, where a weighing lysimeter had been installed. Sorghum (*Sorghum bicolor* (L) Moench.) crop was grown in the field. A sprinkler irrigation system was employed to irrigate the crop in the sandy soil field. Plant densities, both around and inside the lysimeter, were about 8 plants m⁻². Measurements were performed from June 20 to August 31, 1994. In this experiment, the imitation leaves were made from green paper by selecting a paper which had nearly the same color as the plant leaf and cutting the paper into the shape of a plant leaf. Then the green paper leaf was inserted in the upper part of the sorghum canopy to avoid shade from the canopy (Fig. 1). Actual evapotranspiration was measured by using a weighing lysimeter. Soil evaporation was measured daily with the microlysimeters. The plant leaf area was measured with a leaf area meter (AAC-400, Hayashi Electric Co., Ltd.) weekly throughout the experimental period to estimate plant coverage and calculate the leaf area index (LAI). Temperatures of the imitation leaf and canopy (sunlit leaf) were measured with Cu-Co thermocouples. Stomatal resistance was measured with LI-1600 Steady State Porometer (Li-Cor. Inc.). Solar radiation and air vapor pressure were obtained from the meteorological station of the Arid Land Research Center, Tottori University. The experimental procedures were also described in detail by Qiu et al. [26,27](#).

Fig.1. Imitation leaf used sorghum experiment

2) Experiments in a greenhouse with melon crop

This experiment was conducted from April to July, 1998 in a glasshouse at the National Research Institute of Agricultural Engineering (Tsukuba, Japan). The dimensions of the glasshouse were 60.4 m in length, 14.4 m in width, and 3.9 m in height (ridge). The orientation of the ridge line was South/North. Soil consisted of loam (2.60-2.65 g cm⁻³ specific gravity, 0.7-0.8 g cm⁻³ dry bulk density, and 70% porosity) and the soil surface was covered by a plastic film to prevent evaporation. Melon crop (*Cucumis melo* L.) was used in this experiment in rows 1.5 m apart and the distance between individual plants was 0.8 m. Water was supplied by the drip irrigation method under the film. Two irrigation treatments were arranged. One area was fully irrigated (area A, volumetric water content varied in the range of 0.3-0.4

m^3m^{-3}). Another area was not fully irrigated (area B, volumetric water content varied in the range of 0.2-0.3 m^3m^{-3}). Radiation, air humidity, and temperatures of the imitation leaf and air were measured by the same method as in the field experiment. Sunlit leaf temperature of melon was measured using an infrared thermometer (THI-500, Tasco Co., Ltd.). Soil water was measured using a TDR soil moisture measurement system (Campbell Scientific Inc.).

Results and discussion

1) Transpiration

Fig. 2 depicts the daily variations of net radiation and temperatures of greenhouse melon. The canopy temperature and net radiation in Fig. 2 are the average values of area A and area B. During sunshine time, the R_n value was higher than that of R_{np} . The maximum value of R_n was close to 550 W m^{-2} and the maximum value of R_{np} was close to 400 W m^{-2} . The difference between the values could be as large as 150 W m^{-2} (Fig. 2a). Fig. 2b shows the diurnal changes in the measured T_p , T_c , and T_a . The variation of temperature was affected by the radiation and other weather conditions. The maximum and minimum values of radiation and temperature appeared at the same time. Besides these common characteristics, T_p , T_c , and T_a also displayed specific features. T_p was always higher than T_c and T_a during the daytime. The temperature difference between T_p and T_c could be as large as 20°C in the daytime. During the night, the values of T_p and T_c were identical. All the data of the other days over the experimental period showed similar results. Since the soil surface was not fully covered by the melon canopy, solar radiation could be directly absorbed by soil. Moreover, the plastic film used as a cover prevented evaporation from soil and the soil surface temperature could be as high as 50°C . Therefore, the absorbed solar energy directly affected the air temperature through sensible heat transfer and T_a was higher than T_c . However, as reported by other researchers, T_c could sometimes be higher or lower than the T_a under field conditions^{13,26,27}. These distribution features of the 3 temperatures enabled to detect crop transpiration and water stress.

In this study, by using the imitation leaves made from green paper, satisfactory results were obtained. However, if the paper were to be wetted due to rainfall or irrigation, the results may be affected. Therefore, further studies should be carried out to select different materials to replace the green paper.

Fig. 3 shows the distribution of melon canopy temperatures in 2 different irrigation areas. During the experimental period, the soil water content varied in the ranges of $0.3\text{-}0.4 \text{ m}^3\text{m}^{-3}$ in area A and $0.2\text{-}0.3 \text{ m}^3\text{m}^{-3}$ in area B. Though daytime average canopy temperatures in both areas varied in the ranges of $17\text{-}33^\circ\text{C}$, in area A, since the soil water content was higher, the canopy temperature was consistently lower than in area B. The temperature difference between the 2 areas was usually less than 1°C . However, maximum difference could be as much as 1°C . These results suggest that the canopy temperature is a good indicator of the soil water status.

Fig. 4 shows the daily transpiration of sorghum under field conditions. Daily estimated transpiration (T) was obtained by $ET-E$, where ET was the evapotranspiration measured with the weighing lysimeter and E the soil evaporation measured with the microlysimeters. The calculated daily T was obtained from Eq. (4). Fig. 4 shows that calculated T agreed well with the estimated T . The maximum difference between calculated and estimated transpiration was less than 1 mm day^{-1} . The transpiration differences on most of the days were within 0.5 mm day^{-1} . The regression analysis showed that the estimated T was closely correlated with the calculated T . The regression coefficient was $r^2=0.88$. Crop transpiration can thus be accurately calculated by the proposed method.

Fig. 5 shows a comparison of calculated T under different irrigation treatments of melon under greenhouse conditions. During the experimental period, calculated T in both irrigation areas varied with the changes of the weather conditions. On clear days, the T value could be as high as $5\text{-}6 \text{ mm day}^{-1}$,

while on cloudy days the T value could be as low as 1-2 mm day⁻¹. However, T in area A was consistently higher than in area B, the difference being as large as 1 mm day⁻¹. Cumulative T was near 75 mm in area A and 65 mm in area B.

On the basis of the above data, it can be concluded that the proposed method gives a reasonable estimation of crop transpiration under field and greenhouse conditions.

2) Crop water stress

(1) Upper limiting canopy temperature

In Jackson's method, upper limiting canopy temperature (T_{cu}) is expressed by the equation:

$$T_{cu} = \frac{r_a R_n}{A C_p} + T_a \dots\dots\dots(9)$$

In the proposed method, T_{cu} is equal to T_p . [Fig. 6](#) shows that the measured T_p agreed with T_{cu} calculated by Eq. (9). Due to the assumption that the canopy resistance was infinite, T_{cu} was slightly larger than T_p in the high temperature ranges. The regression coefficient between T_p and T_{cu} was $r^2=0.997$.

(2) Comparison with Jackson's CWSI

In addition to T_c and T_p (or T_{cu}), T_{cl} is also required to evaluate CWSI by the proposed method and Jackson's method. As shown in Eq. (8), the canopy resistance without water shortage r_{cp} is required to estimate T_{cl} . Values of r_{cp} can be estimated by the following empirical equation^{1,27}:

$$r_{cp} = \frac{r_{sp}}{LAI} \dots\dots\dots(10)$$

where r_{sp} (s m⁻¹) is the stomatal resistance without water shortage and LAI is the leaf area index. During the early period of the field experiment, sorghum was well irrigated. From 520 measured values of stomatal resistance, 10 minimum values were selected to represent r_{sp} . The average value of these 10 data was 41.6 s m⁻¹. Therefore, the equation $r_{cp}=r_{sp}/LAI=41.6/LAI$ was used to estimate CWSI in this study. [Fig. 7](#) shows that the CWSI determined by the proposed and Jackson's methods agreed well, with a regression coefficient $r^2=0.997$. Since Jackson's method is sound in theory, the agreement of the 2 methods indicates that CWSI by the proposed method is suitable for detecting crop water stress.

(3) Relations with soil water status

[Fig. 8](#) shows a comparison of CWSI in the 2 different irrigation areas of greenhouse melon. During the experimental period, the soil water content in area A varied in the ranges of 0.3-0.4 m³m⁻³, values about 0.1 m³m⁻³ higher than the values in area B. Meanwhile, CWSI in area A was consistently lower than the CWSI in area B, with a difference as large as 0.1. Compared with the soil water content, fluctuations of the CWSI curves were larger than the fluctuations of the soil water content curves. This phenomenon revealed not only that CWSI was mainly affected by the weather conditions at a relatively high water content but also that the use of temperature-related CWSI enables to predict plant water stress earlier than the soil water-based method. Our results agreed with those of Qiu et al.²⁷ and Stanghellini and

Lorenzi²⁹⁾ who showed that canopy temperature-based crop water stress index methods are more likely to be suitable for early detection of water shortage than soil water-based methods.

Summary

A new method for estimating crop transpiration and *CWSI* by using a temperature-related approach was developed and verified in this study. In the proposed method, 3 temperatures (sunlit leaf temperature, imitation leaf temperature, and air temperature) and a few meteorological variables (net radiation and humidity) were required. The imitation leaf referred to an artificial leaf without transpiration. The major advantage of the proposed method is that plant correction factors, empirical coefficients, and canopy and aerodynamic resistances are not required for calculating the plant transpiration and *CWSI*.

Experiments in a sandy field with sorghum crop (*Sorghum bicolor* (L) Moench.) and in a greenhouse with muskmelon crop (*Cucumis melo* L.) were conducted to verify the proposed method. Results were compared with the amount of transpiration determined by using a weighing lysimeter and microlysimeters, soil water status determined by TDR, and *CWSI* estimated by Jackson's method. The calculated transpiration by the proposed method was consistent with the results obtained by using a weighing lysimeter and microlysimeters, with a regression coefficient $r^2=0.88$. Values of *CWSI* calculated by the proposed method were in agreement with the Jackson's *CWSI*, with a regression coefficient $r^2=0.997$. These results indicate that the proposed method can be applied to estimate crop transpiration and water stress index under both field and greenhouse conditions.

Abstract

Earthquakes have caused considerable damage to fill-type dams. Research into earthquake damage has contributed to the study of earthquake resistance of dams. However damage to fill dams occurred almost only in the case of small-scale earth dams, especially in the few cases of serious damage. This report describes the damage and performance of earth dams and fill dams more than 15 m high during earthquakes, based on literature data as well as field surveys. The results indicated that even stronger earthquakes than the designed earthquake intensity did not cause heavy damage to large well-constructed modern dams. The above analysis of the performance of fill dams during earthquakes shows that large-scale dams are earthquake-proof.

Discipline: Agricultural engineering

(Received for publication, April 20, 1999)

Introduction

A survey conducted in 1978 showed that there are more than 250,000 fill dams in Japan, 75% of the dams are more than 100 years old and generally small, and 80% are less than 10 m high. [Fig. 1](#) shows the distribution of earth dams and fill dams. Like other soil structures, fill dams have experienced damage in past earthquakes. Analytical geotechnical/soil-engineering surveys of earthquake damage to fill dams have provided useful information for implementing measures against earthquake damage. The surveys revealed that the majority of the fill dams which experienced earthquake damage were small-scale earth dams, while no large-scale fill dams higher than 15 m, except for the "Manno-ike" dam (which was damaged in the 1854 "Ansei Nankai" earthquake), experienced serious damage²). This report summarizes the behavior of fill-type dams higher than 15 m during earthquakes, including cases where fill dams were damaged.

Earthquake damage to earth dams

Earthquake damage to fill dams in Japan has paralleled the history of fill dam construction. "Manno-ike" dam is the first reported case of earthquake damage to fill dams. The Manno-ike dam was damaged presumably due to the phenomenon referred to as "piping" that occurred one month after the Ansei Nankai earthquake (1854). The Nohbi earthquake (1891) damaged the "Iruka-ike" dam (Aichi Prefect.). The first post-earthquake survey was performed after the Kitatango earthquake (1927). [Table 1](#) reviews the earthquake damage to earth dams since 1927. The damage by Oga earthquake (1939) was surveyed by Akiba¹). The major conclusion was that earth dams with embankments of sandy soil experienced severe damage, suggesting that "liquefaction" could have been incriminated. Subsequently, detailed surveys of earth dam damage were conducted after the past several earthquakes^{5,6}).

Fig. 2 shows the relationship between the damage rate of earth dams and the average distance from the epicenter of the affected districts in the case of Hyogoken Nambu earthquake. The solid line in the Figure represents the maximum value for the relationship between the damage rate and distance from the epicenter. Although this relationship differs depending on the conditions of the ground and dam bodies, the line in the Figure represents the maximum values of the distance from the epicenter and the reservoir damage rate, which was attributable to the earthquake.

Fig.2. Average epicenter distance and damage rate of earth dams in the case of Hyogoken Nambu earthquake

Fig.3. Relationship between average distance from epicenter and damage rate based on past earthquake data

Fig. 3 depicts the relationship between the average distance from the epicenter and estimated maximum damage rate as a function of the magnitude for the Tokachi-oki, Niigata, Nihonkai Chubu, and Hyogoken Nambu earthquakes shown in Table 1. Since the degree of damage and ground and dam conditions were not taken into account, the estimates are merely conservative.

Fig. 4 shows the relationship between the earthquake magnitude (M_j) and the earth dam farthest from the epicenter, which was damaged by the earthquake (hereafter referred to as "critical distance from epicenter"). Using past data, the relationship between M_j and the critical distance from the epicenter can be expressed as:

$$R = 11 \quad 5 M_j 6.1 \dots \dots (1)$$

$$\log R = 0.846 M_j 4.14 \quad 6.1 f M_j 8 \dots \dots (2)$$

where M_j : magnitude, R : critical distance from epicenter (km).

This relationship is indicated by the solid line in the Figure, which also delineates the boundary of the damaged area. The upper area did not sustain any damage and the lower area shows the zone where damage is likely to have occurred. Therefore, the damage rate increased in a downward direction in the Figure. It should be noted that the critical distance from the epicenter represents the distance from the epicenter shown in Fig. 4 at which the damage rate became zero. The value of Equation (1) depends on the properties of the earthquake, ground conditions, and earth dam conditions. However, the approximate distance from the epicenter at which damage starts to occur can be determined by calculating the distance from the epicenter and the magnitude.

Table 2 summarizes the outline of earth dam damage caused by 5 past earthquakes. The damage can be divided into the damage to the dam body and dam facilities (spillway, outlet works). In addition, the dam body damage can be classified into functional defects (crack, settlement, slip) and failure which prevents water storage. These damages may occur at the same time: e.g. settlement occurs along with slip, or settlement and crack may occur independently. Table 2 lists all the possible damages.

As for the cracks, most of them are longitudinal cracks parallel to the dam body axis. They are frequently generated on upper slopes and crests of dam, presumably due to the difference in stability between upper and lower slopes. Lateral cracks in the direction perpendicular to the dam axis can be associated with serious damage because water may leak from the dam bodies although such cracks occur only at a low rate. Most of the lateral cracks cross the dam body. In the Nihonkai Chubu earthquake, lateral cracks were generated on the border between the abutment and dam body, and near outlet works at a rate of about 50%. The same phenomenon was noted in the survey of Oga earthquake. This trend may be due to the difference in the behavior between the abutment and dam body, and between the dam body and outlet works.

Type of earth dam damage

For grouping the type of damage in Nihonkai Chubu earthquake, a classification was carried out on the basis of the major causes of damage, according to the damage classification for river dikes and railway embankments. [Fig. 5](#) shows the classification of damage types. [Table 3](#) shows the types of damage. Types I and III accounted for 30% respectively, followed by Types II, IV and other types. Type V accounted for only 1.8%. In Type I (crack) the shape of the dam body was maintained with little settlement and cracks alone were generated. This type is characterized by the fact that many dam bodies are made of clay on good foundation ground. There were 3 examples of cracks generated along the line grouted in the past. In Type II (settlement) the shape of the dam body was maintained with accompanying cracks, and the major cause was attributed to the settlement of the foundation ground. Type III (failure of slope) and Type IV (slip) showed basically the same type of damage, but in Type III the damage was less severe than in Type IV. Most of the dam body remained sound and serious damage was not observed in Type III. A slip was recognized in Type IV, though this type accounted for only a few cases. Most part of the dam body experienced settlement by slip in Type IV, frequently causing large damage such as failure. In Type V, the dam body and the foundation ground were broken. Though the number of cases was very low, earth dam failure occurred in many cases like in Type III. The estimated causes included liquefaction of the dam body and foundation ground. In addition, outlet works, spillway, abutment break, and damage to only the covering block accounted for about 10% of the total.

[Table 4](#) shows the number of cases with damage and damage rate for each dam body soil obtained from a questionnaire for 218 damaged earth dams and 1,834 non-damaged earth dams in Nihonkai Chubu earthquake. The cases of damage in clay and gravelly clay soil accounted for 80% in comparison with sandy soil. On the other hand, the damage rate of sandy soil against all earth dams including non-damaged earth dams was as high as nearly 20%, which was nearly twice the rate of that in the case of clay and gravelly clay. This tendency was more obvious for the damage rate of earth dams with serious damage. Dam body soil was sampled in 39 areas of damaged earth dam and in 18 areas of non-damaged earth dam, and subjected to physical soil tests. As for the non-damaged earth dams, those located in a similar region, which showed similar geographic characteristics and height were selected as far as possible.

Damage to fill dams more than 15 m high

[Table 5](#) shows the time of construction of fill dams for irrigation, with heights of more than 15 m prior to 1985. The total number of fill dams was 1,872, with 1,506 earth dams and 438 were very old, being constructed before the Meiji era (1868~1911). Most of these were brought into service during the Edo period (1603~1867). The following refers to the damage of fill dams with heights of 15-30 m in Japan. [Table 6](#) lists major earthquake damage to fill dams with heights of 15-30 m in Japan⁷⁾. This table shows that no large-scale fill dams with a height of 15-30 m had experienced serious earthquake damage, except for the Manno-ike dam. [Table 7](#) shows observations made during earthquakes in typical large fill dams with heights of more than 30 m in Japan. The table includes the Akita-Toho earthquake (1970) with $M_J=6.5$ where the "Ainono Dam" was damaged. This dam was completed in 1961. It showed a uniform type and was 41 m high. This dam had a seismometer installed at the dam site. It was reported that the seismometer swung outside the scale, thus failing to register the earthquake intensity. An attempt to calculate the earthquake intensity, from an epicenter distance of 15 km, indicated that the maximum input acceleration of seismic waves transmitted to the bedrock was around 150 gal. The post-earthquake

survey report disclosed that major damage occurred on the crest of the dam in the form of several vertical cracks extending over 40 m, each 5 to 25 cm in width.

The Nihonkai Chubu earthquake was recorded at the Namioka dam, 146 km from the epicenter. The recorded data showed that the maximum input acceleration of seismic waves transmitted to the bedrock was 94 gal, with the embankment crest exhibiting a seismic response of 223 gal. The earthquake occurred when the dam was empty, and only slight damage occurred. The Naganoken Seibu earthquake (1984; $M_J=6.9$) did not result in severe damage of the Makio dam close to the epicenter. This dam was completed in 1961 as a central core-type rock fill dam with a height of 105 m. The dam was equipped with strong-motion earthquake response seismometers, with a maximum scale limit of 300 gal, one on the top and another in the bedrock. It was suggested that the earthquake motion could have exceeded the scale, possibly reaching 500 to 600 gal. A post-earthquake investigation revealed that the downstream crest slipped along the slope over a width of 20-50 cm, and a height of 10-50 cm, without causing serious damage. The Makio dam design included protection against a horizontal seismic intensity of $K_h = 0.15$, and a minimum safety factor of 1.40. The Chibaken Toho-oki earthquake (1987; $M_J=6.7$) damaged the Nagara dam. This dam was completed in 1985, and was an earth dam 52 m high, located at a distance of 29 km from the epicenter. The earthquake caused a maximum input seismic wave acceleration of 262 gal propagating in the bedrock in the upstream/downstream direction, and 365 gal recorded on the crest where only cracks occurred. The Hyogoken Nambu (Great Hanshin-Awaji) earthquake (1995; $M_J=7.2$) damaged many soil structures but there was no serious damage affecting large fill dams. Taniyama Dam is located at a distance of about 7 km from the epicenter and as close as 3 km for the Nojima Fault.

These instances show that fill dams characterized by modern geotechnical/soil engineering designs are earthquake-proof and are not subject to heavy damage. Dams experienced only slight damage even with seismic intensities above that considered in the dam designs.

Some instances of earthquake damage to typical fill dams outside Japan are depicted in [Table 8](#). In the United States, the Santa Barbara earthquake (1925) damaged the Sheffield dam^{3,4}. The banks of this dam were 11 m high and were insufficiently compacted. They failed to withstand the rise in pore water pressure in the lower part of the dam and collapsed. The San Fernando earthquake (1971) caused serious damage to both the Lower San Fernando dam with a bank height of 43 m and the Upper San Fernando dam with a bank height of 25 m. These 2 dams had been constructed according to a hydraulic-fill process, and were in the neighborhood of a fault. Therefore they experienced damage. Recently, the Loma Prieta earthquake (1989) has caused slight damage to 9 earth dams. The seismic data from the Lexington dam show that the dam abutment (approximately corresponding to the bedrock) experienced a maximum seismic wave input acceleration of 452 gal.

The center of Luzon Island, Philippines, had an earthquake with a magnitude of 7.8 on July 16, 1990, and the Pantabangan (107 m high) and Masiway dams (25 m high) near the epicenter were damaged. The damage to the Pantabangan dam was relatively slight, including a settlement of the crest (25 cm) and the release of joints in the upstream concrete wall with gaps in some joints. Masiway dam suffered more severe damage than the Pantabangan dam. The earthquake caused a settlement of 1.5 m on the crest near the spillway. However, the dam remained safe to use in terms of leakage and sliding surface. Considering the distance of this dam from the epicenter, and the magnitude of the earthquake, it is estimated that the maximum input acceleration of the seismic waves transmitted to the dam was approximately 300 to 400 gal. These values clearly exceeded the design criteria for earthquake intensities, but no serious damage occurred.

These findings based on earthquake surveys show that large-scale fill dams have never experienced serious damage, suggesting that current dam design methods (material characteristics and slope stability analysis method) are technologically sound.

Conclusion

We have compiled data on earthquake damage to fill dams in Japan and in other countries. The majority of the fill dams that experienced earthquake damage were small, and fill dams for which modern geotechnical/soil engineering designs were applied did not experience serious damage even with earthquake intensities above the design criteria. Therefore, it is considered that large-scale fill dams are markedly resistant to earthquakes. The conclusions are as follows.

1) For small earth dams

(1) Based on the data of 5 earthquakes, the distance from the epicenter at which earth dam damage occurs is expressed using magnitude as follows;

$$R = 1155 \quad 5M_J - 6.1 \quad \dots\dots\dots(1)$$

$$\log R = 0.846 M_J - 4.14 \quad 6.1 - 0.1 M_J \quad \dots\dots\dots(2)$$

where M_J : magnitude, R: critical distance from epicenter (km).

(2) Most cracks generated on dam bodies are longitudinal cracks parallel to the dam body. There are few lateral cracks perpendicular to the dam body and they occur frequently on the border of the abutment and near outlet works.

(3) As for the physical properties of the dam body, the damage is serious for sandy soil dams, particularly in the case of failure. It is estimated that liquefaction was the major cause of damage for many dams.

2) For large fill dams

(1) The only case of earthquake damage to a fill dam with a bank height of more than 15 m is that experienced by the Manno-ike dam.

(2) Earthquakes have subjected fill dams to maximum input accelerations of 260 to 600 gal. Conversion to static earthquake intensity shows that these values exceed the earthquake magnitudes considered in design criteria. It is evident that even such high intensities do not cause serious damage to large-scale fill dams.

(3) Although fill dams with heights above 15 m in the United States have experienced serious damage, it must be noted that they were constructed based on the hydraulic-fill process. The above review indicates that large fill dams with heights above 15 m and constructed with the current dam designs exhibit a high earthquake resistance and provide sufficient safety against earthquakes.

Decrease of Nitrate and Restoration of Mineral Balance in Forage Field Soil and Corn Plant in Dairy Farms

Yoshikuni MASAOKA, Yusuke ARAKAWA and Taizo MASUDA*

Kyushu National Agricultural Experiment Station (2421 Nishigoshi, Kumamoto 861 - 1192 Japan)

Abstract

Excess nitrogen corresponding to about 2-3 times the amount required for forage plant growth had been applied continuously for many years in dairy farms at Shisui machi, Kumamoto Prefecture in Kyushu because of the limited area of crop fields. Field experiments with reduced application of animal wastes (RAAW) which contained only half the amount of requirements for corn plant growth were conducted to decrease nitrate nitrogen (NN) accumulation and restore the mineral balance in corn plants and crop field soil in 6 dairy farms. (1) The NN concentration in the corn stem decreased to less than 5 g/kg (dry matter basis) and no whole plant shoots with a NN concentration above 2 g/kg were observed after the reduction of animal waste application for 1 year. (2) The content of exchangeable potassium (EK) in the dairy farm soil decreased from 60 to 27 mg/100g after RAAW for 2 years. (3) Average dry yield of corn plants in the 4th year was 16% lower in the case of RAAW than in the case of excess utilization of animal composts, but the difference was not significant. The concentration of K was lower in RAAW, which resulted in the decrease of the K/(Ca+Mg) equivalent ratio from 1.78 to 1.15 in the corn plants. These data suggest that RAAW can improve the feed quality by reducing the NN content and restoring the mineral balance in plant.

Discipline: Soils, fertilizers and plant nutrition

Additional key words: environmental conservation, K/(Ca+Mg) equivalent ratio, nitrate nitrogen, potassium, sustainable agriculture

(Received for publication, March 31, 1999)

Introduction

Recycling of animal wastes in agrosystems is very important for sustainable agriculture and environmental conservation³⁾. Animal wastes contain most of the plant nutrients such as nitrogen, phosphorus and potassium (K). For example, nitrogen occurs in both ammonia and organic forms, while the latter one may be transformed into ammonia through the mineralization process in soil, which may be further transformed into nitrate through the nitrification process in soil under aerobic conditions. Nitrate can be readily taken up by plants. However, if an excessive amount of animal wastes is applied into

fields, the residue part of the nutrients which could not be absorbed by plants tends to accumulate in the soil, resulting in the pollution of the surrounded environment including surface water, groundwater and air through drainage, leaching, and denitrification processes.

In fact, excessive amounts of animal wastes have been applied onto many dairy farms for many years in Japan due to the limited area of forage crop fields²⁾. It is generally recognized that nitrate nitrogen (NN) from animal wastes is leaching into the groundwater and sometimes causes nitrate pollution of drinking water in some regions. Moreover, as the excessive amount of nitrate taken up by plant roots can not be metabolized into organic forms, nitrate tends to accumulate together with K in the stems of the forage. And if such kind of forage is fed to dairy cattle, nitrate will be converted into nitrite in the rumen. Nitrite can react directly with hemoglobin in livestock animals to produce methemoglobin, which impairs the ability of red blood cells to transport oxygen and damages livestock's health¹⁾.

Therefore it is essential to decrease the application volume of animal wastes onto forage fields. In this report the restoration of the nitrate and mineral balance in dairy farm soils and forage plants which had not been thoroughly investigated in Japan hitherto will be confirmed.

Materials and methods

Six dairy farmers operating 16 forage fields were surveyed in this study. The dairy farms were located in Shisui machi, Kumamoto Prefecture in Kyushu. On the average, one farmer operates 6 ha of arable land and owns 67 milking cows. Usually forage corn is grown for summer cropping followed by Italian ryegrass for winter cropping every year, and sometimes corn is grown 2 times annually in summer and autumn. In 1994, we collected data about the application rate of animal wastes from these 6 farms, while soil and corn samples were taken from 10 fields belonging to 2 representative farmers. From late 1994, a composting facility was built in the dairy farm and part of the wastes was converted to organic fertilizer to be used in other farms, so as to reduce the load volume of animal wastes in some forage fields. Therefore, from late 1994, we recommended that the farmers reduce the application rate of animal wastes in part of their fields. The outline of the reduction of application of animal wastes (RAAW) is shown in [Table 1](#). About half the amount of nitrogen requirement for corn growth was applied to decrease NN accumulation in the corn plant and to restore the soil mineral balance. The soil pH (0-30 cm in depth) ranged from 6.01 to 6.85 at the time of corn harvest in 1994. We suggested that the volume of application of ground dolomitic limestone should decrease because a rate of 1 to 2 t/ha had been used every year until 1994. Three farmers reduced the application time every other year and the other 3 farmers discontinued the application in the following year. Soil pH did not change and remained stable after these treatments. In 1995 and 1996, 4 fields from 1 representative farmer were continuously monitored, and in 1997, soil and corn samples at the harvesting stage in all the 16 forage fields were collected to determine the effect of this practice on soil properties and corn growth.

BACK

Results

1) Nitrate accumulation and mineral imbalance in soil and forage before 1994

Before the sowing of corn in the spring, chemical fertilizer had been applied to each field at the rates of 39 kg N, 54 kg P₂O₅ and 18 kg K₂O/ha. However most of the nutrients required for corn growth were derived from animal wastes. Table 1 shows the average input and output value of nitrogen and K estimated based on statistical data^{7,8)} from 6 dairy farms. In this Table we also listed the volume of chemical fertilizer and animal wastes utilized for corn production after RAAW treatment. As the dairy cattle density was very high, the farmers had to apply all the animal wastes in winter. Obviously, the amount of nitrogen applied in animal wastes was about 2-3 times higher than that removed by corn and Italian ryegrass. [Table 2](#) gives the mineral content in the soil and corn plant at the harvesting stage in 1994. The amounts of EK and magnesium (Mg) were very high in the soil, and hot water-soluble nitrogen¹⁰⁾ was still present in the soil at high concentrations even at the harvesting stage. A value as high as 0.2% nitrate nitrogen (NN) on a dry matter basis was detected in corn even at the yellow ripe stage. Therefore, it was demonstrated that an excessive amount of nutrients from animal wastes accumulated in the dairy farm every year and a larger amount of nitrate also accumulated in corn before 1994.

2) Effect of RAAW on forage NN content

Reduced application of animal wastes decreased the NN content in the corn stems (Fig. 1). In Field 1, the NN content of the corn stems decreased significantly from 1994 to 1997. Especially, the value decreased by 50% in 1995 just after 1 year's practice. In Field 3, since animal wastes had been heavily applied for many years, the NN content remained high, but also decreased in 1997. Fields 2 and 4 showed different patterns, because these 2 fields were located far away from dairy cattle, and the animal waste load volume varied. In 1996, the nitrate nitrogen content of corn stems increased sharply in Field 4 due to the large increase of animal waste load volume. It is likely that nitrate accumulation in the corn stems depended on the animal waste load volume and might have decreased within 2 or 3 years if the load volume could have been controlled.

3) Exchangeable K (EK) in soil

Fig. 2 shows the content of exchangeable K (EK) in soil. The EK content in all the fields was relatively higher at the beginning of the practice, but after 3 years, the EK content significantly decreased except in Field 4, which suggested that the EK content in soil could also decrease within 2 or 3 years.

Fig.2. Time course of exchangeable potassium content in the forage field soil (0-30 cm in depth) under reduced application of animal wastes

4) Effect of reduced application of animal wastes for 3 years

[Fig. 3](#) shows the effect of RAAW in the 16 farm fields in 1997. In 10 fields RAAW was implemented compared with 6 fields with continued heavy application of animal wastes. Although the corn dry yield relatively decreased due to the decrease of animal waste application, the nitrogen content, K content and K/(calcium(Ca)+Mg) equivalent ratio in the corn plant as well as the contents of hot water-soluble nitrogen and exchangeable K in soil decreased, while the contents of exchangeable Mg and Ca increased in soil.

Discussion

Animal wastes are rich in nutrients for increasing crop yield and improving soil fertility. However, the nitrogen content in soil has increased significantly by heavy application of animal wastes for many years since large-scale animal production was introduced in Japan⁵⁾. Nitrogen enrichment in forage fields has caused problems in animal health¹¹⁾, and resulted in groundwater pollution by nitrate. Besides nitrogen enrichment, K also accumulated in such fields. Owing to the antagonistic effect of K, absorption of Ca and Mg by crops was retarded, resulting in the increase of the K/(Ca+Mg) equivalent ratio⁹⁾. It was

reported that if the $K/(Ca+Mg)$ ratio in forage crops increases to a large extent, there will be a higher risk of grass tetany⁴⁾. Also, a high K level induces metabolic alkalosis in prepartum dairy cows, which reduces the ability of the cows to maintain Ca homeostasis¹⁾. Therefore, not only for the farmers but also for the people living in such rural areas better management of animal wastes should be implemented⁶⁾.

In the dairy farms, the nitrogen volume applied as animal wastes was estimated to amount to about 2 times that of the corn requirement before 1994 (Table 1). Even at the harvesting stage, a higher amount of hot water-soluble nitrogen was still present in the crop field soil (Table 2). The average EK content in the fields tested also increased to about 3 times that of the standard soil diagnosis value in volcanic soil.

From late 1994, the mean amount of nitrogen applied as animal wastes decreased to half of that required by corn approximately. However, the amount removed by corn still exceeded 200 kg/ha (Table 1), indicating that the organic nitrogen from the wastes which had accumulated in the soil for many years had undergone nitrification, and that the amount of nitrate was adequate for corn growth. Furthermore it is important to decrease nitrate accumulation in the corn stems (Fig. 1). Obviously, after several years of continuous RAAW, the amount of N and K nutrients in soil may become insufficient for plant growth. That is to say, soil nutrient diagnosis tests should be carried out every few years to determine the suitable application volume of animal wastes, should the nutrients be unable to meet the requirement for crop growth.

In the present investigation, we observed that exchangeable K had accumulated in soil in 1994, the content being 2-7 times higher than the standard value of soil diagnosis (Table 2). Ito et al. (1982) reported that the movement of K down the soil profile was fairly large in the case of humus-rich volcanic ash soil⁴⁾. It is possible that the EK may move out from the soils investigated by leaching in the rainy season. Furthermore, owing to the large biomass of corn and higher requirement of K, as much as 365 kg/ha K was removed during the cultivation of corn in summer (Table 1). These factors led to the decrease of the content of exchangeable K after the amount of animal waste application was reduced (Fig. 2).

As shown in Fig. 3, the mean value of corn yield after reduced application of animal wastes for 3 years exceeded 18 t/ha. The volume was about 4 t/ha less than that in the case of heavy application and no significant difference was observed. Moreover, the reduction of application of animal wastes led to the decrease of the nitrogen content and the restoration of the mineral balance in both forage field soil and corn plant as shown in Table 2 and Fig. 3. The $K/(Ca+Mg)$ equivalent ratio is an important parameter to evaluate the mineral balance in plant. The decrease of this ratio was caused by the decrease of the EK value in soil. We also observed an increase of the contents of exchangeable Ca and Mg in soil with RAAW, for unknown reasons. The decrease of the K content in the plant should enable livestock to obtain more Ca and Mg, which are essential to maintain Ca homeostasis¹⁾ and to avoid the risk of grass tetany. It was considered that the restoration of the mineral balance in these field soils may require a long period of time. The present study shows that the restoration of the mineral balance in plant and soil was very rapid within 2 or 3 years of reduced application of animal wastes in the dairy farmer fields.

The farm size of the dairy farmers surveyed here is representative of that in Japan. Many of these farmers have been burdened by the large volume of animal wastes required for application in their fields. With the production of compost fertilizer, the application volume could be reduced, and nitrate accumulation and the mineral balance in forage could be improved simultaneously within 2 or 3 years.

Abstract

Palatability of 14 varieties of orchardgrass (*Dactylis glomerata* L.) was evaluated with Holstein heifers by using a trough cafeteria method for 4 years. Highly significant differences in the palatability of varieties were recognized throughout the growing seasons in each year. Multiple regression analysis was carried out in 15 cafeteria trials to identify the variables which could predict the palatability of varieties. Among 41 available variables, the best combinations of 2 variables were identified in each growing season. For all the seasons, the concentration of Ca, the concentration of P, and flexibility of leaf and stem were considered to be the best positive predictors for the palatability. In contrast, ADF and 3 kinds of diseases (Rhynchosporium scald, rust and total leaf diseases) were considered to be the best negative predictors for the palatability. Lude, a French variety, exhibited superior characteristics in quality compared with other varieties, namely, high palatability, resistance to rust and total leaf diseases, high flexibility of leaf and stem and the highest concentration of Ca among the tested varieties. Intake of fresh materials in 2 varieties, Lude and Akimidori was compared by using Holstein heifers. It was observed that the estimated increase of dry matter intake (DMI, g/kgBW^{0.75}) of Lude over Aki- midori was 3.49 g at the same DMD level. High palatability in Lude might have a positive effect on the DMI level and could increase it more than expected from the DMD level. A model for the improvement of both palatability and quality which includes digestibility and mineral-balances was proposed as a part of the forage breeding program in Japan.

Introduction

Orchardgrass (*Dactylis glomerata* L.) is one of the most important pasture grasses with high adaptability in a wide range of environments. It is grown in Japan very widely from cool regions (Hokkaido and Tohoku areas) to warm regions (Kanto to Kyushu areas). Several varieties with high yield and resistance to main diseases have been bred in Japan. However, compared with other temperate grasses, some reports indicated that the quality, palatability^{2,7,16,17}, and animal productivity^{1,3,4,6} in the case of orchardgrass were not appreciably high. Research and programs for the improvement of quality in orchardgrass should be urgently promoted in Japan. This study was conducted to analyze the variations among varieties of orchardgrass in palatability and quality traits with a view to developing a breeding program for both high palatability and high quality in Japan.

Varietal differences in palatability

1) Analysis of relative palatability values

Palatability of varieties of orchardgrass was evaluated with Holstein heifers by using a trough cafeteria method during a period of 4 years⁹⁾ ([Table 1](#)). The 14 varieties used in this study were Akimidori, Makiba- midori, Kitamidori, Lude, Lully, Lutetia, Lucifer, Prairial, Potomac, Cambria, Sylvan, Jesper, Juno and Frode ([Table 2](#)). Among these varieties, Akimidori was used as the standard variety for all the cafeteria trials. [Table 3](#) shows the results of 45 trials. Relative palatability value of each variety was expressed in percentage of intake per diet of the variety within the same variety group. The analysis of variance was based on this value. F values of sources for the variety indicated that the differences in the relative palatability values among varieties were highly significant ($P < 0.001$ or $P < 0.01$) for 42 out of 45 trials.

According to the relative palatability value, [Table 3](#) shows that a French variety Lude (L) exhibited a high palatability in most seasons of the years in the current study. Compared with the standard variety Akimidori (A), significant differences ($P < 0.05$) in the value of Lude (L) were recognized throughout the seasons of the years, except for the reproductive stage in the 2nd cutting, the 4th cutting in 1993 and 3rd cutting in 1994.

2) Palatability of the variety Lude

In order to compare the relative palatability values of the varieties obtained from 3 different variety groups in the same cutting period, as shown in [Table 3](#), the value of palatability (%) of each variety was defined as the difference between the relative palatability value of the variety and the value of the standard variety Akimidori. The values of palatability in Akimidori were always expressed as 0% in this definition. The values of palatability of Lude and Akimidori are shown in [Fig. 1](#) with the maximum and minimum values of palatability obtained from all the variety groups in the same cutting period. As pointed out in [Table 3](#), it was also confirmed in [Fig. 1](#) that Lude showed a high palatability among all the tested varieties for most of the seasons of the years.

Predictors for palatability

Multiple regression analysis was carried out to identify variables which could predict the values of palatability of varieties in 15 cafeteria trials in spring, summer and autumn seasons¹³⁾. Characters used in this analysis are listed in [Table 4](#). Agronomic characters¹⁰⁾, fiber and degradability characters¹¹⁾, mineral elements¹²⁾, free sugars¹²⁾, leaf morphological¹⁰⁾ and physical characters¹¹⁾ were measured or analyzed to predict the values of palatability. Among 41 available variables, which represent these characters, best combinations of 2 variables were detected in each growing season ([Table 5](#)). Contribution ratios due to regression (R^2) of the palatability on 2 best variables ranged approximately from 0.6 to 0.95 in all the 15 trials. For all the seasons, the concentration of Ca, the concentration of P and flexibility of leaf and stem measured by the hand-touching method were considered to be the best positive predictors for the palatability of varieties. In contrast, ADF and 3 kinds of diseases (Rhynchosporium scald, rust and total leaf diseases) were considered to be the best negative predictors for the palatability of varieties¹³⁾.

Characters of the palatable variety Lude and positive effect of palatability on intake

1) Characters of the variety Lude

Lude, a French variety, exhibited superior characteristics in quality compared with other varieties in our study, namely, high palatability, resistance to rust and total leaf diseases¹⁰⁾, high flexibility of leaf and stem¹⁰⁾, the highest concentration of Ca and ratio of Ca/P, and the lowest ratio of $K/(Ca+Mg)$ among all the tested varieties ([Fig. 1](#)). Although Lude is susceptible to summer blight and its value of DM degradability by cellulase solution is average among the varieties, it could become a promising breeding material for the improvement of both palatability and quality in orchardgrass, especially for the warm region of Japan because of its high adaptability to the climatic conditions.

2) Positive effect of palatability on intake

Intake of fresh materials in 2 varieties, Lude and Akimidori was compared by using Holstein heifers¹⁴⁾. Each measurement of the intake was carried out during a period of 3 days together with palatability tests. Mean value of dry matter intake (DMI, $g/kgBW^{0.75}$) of Lude was 0.8 g, 2.3 g and 2.5 g higher than that of Akimidori in the first trial in July 1993, second trial in November 1993, and third trial in June 1994, respectively. Dry matter digestibility (DMD) of each variety was predicted from the degradability by 1% cellulase solution. Regression equation of DMI on DMD was calculated in each variety. According to the t-distribution statistics, the regression coefficient of original equations in each variety could be pooled statistically. The pooled equations were as follows: DMI of Akimidori = $-44.72 + 1.79 \text{ DMD}$; DMI of Lude = $-41.23 + 1.79 \text{ DMD}$ ([Fig. 2](#)). The intercept of regression line on these equations was, however, significantly different. Based on the difference in the values of intercept, the estimated increase of DMI value in Lude over Akimidori was 3.49 g at the same DMD level. Palatability of Lude measured by using the same heifers was also significantly higher than that of Akimidori in each trial¹⁴⁾. High palatability in Lude might have a positive effect on the DMI level and could increase it more than expected from the DMD level.

Fig.2.

Relationship between dry matter in take (DMI) and predicted dry matter digestibility (DMD)^{a)} in 2 varieties of orchardgrass

a): *In vivo* DMD (Y,%) was predicted from the following equation.
 $Y = 25.1 + 0.917 \times (\text{DM degradability by 1\% cellulase solution for 48 h, \%})$.

According to the t-distribution, the regression coefficient of the original equations on Akimidori and Lude can be pooled statistically to the value 1.79, but the intercept of the regression line on (1) and (2) is significantly different at 5% level.

Proposed model for developing new varieties with high palatability in Japan

1) Methods for selection of palatability and digestibility

(1) Palatability

In order to develop useful selection criteria for palatability, the flexibility of leaf and stem and the concentration of Ca were considered¹⁵⁾. As for the flexibility, 6 persons gave independently similar scores for the flexibility of tested strains by using a simple method of hand-touching and it was considered that the method for measuring the flexibility might be easy and reliable. Therefore, it could be one of the most useful criteria for estimating the palatability of breeding materials in orchardgrass. As for the Ca concentration, the increase of the Ca concentration in orchardgrass was considered to be effective for the improvement of both palatability and mineral-balances with Mg, K and P.

(2) Digestibility

In addition to the palatability, digestibility is the most important character for the quality of grass varieties. Near infrared reflectance spectroscopy (NIRS) could successfully predict cellulase degradability of unknown samples of orchardgrass, and NIRS was considered to be one of the most effective methods to improve the digestibility in grass breeding^{8,15)}.

2) Proposed model for breeding

A model for developing new varieties with a high palatability was proposed¹⁵⁾ (Table 6), in which 3 stages were designed for 2 regions in Japan. For the breeding of varieties suitable for the cool region, promising plants in the original population could be selected based on winter hardiness and resistance to diseases, and their seeds would be harvested as maternal lines in Stage 1. Then, superior maternal lines could be selected based on the flexibility of leaf and stem and the Ca concentration in Stage 2. Finally, new varieties could be selected through the evaluation of palatability measured by using cattle from the final candidate lines in Stage 3.

For the breeding of varieties suitable for the warm region, variety Lude would be one of the most important breeding materials. Promising plants in the original population could be selected based on summer productivity and resistance to summer blight to breed maternal lines in Stage 1. Then, superior maternal lines could be selected based on the digestibility by using a cellulase solution or by NIRS in Stage 2. Finally, new varieties could be selected through the evaluation of palatability measured by using cattle in Stage 3.

This model was the first to be proposed for the improvement of both palatability and quality, which includes digestibility and mineral-balances in forage breeding in Japan.

Abstract

Ulin Ulin (*Eusideroxylon zwageri*) is an ironwood species whose growing stock has decreased due to over-exploitation. *Ulin* trees occur in lowland forests as scattered individuals in Kalimantan and naturally regenerated seedlings are usually restricted in the area near seed parents. They are recruited almost every year although the recruitment rates fluctuate. Seedlings of *Ulin* in a closed rain forest seldom die. However, as they grow slowly, natural regeneration appears to be poor in terms of timber production. Canopy opening and weeding (release cutting) accelerate the seedling growth by improving the light conditions. Release cutting applied to seedlings about 5 years old and 92 ± 36 cm tall in this study enabled to increase seedling growth rates and possibly decrease the time required for the *Ulin* stem to reach 10 cm in dbh (diameter at breast height) from 78 to 26 years. However, sudden felling caused an increase in the death rate of the seedlings. Since seedlings less than 3 years old are sometimes more sensitive to sunlight and dry weather conditions than older seedlings, release cutting should be carried out in the case of 3-year-old seedlings or older. *Ulin* is fire-resistant after becoming large. However, it is still sensitive during small seedling stages. Appropriate release cutting should thus shorten the time required for *Ulin* to become fire-resistant.

(Received for publication, April 6, 1999)

Introduction

Ulin (Borneo ironwood, *Eusideroxylon zwageri*) is a species of Lauraceae that grows up to 40 m tall. Natural trees are found in South Sumatra, Kalimantan, and on the nearby small islands. In Kalimantan, *Ulin* is common along rivers and adjacent hills, sometimes forming pure stands in primary and secondary forests, up to 500 m altitude, on sandy well-drained soils⁶. In South Sumatra, it forms pure stands on clay-rich soils¹⁴ unlike in East Kalimantan¹⁵.

Since the wood is strong and extremely durable, it is in great demand for heavy construction, roofing, agricultural uses, and others. In Kalimantan, *Ulin* is originally a common species occurring in lowland areas. The original areas of *Ulin* forests in Borneo have been estimated to cover 1,440 km² but presently only about 40% of these areas remains⁸). Along roadways near Bukit Soeharto in East Kalimantan, farmers settled and started pepper farming using *Ulin* support stakes mostly in the 1970s⁷). By the late 1990s, *Ulin* trees with a large diameter were seldom observed in the region. In parts of Kalimantan, this species is already considered to be endangered⁹). The decrease in growing stock is due to exploitation beyond the growth.

In natural forests, *Ulin* grows slowly when its stem diameter at breast height (dbh) is below 10 cm (**Fig. 1**). The growth markedly accelerates when the dbh ranges between 10 and 30 cm. Growth is then reduced to a level intermediate between that of the former stages, and remains steady until the dbh reaches 1 m or more. By following the method of Brown¹), the time required for the *Ulin* stem to reach 30 cm in dbh is estimated at 120 years, and for 120 cm, at 403 years (Fig. 2). It is very easy to accelerate the growth at the initial stages silviculturally. Actually, one individual with a dbh of 6.85 cm (closed circle in Fig. 1) under a canopy gap grew faster than the others in the same diameter class. Appropriate treatment such as release cutting could accelerate the growth of the seedlings and such a silvicultural practice may prevent a decrease in the growing stock of *Ulin*.

Fig.2

Estimated stem growth rate of *Eusideroxylon zwageri* in logged-over and burned lowland forests (modified from Hastaniah and Kiyono, 1995⁴)

In the present study, we analyzed the effects of the variations in growing environments such as light on the growth of *Ulin* seedlings in Bukit Soeharto Education Forest (BSEF) in East Kalimantan. Such information could contribute to the improvement of silvicultural practices such as release cutting and enrichment planting to preserve *Ulin* resources in Indonesian forests.

Seedling growth in contrasting light environments

1) Setting of study sites

The forests of BSEF underwent commercial logging followed by logging and slash-and-burn by local people in the 1970s, then experienced drought and fires in 1982-1983. In 1992, trees more than 50 m tall survived the fires in some areas and among them mostly secondary trees of *Macaranga gigantea* and *Macaranga triloba* were established after the fires³. Fertile trees of *Ulin* partly remained in abundance. Seedlings are usually restricted to areas near seed trees because the fruit is heavy.

The effects of light environments on the seedling growth were examined in 2 experimental plots arranged in seedling banks on a slope with top soils consisting of sandy clay loam-sandy loam in July 1992 (Plots 1 and 2 in [Table 1](#)). Dominant overstory trees included *Ulin*, *Endospermum diadenum*, *Dipterocarpus tempehes*, and other trees. Both plots contained 2 fertile *Ulin* each. The 4 *Ulin* trees, 30-60 cm in dbh, flowered almost every year during the period 1991-1996. Under them were 467 naturally regenerated seedlings in Plot 1 and 190 seedlings in Plot 2 in July 1992. The *Ulin* seedlings were estimated to be mainly derived from the seeds from mast-fruiting around 1988 (Sopiyani, personal communication, 1996). For one plot (Plot 1), a canopy gap covering a 32 x 32 m land area was made and weeding was started in May 1993. Another plot (Plot 2) was used as the control. Based on the differences in the light environments, Plot 1 is referred to as gap site and Plot 2 as closed site.

All the seedlings including recruits in Plots 1 and 2 were labeled and their height, diameter at 0.3 m height, and other characteristics were measured in 1992, 1993, 1994, and 1996. The percentage of canopy opening was determined by hemisphere photographs 4 times in 1993-1996 in Plots 1 and 2. In each plot, top soils were sampled in 1995 and 5 seedlings were sampled in 1996 to determine the amounts of leaves, branches, stems, and roots. Since fresh fine roots of *Ulin* are dumpy, 1.2-2.2 mm in diameter, their surface area was easily measured.

The monthly rainfall at the research station of Bukit Soeharto Education Forest in 1988-1997 averaged 163 ± 94 mm year⁻¹. After July 1992, low monthly rainfall of below 70 mm was observed in July-September and November 1993, in July-September 1994, in June and August-October 1997, and in January-April 1998 at the research station near the plots.

In March 1998, forest fires occurred in BSEF. Although almost all the seedlings were green before the fires, they burned to death, except for some seedlings in Plot 1. In October 1998, all the living seedlings in Plot 1 and some dead seedlings in each plot were selected and their height, diameter, and other characteristics were measured. Since the seedlings that had burned to death were standing with branches and leaves in perfect shape, their height and diameter were considered to correspond to the values recorded in March 1998. For the living seedlings, height and diameter in March 1998 were estimated from the values recorded in March 1996 and October 1998.

2) Growth of seedlings depending on changes of light conditions

The death rate of the seedlings at the closed site was 2.8% year⁻¹ ([Table 2](#)). This value is lower than that of red meranti-Shorea seedlings of almost the same age recorded in a similar rain forest in Sabah, Borneo

(9.8-16.0% year⁻¹)¹²) and shows that *Ulin* is a shade-tolerant species¹³.

Sudden canopy opening resulted in an increase in the seedling death rate. The death rate at the gap site was about twice as high as the death rate at the closed site (Table 2). For the first 5 months after canopy opening, the highest death rate (12.2% year⁻¹) was recorded ([Table 3](#)). One month after canopy opening, a low rainfall period occurred during 5 months. It is likely that the very high death rate was due to the drought and sun exposure.

The death rate after sudden canopy opening depended on the differences in seedling age. During the low rainfall period of 1994, some cohorts of below-3-year-old seedlings exhibited higher death rates than the older seedlings (Table 3). Jong⁵, Endert², and Tuyt¹¹) also reported that 3- to 8-year-old seedlings grew well when the canopy was open.

Although *Ulin* is considered to be a shade-tolerant species, the seedlings require appropriate canopy opening to grow faster. The seedlings at the gap site displayed higher relative growth rates for height and diameter than the seedlings at the closed site (Table 2). The diameter growth of the tallest 10 seedlings at the gap site averaged 0.389 cm year⁻¹, while that at the closed site was 0.123 cm year⁻¹. Assuming that these diameter growth rates remained unchanged, canopy opening and weeding at the gap site decreased the time required for the *Ulin* stem to reach 10 cm in dbh from 78 to 26 years.

The seedlings grown under strong light conditions developed thick leaves and large root systems. Canopy opening apparently resulted in low humid conditions on the forest floor. At 42 months after gap formation, the total dry mass of the seedlings at the gap site was 5.9 times higher than that at the closed site ([Table 4](#)). The thick roots at the gap site were 2.5 times longer horizontally and 1.7 times deeper than at the closed site. The total leaf area (LA)/fine-root mass ratios of individual seedlings were smaller (0.85 times) at the gap site than at the closed site. On the other hand, the leaf mass/fine-root mass ratios were 1.23 times larger at the gap site than at the closed site. Such morphological characteristics seem to be common for various tree seedlings grown under different light conditions¹⁰.

Influence of fire on seedling survival and regeneration

Relatively large *Ulin* trees display a fire resistance capacity³), and also are less vulnerable to cutting owing to effective sprouting. Of 26 *Ulin* trees with a dbh of 44-92 cm, 24 (92%) sprouted new shoots from stumps in fallow land of slash-and-burn agriculture⁷). The ground fires in March 1998 burned the research sites. All of the 4 *Ulin* mother trees (30-60 cm in dbh) at the closed and gap sites survived the fires, whereas, only 30 (7.6%) seedlings at the gap site survived the fires. The vulnerability to the fires was higher in the case of smaller seedlings than in larger ones at the gap site. After the fire events at the gap site, the survivors were 302 ± 90 cm tall with a diameter of 2.37 ± 0.83 cm at 0.3 m height, while the dead seedlings at the gap site were 208 ± 73 cm tall with a diameter of 1.52 ± 0.77 cm. Considering that all the seedlings (110 ± 55 cm tall with a diameter of 0.90 ± 0.40 cm) died at the closed site, release cutting prevented some *Ulin* seedlings from burning to death.

Abstract

Acetylene reduction activity, an index of nitrogen fixation, by epiphytic and epibenthic algae and coral debris was measured in seagrass beds around Green Island, Australia. Epiphytic blue-green algae showed a high activity, ranging from 56.1 ± 31.9 to 729 ± 105 $\mu\text{mol (g chl a)}^{-1} \text{d}^{-1}$ on a chlorophyll basis, or $3.9 \frac{1}{4} \text{mol N}_2 \text{ m}^{-2} \text{ d}^{-1}$ to $16 \text{ mol N}_2 \text{ m}^{-2} \text{ d}^{-1}$ on an areal basis. The activities on an areal basis were comparable to those reported in a Fijian seagrass bed, whereas activities on a chlorophyll basis were higher on Green Island than on Fiji. A relatively high activity was observed on the leeward side of the island, partly due to the high seagrass biomass and partly due to the high epiphyte biomass. This trend of high activity on the leeward side of the island suggested that the biomass and/or activity of nitrogen fixing blue-green algae could be affected by unknown mechanism(s) related to the island environment. Algae on (or in) coral debris, which were abundant around live corals, were able to reduce acetylene.

Discipline: Fisheries / Environment

(Received for publication, March 18, 1999)

Introduction

Seagrass beds in coastal waters in the tropics are among the most productive ecosystems¹⁾, although they are often washed with nutrient poor waters²⁰⁾. From seagrass beds, there are inevitable losses of nutrients by export of detached leaves, exudates, leaching, grazing¹⁴⁾, etc. To compensate for those losses, nutrients should be supplied, and the supply sometimes limits the production of dominant producers in seagrass beds, e.i. seagrasses themselves for nitrogen⁶⁾ or for phosphorus^{7,17)}.

In a Fijian seagrass bed, atomic ratio of nitrogen to phosphorus of nutrients in a water column ranged from 2.5 to 4.7, values which are lower than those of seagrasses (7.9 ~ 49) and epiphytes (87 ~ 102)²⁰⁾, suggesting that nitrogen might be the limiting nutrient for the primary producers in tropical seagrass beds. As tropical seagrasses take up nutrients mainly from sediments where nutrient concentrations are

relatively high, nitrogen supply to the sediments has been a main target of interest, and belowground nitrogen fixation has been investigated^{4,13,15}). However, in tropical coral reefs and seagrass beds, nitrogen-fixing blue-green algae commonly occur on reef sediments or seagrass shoots^{3,8,11,21,22}). In a Papuan seagrass bed, nitrogen fixation (acetylene reduction) activity was detected on the surface of almost every object at the bottom including seagrasses, shells, detrital leaves, etc.⁹). In a Fijian *Syringodium*-dominated bed, a nitrogen-fixing blue-green alga, *Hydrocoleum cantharidosmum* (Mont) Gom (= *Microcoleus lyngbyaceus* (Kutzing) Crouan, *sensu* Drouet), formed tuft-shape colonies on leaves, showing that the magnitude of nitrogen fixation was in the same order as that of nitrogen requirement for seagrass production¹⁰). Nitrogen fixed in the aboveground parts of seagrass beds are likely to be cycled through detrital microbial chains in water columns or sediments and utilized by primary producers.

In a seagrass bed on a lagoonal reef around Green Island on the Great Barrier Reef, Australia, spatial variability of nitrogen fixation (acetylene reduction) by blue-green algae was investigated to examine the significance of nitrogen fixation on a coral cay.

Materials and methods

1) Study site

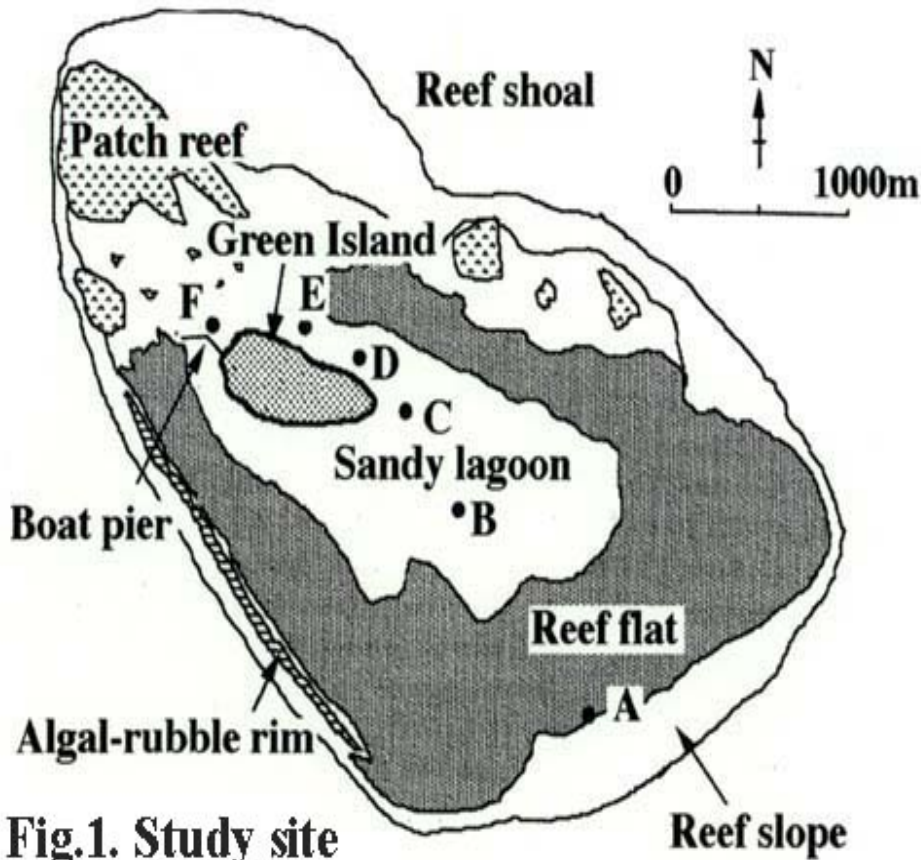

Fig.1. Study site

Green Island (16°46'S., 145°58'E.) is a coral cay (ca. 4 km in long axis and ca. 2 km in short axis), ca. 27 km offshore from Cairns, Australia (Fig. 1). A lagoonal platform or planar reef has developed around the island²⁾, with a wider area on the windward sides (eastern and southern) of the island than on leeward sides. Several species of seagrasses (*Thalassia hemprichii*, *Cymodocea serrulata*, *Cymodocea rotundata*, *Halodule uninervis*, *Syringodium isoetifolium* and *Halophila ovalis*) formed meadows in the lagoon (Lee Long, W., personal communication). Dense patches were observed on the leeward side of the island, while sparse seagrass patches were scattered all over in the sandy lagoon. Six stations

(A, B, C, D, E, F) were set up in the lagoon along the water current over the reef (from SE to NW), namely Stn. A on the windward edge of the lagoon, ca. 1.7 km SSE of the island, and Stn. F on the leeward side, ca. 100 m NW of the island. Water depth at all the stations was shallow at low tide, less than 30 cm, except for that at Stn. F, which was ca. 3 m.

2) Acetylene reduction assay

Acetylene reduction activity was measured to estimate the nitrogen fixation activity¹⁸⁾. Samples consisted of intact leaves with epiphytes, epiphytes that were scraped from leaves with a razor blade, epibenthic algal mats that were carefully peeled from the sediment and cut into rectangles, and coral debris. Samples were put in plastic containers (80 or 230 mL in volume), together with GF/F glassfiber-filtered seawater so as to leave 40 or 110 mL of headspace. Acetylene was injected into the headspace through a rubber septum on the lid of the container. Final concentration of acetylene was 10 to 15% (v/v). Containers were incubated in an outdoor tank for one day. Ethylene concentration in the headspace was analyzed with an ethylene analyzer (GC-2, Kiya Seisakusho Co.). In situ temperature and irradiance were monitored at 10 min intervals with temperature and irradiance recorders (MDS-T, MDS-L, Alec Electronic Co.). Temperature in the tank, which was 22~27°C, was ca. 1°C higher than that in the field. Irradiance in the tank was 60% of in situ irradiance at Stn. E.

3) Isotope ratio analysis of blue-green algae

The entangled visible materials other than blue-green algae were removed with a pair of pincettes under a binocular microscope. After being freeze-dried, the organisms were powdered and homogenized by using

an agate mortar and pestle. To determine the stable isotope ratios, organisms were combusted at 1,050°C in a CN analyzer (Fisons Instruments EA1108), and the combustion products (N₂ gas) were introduced into an isotope-ratio mass spectrometer (Finigan Mat 252) in a continuous flow of He carrier. Isotope ratios were expressed as the deviation from a standard represented by the following equation:

$$\delta^{15}\text{N}(\text{‰}) = \{R(\text{sample})/R(\text{standard}) - 1\} \times 1000, \text{ where } R = {}^{15}\text{N}/{}^{14}\text{N}, \text{ standard} = \text{N}_2 \text{ in air.}$$

4) Biomass

At each station, 3 quadrates (50 x 50 or 10 x 10 cm) were set up and seagrasses above the sediment were harvested. Samples were dried at ca. 60°C for dry weight measurement. Chlorophyll a content of epiphytes was analyzed fluorometrically after extraction with N,N-dimethylformamide¹⁹).

Results and discussion

Seagrasses were widely observed on the reef ([Fig. 2](#)). At Stn. A, *T. hemprichii* formed sparse patches in sand pockets on reef flats. As the quadrates were placed on these patches, the biomass shown in the figure corresponded to that in the patches. Total aboveground bio-mass values were 3.5 ± 0.8 , 63.4 ± 72.9 , 98.9 ± 35.3 , 42.6 ± 5.6 , 96.7 ± 24.6 , and 55.2 ± 16.0 g m⁻² at Stns. A, B, C, D, E, and F, respectively. As shown by standard errors, the distribution of each seagrass was patchy, but seagrass beds, irrespective of their species composition, developed on the sandy lagoon around the island. This finding indicates that substrata to which surface epiphytes could become attached were commonly distributed on the reef, except on the windward edge of the reef.

Intact seagrass leaves showed a high acetylene reduction activity ([Table 1](#)). As young leaves, which accumulated few epiphytes, did not show any activity (data not shown), epiphytes were assumed to be responsible for the activity⁹). It was observed that a blue-green alga, *H. catharidosmum*, was the dominant alga, forming tufts on leaves of seagrasses, as observed in a Fijian seagrass bed¹⁰).

One-way analysis of variance (ANOVA) of the activity on a chlorophyll basis indicated that the activity of the epiphytes at Stn. C was significantly ($p < 0.01$) higher compared with that of the epiphytes at other stations (Stns. B, E and F). It was observed that the concentrations of particulate organic carbon and nitrogen in seawater tended to increase when the seawater flowed around the island from Stns. A to F¹²). Concentrations of dissolved inorganic nitrogen and phosphorus in pore water of the sediments were higher in the seagrass beds than in unvegetated areas¹²), suggesting that the supply of nutrients for epiphytic algae could be more abundant at Stns. C to F than at Stns. A and B ([Fig. 2](#)). Nitrogenous and phosphorous nutrients recycled from organic matter which were supplied from seagrasses or transported from other areas and trapped in the seagrass beds may be an important source of nutrients for epiphytic algal communities. However, the low isotopic ratios of algal nitrogen suggested that nitrogen fixation is the main source of nitrogen for these algae ([Table 2](#)).

The same epiphytic algae with a tuft shape (*H. catharidosmum* was the dominant alga) were found to fix nitrogen in a Fijian seagrass bed¹⁰). Acetylene-reducing activity by the epiphytes was 25.2 ± 0.75 mmol reduced (g chl a)⁻¹ d⁻¹. Epiphytes in seagrass beds on Green Island showed a higher reduction activity

than that in Fijian seagrass beds. The difference might be due to the grazing effect. A cage experiment on a coral reef on the Great Barrier Reef indicated that fish grazing reduces algal biomass and leads to the shift of the epiphytic community from red algae to rapidly colonizing and growing blue-green algae in a year²³). Though data on fish grazing or fish biomass at our study site were not available, fish were apparently abundant on Green Island whose environment is protected for a marine park. Instead, local people are fishing in the Fijian seagrass beds. Even if the dominant alga is the same, fish grazing is likely to improve microenvironments of light and/or nutrients on the leaf surface and stimulate the turnover of algae, hence the enhancement of the nitrogen fixation ability.

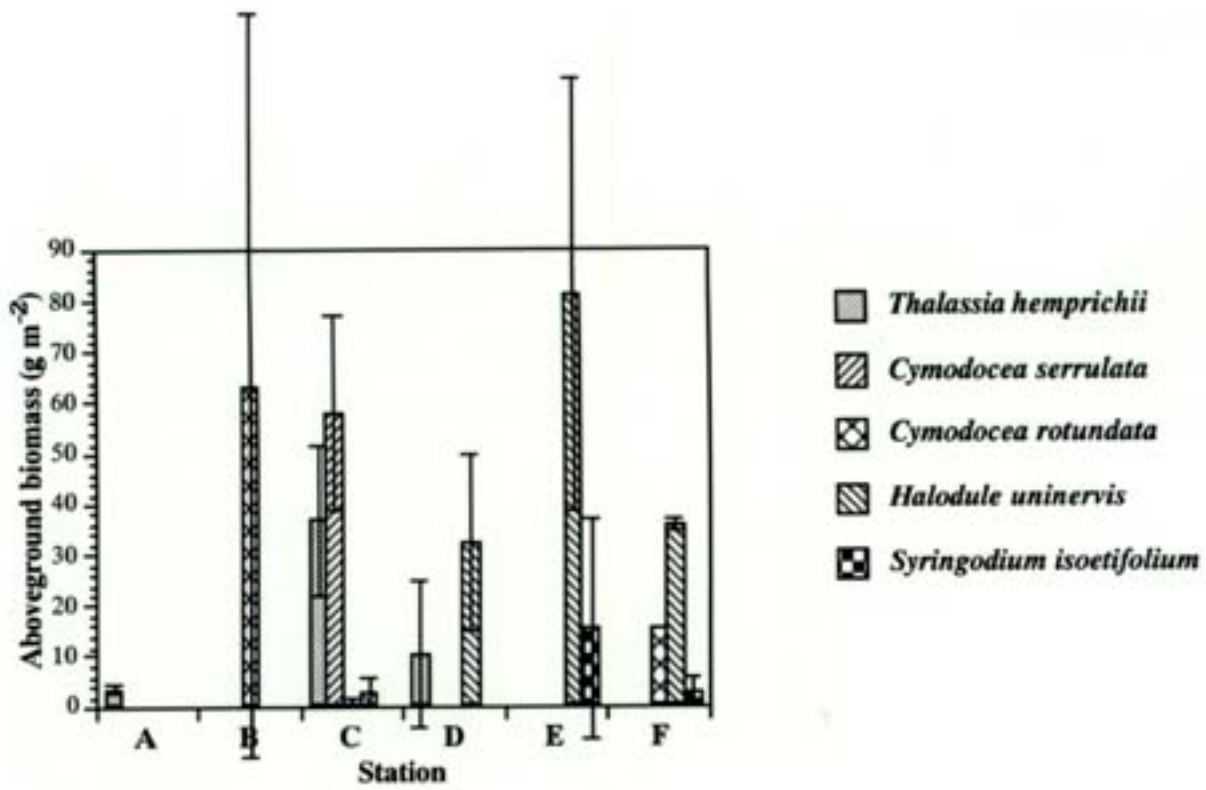

Acetylene reduction activity on an areal basis was higher on the leeward side than on the windward side ([Fig. 3](#)), partly due to the larger seagrass biomass on the leeward side, or to the larger abundance of nitrogen-fixing algae on seagrass leaves. *Thalassia hemprichii* on the eastern (windward) edge of the reef accumulated fewer epiphytes. This distribution of the nitrogen fixation activity around the island suggests that the biomass of epiphytic and epibenthic blue-green algae is controlled by factor(s) other than nitrogen supply through nitrogen fixation. Supply of nutrients from the island or mechanisms other than nutrient supply could enhance the production of epiphytes on seagrass leaves, resulting in the increase of nitrogen fixation. After seagrasses started to thrive since the construction of a resort on the northwestern side of the island (Lee Long, W., personal communication), the biomass and nitrogen fixation activity of epiphytes may have increased. Further studies should be carried out to analyze the effect of the island environment on nitrogen fixation around the island.

Nitrogen fixation activity was estimated to be $3.9 \frac{1}{4} \text{mol N}_2 \text{ m}^{-2} \text{ d}^{-1}$ at Stn. A and $16 \text{ mmol N}_2 \text{ m}^{-2} \text{ d}^{-1}$ at Stn. F, assuming that the $\text{C}_2\text{H}_2/\text{N}_2$ conversion factor is 4.4¹⁶). The average activity at all the stations ($5.2 \text{ mmol N}_2 \text{ m}^{-2} \text{ d}^{-1}$ or $145 \text{ mg N m}^{-2} \text{ d}^{-1}$) was comparable to the rate estimated in a Fijian seagrass bed ($113 \text{ mg N m}^{-2} \text{ d}^{-1}$)¹⁰). However, these activities were larger by 2 to 3 orders of magnitude than those reported in seagrass beds at Weipa and Groote Eylandt in northern Australia¹⁴), for unknown reasons.

Coral debris displayed an acetylene reduction activity (Table 1). It remains to be determined whether the activity was related to algae on the surface of the samples or algae penetrating into the skeleton of corals⁵). Dead corals play an important role in supplying a support for nitrogen-fixing organisms and in enhancing nitrogen import to the ecosystem.

Abstract

Statolith preparation and observation methods adopted in Japan were reviewed for 4 ommastrephid squids, *Ommastrephes bartramii*, *Dosidicus gigas*, *Sthenoteuthis oualaniensis*, and *Illex argentinus*. Relationships between mantle length and age were exponential at the early life stages and almost linear at the subadult and adult stages.

Discipline: Fisheries

Additional key words: growth

[1...20](#): [References](#)

(Received for publication, January 14, 1999)

Introduction

The flying squid family Ommastrephidae is an important component in the marine ecosystem and has been targeted by commercial fisheries in many coastal and pelagic waters of the world. *Todarodes pacificus*, *Illex argentinus*, *Ommastrephes bartramii* and *Dosidicus gigas* are major species accounting for about 50% of the world cephalopod catches which amounted to approximately 2.8 million t year⁻¹ during the early 1990s¹. Since most of these ommastrephid squids have a one-year life cycle, and are usually composed of several seasonal cohorts¹¹, it is essential for sustainable use of these stocks to determine their age, hatching date, and growth⁶. Until the late 1980s, growth of squids had been studied by using consecutive series of mantle length frequency distributions. Length-based methods, however, are generally inappropriate for fast-growing and highly migratory squids^{6,12}. Statolith microstructure is useful for age determination of squids as are otoliths in teleost fishes, and direct or indirect validation studies revealed daily deposition of increments in squids^{11,15}. Therefore, recent studies on squid growth are mostly relying on statolith daily increments, with a few exceptions where *gladius* were used. The purpose of this report is to describe (1) preparation methods of statoliths that have been adopted for age

determination in Japanese fisheries research institutes and (2) growth of 4 species targeted by international fisheries.

Structure of statolith

Statoliths are mainly composed of calcium carbonate in the crystal form of aragonite and are located in statocysts in the cartilaginous cranium^{7,15}. A squid statolith consists of a dorsal dome, lateral dome, rostrum and wing (**Fig. 1**). Posterior plane of a statolith is convex, and anterior plane is slightly concave. Anterior surface of the wing is attached to the statocyst wall via connective tissue. Growth increments, with a 3-dimensional structure, are deposited from the core (nucleus) of a statolith.

Statolith preparation

In order to extract a pair of statoliths from a squid, cartilaginous cranium was sectioned along a transverse plane in the center of the statocysts from the ventral side of the cranium with a small knife. Then, each statolith was extracted from a statocyst with fine forceps, cleaned with ethanol, and deposited in a pit (ca. 7 mm in diameter) of plastic trays, "microplate", which had been filled with liquid paraffin. After removal of liquid paraffin with xylene and ethanol, statoliths were suitable for preparation. Daily increments were observed in 4 different ways. Details of the preparation methods were described in previous reports^{5,8,13}.

1) Scanning electron microscopy (SEM)

Each statolith was mounted individually in a small mold with epoxy. After hardening, the epoxy block was removed from the mold, attached to a glass slide with the medial (wing) side up and ground on a longitudinal plane until the core was exposed (Figs. 1-3). Fine-grained carbon carbide (1500-grade) waterproof paper was used for grinding and statoliths were polished with 0.3 μ m alumina powder. Statoliths were etched with 1% HCl for 150 seconds and coated with gold for SEM observation at 15 kV.

2) Light microscopy (LM)

In order to enhance the contrast of increments, statoliths were heated in small glass tubes filled with silicone oil at about 190°C for 24 h. Then, silicone oil was removed with xylene and ethanol. Heating was not necessary for *I. argentinus* and small individuals (< 300 mm ML) of *O. bartramii*.

(1) Longitudinal sectioning

After the core of a statolith was exposed in a similar way for SEM observation, the epoxy block was detached from the glass slide, attached to a glass slide with the lateral side up, and ground again to the level immediately above the core. This method had been applied for *Ommastrephes bartramii*¹⁸ and *Dosidicus gigas*.

(2) Polishing of posterior plane

Each statolith was mounted on a glass slide with super glue or Eukitt with the posterior (convex) plane up. The posterior plane of the statoliths was slightly ground with fine-grained carbon carbide waterproof paper, and polished with 0.3 μ m alumina powder. This method had been used for *Illex argentinus* and *Dosidicus gigas*^{14,17}.

(3) Polishing of anterior and posterior planes

Each statolith was mounted on a glass slide with Eukitt with the anterior plane up. Anterior plane of statoliths was slightly ground and polished as described in the previous method. Statoliths were removed by applying xylene, and attached on the glass slide with the posterior plane up. Then, statoliths were similarly ground and polished. This method had been applied for *Sthenoteuthis oualaniensis* and *Dosidicus gigas*^{14,16}.

Observation of daily increments

A light microscope (LM) equipped with objective lenses (x10, x20, x40, and x60) was connected to a TV camera and a high-resolution monitor, with final magnifications of 900-4500x. For LM observations, cover glasses are not necessary, but a drop of liquid paraffin markedly enhances the visibility of increments. Visibility may also be improved by controlling transmitted light with manipulation of a condenser and filters. Sketches of tracing increments⁸⁾ or graphics from an image-analyzing system are useful for precise counting, i.e. for checking results within multiple counts for a specimen by a reader or among multiple readers.

A single increment is composed of a pair of dark and light rings when viewed with LM ([Fig. 3A](#))¹¹⁾. The dark rings are more deeply etched with HCl because of the larger abundance of amino acids than in the light rings (Figs. 2 and [3B](#)). In the ommastrephids, increments are usually prominent on the anterior plane of statoliths, and counts were made from the core to the dorsal dome (Fig. 2).

Fig.2

Scanning electron micrographs of a sectioned and etched statolith from a 390 mm ML *Dosidicus gigas*.

A: From core to dorsal dome.

B: Dorsal dome area.

The core (nucleus) is usually dark and oval, with a size of approximately 20-30 $\frac{1}{4}$ m x 15-20 $\frac{1}{4}$ m for *O. bartramii*, *I. illecebrosus* and *I. argentinus* (Figs. 3 and [4](#))^{2,4)}. The size of the core is considered to correspond to that at the time of hatching in *Illex illecebrosus*^{3,9)}. This assumption has been extended to other ommastrephid squids. In artificially reared *D. gigas*, the maximum diameters of 2 statoliths examined were 37 and 44 $\frac{1}{4}$ m on the day of hatching, and the size of the statolith linearly increased until the 6th day after hatching, but without distinct increments ([Fig. 5](#))²⁰⁾. Bigelow and Landgraph⁴⁾ also observed an inconsistent increment structure around the 10-to-15 $\frac{1}{4}$ m area immediately distal to the core. In some squid species, increments may not be produced daily during the embryonic development¹¹⁾. Therefore, caution must be paid to uncertainties in age estimation during the earliest life stage.

In *O. bartramii*, increment width increased from 3- 4 $\frac{1}{4}$ m near the core to up to 7 $\frac{1}{4}$ m at a distance of 200 $\frac{1}{4}$ m, then gradually decreased to 2 $\frac{1}{4}$ m or less after a distance of approximately 400 $\frac{1}{4}$ m¹⁹⁾. A similar pattern was also observed in *S. oualaniensis* and *D. gigas* (Fig. 2). In *Illex argentinus*, increment width increased from 1.5-3 $\frac{1}{4}$ m in the

post-nucleus zone, to 2-5 $\frac{1}{4}$ m in the dark zone and decreased to 1.5-3 $\frac{1}{4}$ m in the peripheral zone of the dorsal dome²⁾. Increment width is also subject to variation with environmental conditions, mainly temperature, which in turn results from the difference in the hatching season²⁾. In a stock of *I. argentinus* which spawns in summer, increment width may be as narrow as 0.9 $\frac{1}{4}$ m in the post-nucleus zone (Fig. 3). Such fine increments can be observed with SEM or LM equipped with a high magnification lens (x 60 objective lens).

Comparison of preparation methods

In SEM observations, it was difficult to count the total number of increments from the core to the dorsal dome because some areas were not sufficiently etched for counting (Fig. 2). Increment width can be precisely measured with SEM photographs for adequately etched areas. In LM observations, increments were diffuse or duplicated depending on the thickness of the samples, magnification levels, and depth of focus. For example, subdaily rings (faint increments formed through non-endogenous rhythm, see Fig. 4 of Bigelow and Landgraph⁴) may become more prominent in over-ground statoliths for LM observation¹¹. For accurate (unbiased) age determination, therefore, SEM observation is recommended for a limited number of samples before routine counting with LM, where several hundreds of readings are required in fisheries research¹³.

The sectioning method for LM observation was effective for all the 4 species, and led to more reliable counting than the 2 other methods for LM, because it was possible to avoid occulting crystals and dark zones, where increments are sometimes not sufficiently clear to obtain consistent counts. Sectioning method is, however, more labor-intensive and it is difficult to estimate earlier growth (back-calculation) owing to the "curved axis" of the statoliths (Fig. 4)⁸. The polishing method of the posterior plane is suitable for *Illex argentinus* whose statoliths have few occulting crystals. Polishing of both anterior and posterior planes is indispensable for *Stheneteuthis oualaniensis* because of the existence of abundant occulting crystals.

Growth

Growth at the early life stages has been estimated to be exponential based on statolith daily increment counts for either wild or artificially reared paralarvae (Fig. 6). ML-age relationships at the subadult and adult stages are more or less linear (Fig. 7)¹¹. Although Uozumi and Shiba¹⁷ applied a logistic curve for the autumn brood of *Illex argentinus* (Fig. 7), a linear model can be also valid for their data¹⁰. Growth rates vary with sex, seasonal cohorts, geographic area, and year^{2,14,18}. Females grew faster than males in all the 4 species examined, although the difference was small for *D. gigas*¹⁴. Since ambient temperature, food availability and maturation affect squid growth, these environmental and physiological factors should be considered for future analyses¹¹. Such growth histories may be reconstructed from increment width and trace element analyses^{11,19}.

Conclusion

Squid growth is affected by geographic, seasonal, and year-to-year changes in environmental conditions. The growth variability, together with extended spawning season (seasonal cohorts) and short life span (usually 1 year), is an important aspect of squid ecology. For age and growth studies of squids, it is preferable not to use length-based methods and not to fit *a priori* asymptotic growth curves (or any single model), which are usually applied in fin-fish studies^{6,11}. Therefore, routine age estimation studies are essential for cephalopod fisheries management, although such a task is labor-intensive.

Abstract

Angelonia protoplasts were irradiated with X-rays or UV to obtain a half survival rate. To evaluate the DNA damage, total genomic DNA was prepared from protoplasts irradiated with X-rays or UV and nonirradiated control protoplasts, respectively. An aliquot of DNA was subjected to polymerase chain reaction (PCR) with a decamer arbitrary primer in the presence of radiolabeled nucleotides under annealing conditions of low stringency. Randomly amplified PCR products were analyzed using a denaturing polyacrylamide gel. All the DNA bands detected by autoradiography were compared. The number of DNA bands detected in one lane was approximately ~150. The results indicate that the arbitrarily amplified PCR method is very sensitive for monitoring the DNA polymorphism caused by X-ray and UV irradiation. This novel procedure, designated as RI (radioisotope incorporated)-RAPD, could be applied to detect precise DNA polymorphism in plant cells.

(Received for publication, February 3, 1999)

Introduction

Randomly amplified polymorphic DNA (RAPD) analysis has been widely used to identify genetic polymorphism in many organisms^{11, 12}). Using arbitrary decamer primers, polymerase chain reaction (PCR) is performed under the conditions of low stringency annealing temperature. PCR products are

conventionally separated on agarose gel, and stained with ethidium bromide (EtBr). This method is very simple and rapid. However, the resolution of detailed and complex DNA bands in agarose gel is limited. Another improvement was achieved by introducing silver staining²⁾ or digoxigenin (DIG)-based¹⁰⁾ methods into RAPD. Since the DNA bands observed in an agarose gel or an acrylamide gel are sometimes indistinct, the reproducibility of the RAPD methods has been doubtful.

We are currently examining the effects of X-ray and UV irradiation on mesophyll protoplasts of *Angelonia salicariifolia* to inactivate nuclear DNA. Protoplasts whose nuclear DNA is partly inactivated by the application of irradiation techniques are subsequently utilized for asymmetric plant cell hybridization^{1, 4)}.

To identify the DNA polymorphism induced immediately after the exposure of protoplasts to X-rays and UV, we applied an improved RAPD analysis procedure for the genomic DNA prepared from control and irradiated protoplasts. A conventional RAPD analysis of DNA from the 3 different protoplasts (control, X-ray irradiated, and UV irradiated) revealed only slight differences, while significant differences between the control and irradiated protoplasts were detected by the novel procedure. Here we describe the protocols for an improved RAPD method which could be applied in general.

Materials and methods

1) X-ray and UV irradiation of protoplasts

Mesophyll protoplasts from leaf segments of *Angelonia salicariifolia* L. were cultured in liquid MS16 medium as previously described⁷⁾. Protoplasts (~5 x 10⁴ cells/mL) were irradiated with X-rays (60 kVp, 4 mA, dose of 15 K) or UV (2.5 mW/cm²/s, dose of 25 mW/cm² at 254 nm). Under these conditions, the cell division frequency of the irradiated protoplasts was reduced to half, compared to that of control cells after 7 days of culture (unpublished data). Immediately after the exposure to X-rays and UV, protoplasts were frozen and kept at -70°C until the preparation of DNA.

2) DNA preparation

Total genomic DNA from protoplasts was prepared according to the method of Comczynski³⁾ for simultaneous DNA and RNA extraction from tissues or cultured cells. We found that this single step procedure which is very simple and rapid can be used to prepare reasonable amounts of total genomic DNA from protoplasts. The guanidium isocyanate/phenol solution (ISOGENTM) was obtained from Nippon Gene.

3) Polymerase chain reaction (PCR)

Three decamer oligonucleotides, designated as RA1, RA3, and RA5 whose sequences were 5'-GTCTGACGGT-3', 5'-CGATCGAGGA-3', and 5'-AAGCAGCAAG-3', respectively, were used as RAPD primers⁸⁾. The standard PCR solution (20 μ L) was composed of 100 ng of template DNA, 20 μ M of primer, 200 μ M of dNTP, 10 μ Ci of [\pm -³²P]dCTP (Amersham, 3,000 Ci/mmol), 2.5 units of *Tth* Polymerase (Toyobo) in the recommended buffer. PCR was carried out in an IWAKI thermal sequencer (TSR-300) and the conditions were as follows; 94°C denaturation for 30 s, 42°C annealing for 60 s, and 72°C extension for 30 s with 40 cycles, and another 72°C extension for 5 min. For DNA standard molecular markers, λ Ex174/*Hae*III digests and DNA sequencing ladder (M13 DNA as a template) were used for an agarose gel and a denaturing polyacrylamide gel, respectively.

4) Gel electrophoresis

Following 1.5% agarose gel electrophoresis in TBE buffer, the PCR products were visualized by staining in EtBr solution (1¹/₄g/mL) and photographed. For denaturing gels, a 6% polyacrylamide gel (acrylamide : BIS=19 : 1) containing 42% urea was used in Tris borate buffer. The size of the denaturing gel was 200 mm (width) x 600 mm (length) x 0.35 mm (thickness). Electrophoresis was carried out for 8 h at 1,500 V, the gel was dried on 3MM paper (Whatman) subsequently, and autoradiographed overnight without the use of an intensifying screen.

Results and discussion

Fig. 1 shows the PCR products derived from the X-ray irradiated (X)-, the control (C), and the UV-irradiated protoplasts (U), using 3 different primers (RA1, RA3, and RA5). In lane 1 using a primer RA1, some extra DNA bands were observed in the X-ray (X)- and UV (U)-irradiated cells compared to the control (C). Similar results were also obtained using RA3 (Fig. 1, lane 2) and RA5 (Fig. 1, lane 3), respectively. These results indicated that irradiation with X-rays and UV led to DNA rearrangements in the portion of genomic DNA.

To identify a RAPD profile more precisely, we adopted a radioisotope-incorporated PCR (RI-based PCR) method. **Fig. 2** shows one example of the autoradiograph of the PCR products. The order of samples was the same as that in Fig. 1. The DNA bands observed in the X-ray (X)- and UV (U)-irradiated protoplasts were distinct from those of the control (C). The sizes of the DNA bands were estimated to be in the range of ~100 to ~500 bp by comparison with the sequence ladder of M13 (data not shown). The total number of bands in each lane shown in Fig. 2 was determined (Table 1), and found to be larger than that shown in Fig. 1, presumably due to the higher resolution in polyacrylamide denaturing gels.

Table 1. DNA bands detected by RI-based RAPD

Primer	Total DNA bands			DNA bands appearing in (+) or disappearing in (-)			
	C ^{a)}	X ^{b)}	U ^{c)}	X		U	
RA1	159	157	150	+23	-25	+14	-23
RA3	126	138	132	+22	-10	+22	-16
RA5	153	153	152	+0	-0	+1	-2

The numbers of DNA bands detected in Fig. 2 are indicated.

a): C; Control. b): X; X-rays-irradiated protoplasts. c): U; UV-irradiated protoplasts.

Approximately 120 to 160 DNA bands were detected in the range of ~100 to ~500 bp in each lane. The total number of DNA bands was not significantly different among the primers, especially between RA1 and RA5. However, the number of bands that disappeared or the appearance of new DNA bands depended on the primer used (Table 1). It should be noted that PCR products less than 100 bp could not be detected easily by autoradiography because the amount of [\pm - 32 P]dCTP incorporated into the PCR products was very small. In brief, the present study revealed that (1) DNA rearrangement in protoplasts by X-rays and UV could be effectively monitored by RI-based PCR, (2) a denaturing polyacrylamide gel is superior to an agarose gel for the resolution of PCR products in the range of ~100 to ~500 bp, and (3) some primers enabled to detect DNA damage more effectively than others.

Hall et al.⁵⁾ examined the effects of X-rays and UV on DNA isolated from a protoplast culture of sugar beet (*Beta vulgaris*). They showed a significant fragmentation of nuclear DNA by pulsed-field gel and conventional agarose gel electrophoresis. They were the first to demonstrate the DNA damage by X-rays and UV at the molecular level. However, only large DNA fragments were analyzed in that study. To detect the DNA damage caused by UV irradiation, Stapleton et al.⁹⁾ measured pyrimidine dimers using a specific antibody. Since their method was based on immunoreactive detection and was quantitative, only the total amount of pyrimidine dimers induced by UV-irradiation could be measured. Our present work focused on the detailed and complex changes at the nucleotide level resulting from X-ray and UV irradiation of protoplasts, and the use of powerful tools (conventional RAPD, Fig. 1, and RI-based PCR, Fig. 2) to monitor such DNA rearrangements.

The length of the PCR products indicated in Figs. 1 and 2 seems to be relatively shorter than that of the products obtained in previous studies^{11, 12)}, which may be due to the shorter extension time (30 s) than in conventional methods (for example, 120 s in Refs. 11, 12). However, our procedure was effective for detecting polymorphic DNA bands. By using 20 mer sequence derived from the bacteriophage T3 promoter region, Kubota et al.⁶⁾ reported the detection of 3 -ray-induced DNA damage in the Japanese medaka. They obtained DNA-fingerprinting of fish genomic DNA, but the numbers of PCR products were still small, presumably due to the longer length of the arbitrary primer used in their study.

In conclusion, RI-based PCR is a very sensitive method to detect a very low DNA polymorphism. This method is rather

laborious and requires the use of radioisotope-labeled compounds in contrast to conventional RAPD analysis. However, the system consisting of a denaturing polyacrylamide enables to detect a difference of even one nucleotide. When conventional RAPD is not adequate for distinguishing a DNA band profile of PCR products, RI-based RAPD method would be a suitable alternative to detect polymorphic DNA.

Gamma-Ray-Induced Mutation Breeding in Fruit Trees: Breeding of Mutant Cultivars Resistant to Black Spot Disease in Japanese Pear

Toji YOSHIOKA, Tetsuo MASUDA* ¹, Kazuo KOTOBUKI* ², Tetsuro SANADA* ³ and Yuji ITO

Institute of Radiation Breeding, National Institute of Agrobiological Resources (NIAR)
(Ohmiya, Ibaraki, 319-2293 Japan)

Abstract

Black spot disease, caused by *Alternaria alternata* Japanese pear pathotype, is the most important and serious disease of the susceptible cultivars of Japanese pear. The fungus produces a host-specific toxin (AK-toxin) which is highly toxic to the susceptible cultivars. Susceptibility to this disease is controlled by a single dominant gene, and all the susceptible cultivars are heterozygous. Mutants resistant to black spot disease were induced by irradiation of susceptible cultivars with gamma-rays. Nine resistant mutants were selected from chronically irradiated 'Nijisseiki'. One of these mutants was registered as 'Gold Nijisseiki'. A resistant mutant derived from acutely irradiated dormant scions of 'Shinsui' was registered as 'Kotobuki Shinsui'. One resistant mutant, which was induced from acutely irradiated dormant scions of 'Osanijisseiki', displayed unfavorable characteristics. Four resistant mutants were selected from chronically irradiated 'Osanijisseiki'. One of them was registered as 'Osa Gold'. A list of these resistant mutants is shown in [Table 4](#). It was confirmed that all of the mutants showed an intermediate resistance to black spot disease and conferred various levels of resistance. Moreover, mutations with a higher level of resistance than that of 'Gold Nijisseiki' were induced from 'Gold Nijisseiki' by acute and chronic gamma-ray irradiation. The reason why various levels of resistance were induced could not be elucidated.

Discipline: Plant breeding

Additional key words: gamma-ray irradiation, *Alternaria alternata*, AK-toxin, intermediate resistance

(Received for publication, February 4, 1999)

Introduction

Black spot disease, caused by *Alternaria alternata* Japanese pear pathotype, is the most important and serious disease of the susceptible cultivars of Japanese pear (*Pyrus pyrifolia* NAKAI var. *culta* NAKAI), for example 'Nijisseiki', 'Shinsui' and 'Osanijisseiki'. The fungus produces a host-specific toxin (AK-toxin) which causes necrosis and permeability changes in the leaves and fruit of the susceptible cultivars^{11,17}).

Susceptibility to this disease is controlled by a single dominant gene³). It is known that the resistant cultivars are recessive homozygous and that susceptible cultivars are heterozygous for this gene.

Dominant homozygous cultivars have never been detected.

In many vegetatively propagated crops or fruit trees, natural mutations have made important contributions to breed improvement. We consider that artificial mutation breeding is an effective method for improving economic agricultural species.

To achieve this objective, induced mutation breeding of temperate fruit trees has been studied in our laboratory since 1962. Gamma-ray irradiation is a promising method to induce mutants resistant to black spot disease.

Development of selection method and selection of resistant mutants from Nijisseiki

Nijisseiki, one of the leading cultivars of Japanese pear, is known to be susceptible to black spot disease. In 1962, grafted trees of Nijisseiki were planted at a distance of 53-93 m (at intervals of 10 m) from a ^{60}Co source in a gamma-field, and were irradiated with gamma-rays chronically to induce resistant mutants.

In 1981, a twig without symptoms of the disease was detected on the tree at a distance of 53 m from the source (dose rate: 0.138 Gy/day, 20 h of irradiation). The scions from this mutated twig were grafted onto rootstocks outside the gamma-field. The resistant mutant was named $^3\text{-1-1}$. Consequently, it was confirmed that it was possible to induce resistant mutants by irradiation with gamma-rays.

Since there was no effective method for selecting mutants, other resistant mutants could not be selected. However, it is possible to test a large number of samples by treating leaf disks with a filtrate of *A. alternata* culture solution^{1,13,14}). By using this simple selection method, 4 resistant mutants ($^3\text{-1-2}$, $^3\text{-2-1}$, $^3\text{-4-1}$ and $^3\text{-5-1}$) were selected from Nijisseiki trees planted at a distance of 53-93 m from the source in a gamma-field¹).

On the other hand, young Nijisseiki trees were planted at a distance of 40-70 m (at intervals of 10 m) from the source in a gamma-field in 1983. Selection of resistant mutants was carried out together with the cutting back pruning method¹⁰). Four resistant mutants ($^3\text{-A-1}$, $^3\text{-B-1}$, $^3\text{-C-1}$ and $^3\text{-C-2}$) were selected from these trees^{13,14}).

Fig.1. Appearance of black spot symptoms on crude AK-toxin treated leaf disks from 1st to 5th leaves of the shoot tip (upper to lower)
Left to right: Chojuro, Nijisseki and³-1-1(2 lanes each).

The leaf disks from young leaves of these mutants showed a small necrotic area by treatment with AK-toxin, although no necrosis was observed on the resistant cultivars¹⁵⁾ (***Fig. 1***). It became obvious that all of the 9 mutants showed an intermediate resistance between resistant and susceptible cultivars.

Registration of a new cultivar 'Gold Nijisseiki'

In 1986, local adaptability tests of ³-1-1, the first resistant mutant from Nijisseiki, were conducted at the National Institute of Fruit Tree Science, MAFF (Ministry of Agriculture, Forestry and Fisheries), and at 27 prefectural horticultural research stations in various pear-growing districts of Japan.

Although ³-1-1 is seldom infected with *A. alternata* in the field, very young leaves in the early growth stage and leaves on secondary growth shoots are slightly more susceptible to the disease. Many uninfected leaves remained on the tree even in late autumn, in contrast with Nijisseiki, in which all the leaves were infected at that time.

³-1-1 bears many fruit spurs and maintains them easily, though there are relatively few axillary flower buds. The flowers are white, and most of them have 5 petals. The flowering time is medium to late. The fruit weighs about 300-350 g. The skin of the fruit is yellowish green at early maturity, and becomes yellow at late maturity. Many russets occur on the skin when the fruit is cultivated without paper bagging. All of these characteristics, except for the slightly later fruit ripening time, are the same as those of Nijisseiki²⁾ ([Fig. 2](#)).

Based on the results obtained, ³-1-1 was designated as cultivar Gold Nijisseiki and registered as 'Pear Norin No. 15' by MAFF on June 22, 1990*. Also it was registered as 'No. 2,932' under the Seeds and Seedlings Law of Japan on December 16, 1991.

Selection of resistant mutants from Shinsui and Osanijisseiki

Shinsui is a russet type pear cultivar whose fruit ripens earlier than that of 'Kosui' and is sweet and rich. Osanijisseiki, an excellent cultivar with a smooth skin, is a self-compatible spontaneous bud sport of Nijisseiki. Both cultivars are susceptible to black spot disease. Since 1987, the Institute of Radiation Breeding, NIAR, in collaboration with Tottori Horticultural Experiment Station, has carried out research on radiation breeding for the selection of mutants resistant to black spot disease from these 2 susceptible cultivars by using acute or chronic gamma-ray irradiation.

By using acute irradiation in a gamma-room, dormant scions were irradiated to a total exposure of 60 and 80 Gy at a dose of 2.5 Gy/h. Irradiated dormant scions were top-grafted onto mature trees of Japanese pear. By using a convenient selection method, one mutant resistant to black spot disease (IRB 502-11T) was selected from 5,736 leaves of 'Shinsui' tested ([Table 1](#), [Fig. 3](#)).

Additionally, one resistant mutant (IRB 502-12T) was selected from 5,762 leaves of Osanijisseiki tested⁹⁾ ([Table 2](#)). These results demonstrate that the development of mutants resistant to black spot disease is possible not only through chronic irradiation but also through acute irradiation. In IRB 502-12T, a resistant mutant from Osanijisseiki, chlorosis of leaves and dwarfing of leaf were clearly observed⁵⁾. These findings suggested that the frequency of unfavorable mutations induced together with desirable mutations by acute irradiation is much higher than that by chronic irradiation.

For chronic irradiation, nursery trees of Shinsui and Osanijisseiki were planted in a gamma-field at distances of 45-75 m and 40-70 m from the source, respectively, at intervals of 10 m. Screening tests

using the cutting back pruning method¹⁰⁾ and a convenient selection method were carried out. Four buds which sprouted were selected as resistant mutants (IRB 502-13T, -14T, -17T and -18T) from a total of 12,596 shoots of Osanijisseiki tested ([Table 3, Fig. 4](#)). All of these mutants were derived from the tree planted at a distance of 40 m from the source (dose rate is about 14 mGy/h)^{5,6)}. Resistant mutants from chronically irradiated Shinsui could not be selected.

All of these mutants, obtained 653y both acute and chronic irradiation, showed intermediate resistance to black spot disease, in the same way as 9 resistant mutants induced from Nijisseiki, including Gold Nijisseiki (Figs. 3 & 4)

Registration of a new cultivar 'Kotobuki Shinsui'

In 1993, IRB 502-11T, a mutant resistant to black spot disease induced from Shinsui, was designated as 'Pear Houiku No. 2'. Local adaptability tests of the mutant were conducted at the National Institute of Fruit Tree Science, MAFF, and at 25 prefectural horticultural research stations in various pear-growing districts of Japan.

Fig.5. Fruit-bearing tree of Kotobuki Shinsui

The characteristics of Pear Houiku No. 2 are the same as those of the original cultivar Shinsui, except for the resistance to black spot disease. There were no differences between Pear Houiku No. 2 and Shinsui in the tree configuration and fruit characteristics (Fig. 5). Based on these results, Pear Houiku No. 2 was designated as Kotobuki Shinsui and registered as 'Pear Norin No. 18' by MAFF on August 21, 1996*. Also it was registered as 'No. 5,436' under the Seeds and Seedlings Law of Japan on March 7, 1997⁴⁾.

Registration of a new cultivar 'Osa Gold'

The scions from a twig of IRB 502-13T, one of the resistant mutants induced by chronic irradiation with gamma-rays, were grafted onto rootstocks outside the gamma-field. The characteristics of IRB 502-13T were compared with those of the original Osanijisseiki. Shoot and leaf characteristics of IRB 502-13T were similar to those of Osanijisseiki. Flower characteristics, including self-compatibility, of IRB 502-13T were also the same as those of Osanijisseiki. The fruit characteristics of IRB 502-13T were similar to those of Osanijisseiki⁶⁾ ([Fig. 6](#)).

Based on these results, IRB 502-13T was designated as cultivar Osa Gold and registered as 'No. 5,620' under the Seeds and Seedlings Law of Japan on July 15, 1997⁷⁾*.

Selection of 'Super Gold' family lines

All the 9 resistant mutants induced from Nijisseiki by gamma-ray irradiation showed an intermediate resistance between resistant and susceptible cultivars. It was obvious that this character was inherited¹⁶⁾. Therefore, selection of mutants with a high level of resistance to black spot disease was performed by

gamma-ray irradiation of Gold Nijisseiki. By acute irradiation in a gamma-room, 4 mutants (IRB 502-20-23) with a high level of resistance were selected. By chronic irradiation in a gamma-field, 2 mutants (IRB 502-24 and -25) were selected^{8,18}. They were designated as 'Super Gold' family lines.

Investigation of the necrotic area resulting from AK-toxin treatment revealed that although these 6 mutants with a high level of resistance were clearly more resistant to black spot disease than Gold Nijisseiki, they still exhibited only an intermediate resistance¹⁸ ([Fig. 7](#)).

To estimate the resistance levels of these mutants to black spot disease, sensitivity to AK-toxin was tested based on the toxin-induced electrolyte loss from leaf tissues¹². The rate of increase of the electrolyte loss derived from AK-toxin for Gold Nijisseiki compared with deionized water was considerably lower than that for Nijisseiki. Toxin-induced losses of electrolytes for 'Super Gold' family lines were clearly lower than that of Gold Nijisseiki¹⁹. Moreover, differences in toxin-induced loss rates were confirmed among the 'Super Gold' family lines ([Fig. 8](#)).

We could not clearly determine why the induced mutants conferred various levels of resistance to black spot disease. It will be interesting to address this problem through further investigations. The 'Super Gold' family lines, including Gold Nijisseiki, will be good materials for studies of the mechanisms of the resistance function of host-specific toxin and mutation induction by gamma-ray irradiation.

Abstract

The objective of this study was to increase the productivity of soybean seeds by the application of controlled release nitrogen fertilizers (coated urea). Based on the results obtained in field experiments carried out for 3 years (1989-1991), deep placement of coated urea consistently enabled to increase the seed yield by about 10-20% over the conventional treatment. Deep placement of coated urea did not depress the N₂ fixation activity throughout the growth stages until maturity, though N from fertilizer was actively absorbed. The basal deep placement of coated urea for soybean cultivation enabled to supply N from the lower part of roots without concomitant depression of N₂ fixation, and consequently seed yield increased. High recovery rate (over 60%) of fertilizer N was also advantageous from economical viewpoints.

Discipline: Soils, fertilizers and plant nutrition/Crop production
Additional key words: N₂ fixation, ureide, root growth, Rb uptake

Introduction

Soybean is the most important leguminous grain crop used by human beings and livestock as food or feed, respectively, worldwide. In Japan there are many traditional soybean products, such as 'tofu,' 'miso,' soy sauce, 'natto' (fermented soybean), etc. Soybean seeds are useful materials for the food industry, because they are very rich in oil and protein with a good nutritive value.

Soybean plants require a continuous supply of a large amount of N for maximum seed yield, and N is generally derived from 3 sources under field conditions; from symbiotic N₂ fixation by root nodules, from N absorbed from soil mineralized N and from fertilizer. In spite of the high demand for N, a large supply of N fertilizer markedly depresses nodule development and N₂ fixation activity, resulting in the reduction of the seed yield.

In Niigata Prefecture, about 80% of the soybean plants are cultivated in upland fields converted from drained rice paddy fields. The fields consist mostly of clayey Gray soil, and adverse soil conditions such

as poor water drainage lead to a low average soybean seed yield of 1.3 Mg ha^{-1} . On the other hand, the contribution of N_2 fixation is estimated to be relatively high in soybean plants cultivated in drained paddy fields in Niigata, and about 60-80% of total accumulated N in shoot originates from fixed N_2 .

In the present studies, a new technique consisting of deep placement of coated urea fertilizer has been developed to obtain high yield, efficient fertilizer utilization, and high N_2 fixation activity^{6,8,14}).

Materials and methods

1) Cultivation

Soybean *Glycine max* (L.) Merr. cv. Enrei plants were grown in an upland field converted from a drained paddy field of Niigata Agricultural Experiment Station. Seeds were sown on May 31-June 4, in 1989-1991. The seeds were stripe-sown at a density of 8.9 seeds m^{-2} (15 x 75 cm) by single stem training. Cultivation method was applied according to the guidebook for soybean cultivation published by Niigata Prefecture. Main operation sequence was as follows: fertilization'tillage; harrowing'herbicide application'seeding-intertillage; earthing up (late in June^early in July). Agricultural chemicals were spread 2 or 3 times to control the insect pests.

The terminology of the reproductive stages followed that reported by Fehr and Caviness¹). Corresponding description with the stage numbers was as follows: R1, beginning of bloom; R3, beginning of pod development; R5, beginning seed of development, R7, beginning of maturity; R8, full maturity.

2) Field conditions

The experimental field had been converted from a paddy field in the previous year. The soil was a fine-textured Gray Lowland soil. Chemical properties of the soil were as follows: texture, clay loam; pH (H_2O), 7.1; CEC ($\text{cmol}(+)\text{kg}^{-1}$), 31.3; total carbon content ($10^{-2} \text{ kg kg}^{-1}$), 1.0; total nitrogen content ($10^{-2} \text{ kg kg}^{-1}$), 0.11; C/N, 9.1; amount of mineralized N determined by the incubation of air-dried soil under upland conditions for 4 weeks at 30 ($10^{-7} \text{ kg kg}^{-1}$), 4.8.

3) Fertilizer application

Fertilizer application is outlined in [Table 1](#). Three treatments were designed as follows:(a) control, basal dressing of ammonium sulfate (16 kg N ha^{-1});(b) deep placement, basal dressing of ammonium sulfate (16 kg N ha^{-1}) and deep placement of coated urea,100-day type (100 kg N ha^{-1}); (c) top dressing, basal dressing of ammonium sulfate(16 kg N ha^{-1}) and top dressing of coated urea,70-day type (100 kg N ha^{-1}). In addition, phosphorus and potassium fertilizers were supplied as basal dressing for all the experimental plots ($60 \text{ kg P}_{2}\text{O}_5 \text{ ha}^{-1}$, $80 \text{ kg K}_2\text{O ha}^{-1}$), respectively. Each treatment was triplicated in randomized plots.

Two types of coated urea fertilizer were supplied by Chisso-Asahi Co., Ltd., namely the 100-day type of coated urea was used for the deep placement and 70-day type of coated urea for the top dressing treatment, which require 100 days and 70 days to release 80% of N by incubation in water at 25, respectively.

The deep placement of coated urea was carried out using the fertilizer injector ([Fig. 1a](#)) devised by Shioya (1985) or a fertilization machine ([Fig. 1b](#)) produced by Niigata Agric. Exp. Stn. on an experimented basis in 1991. Fertilizers were injected just under the seed-placement lines at a 20 cm depth along the ridges. Top dressing of 70-day type coated urea was carried out just before the flowering stage. In the control treatment, N 16 kg ha⁻¹ (NH₄)₂SO₄ was supplied as basal application.

Effect of deep placement

The accumulation of dry matter and total N content in shoot were always the highest in the plants with the deep placement treatment at R7 stage ([Table 2](#)). On the other hand, in the top dressing treatment, the amount of N accumulated from the R3 to R7 stages was lower than in the deep placement treatment (Table 2). Consequently, the seed yield in the deep placement was 4.17-5.92 Mg ha⁻¹, surpassing that in the control (3.73-4.80 Mg ha⁻¹) and the top dressing (3.59-5.32 Mg ha⁻¹) treatments ([Table 3](#)).

The promotive effect of seed yield by the deep placement was analyzed from the characters in the shoots at the R8 stage. Since the number of pods per node of the plants with deep placement was higher than in the control ones, total pod and seed number increased by deep placement ([Tables 3, 4](#)).

The average seed size expressed as 100-seed weight shown in Table 3 indicates that the seed size in the deep placement was larger than or the same as that of the control or top dressing treatments. The chemical composition of seed such as, protein, oil, carbohydrates, minerals, etc., was almost similar among the treatments⁶⁾. Therefore, the seed quality was not lower in deep placement of coated urea.

Evaluation of N₂ fixation

A modified relative ureide method has been employed for the estimation of the proportion of plant N derived from N₂ fixation by analyzing the N content of ureides, nitrate, and amino N in xylem sap collected from root bleeding xylem sap³⁾. We used the relative abundance of ureide-N (ureide-N/(ureide-N + NO₃-N + amide-N)) as an indicator for the relative dependence on N₂ fixation, based on the fact that the major part of fixed N₂ is transported in the form of ureides⁴⁾, whereas the transport forms of absorbed N from soil and fertilizer N, were mainly nitrate, amino acids, and amides⁵⁾. We compared the "relative ureide-N method" with the conventional "N-balance method" using nodulating (T202) and non-nodulating (T201) isolines grown in the field, and the results suggested that the relative ureide method is a useful technique for estimating the current ratio of N derived from N₂ fixation versus the total N assimilation⁹⁾.

By using the relative ureide method we obtained the following results ([Fig.2](#)). Top dressing treatment depressed the N₂ fixation activity during the maturation stage (R5-R7) and the N absorption rate was higher than that of the control plants. On the other hand, deep placement of coated urea did not depress the N₂ fixation activity throughout the growth stages until maturity, although active N absorption from fertilizer was confirmed by the ¹⁵N tracer experiments. The N recovery rate in the plants with deep placement of coated urea was about 62%, a value much higher than that of the plants with top dressing of coated urea (33%) at the R7 stage ([Table 5](#)).

Root growth and activity

The effects of placement of coated urea fertilizer on the root growth and activity were investigated by measuring the root dry weight and Rubidium (Rb) absorption activity (Figs. 3, 4). Alternatively ^{32}P and Eu tracer have been used to study the root activity. However these methods are expensive and require a special equipment for analysis.

Fig.4. Amount of Rb uptake depending on the cultivarsts, and depth of Rb injection

Recently Rb has been used in field studies as a convenient tracer and some reports were published²⁾. We employed the Rb tracer method to measure the moisture uptake activity and the root density.

Fig.4

Control Deep placement Top dressing

The results shown in Fig.3 suggested that the deep placement of coated urea promotes the growth of roots, especially during the reproductive stages (R1-R7). Also top dressing treatment slightly enhanced the root growth.

When Rb was injected at a 10 cm depth in soil, the total amount of Rb accumulated in the plants was larger in the sequence of control<deep placement<top dressing. On the other hand, the amount of Rb accumulated from an area at a 25 cm depth was always the largest in every variety subjected to deep placement of coated urea followed by the top dressing treatment. Consequently, it was considered that deep placement of coated urea exerts a beneficial effect on the growth of soybean plants, where the extended roots are able to absorb moisture from deeper areas and drought can be avoided. Moreover, it is possible that deep placement of coated urea does not exert a harmful effect on nodule development especially those located near the surface layer.

Behavior of fertilizer-N in soil

The behavior of fertilizer-N in soil was investigated in order to analyze the effect of deep placement of

coated urea. At the same time, the deep placement technique was evaluated to prevent groundwater pollution by NO_3^- originating from fertilizer-N.

Theoretically, more than half of the amount of N should be released from deep placement of coated urea during the first half of the growth period in soybean plants ([Fig. 5](#)). Fertilizer-N was mainly absorbed during the latter half of the growth period as revealed by the ^{15}N tracer experiment ([Table 5](#)). The time lag of the absorption was due to ammonium adsorption and accumulation in soil released from fertilizer N^{14} (data not shown). Although the eluted urea was rapidly hydrolyzed to ammonia by urease activity in soil, the NH_4^+ -N could not be easily nitrified owing to the low activity of nitrification in the deep layers of soil ([Fig. 6](#)). And the adsorbed NH_4^+ -N on the negative electric charge of clayey soil was absorbed effectively by the roots in deep layers. As a result, soybean plants could absorb N during the maturation stage when soybean required a large amount of N for seed production. Then, the absorbed N contributed effectively to the increase of soybean yield.

When the 70-day type of coated urea was applied in surface layers, the fertilizer-N was easily converted to NO_3^- -N due to the high activity of nitrification in the surface soil, and eluviated from the rhizosphere soil in the NO_3^- form⁸ (data not shown).

Several advantages of deep placement of coated urea include the high recovery rate of fertilizer-N by crop plants and prevention of groundwater pollution originating from fertilizer-N.

Application in farmer's field

The deep placement technique was applied in a farmer's field. In 1993 soybean plants sustained damage from extremely cold weather and wet injury. However the seed yield in the case of deep placement of coated urea increased by 22% over that in the conventional treatment. As a result, due to deep placement of coated urea, the farmer's income increased by 43% compared with conventional fertilization. The increased income associated with a higher seed yield compensated for the cost of coated urea and fertilization machine.

Conclusion

Deep placement of coated urea with whole layer basal dressing of ammonium sulfate enabled to increase the soybean seed yield by about 10-20% over that by the conventional whole layer basal dressing of ammonium sulfate. The promotive effect of deep placement on seed yield was due to the lack of depression of N_2 fixation throughout the growth stages, and to the active absorption of fertilizer-N. The N recovery rate in the plants with deep placement of coated urea was about 62%, a value much higher than that of the plants with top dressing (33%) at the R7 stage. We confirmed that the deep placement of coated urea exerted a beneficial effect on the growth of deeper roots based on the Rb tracer experiment. Although the urea released from coated urea was rapidly hydrolyzed to ammonia, NH_4^+ -N could not be easily nitrified owing to the low activity of nitrification in the deep soil layers. As a result, soybean plants could absorb the N during the maturation stage when soybean requires a large amount of N for seed production.

Resource-Recycling System for Domestic Wastewater Treatment Using Biogeofilter Ditches Planted with Useful Plants

Yasuo OZAKI

Department of Soils and Fertilizers, National Agriculture Research Center
(Tsukuba, Ibaraki, 305-8666 Japan)

Abstract

It is necessary to develop an energy-saving and resource-recycling system for water purification in rural and mountainous areas. This paper outlines the development of a resource-recycling system for water purification. The purification system consisted of a combination of anaerobic/aerobic treatment plant and biogeofilter (BGF) ditches filled with zeolite and Kanuma soil as bed filter materials. The BGF ditches were planted with useful aquatic and terrestrial plants. The average rates of total nitrogen (T-N) and total phosphorus (T-P) removal by the aquatic plants were $1.34 \text{ g m}^{-2} \text{ d}^{-1}$ and $0.34 \text{ g m}^{-2} \text{ d}^{-1}$, respectively. The water purification system decreased the average T-N concentration to 0.31 mg L^{-1} and average T-P concentration to 0.22 mg L^{-1} from domestic wastewater in summer. The useful plants planted in the BGF ditches grew vigorously and produced more fruits indicating that the secondary effluent of the domestic wastewater contains essential nutrient elements. Thus, the use of this effluent for water culture of useful plants enables to purify the domestic wastewater and is also an effective means of nutrient recycling.

Discipline: Agricultural environment/Horticulture

Additional key words: domestic wastewater purification, nitrogen, phosphorus

1...13): [References](#)

(Received for publication, February 9, 1999)

Introduction

The nitrogen (N) and phosphorus (P) contained in domestic wastewater have recently been the major causes of water pollution in semi-closed water bodies such as Kasumigaura Lake. Until about 1955, human feces and urine were mostly returned to farmlands and used as valuable manure resources⁸). As a result, the water of rivers and lakes remained clear and a large number of species of organisms were able to live there, while children were provided with areas to observe nature, play, fish, and engage in other recreational activities.

Based on previous basic studies^{3,5-7,12,13}), the researchers of the Water Quality Control Laboratory constructed on an experimental basis biogeofilter (BGF) ditches filled with filtering materials and planted with useful plants^{1,2,9-11}). These ditches can effectively use the adsorbing and filtering function of filtering materials, nutrient-absorbing function of plants, and water-purifying function of

microorganisms. Using BGF ditches, the Laboratory has developed a resource-recycling water purification system for rural and mountainous areas. This BGF ditch is not costly and functions as an energy-saving wastewater treatment system suited to rural areas.

Characteristics and operation of BGF ditches

The resource-recycling water purification system consisted of a combination of anaerobic/aerobic treatment plant and 2 BGF ditches 0.4 x 19.5 x 0.4^H m in size. The BGF ditches were filled with zeolite and Kanuma soil as bed filter materials. The Kanuma soil is one of the volcanic ash soils rich in allophane. The packing height of the filtering materials in the ditch could be adjusted according to the moisture tolerance of plants ([Fig. 1](#)). In this way, vegetables, and other useful terrestrial plants could be used for water purification purposes. As an example, in the ditch where some terrestrial plants were planted, the filtering material was packed up to a height of about 10 cm above the water level.

The water purification experiment was initiated in October 1993 using the domestic wastewater effluent from a family of five. The amount of wastewater was about 1 m³ per day with 40 to 60 mg L⁻¹ total N (T-N) and 4.5 to 7.0 mg L⁻¹ total P (T-P). The domestic wastewater was treated in the combined anaerobic/aerobic treatment plant (Kirin Machinery Corp. Type KY-N7A) and introduced into the adjustment tank. Then the treated water was pumped to the BGF ditches at a rate of 30 to 45 L h⁻¹, which was measured by an instantaneous and integrating flowmeter. The amount of water flowing out of the ditches was measured by using tipping-water flowmeters ([Fig. 2](#)). Influent, water running in the ditch and effluent were sampled at least once a week and analyzed to evaluate the changes in the water purification function. The useful plants were replaced with new ones when they almost lost their nutrient-absorbing function after they had flowered and fruited.

Comparison of water purification function between a ditch with terrestrial plants and a ditch with aquatic plants

[Fig. 3](#) shows the results of the water purification experiment in which terrestrial plants were grown in the first ditch (H ditch) while aquatic plants were grown in the second ditch (M ditch) in August 1996. In the M ditch planted with swamp cabbage (*Ipomoea aquatica* Forsk) and Chinese arrowhead (*Sagittaria sagittifolia* L.), the average reduction of the T-N concentration in the water was 12.7 mg L⁻¹. On the other hand, in the section of papyrus (*Cyperus papyrus* L.), the average decrease in the T-N concentration was 5.2 mg L⁻¹ while only 1.9 mg L⁻¹ in the section of rice (*Oryza sativa* L.). As a result, the average T-N concentration of effluents was 0.46 mg L⁻¹. In the H ditch, the concentration decreased roughly at the same rate when the water ran down to the end of the ditch. The T-N level of the effluents was reduced to 0.80 mg L⁻¹. The roots of the terrestrial plants reached only an area of about 10 cm below the water surface while the roots of papyrus, swamp cabbage and other aquatic plants reached the ditch bottom and displayed a much higher water purification function.

Fig. 4. shows the growth conditions of the plants cultivated in the BGF ditches. Tomato (*Lycopersicon esculentum* M.) plants produced more fruits while swamp cabbage, Chinese arrowhead grew very well. Kenaf (*Hibiscus cannabinus* L.) and papyrus planted in the rear of the ditches grew to a height of more than 2.5 m high. [Fig. 5](#) shows the growth stages of papyrus planted in the last section of the 7.3 m long M ditch.

The height of papyrus was 2.5 m in the upper part of the section but only about 1.2 to 1.5 m in the lower part. The plant growth decreased further when the growth of swamp cabbage and Chinese arrowhead planted in the upper ditch increased from mid-July to mid-September. This trend indicates that the papyrus in the upper part might have absorbed most of the nutrients from the influents. As shown in Fig. 3, the T-N concentration of the water in the lower part of the section was 0.2 to 0.3 mg L⁻¹, probably corresponding to the plants' critical purification function.

Simultaneous removal of T-N and T-P using zeolite and Kanuma soil

The changes in the T-N concentration of the effluent in the M ditch, in which zeolite and Kanuma soil were used as bed filter materials, and in the H ditch, in which only zeolite was used, are shown in [Fig. 6](#). Transplanting was performed from April 20 to May 20. Aquatic plants such as swamp cabbage, Chinese arrowhead, taro (*Colocasia esculenta* S.C.) and papyrus were planted in the M ditch while terrestrial plants such as tomato, basil (*Ocimum basilicum* L.), mint (*Mentha* spp.) and kenaf were planted in the H ditch. The initial 5 mg L^{-1} T-N concentration of the effluent from the H ditch decreased to 0.4 mg L^{-1} when the growth rate of the terrestrial plants increased markedly at 6 weeks after planting. On the other hand, T-N concentrations of the effluent from the M ditch ranged from 0.21 to 0.54 mg L^{-1} .

The T-P concentration of the effluent from the H ditch ranged from 1.10 to 4.69 mg L^{-1} while in the M ditch, from 0.01 to 1.63 mg L^{-1} ([Fig. 7](#)). [Tables 1 and 2](#) indicate the total N and P contents of the effluents from the M ditch in summer. From August to September, the total N and P concentrations were lower than those corresponding to the environmental water quality standards (T-N $\leq 0.4 \text{ mg L}^{-1}$, T-P $\leq 0.03 \text{ mg L}^{-1}$) in Kasumigaura Lake⁴). Swamp cabbage, taro, tomato and garland chrysanthemum (*Chrysanthemum coronarium* L.) planted in the Kanuma soil showed similar growth rates to those when planted in zeolite. Moreover, no evidence of micronutrient deficiency symptoms was observed. Especially, the height of the taro plants was 2.3 m and the yield was 22 kg m^{-2} ([Fig. 8](#)).

Applications of the BGF ditch system

The members of the family who evaluated the resource recycling system using BGF ditches, reassessed their previous lifestyle and paid much attention to the cycle of resources. Since they voluntarily stopped using chemical pollutants such as bleach and synthetic detergents, the water from their BGF ditches became very clear and odorless. In the fish culture pond to which the water was discharged, fishes like killifish, loach and goldfish started breeding and dragonfly larvae and frogs built their habitat, creating an ecosystem similar to that of a natural pond.

Fig.9. Tomato harvest in BGF in ditch (August 1996)

The family ate tomato (Fig. 9), taro, swamp cabbage, garland chrysanthemum, radish (*Raphanus sativus* L.), and other crops grown in the ditch. The family also enjoyed a bath using the herbs harvested from the ditches. Moreover, in their papermaking classes, the pupils of the elementary schools in Tsukuba, Ibaraki Prefecture, became interested and tried to make paper out of the papyrus cultivated by the BGF ditch system.

In addition to the water purification function, the BGF system could supply the following functions:

1. Domestic waste water facilities for rural communities to provide parks with water amenities and areas to enjoy the waterside;
2. Facilities for islands and arid areas to recycle water resources and essential nutrient elements;
3. Horticultural facilities to efficiently use fertilizer resources and provide people with places for enjoying recreational and other activities;
4. Facilities for households to use home gardens, flower beds, and hedges;
5. Facilities for schools, nurseries, and similar establishments to provide children with areas for environmental education and nature observation; and
6. Facilities for hospitals, schools for handicapped children, homes for senior citizens and for providing patients and others with areas for herbal therapy.

Conclusion

This study showed that domestic wastewater treated in a combined anaerobic/aerobic treatment plant became an excellent liquid fertilizer with a balanced nutrient composition. Consequently, by using this liquid for water culture of vegetables and useful plants, the natural cycle of resources and water purification could be achieved simultaneously.

The rapid population growth and increase in human activities today generate environmental issues. Population problems are not only due to food and agriculture production but also to the person's lifestyle including eating habits. For nature and human beings to coexist in a harmonious community, it is necessary to change the way of life into a more eco-friendly one.

Determination and Simulation of Soil Moisture Dynamics in Upland Fields in the Cerrados Area (Brazil)

Kazuhiko OHBA

Department of Agro-Environmental Management, Kyushu National Agricultural Experimental Station (Nishigoshi, Kumamoto, 861-1192 Japan)

Abstract

The objective of the studies was to analyze the soil moisture dynamics of upland fields in the Cerrados area of Brazil. Soil moisture level obtained by using tensiometers set in the soil layers was compared with the soil moisture dynamics simulated by the TANK-model. It was found that the actual soil moisture dynamics agreed well with the simulated results, suggesting that the TANK-model could be used to predict the soil moisture dynamics of upland fields based on meteorological and soil property data.

Disciplines: Agro-meteorology, Irrigation, drainage and reclamation

(Received for publication, February 9, 1999)

Introduction

The Cerrados of Brazil account for about 21% of the total land area ($850 \times 10^4 \text{ km}^2$). The annual mean temperature ranges between 22 in the southern part and 27 in the northern part. The monthly mean temperature at CPAC (Centro de Pesquisa Agropecuaria dos Cerrados) located in the center of this area ranges from 26.7 in October to 17.7 in July. Although the annual precipitation in this area is known to be in the range of 1,200~1,800 mm, 90% is concentrated in the warm rainy season from October to April. However, this warm rainy season is often interrupted by a relatively longer dry spell called "Veranico." During the remaining period of the year, the weather is dry with little precipitation.

Therefore, crop cultivation in this area is strongly affected by hydrological conditions as mentioned above. Major techniques for improving and stabilizing crop production in the area aim at the development of irrigation practices appropriate to the natural and farming conditions of this area, selection and cultivation of crop species and/or cultivars with higher drought resistance, and development of cropping systems suitable for the annual hydrological conditions.

The data on soil moisture dynamics play an important role in developing more appropriate farming systems in this region with a relatively longer dry spell. For this reason, several researchers^{3,7,9,10)} have studied the seasonal and geographical changes of potential and actual evapotranspiration in the Cerrados area. However, research on the soil moisture dynamics of crop fields in this area is too limited to enable

the development of farming systems appropriate to the climatic conditions.

Modelling of waterbalance of upland fields

Data on soil moisture dynamics in surface soil layers (root zone) are very important to determine the initial and final time of application of irrigation water into crop fields. These data play also an important role in preventing the occurrence of nitrogen pollution of the soil in the root zone and shallow groundwater caused by long applications of nitrogen fertilizer.

Several methods have been applied to study the soil moisture dynamics in upland crop fields^{8,11,12}). In this paper, the TANK-model developed by Ohta et al. (1990)⁸), which was originally designed to predict evapotranspiration and the soil moisture level in upland fields consisting of Kanto loam, was applied to simulate the soil moisture dynamics in upland fields in the Cerrados area.

As shown in [Fig. 1](#), the TANK-model consists of 5 tanks and a groundwater tank. The first tank corresponding to the first surface soil layer has 2 holes (e_0 and e_1) for water evaporation, one hole (P_1) for deeper percolation of water, and one hole (r_1) for surface runoff of precipitation. Each tank from the second tank to the fifth one has, respectively holes (E_1, E_2, E_3, E_4, E_5) for rupture of capillary water rise and holes (P_2, P_3, P_4, P_5) for deep percolation of water. The 2 holes for evaporation of the first tank mentioned above were utilized to simulate the following 2 stages of evaporation of water¹): first evaporation hole (e_0) simulates the constant-rate stage of evaporation, and second evaporation hole (e_1) simulates the falling-rate stage of evaporation.

The water balance in the first tank is mathematically represented in Fig. 1, by the following equations:

$$H_1 = S_{10} + R_0 \text{ ----- (1)}$$

$$Q = (H_1 - P_0) \times r_1 \text{ ----- (2)}$$

$$ET = (H_1 - E_0) \times e_0 + (H_1 - E_1) \times e_1 \text{ ----- (3)}$$

$$F_1 = (H_1 - P_1) \times p_1 \text{ ----- (4)}$$

$$S_1 = H_1 - (Q + ET + F_1) \text{ ----- (5)}$$

In equations (1)-(5), Q , ET , and F are the surface runoff (mm/day), evapotranspiration (mm/day), and percolation (mm/day), respectively; H_1 and S_{10} are the daily retention (mm/day) and storage change in the previous day in the first tank. R_0 is the precipitation on that day (mm/day). r_1 , e_0 , e_1 , and p_1 are the coefficients of ground surface runoff, evapotranspiration, and percolation, respectively.

The water balance in the second tank can then be written as:

$$H_2 = S_{20} + F_1 \text{ ----- (6)}$$

$$MT_2 = (H_2 - E_2) \times e_2 \text{ ----- (7)}$$

$$F_2 = (H_2 - P_2) \times p_2 \text{ ----- (8)}$$

$$S_2 = H_2 - (MT_2 + F_2) \text{ ----- (9)}$$

Where MT_2 is the capillary rising water (mm/day).

As indicated previously, the water budget from the third to the fifth tank can be expressed by equations (6)^(9) in a similar way. The groundwater level is calculated from

$$H_6 = S_{60} + F_5 \text{ -----(10)}$$

$$F_6 = H_6 \times p_6 \text{ -----(11)}$$

$$Q_2 = H_6 \times r_2 \text{ -----(12)}$$

$$S_6 = H_6 - (F_6 + Q_2) \text{ -----(13)}$$

$$S_T = S_1 + S_2 + S_3 + S_4 + S_5 \text{ -----(14)}$$

Where S_6 , F_6 , Q_2 and S_T are the groundwater level (mm), groundwater percolation (mm/day), discharge of groundwater (mm/day) and sum of storage soil-water amounts, respectively. r_2 is the coefficient of discharge across groundwater movement. The subscripts 1~6 refer to the number of tanks, respectively.

The hydrological behavior of these tanks was characterized by hydrological constants as shown in each tank. These constants were estimated using experimental data on the soil-water relations in this area. The unit of calculation in the water balance was represented in terms of the water depth, and the volumetric water content corresponds to the thickness of the soil layer.

Fig.1. Schematic illustration of the TANK-model

[Back](#)

Experimental method

1) Geographical characteristics of experimental fields

[Fig. 2](#) illustrates the aerial distribution of soils and vegetation, and topographical characteristics of the experimental fields at the CPAC in Brazil. This figure was quoted from Hayasaka²⁾. As shown in Fig. 2, the experimental fields can be divided into 3 parts such as tertiary peneplain, diluvial declining slope, and alluvial deposit area. The diluvial declining slope can be furthermore classified into 3 subparts such as upper, middle, and lower parts. The most representative soil in the Brazilian Highlands is a latosol (oxisol in 4s soil Taxonomy).

However, soil types in the experimental fields ranged from red-yellow latosol on the Tertiary preneplain, through dark-red latosol in the middle subpart of the diluvial declining slope and hydromorphic soil in the lower subpart of the diluvial declining slope, to organic soil on the Alluvial deposit part.

2) Physical characteristics of vertical profiles in each pit

In Fig. 2, Pit 1, Pit 2, and Pit 3 are located, respectively, in a non-irrigated upland field with red-yellow soil on the plateau, in an orchard field with dark-red soil on the upper diluvial declining slope, and in an irrigated upland field with dark red soil on the middle diluvial declining slope.

When the soil moisture corresponded to the field capacity, solid phase of soils collected at Pit 1, Pit 2, and Pit 3 was found to range from 35 to 45% of the volume. The saturated hydraulic conductivity of these sample soils changed from 10^{-2} to 10^{-3} cm/s. The vertical profile of the soil moisture level in the sample soil columns was found to be rather even, indicating that soil water can move very freely upward and / or downward. The groundwater levels at Pit 1 and Pit 2 were about 5 m and 2 m, respectively.

Soil moisture and meteorological data and calculation method

1) Method of measurement of soil moisture

As described already, in this report, the soil moisture dynamics simulated by the TANK-model using soil hydraulic constants estimated from experimental data was compared with the soil moisture data obtained by Hayasaka in upland fields in this area (personal communication).

Fig.3. Method of measurement of soil moisture content²⁾

As shown in Fig. 3, each Pit was a rectangular solid structure with 4 sides (square) measuring each 1.2 and 5.0 m in depth. The tensiometer was set up with the pit walled in on one side. The soil moisture data at these pits were obtained using tensiometers set in the soil at an interval of 25 cm from the surface

up to a 400 cm depth. Observation data of groundwater level and soil moisture tension in upland fields of the Cerrados were continuously obtained at 3⁷ days intervals during the period between 1983 and 1985. The soil moisture could not be measured in the soil layer of the ground surface in the dry season in and after April.

Fig.3

2) Water characteristics of soils in the Cerrados

Fig. 4 shows the water content – pF curve for representative soils obtained using undisturbed soil samples (red-yellow and dark-red latosols)^{2,4,6,7)}. Using a non-linear regression analysis, it was found that the following polynomial expression could approximate the dependence of the volumetric soil moisture content (Y : %) on the pF-value (X):

$$Y = 1.07X^3 - 5.38X^2 - 5.31X + 64.76 \text{ -----(15)}$$

The above equation can be used to estimate indirectly and easily the volumetric soil moisture from data of pF-value or soil-water suction (head cmH₂O) obtained by tensiometers.

3) Simulation method of soil moisture dynamics

The quantitative water movement in the soil profile can be predicted by the optimized simulation tank model. In the model each soil layer was considered as a tank having holes at different heights representing the water balance parameters including surface runoff, deep percolation, capillary water rise and evapotranspiration. Hole heights representing the limited magnitude of the parameters were determined based on the soil physical properties, namely water constants. Hole diameters representing the coefficient of the respective parameters in the model were determined by simulating the measured

values.

The individual tanks (Pits 1 & 3) of the TANK-model corresponded to the 0~50, 50~100, 100~200, 200~300, and 300~400 cm soil layers, and Pit 2 corresponded to the 0~50, 50~100, 100~150 and 150~200 cm soil layers, respectively. In the soil layer of Pit 2, the groundwater level appeared at about 200 cm. The measurements of the soil-water suction were performed in the upland field of the campus of CPAC. The measurements of the groundwater level were performed at staff gauges in the individual experimental sites. The soil moisture dynamics was simulated by the TANK-model using meteorological data, namely air temperature, solar radiation, wind speed, humidity, data (precipitation and evaporation of class A pan) obtained at the weather station of CPAC (15°35' S, 47°42' W, SL : 1,000 m) during the period between 1978 and 1990.

Results and discussion

1) *Frequency of occurrence of "Veranico" phenomenon*

As is well known, the term "Veranico" refers to a continuous period without rainfall exceeding 6 days during the rainy season. The frequency of occurrence of the "Veranico" phenomenon was investigated using daily precipitation data obtained at CPAC during the period from 1978 to 1990. It was found that the Veranico phenomenon is most frequent during the period from December to February.

During this study, the longest duration of the Veranico phenomenon was 32 days for the period between February and March. The frequency of occurrence of the Veranico phenomenon over a 20 day period was found to be about 4 times per year. Due to the Veranico phenomenon, upland crops in this area were damaged by drought, at a frequency of once every 3 years.

2) *Application of TANK-model to the prediction of the soil moisture dynamics in upland fields*

In semiarid and arid regions with a distinct dry spell in a year, crop production is markedly affected by the amounts of soil moisture available in the root zone. Therefore, the TANK-model as described in Fig. 1 was used to simulate the soil moisture dynamics in upland fields, using each coefficient empirically estimated. The coefficients are listed in [Table 1](#). The simulation results so obtained were compared with the data on the soil moisture dynamics obtained at the individual experimental sites (Pits 1 & 2).

[Figs. 5](#) and [6](#) show the seasonal changes in related meteorological data and the amounts of soil-water stored in each soil layer at different depths. The observation data of the amounts of soil-water can be calculated by equation (15) with the mean soil-water suction obtained with a tensiometer in each soil layer. The soil moisture dynamics simulated by the TANK-model was also presented to evaluate its applicability to upland fields. Comparison between the observed and simulated results was made using the meteorological data in 1984 with little precipitation.

As shown in Figs. 5 and 6, although there was some discrepancy between the observed soil moisture (circles) and simulated soil moisture (solid lines) data, it appears that the seasonal changes in the soil moisture of the upland fields simulated by the TANK-model agreed well in general with those determined with the tensiometers.

Soil moisture dynamics (S_1, S_2, S_3, S_4) in each soil layer simulated by the TANK-model using weather data agreed well with the measured soil moisture dynamics (\ddot{E}) with an error of $\pm 10\%$. Furthermore, the estimation error for the soil moisture dynamics (S_T) in the total root zone decreased by about $\pm 5\%$.

Seasonal changes in the observed groundwater level (GWL) were found to follow those (S_6) simulated by the TANK-model.

This general agreement indicates that the TANK-model can be applied to simulate seasonal changes in the soil moisture of upland fields using data on meteorological conditions and hydraulic characteristics of soils.

The calculation of the water balance for the root zone of upland fields revealed that the maximum deep percolation of water and the maximum capillary rise of water in this experimental field were 4.0 mm/day

and 1.8 mm/day, respectively. Expected maximum capillary water rise in this field agreed well with the recovery rate of the soil moisture in volcanic ash soils (Japan) during the night¹²). The runoff ratio calculated for the upland fields during the experimental period was found to be 26.3%, with a good agreement with that obtained in flat upland fields of Japan⁵).

3) Soil moisture dynamics during the "Veranico" period

The weather data during the Veranico period in 1981 were used to analyze the soil moisture dynamics for a longer and stronger Veranico period. The soil moisture dynamics simulated by the TANK-model using Pit 1 for this period are shown in [Fig. 7](#), which indicates that soil moisture in the surface soil layer (0~50 cm) decreased very drastically with the start of the Veranico phenomenon.

That is, the soil moisture in this layer decreased from 200 mm at the beginning (Jan. 31) to 156 mm at the end (March 15), because of the very high evaporation loss of water from heated soil surface and the absence of rainfall during this period. The soil moisture at the end (March 15) was about 70% of the field capacity of soils. For this reason, the growth and yield of the soybean crop in this year were severely reduced due to the considerable shortage of available soil moisture in the root zone.

The author thanks Dr. Z. Uchijima, Miyazaki Municipal University, for the correction of this report, and Drs. T. Hayasaka, N. Kosuge and T. Morinaka for their continued support.

Analysis of the Interaction between Surface Water and Groundwater Using Radon-222

Hiromasa HAMADA

Department of Regional Resources, National Research Institute of Agricultural Engineering (Tsukuba, Ibaraki, 305-8609 Japan)

Abstract

It is essential to analyze the interaction between surface water and groundwater in order to use water effectively and predict water quality. The conventional method of analysis, however, measures only the flow of a stream and can not determine groundwater seepage accurately. Since the concentration of Radon-222 (^{222}Rn) in groundwater is much higher than in surface water, the use of ^{222}Rn was examined as an indicator for the analysis of the interaction between surface water and groundwater. Measurement of the ^{222}Rn concentration in surface water was conducted to detect groundwater seepage into a stream. Furthermore, the simultaneous movement of water both into and out of a stream from the underlying strata was quantified by solving the ^{222}Rn and water balance equations.

Discipline: Irrigation, drainage and reclamation

Additional key words: ^{222}Rn balance, water balance

● 1...5): [References](#)

(Received for publication, February 9, 1999)

Introduction

It is essential to analyze the interaction between surface water and groundwater in order to use water effectively and predict the water quality. The conventional method of analysis, however, measures only the volume of flow in a river. As a result, only the difference between groundwater seepage from the river's bed into the river and river water percolation into the underlying strata can be determined, and it is impossible to quantify both if they occur simultaneously. Therefore, since the concentration of ^{222}Rn in groundwater is much higher than in surface water, ^{222}Rn was used to develop a new method of quantifying both groundwater effluent and river water influent, even when they occurred at the same time.

Methodology

1) Characteristics of ^{222}Rn

^{222}Rn is a radioactive gas generated by the decay of ^{226}Ra in strata, with a half life of about 1600 years.

When water infiltrates the strata, ^{222}Rn concentration in water increases along with the increase of radioactivity. After ~ 3 weeks, an equilibrium is reached between the supply, from the decay of ^{226}Ra , and loss, through the decay of ^{222}Rn , which has a half life of 3.8 days. Thus, the concentration levels off. When water leaves the strata as seepage or from a spring, ^{222}Rn concentration begins to decrease, since the supply of ^{222}Rn has ceased. Thus, the concentration in the groundwater is much higher than in the surface water. It is possible to determine where groundwater seeps into a river based on the distribution of ^{222}Rn in water. Furthermore, the solution of the ^{222}Rn and water balance equations enables to analyze quantitatively groundwater effluent and river water influent.

^{222}Rn in river water is supplied both by groundwater seepage and directly from the sediments of the river bed. Since the latter is negligible, groundwater seepage, therefore, can be treated as the only source of ^{222}Rn in river water.

^{222}Rn is lost through river water infiltration, dispersion to the atmosphere and radioactive decay of ^{222}Rn . River water infiltration affects the total amount of ^{222}Rn but not the concentration. The amount of dispersion of ^{222}Rn to the atmosphere is evaluated by assuming that there is a stagnant film which is the boundary layer between water and air (Fig. 1)¹.

Fig. 1. Stagnant film

The decrease in the ^{222}Rn concentration in river water by dispersion to the atmosphere and by radioactive decay is expressed as follows:

$$C_2 = C_1 \exp(-aL) \dots\dots\dots (1)$$

$$a = (D/zhv) + \lambda/v \dots\dots\dots (2)$$

where

C_1 = ^{222}Rn concentration at an upstream station (Bq/m^3);

C_2 = ^{222}Rn concentration at a downstream station (Bq/m^3);

D = molecular diffusivity of ^{222}Rn ($1.2 \times 10^{-9} \text{m}^2/\text{s}$ at 20);

z = thickness of a stagnant film (m);

h = average depth of a stream (m);
 v = average velocity of a stream (m/s);
 λ = decay constant of ^{222}Rn ($2.08 \times 10^{-6} \text{ s}^{-1}$);
 L = distance between stations (m).

It has been reported that the thickness of a stagnant film is about $20\frac{1}{4}\text{m}$ when the distance between stations is several kilometers^{2,3}). It is, therefore, possible to calculate the ^{222}Rn loss in a stream after measuring the average depth and velocity.

The amount of ^{222}Rn supplied by groundwater is expressed by the following equation, assuming that groundwater flows into a river uniformly:

$$m = qC_g \{ 1 - \exp(-\lambda L) \} / \lambda \dots\dots\dots(3)$$

where

m = ^{222}Rn amount supplied by groundwater (Bq);

q = groundwater flux (m^2/s);

C_g = ^{222}Rn concentration in groundwater (Bq/m^3).

Using these equations, the ^{222}Rn balance equation for a stream can be derived.

2) *Measurement of ^{222}Rn*

The ^{222}Rn concentration in water was measured using a liquid scintillation counter after extraction with toluene⁵). This method utilizes the greater solubility of ^{222}Rn in toluene than in water.

In a field, sample water was poured carefully into a vessel and toluene containing scintillators (PPO 4 g/L and POPOP 0.1 g/L) was added. The closed vessel was shaken, and toluene was collected into a vial. The vials were then sent to the laboratory, and the radioactivity was counted for 50 min using a liquid scintillation counter (Packard 2250 CA for groundwater and Aloka LB-II for surface water) for 50 min. On the basis of the count rate, the ^{222}Rn concentration in groundwater was calculated after 4 corrections, i.e. background, counting efficiency, extraction rate and decay.

In the case of groundwater, 40 mL of toluene was added to 500 mL of water and toluene was collected into a 20-mL glass vial. Since the ^{222}Rn concentration in river water is lower than in groundwater, a large amount of water was necessary. In this investigation, 150 mL of toluene was mixed with 10,000 mL of river water and toluene was collected into a 100-mL Teflon vial. The detection limits were 0.04 Bq/L for groundwater and 0.004 Bq/L for river water.

3) *Field investigation*

The investigation undertaken to determine where groundwater seeped into a stream using the distribution of ^{222}Rn concentrations was carried out along a stream in Kyonan City, Chiba Prefecture in an area that had been subjected to a landslide. Downstream in this study area, it was inferred that groundwater flowed into the stream⁴). The ^{222}Rn concentration in the stream water and the volume of flow were measured at intervals of 20 m.

The investigation undertaken to quantify the groundwater effluent and river water influent was conducted in the Omoi River basin, Tochigi Prefecture. Since this area is an alluvial fan where many paddy fields are located, active exchange between river water and groundwater was expected. The ^{222}Rn

concentration in river water and groundwater, flow, water temperature and the groundwater level were measured. The investigation was carried out in June, a period coinciding with irrigation in Japan.

[-Results and discussion-](#)

[Contents](#)

Results and discussion

1. Detection of groundwater seepage into a stream

The results of the investigation in the downstream landslide area are shown in [Fig. 2](#). Since the ^{222}Rn concentration increased markedly in section 14-15, it was obvious that groundwater seeped into the stream in this section. Although the seepage increased the volume of flow in the stream, measurement of only the flow volume may be misleading. For example, in section 15-16, even though the flow volume increased, the ^{222}Rn concentration decreased exponentially. No groundwater seepage at all was detected downstream from observation point 15. Thus, measurement of the ^{222}Rn concentration in surface water enables to detect groundwater seepage more accurately than by measuring only the flow volume.

2. Quantitative between river water and groundwater

[Fig. 3](#) shows the observation points and the analytical model for the exchange between river water and groundwater. It was assumed that influent and effluent seepage was uniform since there was no change in the geology. Substituting $h=0.48$ m, $v=0.36$ m/s and $D=1.1 \times 10^{-9}$ m²/s into the Equation (2), "a" was calculated to be 0.3 km⁻¹.

The water balance is:

$$Q_2 = Q_1 + Q_g - Q_r \dots\dots\dots(4)$$

Where

Q_1 = flow at the upstream station (m³/s);

Q_2 = flow at the downstream station (m³/s);

Q_g = groundwater effluent (m³/s);

Q_r = river water influent (m³/s).

The ^{222}Rn balance is expressed as follows:

$$C_2 Q_2 = [C_1 Q_1 \exp(-aL) + C_g Q_g \{ 1 - \exp(-aL) \} / aL] (1-P) \dots\dots\dots (5)$$

$$P = Q_r / (Q_1 + Q_g) \dots\dots\dots(6)$$

Where

C_1 = ^{222}Rn concentration in river water at the upstream station (Bq/m³);

C_2 = ^{222}Rn concentration in river water at the downstream station (Bq/m³);

C_g = ^{222}Rn concentration in groundwater (Bq/m³);

L = distance between the stations (9 km).

The term (1-P) refers to river water infiltration. [Table 1](#) shows the results of the investigation. ^{222}Rn concentration is an average value. Groundwater effluent was calculated to be 1.3 m³/s and river water influent to be 4.1 m³/s.

Using only the water balance, the amount of groundwater effluent can be considered to be zero and river water influent to be 2.8 m³/s. It was shown, however, that groundwater seeped into the river, because the ^{222}Rn concentration at the downstream station was higher than at the upstream station. Therefore, the

proposed method gave more accurate results than the conventional method, in which only the water balance was calculated.

Conclusion

^{222}Rn was used as an indicator for analyzing the interaction between surface water and groundwater. Since the ^{222}Rn concentration in groundwater was much higher than in surface water, it was possible to detect groundwater seepage into a stream by measuring the ^{222}Rn concentration in surface water. Furthermore, by solving the ^{222}Rn and water balance equations, the amounts of groundwater effluent and river water influent occurring simultaneously were quantified along a section of a river flowing among paddy fields. The results obtained were more accurate than when the conventional method was used, in which only the water balance was calculated. Thus, the method using the ^{222}Rn concentration in water as an indicator is suitable for the analysis of the interaction between groundwater and surface water.

Effects of Medium Conditions on Adventitious Bud Formation in Immature Mulberry Leaves

Hiroaki YAMANOUCHI, Akio KOYAMA and Hiroaki MACHII

Department of Sericulture, National Institute of Sericultural and Entomological Science

(Tsukuba, Ibaraki, 305-8634 Japan)

Abstract

Immature mulberry leaves isolated from winter buds were cultured on MS media⁷⁾ differing in the nitrogen source, sugar(s) or pH, or containing various kinds and concentrations of plant hormones, antibiotics or a herbicide. The ratio of the concentration of nitrate ion to that of ammonium ion remarkably affected the frequency of adventitious bud formation (FABF) and ratios in the ranges of 1:1 and 3:1 were optimum. The most suitable sugars for adventitious bud formation were sucrose, glucose and fructose among the tested sugars. The highest FABF was usually observed in the medium containing 1 ¼M thidiazuron and the addition of 1 ¼M abscisic acid further enhanced FABF. Changes of pH and addition of other plant hormones did not produce better results than in the control. Kanamycin, geneticin, hygromycin and bialaphos suppressed adventitious bud formation, showing that the antibiotics and the herbicide may be effective for the selection of transgenic plantlets of mulberry.

Discipline: Biotechnology

(Received for publication, February 10, 1999)

Introduction

Stable regeneration systems of crops are important for the application of more advanced techniques, i.e. genetic transformation by introduction of foreign gene(s). First successful adventitious bud formation of mulberry was reported by Oka and Ohyama¹¹⁾, who were able to induce adventitious buds on leaves removed from shoots cultured *in vitro*. On the basis of the first report, a more convenient single-step adventitious bud induction method was developed, whereby adventitious buds were formed on cultured immature leaves isolated from winter buds of field-grown mulberry¹³⁾. It is also possible to induce adventitious buds by culturing immature leaves isolated from lateral buds (unpublished data).

Presently, immature leaves inside of winter buds or in lateral buds are the most suitable materials for use for plant regeneration through tissue culture of mulberry for 2 reasons. First, stable regeneration of plantlets was observed only when 2 materials, i.e. immature leaves and leaves of cultured shoots were used. Adventitious bud formation on cultured immature leaves^{5,7,12-15,17-19)} and leaves of cultured shoots¹¹⁾ of mulberry was reported for many cultivars by a large number of researchers. Second, a large

number of materials can be collected easily from the field. Preparation of the leaves of cultured shoots requires previous shoot culture, which is laborious and takes time as in the case of the culture of leaves from cultured shoots. In the case of immature leaves inside of terminal buds, the number of explants is limited. Only several dozens of terminal buds can be obtained from a mulberry tree grown in the field, whereas several hundreds of winter or lateral buds can be obtained from the same tree¹⁷).

This method can be applied to a limited number of mulberry cultivars (unpublished data). Although there are several reports on the improvement of this culture system^{5,7,18}), optimum culture conditions, especially medium conditions, have not been fully elucidated. In this report, we studied the optimum medium conditions for adventitious bud formation using immature leaves isolated from winter buds. Furthermore, we examined the suppressive effect of antibiotics and of a herbicide on adventitious bud formation to identify suitable one(s) for selection of transformed plants.

Materials and methods

1) Plant materials

Winter buds of mulberry (*Morus* spp. cv. Shin-ichinose, Hayatesakari, Kokuso 21, Unryu, Kyukyokusou, Kibajumonji, Garyu, Shidareguwa, Jikunashi, Ryomensou, Shinjiro, Keikansou and Turugisansou) grown in the field were used in this study.

2) Medium

(1) Effect of nitrogen sources¹⁸)

MS medium⁸) containing 3% fructose, 5¼M 6-benzylaminopurine (BAP) and 1% agar, and B5 medium³) containing 2% fructose, 5¼M BAP and 1% agar were used as basal media. The media were modified by the addition of various concentrations of nitrate ion and ammonium ion ([Table 1](#)). The media were adjusted to pH 5.8 and then autoclaved for 15 min before use.

(2) Effect of sugars

MS medium containing 10¼M BAP and 1% agar was used as basal medium. Eight kinds of sugars were tested at various concentrations alone or in combination ([Tables 2, 3](#)). The sugar(s) were added into the basal medium before or after 10 min of autoclaving ([Tables 2, 3](#)). In the latter case, a concentrated solution of sugar was added into the autoclaved medium. The medium was adjusted to pH 6.0 before autoclaving.

(3) Effect of pH

Liquid MS medium containing 10¼M BAP and 3% fructose was used as basal medium with a filter paper as a supporting material. Various volumes of 1N HCl or 1N NaOH were added into the medium before autoclaving. The medium was autoclaved for 10min followed by the measurement of the pH.

(4) Effect of cytokinins

MS medium containing 1% sucrose, 1% glucose, 1% fructose and 1% agar was used as basal medium. BAP, thidiazuron and kinetin were added before autoclaving. In the cases of 2-isopentenyladenine (2-IP) and zeatin, a concentrated solution was added into the medium after autoclaving.

(5) Effect of other plant hormones

MS medium containing 1% sucrose, 1% glucose, 1% fructose, 1¼M thidiazuron and 1% agar was used

as basal medium. 2,4-dichlorophenoxyacetic acid (2,4-D) and naphthylacetic acid (NAA) were added before autoclaving. In the cases of other plant hormones, i.e. 3-indoleacetic acid (IAA), indolebutyric acid (IBA), dicamba, gibberellin A₃, abscisic acid, brassinosteroid and methyl jasmonate, concentrated solutions were added into the autoclaved medium.

(6) Effects of antibiotics and a herbicide¹⁹⁾

MS medium containing 1% sucrose, 1% glucose, 1% fructose, 1¼M thidiazuron and 1% agar was used as basal medium. Antibiotics i.e. kanamycin, geneticin and hygromycin, and a herbicide, i.e. bialaphos, were likewise sterilized by filtering and added into the medium after autoclaving

3) Leaf culture

One-year-old elongated mulberry branches were collected in winter and stored in a refrigerator at 2.5 . The winter buds excised from the branches were sterilized with 70% ethanol for 30 s followed by 0.5% sodium hypochlorite solution containing 0.005% Triton X-100 for 15 min. Then, the sterilized materials were rinsed 4 times with sterilized distilled water. Immature leaves were aseptically isolated from winter buds and were placed on the medium. Culture was conducted at 27 under 14 h light and 10 h dark conditions for 30 days. Frequency of adventitious bud formation (FABF) was calculated as the percentage of leaves on which adventitious bud(s) were formed to the number of leaves that survived after culture.

Results

1) *Effects of nitrogen sources*¹⁸⁾

FABF was remarkably influenced by the changes in the concentration of nitrate ion and ammonium ion in the medium ([Table 1](#)). Higher FABF than 50% was observed in the medium containing 40 mM nitrate ion and 20 and 40 mM ammonium ion in series 1, in the medium containing 25, 40 and 60 mM nitrate ion and 20 mM ammonium ion in series 2, and in the medium containing 25 mM nitrate ion and 10, 20 mM ammonium ion in series 3 (Table1). When the concentration of total inorganic nitrogen was adjusted to 60 mM (series 4), higher FABF than 50% was observed in the medium containing 30-42 mM nitrate ion (30-18 mM ammonium ion). These results indicated that the ratio of the concentration of nitrate ion to that of ammonium ion was more important rather than the concentration of either ion. It was reported that the optimum ratio for adventitious bud formation of apple was in the ranges of 10:1 and 4:1²⁾. The most suitable ratio of the concentration of nitrate ion to that of ammonium ion was in the ranges of 1:1 and 3:1. As for the nitrogen source composition, original MS medium is considered to be suitable for adventitious bud formation of mulberry.

2) *Effect of sugar(s)*

Sucrose, glucose and fructose were more suitable for adventitious bud formation than other sugars ([Table 2](#)). The average length of the leaves cultured on the medium containing each one of these 3 kinds of sugars exceeded 18 mm ([Table 3](#)). No adventitious bud was observed in the leaves cultured on the medium containing mannitol (Table 2). The average length of the leaves cultured on the medium containing mannitol was shortest (Table 3). It appeared that there was a positive correlation between FABF and the average length of leaves. Meanwhile, there were no apparent differences between the average length of leaves which formed adventitious buds and the length of leaves which did not form them among the leaves cultured under the same sugar conditions (data not shown). These results mean that the sugars suitable for the growth of cultured leaf were also suitable for adventitious bud formation and that a higher frequency of adventitious bud formation was not caused by more active growth of cultured leaves. The concentrations of sucrose, glucose, fructose and mixtures for suitable adventitious bud formation were in the ranges of 2% and 4 % ([Table 4](#)).

3) *Effect of pH*

FABF did not vary appreciably among the media, except for the medium with the highest pH (7.18) in which FABF was 0% ([Table 5](#)). It seemed that adventitious bud formation of mulberry was not appreciably affected by the pH of the medium. Since a large amount of precipitation was observed in the highest-pH medium, the inhibition of adventitious bud formation at highest pH was probably caused by nutrient deficiency.

4) *Effect of cytokinins*

So far, only BAP had been used as a cytokinin for the induction of adventitious buds from immature leaves of mulberry^{5,7,11-13,17-19)}. All the 3 adenine-type cytokinins used in this study were less suitable for mulberry adventitious bud formation compared with BAP ([Table 6](#)). Thidiazuron, which is a phenylurea compound with a strong cytokinin-like activity^{4,9)} and which induced adventitious buds on the immature leaves isolated from apical buds of mulberry¹⁵⁾, induced adventitious buds on the cultured

immature leaves isolated from winter buds ([Table 7](#)). The optimum concentration of thidiazuron which was about $1\frac{1}{4}$ M was approximately 10 times lower than that of BA ([Table 7](#)). FABF was higher or similar when $1\frac{1}{4}$ M thidiazuron was used compared with $10\frac{1}{4}$ M BA in 8 of the 10 cultivars examined, although the reverse was observed in 2 cultivars ([Table 8](#)).

5) Effect of auxin, gibberellin A₃, abscisic acid, brassinosteroid and methyl jasmonate

The effect of auxin on FABF was not beneficial ([Table 9](#)). High concentrations of auxin suppressed adventitious bud formation and induced callus, except for IAA ([Tables 9, 10](#)). Addition of $1\frac{1}{4}$ M abscisic acid promoted adventitious bud formation ([Table 11](#)). FABF was not significantly affected by gibberellin A₃, brassinosteroid and methyl jasmonate ([Tables 12, 13](#)).

6) Effect of antibiotics and a herbicide¹⁹⁾

All the antibiotics and the herbicide used in this study suppressed adventitious bud formation ([Table 14](#)). It was observed that precultured explants were more highly resistant to the antibiotics and the herbicide than the non-precultured ones. However, total suppression of adventitious bud formation was observed in the medium containing the highest concentration of geneticin, hygromycin and bialaphos even in the case of precultured conditions.

Discussion

In a previous paper⁶⁾, successful genetic transformation of mulberry by *Agrobacterium* Ti-plasmid was reported, but the frequency was low. One possible modification for improving the mulberry transformation system is to increase the selection efficiency of the transformed organs. In this report, investigations were carried out to determine whether the genes that inactivate geneticin, hygromycin and bialaphos could be used as selection marker genes. Another possible modification is to improve the tissue culture system. We showed that the frequency of adventitious bud formation varied with the medium conditions. It may be important to analyze the physiological and molecular biological events that occur during the process of adventitious bud formation.

Callus was induced most efficiently on the medium that did not contain ammonium ion¹⁰⁾, on which no adventitious buds were formed. It is interesting to note that the optimum ratio of nitrate ion to ammonium ion for callus induction of mulberry was different from that of adventitious bud formation, which suggested that metabolic alterations affect directly or indirectly adventitious bud formation.

The kind of sugar rather than the concentration affected FABF. High FABF was observed in the medium containing sugar(s) that promoted vigorous growth of leaves, which indicates that metabolic pathways play a role in adventitious bud formation.

Abscisic acid exerted a beneficial effect on adventitious bud formation. It is generally recognized that abscisic acid promotes the expression of genes related to the resistance to various stresses¹⁾. Since the culture environment is a kind of stress, the beneficial effect of abscisic acid on adventitious bud formation may be related to stress resistance.

As mentioned above, various physiological reactions controlled by many genes may be related to

adventitious bud formation in mulberry. Many genes expressed during the regeneration process have been isolated²⁰⁾. This information is important to improve the tissue culture system of mulberry. On the other hand, it was reported that no adventitious buds were formed when immature leaves of sprouting winter buds of mulberry were cultured¹³⁾. We also previously reported that the regeneration potential of immature mulberry leaf was lowered and was completely lost with growth, even if the leaf size was 10 times smaller than that of the mature one¹⁷⁾. These observations indicate that the expression of genes related to regeneration varies with the development of the organ. On the other hand, adventitious buds were formed whereas callus was scarcely formed on the medium containing 10-100 $\frac{1}{4}$ M IAA and 1 $\frac{1}{4}$ M thidiazuron in this study, although callus was induced from cotyledon by 2-10 $\frac{1}{4}$ M IAA and 2 $\frac{1}{4}$ M thidiazuron in a previous study¹⁶⁾. These findings imply that the medium conditions and the endogenous differentiation potential of explant play a role in adventitious bud formation. Since immature leaf is one of the few organs with a potential for differentiation in mulberry, immature leaf culture system of mulberry should be used to analyze processes of regeneration.

Development of an Automatic Steering System for Compact Tractor Used in Mulberry Fields

Toru KOBAYASHI

Department of Sericulture, National Institute of Sericultural and Entomological Science
(Tsukuba, Ibaraki, 305-8634 Japan)

Abstract

In order to promote sericultural labor saving and to decrease costs, this study was carried out to develop an automatic steering system for a compact tractor used in mulberry fields. A new experimental vehicle for automatic steering was developed characterized by hydraulic transmission, front-wheel drive, and microcomputer control. A magnetic azimuth sensor and an ultrasonic sensor were selected as noncontact-type position sensors. Then, the sensor systems were developed to determine the positions automatically by using a microcomputer. Moreover, an automatic steering system that consisted of a microcomputer (8-bit CPU), the position sensor systems and the vehicle was developed and tested. As a result, the system enabled to control the travel of the vehicle in a mulberry field.

Discipline: Agricultural machinery

Additional keywords: microcomputer, control, sensor, automatic travel

(Received for publication, February 10, 1999)

Introduction

The mechanization of sericulture in Japan has proceeded only slowly, and silkworm rearing and mulberry cultivation are still mainly performed by human labor. Cocoon yield has been decreasing in recent years. Therefore, by expanding the scale of sericultural farming with multiple rearing of silkworms, it is important to save labor and reduce the cost of production in sericulture through the promotion of mechanization and automation.

Then, in order to increase sericultural productivity, this study was carried out to develop an automatic steering system for a compact tractor used in mulberry fields, based on the results of recent studies on agricultural machinery^{1,4-6)}. This report gives an outline of the system developed, which is characterized by travel controlled by a microcomputer with hydraulic transmission, use of noncontact-type position sensor systems to detect the tractor travel position in the system and automatic steering and turning in mulberry fields.

Experimental vehicle with automatic steering³⁾

In order to improve the performance of the automatic steering system, based on the results of an

experimental study on a previously developed automatic steering system using a contact-type position sensor²⁾, we developed an experimental vehicle for automatic steering. The vehicle is characterized by hydraulic transmission, front-wheel drive, and microcomputer-controlled steering.

The size of the vehicle was approximately that of a compact 4-wheel tractor. The dimensions of this vehicle were as follows: 140 cm in overall length, 80 cm in overall width and 110 cm in overall height. A gasoline engine (4.4 kW, 6 Ps) and hydraulic transmission driven by independent front wheels, were used for the driving system. Double pumps with double swash plates type ran 2 oil-hydraulic motors, then front wheels (driving wheels) were driven through 1/5 speed-reduction gears ([Fig. 1](#)).

The vehicle was designed to move forward and backward at a continuously variable speed of 0 to 50 cm/s. The power wheeled steering method, with a difference in speed between right and left driving wheels by the operation of each discharge regulation shaft of the double oil-hydraulic pump, was applied for the design of the system for vehicle steering. The steering apparatus of the vehicle consisted of a microcomputer, RS-232C interface, stepping motor drivers, 4-phase stepping motors, gears, cams, etc. (Fig. 2).

Fig.2. Steering mechanism of experimental vehicle

Since the microcomputer could approximately control the revolution of each discharge regulation shaft of the oil-hydraulic pump, this vehicle could drive forward and backward at a continuously variable speed of 0 to 95 cm/s. As a result, the performance of the vehicle was similar to that outlined in the design specifications.

[Noncontact-type position sensors for compact tractor^{3\)}](#)

Automatic steering system and automatic steering control³)

Based on the results of the above experiments, a position sensor system combining the 2 sensor systems was installed on the experimental vehicle, and then an automatic steering system was constructed. The automatic traveling trial of the experimental vehicle was operated by using a program developed in BASIC language for automatic steering control in a mulberry field.

1) Automatic steering system

The automatic steering system was equipped with a hand-held microcomputer (8-bit CPU, 3.68 MHz) as controller, an ultrasonic range finder (ultrasonic sensor system), a magnetic declinometer (magnetic azimuth sensor system) as sensors, and a steering mechanism and front-wheel drive by hydraulic transmission, etc. as actuators for the method of automatic steering control ([Figs. 7, 8](#)).

Fig. 8. Experimental vehicle equipped with steering control system

A: Ultrasonic sensors, B: Bumper, C: Auto-battery, D: Control and instrumentation apparatus, E: Magnetic sensor.

Two ultrasonic sensors for the ultrasonic range finder system were located 30 cm apart outside of the left front wheel of the vehicle. The system measured ranges at a maximum rate of 0.2 sec by using the microcomputer.

In order to avoid the influence of magnetic fields, the magnetic azimuth sensor was mounted on a plywood board on the right side of the rear of the vehicle because the magnetic declinometer was affected by the magnetic field of its iron body. The resolution of this azimuth was 0.1° .

Operation signals of the actuator were transferred through RS-232C, the multiplexer from the microcomputer in the automatic steering system. The actuator rotates the driving wheels of the vehicle at the same speed for starting the travel and traveling straight, and controls differentially rotational speeds between the right and left driving wheels in a steering, turning, and pivot turn.

Power was supplied by using +12 VDC automobile batteries and the voltage was transformed from +12 to +5, +12 and +15 VDC by DC-DC converters.

2) Method of automatic steering control

In a common mulberry field for automatic traveling, row spacing was assumed to be 2.0-2.5 m and intrarow spacing 0.5 m and left-hand sensing method was adopted. The vehicle traveled at a velocity of 24 cm/s along the mulberry stumps by automatic steering. Steering was applied continuously to move

straight or trim (lateral movement with a proportional control action) to maintain a distance from the vehicle to mulberry stumps constant by using both the ultrasonic range finder and magnetic declinometer. The target value for the control of the distance was set at 10 cm. As shown in [Fig. 9](#), after the vehicle turned 90° twice at a headland, it entered another inter-row space and only the magnetic declinometer was used to turn the vehicle.

3) *Steering control program*

The flowchart of an automatic steering control program is shown in [Fig. 10](#). After the start of traveling, the automatic steering system detected a mulberry stump by using the range finding and measuring azimuth. If the controller of this system did not detect a mulberry stump for 3 times continuously the vehicle stopped traveling. If the number of turns was not 0, the vehicle turned 90° twice and entered another inter-row space by the turning subroutine. On the other hand, when the controller continuously detected mulberry stumps, the traveling direction of the vehicle remained parallel to ridges with a turn of 5°. The controller also proceeded to trimming using the range finding and measuring azimuth 3 times. If trimming was needed, the controller trimmed the body by setting the value using the trimming subroutine and the vehicle traveled forward.

4) *Test of automatic steering control*

On a flat mulberry field with an inter-plant distance of 0.5 m immediately after shoot cut, which was used as test field, the vehicle traveled at a velocity of 24 cm/s using the control program over a distance of 70 cm along the row of mulberry stumps. The traveling trace in about the center of the vehicle's front body was drawn on the traveled path.

As a result, the traveling direction of the vehicle was almost parallel to the mulberry stumps and the system detected easily mulberry stumps using the ultrasonic range finder. Then the vehicle traveled automatically according to the row detected and turned at the headland ([Fig. 11](#)). However, the automatic steering control of the first turning at the headland was overrun at a distance of about twice 85 cm. The accuracy of turning at headlands was $90 \pm 5^\circ$ by using the magnetic declinometer alone. Therefore, the results obtained suggested that for the most effective steering control, first the magnetic declinometer and second the ultrasonic range finder should be used, respectively, to maintain the traveling direction of the vehicle parallel to mulberry stumps (rows) within 6°.

Conclusion

As stated above, by using noncontact-type position sensors, an automatic steering system was developed for a compact tractor used in mulberry fields. This system controls the steering, trimming, and turning of the experimental vehicle by the determination of the traveling positions of the vehicle using the range finder and the magnetic declinometer. Therefore, the vehicle was able to travel in the rows, along the mulberry stumps and turn at headlands on the mulberry field.

Moreover, the results suggest that pest control, herbicide spray and manuring could be automated by improving the performance of this system.

Harmful Effect of Dinoflagellate *Heterocapsa circularisquama* on Shellfish Aquaculture in Japan

Yukihiko MATSUYAMA

Harmful Algal Bloom Division, National Research Institute of Fisheries and Environment of Inland Sea (Maruishi, Ohno, Saeki, Hiroshima, 739-0452 Japan)

Abstract

The marine dinoflagellate *Heterocapsa circularisquama* Horiguchi is the causal agent of red tide on the Japanese coast. In the last decade, *H. circularisquama* red tides have destroyed the shellfish aquaculture industries around the western part of Japan because this dinoflagellate shows a detrimental effect on shellfishes particularly on bivalve molluscs. The current proliferation of *H. circularisquama* throughout western Japan is a cause for concern due to economic loss. The outbreaks of *H. circularisquama* are closely related to the environmental conditions: water exchange rate, water temperature, local and global climate changes. Administrative measures such as algal monitoring systems can be successfully utilized for the distribution and short-term prediction of red tide due to *H. circularisquama* in several locations. However, secondary damage, i.e. decline of demand due to misinformation and cost of measures to prevent the damage, adversely affects the development of shellfish aquaculture even if direct killing of the products can be avoided.

Discipline: Animal pest/Aquaculture/Fisheries

Additional key words: red tide, bivalve, toxicity, secondary damage

1.....37): [References](#)

(Received for publication, February 3, 1999)

Introduction

Worldwide development of harmful algal blooms causes serious problems for public health and fisheries industries^{1,4,5,21,23,24}). On the Japanese coast, new marine dinoflagellate *Heterocapsa circularisquama* Horiguchi⁹), appeared in 1988 and then rapidly expanded over the western area. The red tide due to *H. circularisquama* has damaged shellfish aquaculture in most of the region^{3,12,14,34,37}). Although *H. circularisquama* blooms mainly affect bivalve aquaculture, no harmful effects on wild and cultured fish, other marine vertebrates, and public health hazard were recorded. Therefore, this phenomenon is referred to as "novel red tide." Incidence of this species has increased recently, and the economic losses in aquaculture have been a cause for concern for the industry and society¹⁴).

In the present paper, environmental conditions conducive to the red tide occurrence, review of damage caused to aquaculture, toxicity of the organism, and recent monitoring programs based on scientific data are outlined.

Environmental conditions causing *Heterocapsa circularisquama* bloom

1) Coastal currents and water exchange rate

Fig. 1 shows the distribution of red tide events due to *H. circularisquama* ($>10^6$ cells L^{-1}) on the Japanese coast. *H. circularisquama* is distributed over the western part of Japan, especially on the southern coast of Mie, western coast of Seto Inland Sea, and western coast of Kyushu Island. The most frequent area for red tide is Ago Bay, where *H. circularisquama* has been observed every year since 1992. The areas where *H. circularisquama* blooms were recorded are embayments affected by the warm currents: Kuroshio and Tsushima currents (**Fig. 1**).

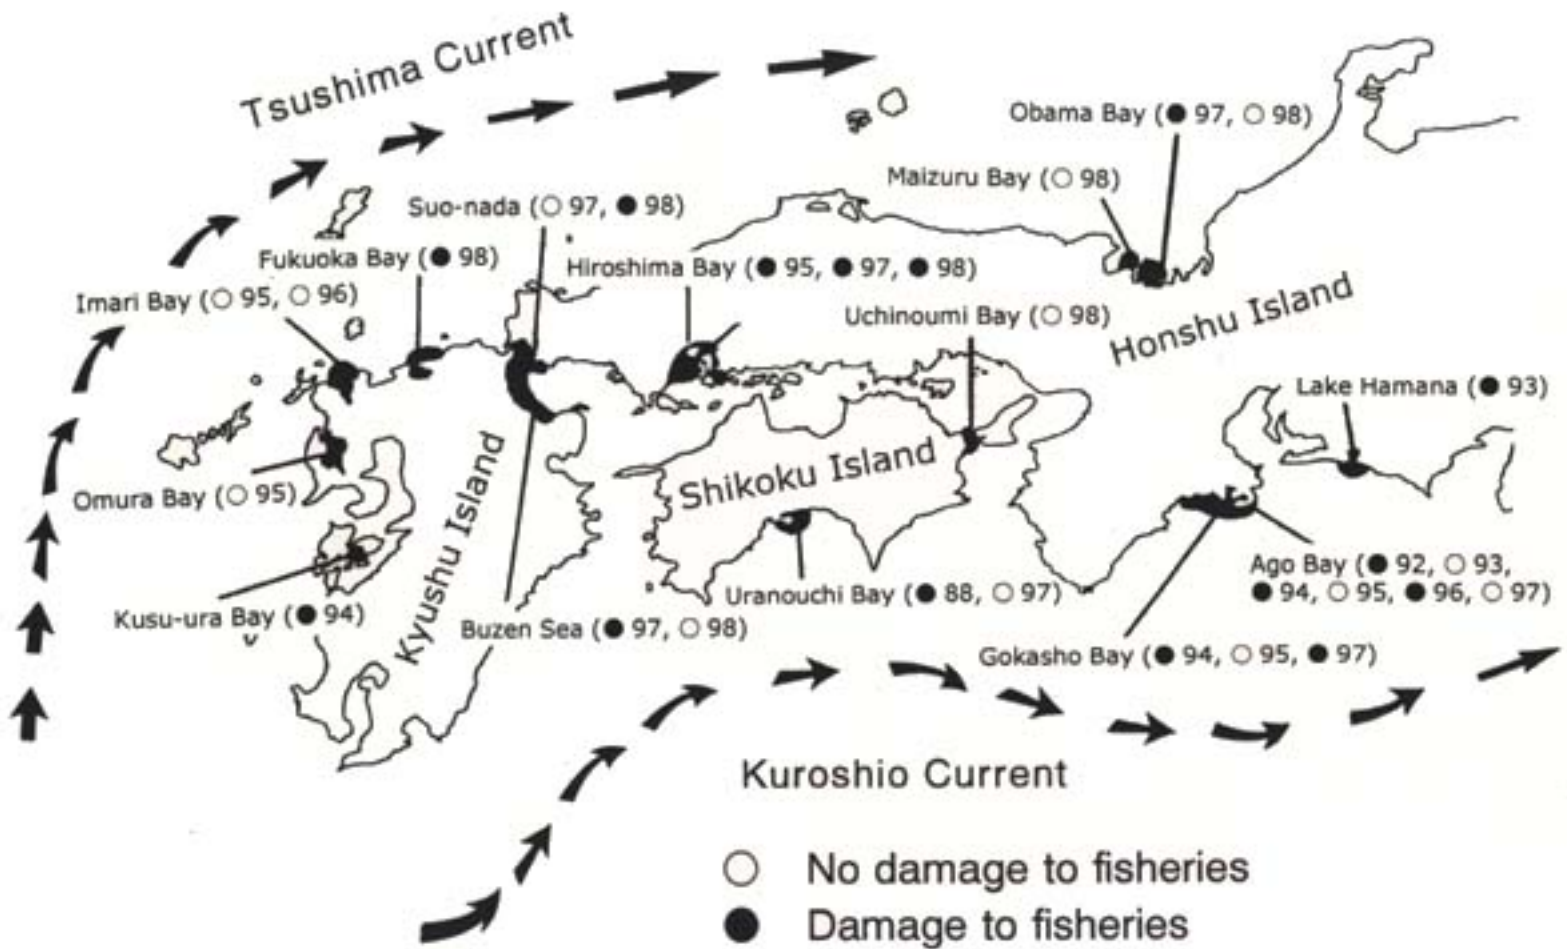

Fig.1. Records of red tide ($>10^6$ cells L^{-1}) due to *Heterocapsa circularisquama* in western Japan

The red tide caused by *H. circularisquama* is commonly observed in semi-closed bays, such as Ago Bay, Uranouchi Bay, and Hiroshima Bay. Dense assemblages of *H. circularisquama* cells have been found in the innermost part of the inlets, but not offshore and in the channels. The distribution pattern of *H. circularisquama* seems to be strongly affected by the water exchange rate. Natural populations of *H. circularisquama* cells significantly increase during the neap tide and decrease during the spring tide (**Fig. 2**). This observation clearly indicates that *H. circularisquama* populations are released from semi-closed bays into the offshore zone responsible for spring tidal current. Similar findings have been reported in *Alexandrium tamarense* blooms on the Maine coast²⁾ and *Gymnodinium mikimotoi* in Gokasyo Bay²⁷⁾. Therefore, water exchange mainly influences the horizontal distribution and the periodic changes of red

tide due to *H. circularisquama* and other harmful algal species.

2) Water temperature and salinity

Red tide associated with *H. circularisquama* occurs between July and November in the embayments of western Japan. In Ago Bay, the water temperature and salinity level during the *H. circularisquama* bloom ranged from 15 to 31 and from 24 to 34 psu, respectively¹⁴⁾. Generally, *H. circularisquama* blooms appear mainly under high water temperature (>23) and salinity (>30 psu) conditions. The results of field surveys show that *H. circularisquama* grows well under high water and salinity conditions.

Based on laboratory culture experiments, optimal growth of *H. circularisquama* occurred in a combination of water temperature of 30 and salinity of 30 psu. However, the growth of *H. circularisquama* decreased significantly below 15³¹⁾. These growth responses to temperature and salinity obtained in laboratory culture correspond to those recorded in field surveys. On the other hand, the optimal growth of representative harmful algae (*Alexandrium tamarense*, *Chattonella antiqua*, *Gymnodinium mikimotoi*, *Heterosigma akashiwo*, etc.) which often cause red tide on the Japanese coast occurred in a combination of water temperature from 20 to 25 and salinity ranging from 20 to 25 psu, respectively^{32,33,35,36)}.

On the coast of western Japan, since the maximum water temperature seldom exceeds 30, the growth pattern of *H. circularisquama* in relation to the temperature is different from that of other harmful algae appearing on the Japanese coast. Based on these physiological characters, *H. circularisquama* seems to be a species of tropical or subtropical origin.

3) Vertical mixing of seawater

Field surveys revealed that seawater mixing and concomitant upwelling of bottom water enhanced the proliferation of *H. circularisquama* blooms. In Ago Bay, strong disturbances of water stratification by typhoons preceded the red tide outbreaks of *H. circularisquama* in summer ([Fig. 3](#)). In the 1988 red tide at Uranouchi Bay, a large-scale intrusion of oceanic water into the bay and resultant seawater mixing were observed before the occurrence of red tide due to *H. circularisquama*¹⁸⁾. In the western part of Seto Inland Sea, where water columns are very stable due to stratification, *H. circularisquama* bloom hardly occurs in early to mid-summer. However, in autumn when the stratification begins to break down due to the decrease of the surface water temperature, *H. circularisquama* frequently causes red tide in embayments¹⁵⁾. Temporary or sustained water mixing throughout the water column may provide nutrients and growth-promoting substances from the bottom to the euphotic layer, resulting in increased salinity. Thus, the proliferation of *H. circularisquama* in coastal areas is considered to be triggered by vertical mixing of seawater.

4) Competition with other phytoplankton species

The competition between *H. circularisquama* and other microalgae is also noteworthy. According to field observations carried out over 3-year period in Ago Bay, the growth of *H. circularisquama* occurs when the populations of dominant diatoms *Chaetoceros* spp. begin to decrease ([Fig. 4](#)). Maximum yield and duration of *H. circularisquama* bloom seem to be strongly affected by the *Chaetoceros* spp. populations. It is considered that the decrease of the dominant diatom population is conducive to *H. circularisquama* growth. Uchida et al.²⁹⁾ reported that the growth of *H. circularisquama* was suppressed under bialgal cultures with diatom species including *Chaetoceros didymum*, *Stephanopyxis palmeriana* and *Licmophore* sp. Under the effect of diatoms, the cells of *H. circularisquama* became round to elliptical and were considered to be temporary cysts. It is assumed that diatom populations regulate the

development and decline of red tide due to *H. circularisquama*.

Furthermore, *H. circularisquama* was found to kill a mixotrophic dinoflagellate *Gyrodinium instriatum* and tintinnid ciliate *Favella taraikaensis*^{10,28}). The results show that *H. circularisquama* is toxic to active predators and competitors. From the ecological point of view, this characteristic might be advantageous for bloom formation in natural environments^{10,16}).

5) Long-term trend of *Heterocapsa circularisquama* blooms

The records of red tide due to *H. circularisquama* are shown in [Fig. 5](#). The red tide incidence associated with *H. circularisquama* has rapidly increased since the early 1990s. Why can *H. circularisquama* appear and colonize the Japanese coast? Laboratory experiments reveal that *H. circularisquama* can not grow at 10 or less ³¹), and does not form typical resting cysts that can survive below 10 (Uchida & Matsuyama, unpub. data). Hence, the overwintering vegetative cells are the likely seed population for bloom initiation of this species. This growth strategy is considered to be disadvantageous for the occurrence of this species in temperate and cold seas.

On the Japanese coast, however, the water temperature in winter has significantly increased since the late 1980s¹¹), probably due to global climate change (green house effect and El Nino phenomenon). Recently, the tropical and subtropical dinoflagellate *Prorocentrum sigmoides* Bohm has frequently appeared in western Japan³⁰). In the Seto Inland Sea, the water temperature in winter considerably increased in the last decade, except for the period 1995-1996 (Fig. 5). Accordingly, tropical marine animals, e.g. green shell mussel *Perna viridis*, have frequently appeared in the Seto Inland Sea since the early 1990s. This hydrographic change may be conducive to the overwintering of *H. circularisquama* on the Japanese coast. The relationship between the water temperature in winter and initial occurrence of red tide due to the dinoflagellate *G. mikimotoi* was also observed in the previous study⁷). Hydrographic change in terms of water temperature is likely to bring about changes of the phytoplankton communities in the Japanese coastal waters.

6) Possible origin

There have been no records of *H. circularisquama* red tide and related shellfish mortality in Japan before 1988. It remains to be determined whether *H. circularisquama* is a native species of Japan. Considering the growth response to water temperature, it is possible that *H. circularisquama* originates from tropical or subtropical regions, and has recently invaded Japanese coastal areas by warm current and/or artificial transportation. Recently, simulated experiments have revealed that *H. circularisquama* could easily migrate to distant areas in association with shellfish transportations⁸). During the last 2 decades, large shellfish spats, especially pearl oyster and short-necked clam, have been imported to Japan from Southeast Asia for aquaculture. It is therefore possible that *H. circularisquama* invaded Japan from tropical or subtropical seas (T. Honjo, pers. commun.). However, further studies should be carried out to analyze the artificial dispersal of *H. circularisquama*.

Damage to fisheries and toxicity

1) Shellfish damage to aquaculture industries

In September 1988, extensive red tide due to *H. circularisquama* and subsequent death of short-necked clams *Ruditapes philippinarum* occurred in Uranouchi Bay, Kochi Prefecture ([Table 1](#)). Red tide due to *H. circularisquama* occurred at Fukuoka Bay in 1989, and at Ago Bay in 1992, resulting in high mortality of shellfish^{13,34}).

Until 1998, 26 cases of *H. circularisquama* red tide (including 15 incidences leading to fisheries damage) had been recorded in 14 locations of western Japan ([Fig. 1](#)). The red tide due to *H. circularisquama* was associated with massive killing of commercially important bivalve species: short-necked clam *R. philippinarum*, pacific oyster *Crassostrea gigas*, pearl oyster *Pinctada fucata*, blue mussel *Mytilus galloprovincialis edulis*, etc^{13,14,34,37}). The current proliferation of *H. circularisquama* throughout western Japan destroyed the local shellfish mariculture. Economic losses of shellfish aquaculture by direct killing of marketable products were estimated about at least 10 billion-yen in the last decade.

On the other hand, there are no records of death of finfish and crustacean species or public health hazard due to the consumption of shellfish and other seafood products in association with the red tide of *H. circularisquama*¹⁶). This type of biohazard in marine animals is markedly different from previous damage caused by harmful algae responsible for paralytic shellfish poisoning (PSP), diarrhetic shellfish poisoning (DSP), amnesic shellfish poisoning (ASP), neurotoxic shellfish poisoning (NSP), ciguatera poisoning, and ichthyotoxicity.

2) General characteristic of shellfish affected by red tide

The effects of *H. circularisquama* on bivalve molluscs were described in previous studies^{3, 14,15,19}). Matsuyama et al.¹⁴) observed that exposure of pearl oysters to $5-10 \times 10^6$ *H. circularisquama* cells L⁻¹ resulted in death within several days although the level of dissolved oxygen was not critical. The dead individuals were characterized by a marked shrinkage of the mantle, decrease of glycogen lobe attached to the mantle and gut discoloration ([Fig. 6](#)).

circularisquama

on pearl oyster physiology. Similar harmful effects on oyster *C. gigas* and the mussel *M. galloprovincialis* were observed during the red tide which occurred in Hiroshima Bay¹⁵). Based on detailed field surveys, in most of the bivalve species, the filtration rate is significantly reduced at a density of $5\text{-}20 \times 10^4$ *H. circularisquama* cells L^{-1} . As a result, alterations of bivalve physiology clearly started from a cell density below 1%.

3) Exposure experiment using cultured strain

Nagai et al.¹⁹) showed that the mortality of pearl oyster spats by *H. circularisquama* depends on the cell density of this alga. Pearl oysters exposed to *H. circularisquama* cells at a density above 10^7 cells L^{-1} showed an unusual contraction of the mantle and gills, clapping, sustained valve closure, paralysis, and heartbeat stop within 24 hours. Furthermore, the mussel *M. galloprovincialis* significantly reduced its feeding activity when exposed to 10^4 cells L^{-1} of *H. circularisquama*, but not in culture with 10^6 cells L^{-1} of morphologically similar dinoflagellates *Scrippsiella trochoidea* and *Heterocapsa triquetra*¹⁶). Some harmful algae are known to be toxic to marine shellfish. The blooms associated with the unarmored dinoflagellate *Gyrodinium aureolum* and picoplankton *Aureococcus anophagefferens* referred to as "brown tide" lead to considerable failure in mussel and scallop farming²³). Laboratory-rearing experiments using these algae showed considerable detrimental effects on various bivalve species^{12,20,25}). However, the effect of these harmful algae on marine animals is not species-specific. Red tide due to *G. aureolum* kills not only shellfish but also finfish and crustacean species²⁶). Although *H. circularisquama* frequently kills various bivalve species within a short period of time (<24 h) as described previously^{15,19}), no death and adverse effects were observed in finfish and crustacean. These facts suggested that the harmful effect of *H. circularisquama* on bivalves is specific and pronounced compared to other harmful algal species ([Table 2](#)).

4) *Harmful effects of Heterocapsa circularisquama on other animals*

Laboratory exposure experiments showed that various marine animals such as bivalves, gastropods¹⁷⁾, solitary acidians, and jellyfish are affected by *H. circularisquama* unlike vertebrates, crustaceans, starfish, and sea urchins (Table 2). On the other hand, although the occurrence of illness associated with the consumption of bivalves that accumulated *H. circularisquama* cells may be a cause for concern in humans, shellfish poisoning has never been observed in samples collected from red tide areas. Direct HPCL analysis failed to detect PSP toxins or DSP toxins in the cells of *H. circularisquama*¹⁶⁾. No death or symptoms were observed in 5 mice to which a cultured cell pellet of *H. circularisquama* had been injected intraperitoneally at a rate of 10^6 cells individual⁻¹.

5) *Characterization of Heterocapsa circularisquama toxicity*

Nagai et al.¹⁹⁾ suggested that the toxicity of *H. circularisquama* to bivalves was mediated by a chemical agent. Thereafter, it was shown that the toxic effect of *H. circularisquama* on bivalves was not due to extracellular metabolites, cell exudates, and "naked cells" prepared by sonication and centrifugation. Furthermore, trypsin and SDS (sodium dodecyl sulfate) treatments were found to decrease drastically the toxicity of *H. circularisquama* cells ([Fig. 7](#)). Therefore, labile protein-like complex localized on the cell surface presumably exerts a detrimental effect on bivalves¹⁶⁾. However, purification and characterization of toxic fractions have not been successful because this agent is highly labile under neutral conditions.

6) *Secondary damages to fisheries industries*

Secondary damage to fisheries may occur during the *H. circularisquama* red tide periods, sometimes causing serious economic losses. As mentioned above, *H. circularisquama* bloom does not cause human illness associated with the consumption of harvested products. This fact should be recognized and fishermen and consumers should be informed that "shellfish killing" during red tide due to *H. circularisquama* is different from "shellfish poisoning" due to toxic dinoflagellate blooms such as those of the genera *Alexandrium*, *Gymnodinium*, and *Dinophysis*. This information may lead to a considerable decrease in the demand for shellfish and market price²³⁾. Massive *H. circularisquama* bloom occurred in a restricted area of Hiroshima Bay, in 1997. Although no outbreaks of shellfish poisoning occurred, oyster demand rapidly declined when the occurrence of red tide due to *H. circularisquama* was broadcasted in several TV programs. Market price of oyster decreased by 10-30% due to the decrease of the demand compared with the previous year. In the oyster farming industry of Hiroshima Bay, approximately several hundred persons are employed as oyster shuckers with a low salary. The decrease of the market price directly affects shucker employment.

Monitoring, prediction, and methods of prevention of red tide

1) *Monitoring of red tide due to H. circularisquama*

In Japan, monitoring systems for harmful algal blooms have been developed by the Fisheries Agency and local government organizations (mainly Prefectural Fisheries Experimental Stations) since the early 1970s. These monitoring systems operate successfully and provide information on the incidence of red tide and shellfish poisoning as mentioned previously²¹⁾. Since 1992, in several locations, regular monitoring systems on *H. circularisquama* blooms have been set up. The local government uses early warning systems based on the data obtained from regular oceanographic surveys. Fishermen are routinely able to obtain the information about harmful algal bloom (cell density, water temperature, and distribution of cell assemblages, etc.).

2) **Prevention of fisheries damage due to *H. circularisquama***

To our knowledge, it is difficult to control or destroy the large natural populations of red tide organisms by applying direct prevention methods. Various prevention techniques (i. e. spraying of active clay, hydrogen peroxide, and coagulants, etc.) were developed previously^{6,22}). However, widespread application of these procedures for marine environments may exert a secondary harmful effect on other valuable organisms (i.e. diatoms, zooplankton, fish, benthos, etc.). The simple and most effective method is the transfer of cultured organisms from a red tide area to a non-red tide area. In Ago Bay, pearl oyster aquaculturists began to remove the pearl oysters when the cell density of *H. circularisquama* exceeded about 10^5 cells L^{-1} . No fisheries damage has occurred in this bay recently. However, oyster and clam aquaculturists are still affected by red tide caused by *H. circularisquama* because the removal procedure is costly and labor-intensive. As described above, red tide damage caused by *H. circularisquama* leads to a loss of marketable products and secondary damage such as decrease of demand for the products and loss of competitiveness in the market due to the high cost of the products to compensate for the cost of prevention of the damage.

Microbial Conversion of Macroalgae into a Detrital Hatchery Diet

Motoharu UCHIDA

Marine Biochemistry Division, National Research Institute of Fisheries Science
(Fukuura, Kanazawa, Yokohama, 236-8648 Japan)

Abstract

The formation of algal detrital particles in a completely cell-detached form, namely, single cell detritus (SCD) was reported for the first time by the author during the microbial degradation process of macroalgal thalli. SCD display 3 characteristics suitable for feed for aquatic hatchery animals: 1) The size of SCD is in the 2-14 $\frac{1}{4}$ μ m range, which is similar to that of dietary phytoplankton; 2) The cell wall components of SCD are partially degraded which facilitates digestion; 3) Bacterial cells are attached to SCD, which modifies the algal detritus to protein-rich particles. The use of SCD as a potential hatchery diet instead of phytoplankton culture, which is labor-intensive, was successfully demonstrated based on feeding experiments with *Artemia*. Further modification of SCD could include the attachment of bacteria to SCD which would exert beneficial effects on the hatchery animals. Use of SCD diets in fish feeding regimes is an attempt to introduce the concept of detrital food web to aquaculture systems, which could contribute to the development of sustainable fish nursery systems.

Discipline: Aquaculture

Additional key words: detritus, food chain, *Pseudoalteromonas*, seaweed, *Ulva*

This paper is primarily based on a previous paper entitled "Conversion of Macroalgae into a Detrital Hatchery Diet - An Attempt to Introduce Detrital Food Webs into Aquaculture"(in Japanese) published in TechnoInnovation⁹).

This work was supported in part by a grant (Development of highly functional materials by structural modification of carbohydrates) from the Research Council Secretariat of the Ministry of Agriculture, Forestry, and Fisheries, Japan (1991-1996).

(Received for publication, February 3, 1999)

Introduction

Aquaculture techniques have markedly progressed over the last decades, and enabled to produce and release millions of seed fishes important to the aquatic environment. On the other hand, however, the prevalence of fish diseases has become a serious problem in many countries, and an increasing number of people consider that current aquaculture systems require significant changes, both technical and conceptual, for sustainable development.

In the natural aquatic environment, larval fish develop by feeding on grazing and detrital food chain systems (Fig. 1).

However, the present aquaculture systems utilize only the grazing food chain principle⁶). Since the

detrital food web can be considered to be a system whereby biological resources not utilized as feed in the grazing food chain are recycled, a more efficient system could be developed by introducing this recycling system into the present fish-feeding regime. Although our understanding of the detrital food web is still limited, there is an increasing number of studies showing the effectiveness of using detritus^{1, 2, 4}). Since the detrital system has a large input, if it enhances the ecological efficiency, the system could have a large impact on biological production in the natural ecosystems. This paper describes a method of preparing algal detrital materials with a high dietary value to improve the ecological efficiency of the detrital food chain system and introduce it to the present fish culture system.

Fig. 1. The detrital food chain as a system to recycle wastes from biological production

The input (the quantity not grazed and decomposed to detrital materials) is large but the output (the quantity linked to production at a higher trophic level) is rather small in the detrital system.

Initial observations of single cell detritus (SCD)

Our laboratory maintains a collection of over 100 bacterial strains which were isolated from coastal waters of Japan and are able to degrade macroalgal thalli. Strain AR06 (MAFF120006, FERM BP-5024) shows the strongest activity within our collection. AR06 exhibits a decomposing activity toward various kinds of algal polysaccharides such as algin, fucoidan, agar, etc. and is able to degrade macroalgal thalli from brown and green algae, and also presumably from red algae. In our previous studies, we observed the formation of algal detritus in a completely cell-detached form (Fig. 2), namely, single cell detritus (SCD) during the microbial degradation process of *Laminaria japonica*⁸⁾ and *Ulva* sp.¹²⁾. AR06 which was assigned to *Alteromonas espejiana* based on the results of biological and physiological tests⁸⁾, is presently assigned to *Pseudoalteromonas atlantica* based on the results of phylogenetic analysis using 16S rDNA sequence and DNA-DNA hybridization tests with type strains (in preparation). SCD were also found to be formed during the experimental degradation of *Ulva* fronds soaked in natural seawater supplemented with peptone at 5 g/L level. Therefore, SCD can be produced by the activity of indigenous microbial populations without the presence of AR06 which suggests that SCD formation may occur in natural environments.

Fig. 2. Microphotographs showing the decomposition process of *Laminaria japonica* (A, B) and the resulting production of single cell detritus (SCD) by the activity of *Pseudoalteromonas atlantica* AR06 (C, D)

The SCD surface is densely covered with bacterial cells (arrow), which were observed after fluorescent staining (A, B, C) with 4,6'-diamino-2-phenylindole (DAPI).

The size of the SCD formed in these studies is in the 2-14 $\frac{1}{4}$ m range, which is similar to that of dietary

phytoplankton such as *Nannochloropsis* sp., *Isochrysis galbana*, and *Tetraselmis tetrathele*. SCD partially lose their cell wall components by microbial degradation and appear as spheroplasts in the case of *Laminaria* or protoplasts in the case of *Ulva*. Many bacterial cells were attached to the surface of the SCD, especially in the case of SCD produced from *Laminaria*. SCD from *Laminaria* have an algin layer on their surface, which may facilitate the attachment of the bacteria.

It takes about 3-5 days until the production of SCD is observed during the experimental degradation of macroalgal thalli if the degradation is performed by bacterial activity alone. However, the number of particles with the size of SCD increases more rapidly if the degradation is performed with a combination of magnet-stirring during the incubation although the SCD prepared in this manner appear to be more disintegrated compared with intact spheroplasts or protoplasts.

Use of SCD as a hatchery diet

The characteristics of SCD, i.e. a size appropriate for ingestion and a structure associated with digestibility for hatchery animals, suggest that SCD can be used instead of dietary phytoplankton. The preparation of SCD is easy and requires only one to a few days, which is a major advantage compared to the use of phytoplankton. The potential use of SCD as a hatchery diet was tested by feeding experiments with *Artemia*¹⁰). When *Artemia* were given *Laminaria* particles, 105-177¼m in diameter, they could not ingest them because of the size and scarcely grew. In contrast, *Artemia* fed on the same *Laminaria* particles that were degraded to SCD by the AR06 strain exhibited a much better growth and survival rates ([Figs. 3, 4a](#)). When the feeding level was compared to that of a commercial phytoplankton diet consisting of *Nannochloropsis* sp. (Marine Alpha, from Nisshin Science), the growth rate was nearly the same, although the survival rate was slightly lower. In another experiment where *Laminaria* particles less than 44¼m in diameter were used as a control diet, it was demonstrated that the macroalgal thalli themselves had a high dietary value if given as a material with a size suitable for ingestion ([Fig. 4b](#)). However, the degradation of the *Laminaria* particles by contact with AR06 did not result in an increase of the initial dietary value for *Artemia*. In this experiment, a marked increase in the number of detrital particles suitable for ingestion by *Artemia* was observed in case of axenic control when mechanical degradation by magnet-stirring was used while only a gradual increase of SCD was observed when the diet was prepared by contact with AR06 ([Fig. 5](#)). The moderate increase in the number of SCD products was ascribed to the characteristics of AR06 and also to the fact that it consumes the SCD. This assumption is supported by the following observations made during a feeding experiment using another detrital diet prepared by contact with *Pseudoalteromonas* sp. strain TO01. The TO01 strain is able to decompose *Laminaria* particles but does not produce SCD. As a result, the number of detrital particles in the size range of that of SCD, 2-14 ¼m, decreased markedly in TO01-treated *Laminaria*. The dietary value of the detritus was the lowest among the 3 applications of Axenic *Laminaria*, AR06-treated *Laminaria*, and TO01-treated *Laminaria*.

The results from this experiment indicated that the dietary value of the macroalgae differs depending on the kind of microorganisms involved in the macroalgal decomposition. The above results show that the dietary value of the macroalgae is maximum if the decomposition of the macroalgae is performed with a view to producing the maximum number of detrital particles with a size suitable for ingestion. We are currently accumulating information for developing algal detrital diets with a high dietary value through feeding experiments with *Artemia*.

Potential use of surface-attached bacteria as a tool for enhancing the nutritive value of SCD

There are 2 main objectives in our attempts to utilize SCD as a hatchery diet ([Fig. 6](#)). One is to utilize macroalgae resources as a diet by converting them to microalgae. The other is to utilize the bacteria attached to the detrital materials as a diet. Fish require a high level of protein accounting for 35-50% for their diet⁷⁾, while most macroalgae species contain only 10-20% protein. Bacteria have a protein content of about 60-70% on a dry weight basis and therefore have a high potential as a diet^{3,5,11)}. In the case of the SCD diets, bacteria attached to the algal detritus grow by absorbing nutrients from the environment and, as a result, contribute to modifying the algal detritus to protein-rich materials. In our observations, the protein level of the *Ulva* detritus was nearly double, which accounts for the fact that the SCD diets have such a high dietary value^{10,11)}.

In the case of the present SCD diets, bacteria are utilized while still alive, which is a unique characteristic different from the phytoplankton diets or artificial micro-diets. The bacterial strain AR06, which we used for our serial studies, is specialized in the degradation of macroalgae and is not necessarily used for the enhancement of a diet. Diets with specific activities for feeding of animals can be developed by attaching bacteria with beneficial characteristics for fish, for example, regulation of the growth of pathogenic microorganisms or production of growth-promoting materials such as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), and growth hormones for fish with or without the application of genetic engineering techniques.

Fig.6. Two strategies for developing SCD diets

Concept of "trophic enhancement" based on detrital macroalgae

We are presently considering the possibility of converting macroalgal biomass resources to SCD and to utilize them as a hatchery diet in extensive aquaculture systems. This attempt corresponds to the "trophic enhancement" of marine habitats ([Fig. 7](#)). Then, what kind of macroalgae could be converted to SCD, and what kind of aquatic animals could be cultured in this system?

Recently, cumbersome blooms of *Ulva* have been reported from coastal waters in Japan and various foreign countries. *Ulva*, after decaying causes oxygen-limited environmental conditions which often kill marine animals, especially bivalves. To address this problem, fishermen and local governments remove these algal accumulations by labor-intensive methods. The collected materials have no commercial value and their disposal is a major problem in several areas in Japan. Against this background, we attempted to utilize the *Ulva* resources. Coastal waters with large *Ulva* blooms are often good fishing grounds for Manila clams, *Ruditapes philippinarum*, a bivalve with a high commercial value. Moreover, the hatchery season of the bivalve larvae, i.e. June to July, corresponds to the period of growth and subsequent decay of *Ulva* fronds. The hatched bivalve larvae have only a limited mobility and are easily transported, depending on the wind and water current, to the same area where *Ulva* fronds are concentrated. Therefore, if we succeed in preparing detritus with a high dietary value from *Ulva* fronds, it may be possible to link this activity to the production of Manila clam larvae. As a preliminary experiment, we prepared hatched larvae from adult Manila clams caught from Uminokouen, Yokohama, and administered a SCD diet prepared from *Ulva* which was also collected from the same area. Some of the larvae ingested the *Ulva* SCD during overnight incubation in a 300 mL-volume beaker. Whether the SCD diet can contribute to the growth of the larvae or not is now being examined.

Blooms of *Ulva* are attributed to eutrophication caused by human activities. Our attempt to culture fishes in "a trophic enhancement system" utilizing bacterially degraded macroalgal resources is different from the conventional aquaculture systems in that compatibility between commercial fish culture and human activities causing the eutrophication problem could be achieved.

Noncontact-type position sensors for compact tractor³⁾

The traveling direction (heading) of the tractor and the distance from the tractor to mulberry stumps are the basic information required for the position for automatic travel of the small tractor in mulberry fields. Therefore, the noncontact-type position sensors that were readily connected to an 8-bit CPU microcomputer were studied and selected. A magnetic azimuth sensor was used to determine the direction of travel and an ultrasonic range sensor was used to detect the distance from the tractor to mulberry stumps.

Then, the sensor systems were developed to measure the positions automatically by the microcomputer. The magnetic and ultrasonic sensor systems were equipped with a microcomputer, interfaces, sensors (an ultrasonic range finder and a magnetic declinometer), power supply, detecting programs, etc. ([Figs. 3, 4](#)).

We studied the characteristics of the systems and the adaptation to automatic steering control.

1) *Magnetic azimuth sensor system*

The magnetic azimuth sensor system enables to detect terrestrial magnetism and inputs azimuth data through an RS-232C interface every 50 milliseconds. The microcomputer can read the serial data whenever it is necessary by a program in BASIC language. This system was tested using the experimental vehicle equipped with the azimuth sensor. The measuring accuracy of this system ranged from 0.3 to 3.5° in the traveling direction of the vehicle.

2) *Ultrasonic range system*

A reflection-type ultrasonic range finder inputs 12 bits parallel data to an I/O board (82C55A) connected to a microcomputer. The microcomputer reads the range data through the I/O board. Resolution of the system is 4 mm and the ultrasonic frequency is 49.1 kHz. The measurement has a range of 0.29 to 10 m.

This system was tested within the distance from the sensor to model stumps made of polyvinyl chloride pipe and mulberry stumps were measured continuously. That is, the distance was measured by using the sensor, moving at a velocity of 3.7 cm/s in laboratory experiments (analogue data) and using the experimental vehicle equipped with the sensors, traveling at a velocity of 24 cm/s (digital data). Two ultrasonic sensors were installed outside of the left front wheel of the experimental vehicle at a height of 25 cm above the ground. When the distance to the stumps ranged between 60 and 70 cm, the target could be detected continuously by using 2 ultrasonic sensors, which were arranged, at a distance of 30 cm apart. To measure the range with accuracy within a distance of 15 cm, the position of the ultrasonic sensors should be controlled by rotation and tilt of about 5°, respectively ([Figs. 5, 6](#)).

The results obtained suggested that the magnetic azimuth sensor system enabled to determine the traveling direction of the compact tractor and the ultrasonic range system enabled to detect a row of mulberry stumps for automatic steering of the experimental vehicle.

---Abstract -----

To determine whether the *gusA* gene, which encodes ²-glucuronidase (GUS) and *lacZ* gene, which encodes ²-galactosidase are suitable for tracing nitrogen-fixing bacteria in the infection process, *Bradyrhizobium japonicum* strains labelled with each gene were constructed. Both introduced genes were expressed in rhizobia, but it was difficult to specify the sites where *lacZ*-labelled bacteria were present, since endogenous ²-galactosidase levels were high in soybean root tissues. On the other hand, endogenous ²-glucuronidase activity has not been detected in soybean root tissues. The *gusA*-marked *Bradyrhizobium*, *Rhizobium* and *Azospirillum* strains were constructed for assessing the use of their GUS-marked bacteria to trace the presence of introduced bacteria manifested by colonization on the root surface, as well as infection sites, invasion modes and nodulation competitiveness between bacteria. *Bradyrhizobium japonicum* inoculated to soybean colonized in the form of spots on the root surface. In the spots, curling roots with infection threads were observed. In this report, we describe only the *gusA*-marked (*Brady*)*rhizobium* and *Azospirillum* strains which we constructed.

---Introduction-----

Studies for practical use of the biological nitrogen-fixing (BNF) system are being increasingly important, since BNF contributes significantly to the maintenance and promotion of sustainable agricultural production. Ecological studies of the nitrogen-fixing bacteria in soil, root surface, intercellular spaces and nodules of host plants are essential to increase the contribution of nitrogen-fixing bacteria.

Antibiotic-resistant markers and immunofluorescence have been used for these objectives. The strains marked with antibiotic resistance cannot be distinguished by light microscopy from the wild strain. The immunofluorescence method enables the detection of specific bacteria *in situ*, especially in tissues, but it requires a high technological level due to the interference from the background of host tissues. Recently, reporter genes such as *lacZ* and *gusA* have been used to facilitate the detection of individual marked strains of bacteria. Many plants and bacteria of economic importance do not contain indigenous glucuronidase (GUS) and do not show background GUS activity [20](#).

The (*Brady*)*rhizobium* strain encoded with the *gusA* reporter gene can be identified very clearly on the root surface or in infection threads by its blue color, because the marked bacteria turn blue when treated with the substrate. This finding may enable to trace the colonization and movement of marked bacteria and thus the mode of early stages of infection. Moreover, studies on the competition for nodule occupancy, fate of introduced bacteria in the plant-soil ecosystem, and also on the interaction with plants could be very efficiently carried out with the use of the GUS reporter gene.

Evaluation of the advantages and disadvantages of various reporter genes for practical application may enable to use this new technique for future research work in ecological and molecular studies of microorganisms and plant-microbe interaction. Here in this report attempts were made to evaluate the use of reporter genes for tracing introduced bacteria, and the infection mode of rhizobia in the non-nodulating soybean mutant T201 after treatment with synthetic auxin 2,4-dichlorophenoxyacetic acid (2,4-D).

---Materials and methods-----

1) Bacterial strains, plasmids and media

Bacterial strains and plasmids used in this study are listed in [Table 1](#).(40 KB)

Bradyrhizobium and *Rhizobium* were grown at 28-30 in yeast-mannitol (YM) medium for 3-6 days. The antibiotics used in the media for culturing *gusA*-marked *Bradyrhizobium* (*B. japonicum* MA172, MA173, USDA61A124a and *B. elkanii* MA31), *Rhizobium* (*R. meliloti* YAO3M2 and *R. leguminosarum* bv. *trifolii* ANU843 (Tp3) and *B. japonicum* NA-A1017 carrying plasmid pRKRT290 were spectinomycin (50 $\frac{1}{4}$ g mL⁻¹) and kanamycin (200 $\frac{1}{4}$ g mL⁻¹), respectively. *Escherichia coli* was grown overnight at 36 in LB medium [13](#)) or in HM medium[14](#)).

2) Plants

Soybean (*Glycine max* (L.) Merr.) cultivar Enrei, T202 and its non-nodulating isoline T201, wild type soybean (*Glycine soja*), siratro (*Macroptilium atropurpureum*), alfalfa (*Medicago sativa* L. cv. Vernal) and clover (*Trifolium repens* L. cv. California ladino) were used. Seeds of soybean cultivars (Enrei T202 and T201) were kindly provided by Dr. Kokubun (National Agriculture Research Center) and the wild type soybean seeds were provided by Dr. Harada (National Institute of Agrobiological Resources), while siratro, alfalfa and clover seeds were obtained from Yukijirushi Co., Japan.

3) Plant culture and inoculation

The seeds were surface-sterilized by immersion in 70% ethanol for 20 min, followed by soaking in 3% hydrogen peroxide for 5-10 min and then washed 5 times with sterile deionized water. Sterilized seeds were germinated in 2% agar plates or sterile vermiculite placed in 500 mL glass jars. Seedlings were transferred to sterile growth pouches (MEGA International of Minneapolis, USA) supplied with 30 mL of half-strength N-free nutrient solution¹⁾ or to sterile vermiculite placed in 500 mL glass jars supplied with 90 mL of N-free nutrient solution.

Cultures of rhizobial strains as described above were centrifuged at 7,000 rpm, 4 for 15 min. Cells were washed twice with sterile saline and resuspended in sterile deionized water. Cell density of the suspension was measured using a Thoma's haemocytometer and the suspension was diluted with sterile water to 10^7 - 10^8 cells mL⁻¹. For the co-inoculation test, the number of viable cells in the bacterial suspension was confirmed by the plate counting method using 10-fold serial dilution.

4) Conjugal transfer of pRKRT290 through mating

Transfer of the plasmid pRKRT290 carrying *lacZ* gene to *B. japonicum* A1017 was achieved by triparental mating. Culture of the donor *E. coli* HB101 (pRKRT290), HB101 harboring the helper plasmid pRK2013 and the recipient rhizobia from the mid-log phase were mixed on nitrocellulose filters (pore size 0.45 $\frac{1}{4}$ m), grown on YM agar, and incubated at 28 for 3 days. The colonies were suspended in 5 mL of sterile physiological saline solution, and the transconjugants were selected by plating onto HM medium⁷⁾ containing 200 $\frac{1}{4}$ g mL⁻¹ of kanamycin. Transconjugants were again restreaked on selective medium to obtain single colony isolates. The galactosidase activity of the isolates was checked by the presence of the blue color after growth on YM medium supplied with 5-bromo-4-chloro-3-indolyl-²-D-galactopyranoside (X-Gal) as substrate for the blue color staining.

5) Conjugal transfer of transposons through mating

Introduction of transposon into *B. elkanii* USDA31 was achieved by biparental mating. Donor *E. coli* S17-1 π -pir with plasmid pmTn5SS*gusA*20 and recipient rhizobia were mixed on nitrocellulose filter, and incubated. Cells on the filters were washed and resuspended with sterile saline. The suspension was spread on HM plates containing 100 $\frac{1}{4}$ g mL⁻¹ of spectinomycin, and then tested for their GUS activity in stab-culture of HM medium containing 100 $\frac{1}{4}$ g mL⁻¹ of spectinomycin and 50 $\frac{1}{4}$ g mL⁻¹ of 5-bromo-4-chloro-3-indolyl-²-D-glucuronide cyclohexylammonium salt (X-Gluc) at 28 for 6 days.

6) X-Gal staining

The staining was performed by the method of Bovin et al.²⁾. Primary root segments 3 cm long were placed in 10 mL test tubes containing 0.5% glutaraldehyde buffer with 0.2 M sodium cacodylate, pH 7.2, under vacuum for 60 min, cut into three 1 cm segments. One cm segments including nodules were embedded in 5% agar medium and transversely sectioned (0.1 mm thick) with a microslicer. The sections of root with nodules were immersed in the solution containing 800 $\frac{1}{4}$ L of 0.2 M sodium cacodylate pH 7.2, 50 $\frac{1}{4}$ L of 50 mM K₃Fe(CN)₆ and 50 mM K₄Fe(CN)₆, and 40 $\frac{1}{4}$ L of 2% X-Gal in N, N-dimethylformamide overnight.

7) X-Gluc staining

For the detection of GUS-marked rhizobia in the plant tissues, transversal sections (0.1 mm thick) of root

with nodules were used, as well as nodulated root segments (about 3 cm) for nodule occupancy. The samples were immersed in a test tube containing the GUS assay solution (5 mL 0.1 M sodium phosphate buffer at pH 7.0, 20¹/₄L 2% X-Gluc, and 50¹/₄L 10% SDS), *in vacuo* for 15-60 min, and incubated overnight.

---Results and discussion-----

1) Tracing microbes in plant tissues

Soybean inoculated with *BradyRhizobium japonicum* A1017 harboring the *lacZ lacZ* gene shows a deep blue color inside the nodules (infection zone) and some other parts of the plant tissues when stained with the substrate X-Gal ([Fig. 1A](#)). The plant tissues contain indigenous galactosidase, which reacts with the substrate and forms a deep blue color. As a result, it is difficult to trace the infection zone. Hence, to suppress the indigenous galactosidase, root with nodules was treated with glutaraldehyde buffer containing a high concentration (200 mM) of potassium ferri- and ferrocyanide. However, some parts showing a blue color remained along the vascular bundles, and most parts of the rhizobial infection zone filled with bacteroids did not stain. The former indicates that it is difficult to entirely suppress the indigenous galactosidase, while the latter suggests that the induced plasmid pRKRT290 carrying *lacZ* was lost during rhizobial multiplication ([Fig. 1B](#)). As a result, the bacterial infection zone could not be clearly traced by using the *lacZ* gene.

Then the soybean plants were inoculated with *BradyRhizobium japonicum* marked with the GUS (²-glucuronidase) reporter gene. When the root with nodules was treated with GUS substrate X-Gluc., a uniform and clear blue color was observed only in the infection zone ([Fig. 1C](#)), whereas no color was observed in the nodule (infection zone) inoculated with the unmarked (*gus*-) *BradyRhizobium japonicum* strain ([Fig. 1D](#)), because the soybean root nodule tissues did not contain indigenous glucuronidase and there was no background activity in plant.

Jefferson et al. [11](#)) reported that the *gusA* gene, encoding GUS, is the most widely used reporter gene in plant molecular biology and the GUS substrate also enables to detect the spatial localization of reporter gene activity. As such (*Brady*)*Rhizobium* encoded with ²-glucuronidase (GUS) was found to be highly suitable for bacterial infection studies.

* [Fig.1.\(78 KB\)](#)

2) Infection mode of nodulating soybean cultivars and non-nodulating mutants with rhizobia

We previously reported that nitrogen-fixing nodules can be induced in a non-nodulating soybean mutant T201, which is defective in nodulation, by 2,4-D treatment and rhizobial inoculation [1](#)). Nodulating soybeans develop spherical determinate nodules, while the nodules induced in a non-nodulating isolate by 2,4-D treatment are unusual and appear as paired or gourd-like nodules. In the case of the nodulating soybean cultivar Enrei T202, the bacteria colonize the root surface ([Fig. 2A](#)), and in the colonized zone, curled root hairs are observed ([Fig. 2B](#)). The bacteria penetrate into the root tissues through the curled root hair and infection thread ([Fig. 2C](#)), and thus form a nodule ([Fig. 2D](#)). While in the case of the non-nodulating soybean mutant T201, the bacteria colonize the root surface and multiply rapidly, causing the swelling of the root ([Fig. 2E](#)), where no root hair curling ([Fig. 2F](#)) but infection threads are observed ([Fig. 2G](#)). The bacteria penetrate into the plant root tissues through the infection thread. Inside the plant tissues, the bacteria multiply rapidly and form a nodule ([Fig. 2H](#)). In the distal lobe of the paired nodules, *gusA*-marked bacteria are observed showing a blue color.

* [Fig.2.\(89 KB\)](#)

The *gusA*-marked bradyrhizobia are very useful for tracing infection sites of nodules in that the bacteria stain blue and can be clearly identified. In the case of nodulating soybean T202, the bacteria penetrated into the root cells through root hair curling and subsequently infection thread formation, while in the non-nodulating soybean T201, there was no evidence of root hair curling and the bacteria invaded through both intercellular spaces and infection threads. Chandler [5](#)) and Chandler et al. [6](#)) reported that *Arachis* and *Stylosanthus* do not form infection threads and rhizobia penetrate into spaces between epidermal cells and invade cortical cells through their cell walls. Thus, root hair curling and formation of the infection thread may be independent phenomena controlled by different factors in

the nodulation process. Hence, root hair curling or infection threads are not always necessary for the formation of symbiosis, and the plants may receive rhizobia by various ways which can be studied using GUS reporter genes.

3) Competition between host and bacteria

Many leguminous plants can be nodulated by more than one (*Brady*)*Rhizobium* species. Also some bacteria can form effective nodules in several host plants. *Glycine max* cv. Enrei, *Glycine soja* and *Macroptilium atropurpureum* form effective nodules by infection with both *BradyRhizobium japonicum* (USDA110) as well as *BradyRhizobium elkanii* (MA31). *BradyRhizobium elkanii* (MA31) is a *gusA*-marked mutant of *BradyRhizobium elkanii* USDA31. When the above plants were co-inoculated with the bradyrhizobial strains, USDA110 and MA31 at 1:1 ratio, in *Glycine max* cv. Enrei, 81% of the nodules were formed by USDA110 and 19% by MA31, while in *Glycine soja*, 55% of the nodules were formed by USDA110 and 45% by MA31. In *Macroptilium atropurpureum* only 20% of the nodules were formed by USDA110 and 80% by MA31 ([Table 2](#)). These findings indicate that USDA110 is more competitive for nodulation in *Glycine max* cv. Enrei, while MA31 is more competitive for nodulation in *Macroptilium atropurpureum*. However, both strains, USDA110 and MA31 are almost equally effective for nodulation in *Glycine soja*.

Furthermore, a large number of nodules were formed in *Glycine max* cv. Enrei (142) by USDA110 and in *Macroptilium atropurpureum* (64) by MA31, while fewer nodules were formed in *Glycine soja* by either strains USDA110 or MA31.

The GUS transposon was found to be very useful for studying the competition for nodulation in common bean ([17,18](#)). Also, Yuhashi et al. ([23](#)) and Wilson et al. ([20](#)) described the advantages of using the *gusA* reporter gene as a marker for rhizobial competition studies.

Table 2. Relationship between host and rhizobia

Host plant	Nodule numbers			Nodule occupancy(%)	
	USDA110	MA31	total	Usda110	Ma31
<i>G. max cv. Enrei</i>	142	33	175	81	19
<i>G. soja</i>	27	22	49	55	45
<i>M. atropurpureum</i>	16	64	80	20	80

4) Plant-Azosopilium-Rhizobium interaction

Increase in the nodule number and grain yield of various crops has been reported by combined inoculation of *Azosopilium* spp. and *Rhizobium* spp. ([16,22](#)). The role of *Azosopilium* spp. in the infection and nodulation of plants can be clearly examined by using the GUS-reporter gene.

Colonization on the root surface and root tips of white clover was observed when the plant was inoculated with *gusA*-marked *Azosopilium lipoferum* T137-1 alone ([Fig. 3A](#)). However, when white clover was inoculated with both *Azosopilium lipoferum* T137-1 and *Rhizobium leguminosarum* bv. *trifolii* ANU843, many nodules and *Azosopilium* colonization of or near the nodules were observed ([Fig. 3B](#)). Nodule number and acetylene reduction activity in clover increased by more than 100% at 20 days after inoculation by combined inoculation of *Azosopilium lipoferum* T137-1 and *Rhizobium leguminosarum* bv. *trifolii* ANU843 ([Fig. 4](#)).

* [Fig.3.\(16 KB\)](#), [Fig.4.\(21 KB\)](#)

Increase in the nodule number and acetylene reduction activity in white clover by dual inoculation with *Azosopilium lipoferum* T137-1 and *Rhizobium leguminosarum* bv. *trifolii* ANU843 may be due to the fact that *Azosopilium* contributes to the development of additional sites for the rhizobia to form more nodules. Plazinski and Rolfe ([15](#)) and Yahalom et al. ([22](#)) reported that in the case of co-inoculation of *Azosopilium* and *Rhizobium*, *Azosopilium* stimulated the formation of a larger number of epidermal cells that differentiated into infective root hair cells, or created

additional infection sites which were later occupied by the rhizobia. Increase in shoot length, dry weight, number of root hairs and root diameter of alfalfa was also observed by combined inoculation of *Azospilium* spp. and *Rhizobium* spp. [10](#)).

Use of Soil Animals as Bioindicators of Various Kinds of Soil Management in Northern Japan

Yoshinari ENAMI, Hiroyoshi SHIRAISHI and Yoshio NAKAMURA
 Upland Farming Division, Tohoku National Agricultural Experiment Station
 (Arai, Fukushima, 960-2156 Japan)

---Abstract-----

As the soil invertebrate fauna is expected to modify several properties of upland soils in agriculture, the effect of the soil fauna on the soil properties and soybean growth under several kinds of soil management depending on the soil type, nitrogen source, tillage, insecticide and herbicide was investigated. Numbers of hand-sorted earthworms were positively correlated with the amount of soil aggregates (>diam.2 mm) ($r=0.85$, $p<0.01$), and those of oribatid mites (Acari: Cryptostigmata) extracted by using modified Tullgren funnels were positively correlated with the nitrate nitrogen concentration in the soil ($r=0.89$, $p<0.01$). Numbers of oribatid mites were positively correlated with the content of total soil nitrogen and the content of total soil carbon in a Gray Lowland soil (both: $r=0.99$, $p<0.01$) and a Brown Forest soil (not significant), but negatively in an Andosol. The stem length of soybean cultivated on those soils showed a positive correlation with the numbers of earthworms ($r=0.54$, $p<0.05$) and oribatid mites ($r=0.62$, $p<0.05$), while the stem weight of soybean with the numbers of macrofauna organisms ($r=0.61$, $p<0.05$) and earthworms ($r=0.8$, $p<0.01$), respectively. The correlations between the number of soil invertebrates and yield or quality of soybean grain were not significant in this survey.

Discipline: Soils, fertilizers and plant nutrition

Additional key words: soil invertebrates, earthworms, oribatid mites

Received for publication, June 2, 1998

[1..17:References](#)

---Introduction-----

Soil animals are affected by agricultural practices such as tillage, fertilization and weeding ([2,4,10,13](#)), and they influence the physico-chemical properties of soil through fragmentation of crop residues, grazing of microflora and improvement of the soil structure ([8,15](#)). Therefore, the population, biomass and diversity of soil invertebrates could be used as bioindicators to monitor quantitative and qualitative changes of the environment affected by soil use ([14](#)).

In Japan, our group had reported that organic or chemical fertilizer affected crop yield and quality along with the changes of the soil fauna ([5,6](#)). In addition, we observed that fungivorous Collembola and oribatid mites inhibited the incidence of some plant diseases caused by fungal pathogens by grazing of their mycelia ([3,12,16](#)). In this study, attempts were made to study the relation of the soil fauna, especially oribatid mites and earthworms, which were considered to be more useful as indicators than other types of fauna based on preliminary investigations in fields, with the physico-chemical properties of soil and soybean yield under various kinds of soil management.

---Materials and methods-----

1) Experimental design and treatments

The experiment was conducted in the fields of the Upland Farming Division, Tohoku National Agricultural Experiment Station (37°43'N, 140°23'E), Fukushima city, northern Japan. Soil fauna was investigated in Fields I and II as mentioned below. Soil management of the experimental plots in Fields I and II is summarized in [Table 1](#).

Field I was divided into 12 plots (A-L) enclosed with concrete blocks. Soil type of plots A, D, H and K consisted of Gray Lowland soil, that of plots B, E, I and L, Brown Forest soil and that of plots C, F, G and J, Andosol (high-humic). Plot size was 3.3 m x 3.3 m and the soil had been subjected to the following kinds of management for 7 years: Plots A-C and G-I; no-tillage with mulch made of organic materials (wheat plants or soybean plants), and weeds were cut by hand and put onto the soil surface. Plots D-F and J-L; tillage using rotary machine after inorganic (NN444, Nihon Kasei, Japan) or organic (rice straw) fertilization, and weeds cut by hand were brought out from the plots. Kinds of fertilizer applied to each plot are shown in [Table 1\(30KB\)](#). Total amount of fertilizer applied to each plot was 0.2 kg nitrogen per 10 m². Cherry tomato had been grown for 5 years in this field after cultivation of dent- and sweet corn for 2 years.

Field II on light-colored Andosol was cultivated and divided into 15 plots (a-o). The plot size was 2 m x 6 m and the soil had been subjected to the following kinds of management for 4 years: 10 plots (a-j); no-tillage, weeding by hand, no application of insecticides or herbicides, mulch consisting of 4 kinds of organic materials (rice straw, bokashi, mulberry branches and chopped weeds) except for plots a and f, control plots. 5 plots (k-o); rotary digging after fertilization (organic materials applied were plowed under and the soil surface was maintained without mulch), application of Elsan (PAP) and Sumithion (MEP) as insecticides and Simazine (CAT) as herbicide once a year before sowing. Kinds and amount of fertilizer applied are listed in [Table 1](#). Total amount of fertilizer applied was the same as in Field I. Soybean had been grown for 3 years in this field after 2 years of upland rice cultivation.

2) Identification of soil animals and determination of soil properties

In Field I, earthworms were sorted by hand from 2 quadrates (each 50 cm x 50 cm in area, 10 cm in depth) in each plot in October 1993. For the determination of the percentage of aggregation, soil sample (10 cm in diam., 15 cm in depth) was taken from each plot with 2 replications in October 1994, and sifted by the Tiulin-Yorder method. Amount of soil aggregates (%SA, ≥ 2 mm) was obtained from the following calculation.

$$\%SA = 100 \times (A-P) / (T-P)$$

where A; weight of total aggregates (>2 mm), P; weight of aggregates with single-grained structure (>2 mm), T; total weight of tested soil sample.

In Field I, 2 samples were taken from each plot in July and October 1995 by using a rectangular metal sampler (5 cm x 4 cm in area, 5 cm in depth) to extract oribatid mites with Tullgren funnels. Mean number of oribatid mites collected in July and October was used to calculate the correlation coefficient with the values of the soil parameters mentioned below. For the analysis of the soil chemical properties, in October 1995, 3 soil samples (10 cm in diam., 15 cm in depth) were taken from each plot, air-dried for 1 week and passed through a 5 mm mesh sieve. The contents of total soil carbon (T-C) and nitrogen (T-N) were measured by CN-corder (MT-600, Yanaco, Kyoto, Japan) and the concentration of nitrate nitrogen (water-soluble NO_3^-) in soil was determined by ion-chromatography (HPLC column, Hitachi, Tokyo, Japan).

In Field II, 2 soil samples were taken using the above-mentioned sampler to collect oribatid mites, and hand-sorting was performed to collect macro-invertebrates (over 2-3 mm in length) in 2 quadrates in each plot before harvest of soybean in October 1994. Mean values of dry stem weight and length were obtained from 7 soybean plants selected randomly in each plot.

[Continue to: Results and Discussion](#)

[Back to: Contents](#)

---Results-----

Species richness and abundance in this study are indicated in [Table 2](#). The values were higher in plots A-C and G-I. Similarly a high density of earthworms was found in these plots, except for G. In Field II, species number of oribatid mites and individual numbers of macroarthropods differed among the 15 plots. No earthworms were found in plots a, f and k-o. [Fig. 1](#) shows that the lack of uniformity of the oribatid mite abundance among the experimental plots was maintained in 2 seasons, July and October, in other words, the density of oribatid mites was stable in each plot. As for the soil invertebrates used as indicators of soil properties, mean number of oribatid mites in July and October was positively correlated with the concentration of nitrate nitrogen (NO_3^-) measured in October, with a coefficient $r=0.89$; $p<0.01$ ([Fig. 2](#)). The number of oribatid mites also was positively correlated with the content of total soil carbon and with the content of total soil nitrogen in the Gray Lowland soil (both: $r=0.99$; $p<0.01$) and in the Brown Forest soil (not statistically significant), but negatively in the Andosol ([Fig. 3](#)).

Table 2. Species richness and abundance of soil fauna

	Field I	A	B	C	D	E	F	G	H	I	J	K	L
Oribatidsa)	No. of species	14	13	17	4	5	5	16	15	13	5	7	7
	Individual no.	136	107	140	18	24	23	154	389	115	21	42	34
Earthworms	Individual no.	49	14	12	3	0	0	4	22	16	4	6	1

	Field II	a	b	C	d	e	F	G	h	i	j	k	l	m	n	o
Oribatids	No. of species	6	6	9	13	10	3	4	6	12	14	4	4	6	4	6
	Individual no.	87	170	178	348	114	88	55	299	133	109	114	17	28	44	58
Earthworms	Individual no.	0	3	4	1	1	0	6	10	10	3	0	0	0	0	0
No. of macroarthropods		28	90	71	109	59	12	63	57	113	121	19	47	24	37	44

Number relating to oribatids: /200 mL. No. to earthworms and macroarthropods: /2 quadrates.

a): Species and individual number of oribatid mites are expressed as average of July and October.

[•Back](#)

Number of earthworms hand-sorted was positively correlated with the amount of soil aggregates with a diameter above 2 mm ($r=0.85$; $p<0.01$) ([Fig. 4](#)), but the correlation was not significant for the aggregates with a diameter below 2 mm.

As for the relation between the number of soil invertebrates and the growth of soybean in Field II, stem length of soybean was positively correlated with the numbers of earthworms and oribatid mites ($r=0.62$ and 0.54 , respectively, both $p<0.05$) ([Fig. 5](#)). Stem weight of soybean was positively correlated with the number of macroarthropods and earthworms, with coefficients $r=0.61$; $p<0.05$ and $r=0.8$; $p<0.01$, respectively ([Fig. 6](#)).

---Discussion-----

Fujita⁴) reported that the seasonal fluctuations of the density of oribatid mites were different between 2 crop fields (one covered with grass mulch and not tilled, the other treated with chemical fertilizer and tilled using a rotary machine). This study, however, showed that the density of oribatid mites did not change appreciably in 2 seasons in most of the plots of Field I ([Fig. 1](#)). These findings may be attributed to the rather small size of the experimental plots enclosed with concrete blocks and subjected to specific soil management for 7 years. In Field I, the density of soil invertebrates was much higher in plots A-C and H-J covered with organic materials than in the cultivated plots ([Table 2](#)). A similar tendency was found in Field II, suggesting that the soil animals benefit from the organic mulch which provides them a better habitat in keeping the soil moisture and supplying food. Paoletti³) noted that the amount of total soil nitrogen, but not the content of total soil carbon, was positively correlated with earthworm numbers. He, however, did not consider oribatid mites. This study indicated that the correlations between the numbers of oribatid mites and the content of total soil carbon or total soil nitrogen depended on the soil types ([Fig. 3](#)), being positive in the Gray Lowland soil and the Brown Forest soil, whereas slightly negative in the Andosol. These results suggest that the Andosol differs from the other 2 soils in the decomposition pattern of soil organic matter, because oribatid mites must probably play an important role in the decomposition of organic substances in the soil by feeding on various diets, from microbes to dead remains of higher plants. The number of oribatid mites was correlated with the concentration of nitrate nitrogen regardless of the soil types. This fact may indicate that the determination of the number of oribatid mites is a useful indicator of the amount of nitrogen mineralized from organic matter. Earthworm numbers were positively correlated with the amount of soil aggregates ([Fig. 4](#)), which contribute to the structure stability of earthworm casts^{7,9}). High crop yield and stem elongation of soybean were associated with a high density of earthworms¹¹). It was reported that earthworm casts exert a hormone-like effect on plant growth^{1,17}). Although some correlations were also detected between the numbers of soil invertebrates and stem length and weight of soybean in this study, the mechanisms have not been elucidated.

---Abstract-----

Attempts were made to evaluate the regional fertility characteristics of the Philippine lowland soils and to identify the factors determining their productivity for rice cultivation. Eight soil characters, i.e. organic C, total N, available P₂O₅, total P₂O₅, exchangeable K, available SiO₂, clay contents, and CEC for 52 surface soil samples were considered. By factor analysis, 3 factors were extracted, representing the organic matter status, available potassium and silica status, and available phosphorus status. The scores of these 3 fertility components were computed for each sample and based on the mean values for each region, regional characteristics of soil fertility status were determined. Based on the relationship between each of the 3 fertility component scores and rice yield for the 30 plow-layer samples, any of the 3 fertility components was found to be significant for rice production. Furthermore, the lowest among the 3 fertility component scores was considered to control the productivity for rice cultivation. Thus, emphasis was placed on identifying and alleviating the soil constraints, in order to achieve rational nutrient management for higher rice production.

Discipline: Soils, fertilizers and plant nutrition

Additional key words: Factor analysis, fertility components, rice production, soil constraints, soil characters

Received for publication, October 8, 1998

---Introduction-----

In the Philippines, the rice area has not increased since 1975, due to the limit of expansion²⁾. Thus, it is necessary to increase rice production by raising the yield to meet the requirements of the rapidly growing population. In this regard, it is essential to determine the potential capability of the Philippine lowland soils for rice production and to improve nutrient management to achieve a higher yield. The characteristics and fertility evaluation of the Philippine lowland soils were reported by Kawaguchi and Kyuma³⁾. Based on this information, Miura et al.⁵⁾ confirmed that the Philippine lowland soils exhibited a relatively high potential for rice production among the tropical Asian lowland soils, although some regional differences were significant, especially in the organic matter status associated with the rainfall conditions. On the other hand, based mainly on the data from the field experiments carried out during the rainy season in the Philippines, inherent productivity level and response to N rates were revealed for 4 soil orders, i.e. Entisols, Inceptisols, Mollisols, and Vertisols, although the results varied considerably

due to the limited number of experiments⁶). It thus appeared that the relationship of the soil fertility status with rice production had not been well documented.

The present study aims at reevaluating the fertility characteristics of the Philippine lowland soils through the use of factor analysis of selected soil characters and to identify the constraints on rice production.

---Materials and methods-----

1) Study areas and samples

The soil samples used in this study covered 32 lowland soils selected from 6 lowland rice areas in the Philippines ([Table 1](#)). According to Flores and Balagot¹), the mean annual temperature in the Philippines is 27.0 with negligible regional variations, while the mean annual rainfall is 2,533 mm with considerable regional differences ranging from 934 to 4,305 mm. By setting a value of <100 mm rainfall for the dry months, as proposed by Manalo⁴), the whole country can be divided into 3 zones from the humid to arid extreme ([Fig. 1](#)).

An attempt was made to select typical lowland soils which cover large areas in a region. At each site, soil samples were taken from each horizon for laboratory analysis. Furthermore, information pertaining to the cropping pattern, use of fertilizer, rice yield, etc. was collected from the local farmers. Rice yield here refers to rough rice yield, which may not be a quantitative parameter but indicates the representative value for a long period of time under normal growth. As shown in [Table 1](#), rice cultivation was practiced at 30 of the 32 sites examined. For the 24 sites with double or triple cropping of rice, a larger amount of fertilizer was applied in the dry season than in the rainy season since growth was more vigorous in the dry season due to the larger number of sunshine hours. As a result, in general, rice yield was higher in the dry season cropping (average of 5.3 Mg ha⁻¹) than in the rainy season one (4.7 Mg ha⁻¹), although significant differences in rice yield among the sites were observed. In the present paper, rice yield of the rainy season cropping was selected for analysis, since more data were available. As for the rice cultivars, high-yielding modern varieties were adopted except for 1 site, i.e. CO1. In the Philippines, almost 3 million ha or 94% of the total rice area were planted to modern varieties in 1992²).

[*Table 1\(61 KB\) Fig.1. \(26 KB\)](#)

2) Analytical methods

For the soil chemical analysis, the air-dried fine earth samples (<2 mm) were ground to pass through a 0.5 mm mesh sieve. The amount of organic C was determined by wet combustion with a mixture of K₂Cr₂O₇ and H₂SO₄ (Walkley-Black procedure). Total N content was determined by digestion with H₂SO₄, distillation and titration (Kjeldahl procedure). Available P₂O₅ was extracted with an acidic ammonium fluoride and the content was determined by spectrophotometry (Bray & Kurz No. 2 procedure). The total content of P₂O₅, was determined by X-ray fluorescence spectrometry using samples subjected to a pressure of 20 t/cm² for 1 min. The exchangeable bases were extracted with 1 M NH₄OAc (pH 7.0) by percolation. The amounts of exchangeable Ca and Mg were determined by atomic absorption spectrophotometry, and that of exchangeable K by flame emission spectrophotometry. After replacement of exchangeable bases with NH₄OAc, washing with ethanol and replacement of NH₄⁺ with 100g L⁻¹ KCl were successively performed by leaching. To measure the CEC of the sample, NH₄-N content was determined by distillation and titration. Available SiO₂ was extracted with an acetate buffer

solution (pH 4) and the content was determined by spectrophotometry.

For particle size analysis using the fine earth samples, the silt (2 to 20 μm) and clay ($<2 \mu\text{m}$) fractions were analyzed by the pipette method, after removal of organic matter with H_2O_2 and free Fe oxides by the DCB method, and dispersion with NaOH.

3) Statistical methods

For the statistical analysis, 52 surface samples among the 32 soils examined were processed. In order to characterize these surface soil samples, a factor analysis was adopted⁷⁾. Factor analysis aims at transforming the original set of correlated variables into a new set of mutually uncorrelated variables in such a way that a few factors represent a large proportion of the total variance in the original data. In the course of preliminary trials, various attempts were made to select the variables which should be subjected to the final factor analysis. A set of 8 characters, i.e. organic C (OC), total N (TN), available P_2O_5 (AvP), total P_2O_5 (TP), exchangeable K (ExK), available SiO_2 (AvSi), clay (Clay) contents, and cation exchange capacity (CEC) of the 52 surface soil samples was used in the final factor analysis.

[Continue to: Results and discussion](#)

[Back to: Contents](#)

---Results and discussion-----

1) Extraction of fertility component

Based on the factor analysis, 3 factors with eigenvalues larger than 1 were extracted, which together accounted for about 80% of the total variance, as shown in [Table 2](#), implying that these 3 new compound characters retain most of the information in the original variables.

As seen from the final factor loadings after varimax rotation ([Table 2](#)), Factor 1 was significantly related to OC and TN. Highly positive loadings on Clay and CEC reflected the control of organic matter accumulation by the clay content and the contribution of the amount of organic matter to CEC, respectively. Much lower factor loading on TP was ascribed to organic phosphorus to some extent. Thus, Factor 1 which was considered to be related to the characters determined by the amount of organic matter, was thought to represent the "organic matter status (OM)". Factor 2 which was highly related to ExK and AvSi, represented the "available potassium and silica status (AK&Si)". Moderately high loading on CEC may be related to the base status, since positive correlations of the score of Factor 2 with exchangeable Ca ($r=0.498$, significant at the 0.1% level) and with exchangeable Mg ($r=0.473$, significant at the 0.1% level) were observed. Factor 3 clearly represented the "available phosphorus status (AP)", since the contribution of the other variables except for AvP and TP was negligible.

Therefore, it can be considered that these 3 fertility components which are mutually independent, represent different aspects of soil fertility.

Table 2. Eigenvalues, cumulative percentage of the total variance, factor loading of the 3 factors, and communality estimates of the 8 soil characters

	<u>Factor 1</u>	<u>Factor 2</u>	<u>Factor 3</u>	<u>Communality</u>

[Back](#)

2) Regional characteristics of the 3 fertility components

The factor scores were computed for individual soil samples in order to evaluate numerically the fertility characteristics of the lowland soils examined. The scores computed for the samples were standardized with a mean of zero and a variance of unity. Therefore, positive score values indicate above-average status with reference to the overall mean for the 52 sample soils, while negative values below-average status.

The mean values of the 3 fertility component scores estimated for each of the 4 regions on Luzon Island are shown in [Fig. 2](#). The mean values for the Iloilo and Cotabato regions were not used for the analysis due to the limited number of samples. The highest OM score was found in Bicol, due to the highest mean of OC, TN, and Clay. The highest mean of OC and TN was likely to be associated with the effect of humid climatic conditions on the accumulation of organic matter in Bicol ([Fig. 1](#)). The highest mean of Clay may be ascribed to the topography of the sampling sites, mostly on or near the back swamps of the lower reaches of the Bicol River. On the other hand, the lowest mean of OM score was observed in Central Luzon under the much drier climatic conditions ([Fig. 1](#)), although the 3 samples located on or near the back swamps with relatively high Clay, OC, and TN, showed exceptionally positive scores.

The mean AK&Si score was highest in Laguna, while the lowest in Central Luzon. However, appreciable differences in the score were observed among the Cagayan Valley samples: 1 sample on the river terrace showed a very low score, while 2 samples on the valley plain very high scores. The moderately positive correlation of the AK&Si score with the CEC/Clay ratio ($r=0.523$, significant at the 0.1% level) may indicate that available potassium and silica status is associated with the nature of clay, determined by the parent materials or degree of weathering, or both.

The mean AP score was by far the highest in Cagayan Valley, although 1 sample on river terrace showed a very low score. On the other hand, the lowest score was recorded in Bicol, although 2 samples showed very high scores, one of them located on the flood plain in the vicinity of the foot of a mountain where unweathered materials can be easily transported. The weak positive correlation between the AP score and CEC/Clay ratio ($r=0.400$, significant at the 1% level) roughly indicates that the available phosphorus status is related to the nature of clay. The above results on the regional characteristics are in agreement with those obtained previously⁵, suggesting that the adoption of a factor analysis is valid.

[Fig.1.\(26 KB\)](#), [Fig.2.\(14 KB\)](#)

3) Limiting factors to rice production

To analyze the relationship between the soil fertility status and rice yield, a plow-layer soil sample was used here for each of the 30 lowland soils under rice cultivation in the 6 study areas. Based on the relationship between the OM score and rice yield, it appeared that the samples with a higher score tended to show a higher rice yield, except for the 6 samples with relatively high OM scores ([Fig. 3a](#)), suggesting that organic matter exerts a beneficial effect on rice production. The lower rice yield than expected from the OM score for the 6 samples may be

ascribed to some factors, as shown in [Table 3](#). The lowest rice yield in 1 sample from Cotabato, CO1 should be attributed to the cropping of a traditional cultivar which can not attain a higher yield, since no particular constraints were identified from the 3 scores. For the other 5 samples, either of the other 2 fertility components showing a lower score may be significant for determining rice production. As for the relationship between the AK&Si score and rice yield, samples with a higher score tended to show a higher yield, except for 5 samples, indicating the beneficial effect of available potassium and silica ([Fig. 3b](#)). The limiting fertility components for the 5 samples could be deduced from Table 3. A similar trend was observed from the relationship between the AP score and rice yield ([Fig. 3c](#)), except for 6 samples ([Table 3](#)).

Based on the above results, all the 3 fertility components appeared to play a significant role in rice production. Based on the law of the minimum according to which any essential nutrient with a deficient level determines crop production, any fertility component with the lowest level may control rice yield. As shown in [Table 4](#), the possible cause of low rice yield of <4 Mg ha⁻¹ could be identified for the 6 samples. In the case of 3 samples, NE4, IS1, and IL1, all the 3 scores showed negative values, indicating that all these constraints could be responsible for the low rice yield.

Therefore, it is essential to determine the actual soil fertility status in individual rice fields, e.g. through soil diagnosis, in order to identify and alleviate soil constraints on rice production. Rational nutrient management involving adequate and balanced fertilizer application should be applied in the Philippine lowland soils, in order to increase rice production or to secure a stable supply as a whole.

(Sendai, Miyagi, 982-0215 Japan)

* :Faculty of Agriculture, Yamagata University
(Tsuruoka, Yamagata, 997-8555 Japan)

---Abstract-----

This report deals with experiments carried out to examine the possibility of using unrefined rapeseed oil as a substitute for light oil in a small diesel engine. The authors carried out tests on short-term performance, long-term operation and no-load continuous operation using various kinds of unrefined rapeseed oil (deacidified oil, degummed oil and crude oil) produced in the process of refining, and refined rapeseed oil and light oil for comparison. Specific fuel consumption, thermal efficiency, exhaust-gas temperature, and density of black smoke in exhaust-gas were examined in tests on short-term performance and long-term operation. The amount of deposits in the precombustion chamber and on the injection nozzle was determined in tests on no-load continuous operation. As a result, it was considered that deacidified rapeseed oil can be used as fuel for a diesel engine. Degummed oil and crude rapeseed oil were found to be unsuitable for use as fuel due to the high level of incombustible materials in oil.

---Introduction-----

Many studies on the use of plant oil as substitute fuel for a diesel engine have been carried out after the oil price increased in 1973^{2,3,6,7,9-11}). The authors also carried out experiments on the possibility of using unrefined rapeseed oil as a substitute for light oil in a small diesel engine. The main reason for using plant oil as a substitute fuel is that farmers can produce the fuel material by themselves, without requiring the complex process of refining from crude oil. Rapeseed oil was selected in this study because rapeseed is cultivated widely and conveniently in Japan.

The engine must be easily started, and requires low combustion noise and good load performance¹). In addition to these 3 conditions, reliability and stable operation performance over long running periods and low carbon coating to the combustion chamber in the no-load operation with the substitute oil are required.

In this paper, the authors carried out short-term performance tests, long-term operation tests and no-load continuous tests using various kinds of unrefined rapeseed oil (deacidified oil, degummed oil and crude

oil).

---Materials and methods-----

1) Materials

The fuel used for the experiments consisted of various kinds of unrefined rapeseed oil (deacidified, degummed and crude oil) and refined rapeseed and light oil. Preparations of deacidified, crude and refined rapeseed oil were produced by N Co., degummed rapeseed oil by R Co. and light oil consisted of No.2 diesel oil.

The characteristics of each kind of fuel were defined by measuring the density, net calorific value, kinematic viscosity, content of incombustible materials and fatty acid composition ([Table 1](#)). The content of incombustible materials was determined by a method involving the measurement of carbon residues.

The short-term performance tests and long-term operation tests were conducted on an A-diesel engine, and no-load continuous tests on a B-diesel engine ([Table 2](#)).

Engine power was measured with an electric dynamometer connected to a diesel engine by 2 V-belts of B-type. Fuel was supplied through a burette, and fuel capacity was calculated by determining the consumption time of the volume of fuel.

Density of black smoke in exhaust-gas which was inhaled for 4 s through a filter paper was measured with a smoke tester. The measuring point of exhaust-gas temperature was located about 10 cm inside of the muffler.

* [Table 1.\(19 KB\)](#), [Table 2.\(20 KB\)](#)

2) Short-term performance tests

The operating mode of the short-term engine performance tests was as follows: warming operation time was 20 min(1,800 and 2,000 rpm), 75 load operation time 160 min(2,200 rpm), no-load operation time 5 min, and rated load operation⁸) time 25 min ([Fig. 1](#)). Engine power, fuel capacity, density of black smoke in exhaust-gas and exhaust-gas temperature were measured every 10 min in 75 load operation, and every 5 min in rated load operation.

Fuels used included, in the following order, light oil, deacidified oil, degummed oil and crude oil in the test.

3) Long-term operation tests

The conditions for the long-term operation involved rated revolutions and 75 load. The total target time of the long-term operation was 200 h, and of the continuous operation about 5 h in each operation. Engine performance tests were carried out every 25 h in the same way as in the rated load operation shown in [Fig.1\(18 KB\)](#). For the engine performance tests, light oil was used as fuel every 100 h.

The amount of deposits in the precombustion chamber and on the injection nozzle in the long-term operation was monitored. Accordingly, the precombustion chamber and the injection nozzle were replaced each time fuel was replaced.

4) No-load continuous operation tests

The conditions for no-load continuous operation for each kind of fuel included rated revolutions(2,400 rpm), and the target time of the continuous operation was 100 h. As in the long-term operation, the precombustion chamber and the injection nozzle were replaced each time fuel was replaced.

The incombustibility in the precombustion chamber was expressed by the residual quantity after the deposits of the no-load continuous operation were put in the electric furnace at 550 for 30 min. In addition, the combustible materials in the electric furnace consisted of carbon.

---Results and discussion-----

1) Short-term performance tests

[Figs.2 and 3](#) depict the 75 load operation performance and rated load operation performance.

* [Fig.2.\(30 KB\)](#), [Fig.3.\(28 KB\)](#)

The consumption of deacidified oil was almost the same as or slightly lower than that of light oil. The thermal efficiency of deacidified oil was 2.2-5.8 higher than that of light oil in each performance test. The combustion speed of deacidified oil was high because of the oxygen content in the fuel, and the exhaust-gas temperature of this oil was 3-20 lower than that of light oil. Deacidified oil also had a lower density of black smoke in exhaust-gas than light oil.

The fuel consumption of degummed oil was almost the same as or slightly lower than that of deacidified oil and light oil. The thermal efficiency of degummed oil was the same as that of deacidified oil. The exhaust-gas temperature and density of black smoke in the exhaust-gases of degummed oil were about the same as those of deacidified oil and were lower than those of light oil.

The consumption of crude rapeseed oil as fuel was higher than that of deacidified oil and light oil. The thermal efficiency of crude rapeseed oil showed a lower value than that of deacidified oil. The exhaust-gas temperature of crude rapeseed oil in the 75% load operation increased gradually in relation to the running time and increased suddenly after 2 h and 30 min. The density of black smoke in the exhaust-gas also increased suddenly after 2 h and 30 min of operation.

The thermal efficiency of refined rapeseed oil in a diesel engine with 2.57 kW rated power, 2,000 rpm rated revolution and 21.6 compression ratio, was almost the same as that of light oil⁶⁾. The thermal efficiency of refined rapeseed oil in a diesel engine with 4.41 kW rated power, 1,200 rpm rated revolution and 20.0 compression ratio was higher for high load and high revolutions, and lower for low load and low revolutions⁴⁾ than that of light oil. And the thermal efficiency of refined rapeseed oil in a large diesel engine with 41 kW rated power, 3,000 rpm rated revolution was about 2% higher than that of light oil in low to high load operations⁵⁾.

It was considered that the thermal efficiency increased not only under high load but also low load operation conditions, because deacidified oil with defective ignition showed a shorter ignition lag, causing high temperature in the combustion chamber when the engine conditions involved high compression ratio and high revolutions.

Incombustible deposits were detected on the injection nozzle and injected fuel spray was adversely affected by this build-up, which was associated with the incombustible materials present in crude rapeseed oil. As a result, the loaded performance decreased while the exhaust-gas temperature and density of black smoke in exhaust-gas increased.

2) Long-term operation tests

[Fig. 4](#)(33 KB) shows the thermal efficiency of engine performance every 25 h.

Through out the 200 h of operation using deacidified oil, the power was stable for the entire period and no accumulation of deposits was found on the injector nozzle although an amount of 0.153 g of incombustible deposits was detected in the precombustion chamber.

Irregular revolution and detonation noise started to occur after about 20 h of operation in the engine when degummed oil was used as fuel, leading to the interruption of the operation after 25 h. A large quantity of incombustible deposits was detected around and on the injection nozzle after 25 h of operation. Therefore degummed oil produced a large quantity of incombustible materials in the combustion chamber, precombustion chamber and on the injection nozzle. This phenomenon is due to the fact that degummed oil contains a large quantity of incombustible materials which affected the length of the operation time. Since the injected fuel spray was impeded by the incombustible deposits on the nozzle, the ignition lag increased and the engine performance was reduced. Therefore the operation of the engine was impossible under such adverse conditions. Engine operation using degummed oil was satisfactory only when the build-up of incombustible deposits was low.

In the engine fueled by crude oil, irregular revolution and detonation noise started to occur after about 40 h of operation. After 50 h, the precombustion chamber and the injection nozzle were cleaned. But, again after 160 h, irregular revolution and detonation noise were observed, leading to the interruption of the operation after 175 h. A large amount of incombustible deposits was detected in the port connected to the combustion chamber, on the injection nozzle and in the precombustion chamber ([Fig. 5](#))(9KB)

3) No-load continuous operation tests

[Fig. 6](#)(18 KB) shows the relationship between the amount of deposits in the precombustion chamber and the content of incombustible materials in fuel. [Fig. 7](#)(17 KB), shows the amount of incombustible materials in the precombustion chamber.

The amounts of carbon and incombustible materials in the precombustion chamber were 0.222 g and 0.003 g, respectively in the no-load operation when deacidified oil was used ([Table 3](#)). The deposits consisted almost completely of carbon due to the incomplete combustion associated with the low combustion temperature. The content of incombustible materials of the fuel was significantly correlated with the accumulation of deposits in the precombustion chamber in the no-load operation, and the amount of accumulated deposits could be estimated by measuring the content of incombustible materials. In the fuel a very small amount of carbon was found around the injection nozzle when deacidified oil, refined oil and light oil were used as fuel.

Table 3.
Deposits and incombustibility in the precombustion chamber after 100 h of no-load continuous operation

	(unit:g)		
	Deposits ^{b)}	Incombustibility	
Rapeseed oil			
/Deacidified oil	0.225	0.003	
/Degummed oil ^{a)}	1.103	0.833	
/Crude oil	0.655	0.245	a): Operation time: 85 h.
/Refined oil	0.208	0.001	b): Carbon = deposits - incombustibility.
Light oil	0.123	0.012	

During the no-load operation, irregular revolution and detonation noise started to occur after about 80 h of operation in the engine fueled by degummed oil. As a result the operation of the engine stopped after 85 h. The accumulation of deposits in the precombustion chamber of the engine operating with degummed oil was 1.103 g, a value about 5 times higher than when deacidified oil was used. The amount of incombustible materials was 0.833 g. The accumulated deposits contained a large quantity of gum which coated the wall of the precombustion chamber and produced a thin film on the injection nozzle. The gum adhered to the head of the injection nozzle in the no-load operation when degummed oil was used as fuel ([Fig. 8](#)) (8 KB).

Accumulated deposits amounted to 0.655 g in the precombustion chamber when crude rapeseed oil was used, a value 3 times higher than when deacidified oil was used. The amount of incombustible materials was 0.245 g. Gum accounted for a large part of the accumulated deposits and it adhered to the wall of the precombustion chamber and the port connected to the combustion chamber. Gum adhered to the head of the injection nozzle in the no-load operation when crude rapeseed oil was used, in the same way as when degummed oil was used as fuel.

A recently developed method of removing gum from rapeseed oil by the elimination of organic acids does not always remove all of gum present in oil. Therefore, in terms of diesel fuel the degummed oil provided by the manufacturer is, in fact considered to be comparable to crude oil.

The maximum content of incombustible materials in oil for use as substitute fuel was estimated to be about 0.01%.

---Conclusion-----

This report deals with experiments carried out to examine the possibility of using various kinds of unrefined rapeseed oil (deacidified oil, degummed oil and crude rapeseed oil) as a substitute for light oil in a small diesel engine.

The results are summarized as follows:

(1) Deacidified rapeseed oil was superior to light oil in terms of load performance and black smoke density in exhaust-gas. The amount of accumulated deposits in the precombustion chamber and on the injection nozzle after long-term load operation and no-load continuous operation tests was almost the same for deacidified rapeseed oil and refined oil. Deacidified rapeseed oil was considered to be suitable for use as fuel for a diesel engine.

(2) The degummed oil provided by the manufacturer was considered to be comparable to crude oil. When there were no incombustible deposits on the nozzle, the use of degummed oil was preferable to that of light oil in terms of operation performance, and both the exhaust-gas temperature and the density of black smoke in exhaust-gas were lower compared with light oil. However in the long-term load operation and no-load continuous operation, deposits of incombustible materials consisting essentially of gum adhered to the inside of the precombustion chamber and the injection nozzle. The normal spray of injected fuel was difficult, leading to a reduction of the performance and to the interruption of the operation of the engine.

Rapeseed degummed oil produced by the method of removal of organic acids was found to be unsuitable for use as diesel fuel.

(3) The load performance when crude rapeseed oil was used was slightly lower than when deacidified oil was used. A large quantity of incombustible materials, chiefly gum, was deposited in and adhered to the combustion chamber, precombustion chamber and the injection nozzle. The size of the build-up was related to the running time. As a result, the nozzle became blocked, detonation noise occurred and eventually the engine stopped. Crude rapeseed oil with a high content of incombustible materials was found to be unsuitable for use as fuel for a diesel engine.

---Abstract-----

A theory and a method were developed for obtaining temperature characteristics for the flowering period of deciduous and citrus fruit trees from the number of days transformed to standard temperature (DTS) based on the Arrhenius law. Three temperature characteristics, i.e. (1) starting date of calculation (ST day), (2) temperature sensitivity (Ea) or temperature coefficient of growth rate (K) and (3) DTS from ST day to flowering time, were determined in a total of 186 cultivars from 11 species on the Main Island of Japan (Honshu) based on the daily mean air temperature and flowering date recorded over a period of at least 10 years. These temperature characteristics differed among cultivated species and may enable to estimate the flowering date.

Discipline: Horticulture

Additional key words: temperature sensitivity, Arrhenius law, deciduous and citrus fruit trees

Received for publication, November 2, 1998

This paper is designated as contribution No.1119, from the National Institute of Fruit Tree Science. This work was supported in part by a Grant-in-Aid (Development of Information Management for Agricultural Technique System) from MAFF. Part of this research was carried out in collaboration with the Project Research Team of the National Agriculture Research Center.

Present address:

*2 Faculty of Agriculture, Niigata University (Niigata, 950-2102 Japan)

---Introduction-----

The climate of the islands of Japan ranges from subpolar to subtropical. Most of the fruit orchards are located on hillsides and are exposed to extreme weather conditions due to the elevation and topography of the sites. Development of new land for fruit production depends on the accurate estimation of the growing period. Predictive methods for estimating the flowering period could facilitate orchard management practices such as artificial pollination, hormone treatment and cultivation control. A theory was proposed based on the number of days transformed to standard temperature (DTS) derived from the Arrhenius law, and a method (DTS method) was developed by analyzing the relationship between the biological activity and temperature⁴. Although the Arrhenius law has been applied to higher plants ^{6-8,10}, there is no report in which temperature characteristics have been used to improve plant growth. We have shown that temperature characteristics based on the Arrhenius plot can be used effectively to determine the budding and flowering period of Japanese pear trees¹⁰. Omoto and Aono⁹ were able to estimate the flowering date of *Prunus yedoensis* at 21 meteorological stations in Japan by using the DTS method.

An Arrhenius plot of the growth of higher plants has been reported to give a straight line with a negative slope or a line broken into 2 parts, in the range between the temperature of physiological zero and that at which protein denaturation occurs^{6,8}. Our experiments have shown that the Arrhenius plot of the flowering period of Japanese pear trees gives linear plots at 7-20, and that the Arrhenius law can be effectively applied to the flowering period ¹⁰. Thus, temperature characteristics were calculated assuming that the Arrhenius law could also be applied to fruit trees other than Japanese pear.

---Theory and methods-----

The relationship between the growth rate constant(k) and temperature can be expressed by equation (1) according to the Arrhenius law. The DTS is defined as the number of days transformed to standard temperature. The equation for the calculation of DTS can be derived as follows :

The ratio of the growth rate constant (k) at arbitrary temperature (T) to (ks) at a standard temperature (Ts) can be represented by equation (4) using equation (1).

$$k = A \exp(-Ea/RT) \text{-----(1)}$$

$$dk/dT = A \exp(-Ea/RT) \cdot Ea/RT^2 = k \cdot K \text{-----(2)}$$

$$K = Ea/RT^2 \text{-----(3)}$$

$$m = k/ks = \exp;Ea(T-Ts)/RTTs \text{-----(4)}$$

where k: growth rate constant (day⁻¹),

Ea : apparent activation energy (Jmol⁻¹),

R : gas constant (8.314 JK⁻¹ mol⁻¹),

T : absolute temperature (deg⁻¹),

K : temperature coefficient of growth rate (deg⁻¹),

A : constant,

ks : growth rate constant at standard temperature Ts,

m : conversion coefficient.

Selecting 20 as the standard temperature, the daily 20 DTS can be expressed as follows.

$$\text{Daily 20 DTS} = \exp;Ea (t-293)/586T \text{-----(5)}$$

where t is the daily mean temperature.

The following 3 temperature characteristics must be obtained for each tree species to estimate the flowering date.

(1) ST day : Starting date of calculation,

(2) Ea : Temperature sensitivity¹⁰),

(3) DTS : DTS from ST day to the flowering date.

First step was to calculate the mean DTS from arbitrary Ea in each year using the flowering date for at least 10 years. The next step was to compute the residual sum of squares (RSS)for the difference between the estimated and observed flowering period. The optimal temperature characteristics, i.e. ST day, Ea, DTS, gave the minimum RSS.

Calculation was conducted using the personal computer program FLOWER based on the date for fullbloom and the daily mean air temperatures in each year, using 20 as the standard temperature. Phenological data were recorded for apple, pear, grape, peach, persimmon, chestnut, plum, blueberry, satsuma mandarin and other citrus trees. Data used included the daily mean air temperatures. Data on the date of flowering were kindly provided by 57 public research institutes.

---Results and discussion-----

Temperature characteristics were obtained with considerable accuracy from the calculation of the observed dates and the estimated dates of flowering in 186 cultivars from 11 fruit tree species in Honshu. Typical dates for apple, pear, peach, plum, grape, persimmon, chestnut, satsuma mandarin and navel orange trees are shown in [Fig. 1](#). In some cases the estimated dates that were different from the actual observed dates were obtained during a year with unusual weather. These results show that temperature characteristics up to the flowering period can be obtained with a good accuracy using the DTS method from Kagoshima to Hokkaido for almost all the

cultivated species of fruit trees.

The ST day for navel orange was estimated to be January 10 when RSS was smallest, and that for persimmon February 25 when minimum RSS was observed between February 20 through March 1. Except for some cases, estimation of the ST day was easily obtained. Therefore, it is important to give a physiological interpretation to the ST day, rather than a mathematical interpretation. The estimated ST day in the present study fell in early January for citrus trees, early February for peach trees, mid-February for apple, pear and plum trees, late February to early March for grape, persimmon and chestnut trees. Based on the reports on cold hardiness and dormancy, these periods were found to correspond to those when endodormancy had been terminated (1-3,5).

[Fig. 2](#) shows the relationship between the standard temperature and DTS obtained from temperature sensitivity (E_a) values of various fruit trees in the central part of Honshu Island. Since the E_a value varied among tree species, the change in the rate of DTS was different at various standard temperatures and could be classified into 2 groups([Fig. 2](#)). At 20, the first group consisting of apple, pear, peach and plum trees, flowered between 10 and 25 days, the second group consisting of grape, persimmon, chestnut and citrus trees, flowered between 47 and 58 days. In the central part of Honshu, the first group flowered from late March through mid-April, while the second group flowered from mid-May through early June. In the second group, the ST day for citrus fell early in mid-January while that for grapes, persimmons and chestnuts fell in late February. Interestingly, there was a difference in the growth period from the endodormancy to the flowering period even though the groups showed the same flowering period.

[Fig.1.\(59KB\)](#), [Fig.2.\(19KB\)](#)

Temperature characteristics of cultivated species in the central part of Honshu are shown in [Table 1](#). E_a values ranged from 75 to 92 kJ mol⁻¹ except for plums, the difference being negligible among the cultivated species. The K values calculated from equation (3) were in the range of 0.105-0.129, suggesting that the change of one degree in the air temperature caused a 10.5-12.9 change in the growth rate. Plums had a K value of 0.152 and were the most sensitive to the change in the air temperature among the cultivated species. Such a difference in E_a was reflected in the DTS. For example, chestnuts flowered within approximately 58 days at the standard temperature of 20, being the slowest among the tested trees, and yet, below 12.5, they showed the shortest flowering period ([Fig. 2](#)).

Table 1. Values of temperature characteristics determined by DTS method for fruit tree flowering (central part of Honshu Island)

Leading cultivar	Days transformed to the standard temperature (DTS)		Temperature sensitivity (E_a)		Starting date for estimating DTS	r^2 (d)	Number of years used for calculation	Observation site

Mechanism of Off-Flavor Production in *Brassica* Vegetables under Anaerobic Conditions

Kazuhiro DAN, Masayasu NAGATA and Ichiji YAMASHITA

Department of Applied Plant Physiology, National Research Institute of Vegetables, Ornamental Plants and Tea
(Ano, Mie, 514-2392 Japan)

---Abstract-----

Mechanism of the production of off-flavor in *Brassica* vegetables, mainly broccoli stored under anaerobic conditions was studied. Methanethiol and dimethyl disulfide were identified as the volatile sulfur compounds in the headspace of anaerobically stored *Brassica* vegetables, including broccoli. When the activity of C-S lyase, a key enzyme for the formation of volatile sulfur compounds, was measured, no significant changes were observed in the C-S lyase activity in broccoli kept under anaerobic and aerobic conditions. The most obvious difference between anaerobically and aerobically kept broccoli was the degradation of the cell membranes. These results suggest that under anaerobic conditions volatile sulfur compounds are formed by the degradation of cellular membrane lipids and loss of intracellular compartmentation, allowing the enzyme-substrate reaction to proceed. Furthermore, the factors which affect the production of the volatile sulfur compounds, under anaerobic conditions were also investigated. Methanethiol which was one of the first compounds formed under anaerobic conditions appears to be primarily responsible for the off-flavor. Therefore, the chemical nature of the formation processes of methanethiol was also analyzed.

Discipline: Postharvest technology

Additional key words: broccoli, storage, volatile sulfur compounds

---Introduction-----

Modifying the storage atmosphere by lowering O₂ and/or increasing CO₂ prolongs storage life and enables to preserve the high quality of many fresh fruits and vegetables. Packaging with polymeric films with specific gas permeabilities creates a modified atmosphere which exerts a beneficial effect on the extension of the storage life of various fruits and vegetables. The composition of the atmosphere in the package depends on the respiration rate of the commodity and the gas permeation rate of the film. However, when the respiration rate increases because of the increase in the holding temperature, O₂ concentration decreases and CO₂ concentration increases in the package to levels that result in the development of an off-flavor if the gas permeability of the film is insufficient.

In Japan, *Brassica* vegetables are commercially important crops, and among *Brassica* vegetables, broccoli is a highly perishable commodity and its quality and shelf-life markedly depend on the storage conditions. Modifying the atmosphere storage of broccoli under suitable O₂ and CO₂ conditions has enabled to extend the shelf-life of broccoli. However, fresh broccoli kept in modified atmosphere storage with very low O₂ and/or very high CO₂ levels produced an off-flavor, although the original appearance was retained⁷⁾. Although the production of this offensive flavor appears to be a critical factor responsible for market losses in broccoli, the mechanism of off-flavor formation under anaerobic conditions has not been elucidated. An understanding of the mechanism(s) involved in the development of off-flavor could contribute to the improvement of the shelf-life of broccoli and the extension of its postharvest availability. In this paper, the mechanism of the formation of undesirable flavor in *Brassica* vegetables, especially broccoli stored under anaerobic conditions is described.

--Off-flavor production in *Brassica* vegetables stored under anaerobic conditions--

Brassica vegetables stored under anaerobic conditions developed off-flavor. As shown in [Fig. 1](#) (10 KB), ethanol, acetaldehyde, methanethiol, and dimethyl disulfide were identified as the volatile compounds in the headspace of anaerobically stored broccoli (*Brassica oleracea* L. var. *italica*). Ethanol and acetaldehyde formation may result from anaerobic respiration. Volatile sulfur compounds, such as methanethiol and dimethyl disulfide, are mainly involved in the production of the undesirable flavor of broccoli stored under anaerobic conditions. These volatile compounds were also formed in other *Brassica* vegetables, such as cabbage (*B. oleracea* L. var. *capitata*), cauliflower (*B. oleracea* L. var. *botrytis*), Chinese cabbage (*B. campestris* L. ssp. *pekinensis*) and komatsuna (*B. campestris* L.) stored under anaerobic conditions. In *Brassica* vegetables, broccoli easily developed a strong off-flavor under anaerobic conditions. Therefore, broccoli was used as a material for the following experiments.

--Factors controlling the production of volatile sulfur compounds under anaerobic conditions--**1) Plant parts**

A number of microorganisms have been reported to produce methanethiol. However, a recent study carried out by Derbali et al.⁽⁸⁾ suggested that volatile sulfur compounds produced in broccoli under anaerobic conditions were of plant origin, which was confirmed by using sterile broccoli seedlings. The proposed mechanism for the formation of volatile sulfur compounds in *Brassica* vegetables is illustrated in [Fig. 2](#) (19 KB). To determine the levels of volatile sulfur compounds, fresh broccoli florets were divided into flower buds and pedicels which were analyzed for the content of S-methyl-L-cysteine sulfoxide and the activity of C-S lyase. Production of methanethiol and dimethyl disulfide under anaerobic conditions was significantly higher in flower buds than in pedicels ([Fig. 3](#)) (18 KB), and likewise, the content of their precursor, S-methyl-L-cysteine sulfoxide, was about 4 times higher in flower buds ([Table 1](#)). The activity of C-S lyase, which catalyzes the conversion of S-methyl-L-cysteine sulfoxide to methanethiol and dimethyl disulfide, was significantly higher in flower buds than in pedicels ([Table 1](#)).

Table 1. Concentration of S-methyl-L-cysteine sulfoxide and activity of C-S lyase in fresh broccoli flower buds and pedicels⁽⁶⁾

Plant part	S-Methyl-L-cysteine sulfoxide (mg/g f.w.)	C-S lyase activity (units/g f.w.)
Flower buds	2.12 ± 0.004	7.7 ± 0.57
Pedicels	0.51 ± 0.086	1.2 ± 0.06

2) Temperature

Fresh broccoli florets were stored at 10, 20, and 30 under anaerobic conditions. High temperature promoted the production of methanethiol and dimethyl disulfide from anaerobically treated florets ([Fig. 4](#)) (20 KB). It is well known that temperature is the major environmental factor in the postharvest life of fresh vegetables because, within the physiological temperature range, the velocity of a biological reaction, increases 2- to 3-fold for every 10 rise in temperature. Therefore, the formation of methanethiol and dimethyl disulfide from anaerobically treated broccoli was affected by the temperature.

3) Effect of the duration of the low temperature pre-storage period

After fresh heads were pre-stored in the air at 1 for 7, 14 and 21 days, the florets were kept under anaerobic conditions. Low temperature pre-storage reduced the production of volatile sulfur compounds under anaerobic conditions, even though the S-methyl-L-cysteine sulfoxide content and C-S lyase activity did not decrease⁽⁶⁾. It is thus assumed that the decrease in the production of volatile sulfur compounds is due to other factors, along with the increase in the duration of the pre-storage period. The visual appearance, such as green color and tightness of head, deteriorated with the increase of the duration of the period of pre-storage at low temperatures.

---Mechanism of formation of volatile sulfur compounds-----

1) Loss of intracellular compartmentation

To analyze the mechanism of formation of volatile sulfur compounds, freshly harvested broccoli were stored under anaerobic conditions. During the storage, there was no significant difference in the activity of *C-S* lyase between the anaerobically kept and aerobically kept broccoli, though a large amount of volatile sulfur compounds was generated³). These observations suggest that the formation of volatile sulfur compounds may not be associated with the increase in the activity of *C-S* lyase. The percentage of electrolyte leakage from flower buds sections of aerobically kept broccoli increased gradually during storage ([Fig.5](#))(13 KB), whereas that from flower buds sections of anaerobically kept broccoli increased rapidly. Furthermore, the free fatty acid to total fatty acid ratio of both aerobically and anaerobically kept broccoli increased during storage, while the ratio in anaerobically kept broccoli was significantly higher than that in aerobically kept broccoli³)(data not shown). These results suggest that anaerobic treatment accelerated cell membrane degradation compared to natural senescence of broccoli under aerobic conditions. Significant cell membrane degradation was reflected by the large increase in the percentage of electrolyte leakage and the rise in the free fatty acid to total fatty acid ratio. Free fatty acid accumulation in the bilayered membrane has been correlated with the appearance of gel phase domains^{1,11,12}). The occurrence of gel phase lipid domains in the membrane leads to a packing defect resulting in the loss of selective membrane permeability, particularly to ions and small molecules. Presumably, the loss of membrane integrity contributes to the loss of intracellular compartmentation.

Much of the characteristic odor and flavor associated with *Brassica* vegetables is due to the degradation of non-protein sulfur-containing amino acids, such as S-methyl-L-cysteine sulfoxide by *C-S* lyase in the tissues without reaction with the substrate until the tissues are physiologically and/or physically damaged.

These results indicate that, under anaerobic conditions, volatile sulfur compounds, such as methanethiol and dimethyl disulfide are formed by the degradation of cellular membrane lipids and the loss of intracellular compartmentation, thus, allowing enzymes and their substrates to react.

2) Methanethiol production

Methanethiol which was one of the first compounds formed under anaerobic conditions appears to be primarily responsible for the offensive odor. Dimethyl disulfide may evolve from the oxidation of methanethiol. However, the chemical nature of the formation processes of methanethiol in *Brassica* has not been well-characterized. In this study, broccoli tissues were mechanically injured in order to disrupt intracellular compartmentation and the factors responsible for the formation of methanethiol from S-methyl-L-cysteine sulfoxide were investigated.

A solution of disrupted fresh broccoli tissues was mixed with one of the reagents. Addition of L-methionine, L-cystine or oxidized glutathione to the solution did not induce the formation of methanethiol, whereas the addition of L-cysteine or reduced glutathione to the solution resulted in the production of a considerable amount of methanethiol and small amounts of some other unknown volatile sulfur compounds ([Table 2](#)). Reducing agents (L-ascorbic acid or sodium borohydride), however, did not induce the production of more methanethiol, which indicates that free SH of L-cysteine or reduced glutathione is responsible for the formation of methanethiol.

The fresh tissue solution was passed through a filter with a molecular weight cut off of 10,000. The filtrate was mixed with L-cysteine. A significant amount of methanethiol evolved after the addition of L-cysteine ([Table 3](#)), suggesting that the reaction leading to the formation of methanethiol by the addition of L-cysteine, may not be enzymatic. However, the same tests with a tissue solution prepared from previously autoclaved broccoli failed to reveal the production of methanethiol, which indicates that enzyme(s) were involved in some steps of the pathway of methanethiol formation.

[Table 2. Effects of sulfur-containing amino acids, glutathione, L-ascorbic acid, and sodium borohydride on the formation of methanethiol in the headspace of stoppered test tubes containing a disrupted tissue solution of fresh broccoli⁴](#)

<u>Treatment</u>	<u>Methanethiol (peak area x 10⁻⁴)</u>	
Control	0.7	
L-Cysteine	131.4

	5	1.6	Back

The reaction mixture was incubated 20 for 1 h. a): Final concentration in the reaction mixture.

Methanethiol is considered to be produced as a result of the conversion of S-methyl-L-cysteine sulfoxide to an unstable methanesulfenic acid intermediate by C-S lyase in *Brassica* which is then condensed and dehydrated to form more stable methyl methanethiosulfinate. The amount of methyl methanethiosulfinate which was detected in the solution of disrupted fresh tissues immediately after preparation ([Table 4](#)), increased about 10 times during a 2-h incubation at 20. The reaction mixture of the solution of disrupted fresh tissues and S-methyl-L-cysteine sulfoxide released a large amount of methyl methanethiosulfinate. When L-cysteine was mixed with the solution of disrupted fresh tissues, methyl methanethiosulfinate disappeared. No methyl methanethiosulfinate was detected in the disrupted tissue solution, prepared from heat-treated broccoli. The thiolsulfonates, -SO-S-, react rapidly with L-cysteine²⁾. The following reaction might have occurred in the mixture solution of methyl methanethiosulfinate and L-cysteine.

Table 4. Methyl methanethiosulfinate formation in the disrupted tissue solution of broccoli after each treatment ⁴⁾

<u>Treatment</u>	<u>Methyl methanethiosulfinate</u> (peak area x 10 ⁻⁴)
Disrupted fresh tissue solution (initial)	5.2

Disrupted fresh tissue solution + 10 mM S-methyl-L-cysteine sulfoxide ^a) incubated at 20 for 2h	229.9
Disrupted fresh tissue solution + 5 mM L-cysteine ^a) incubated at 20 for 2 h	Not detected
Disrupted tissue solution prepared from tissues exposed to 100 for 10 min	Not detected
a): Final concentration in the reaction mixture.	Not detected

In our study, only a trace amount of methanethiol was produced after fresh tissue disruption, and almost concurrently with methyl methanethiosulfinate. Derbali et al.⁸) and Di Pentima et al.⁹) reported that a considerable increase in the content of free amino acids, particularly sulfur-containing amino acids and their derivatives, was observed in broccoli stored under anaerobic conditions, which resulted in the production of volatile sulfur compounds including methanethiol. Their findings suggest that methanethiol may be formed as a result of the reaction of methanethiosulfinate with free SH-containing amino acids and peptides under anaerobic conditions.

---Prevention of off-flavor production-----

Methanethiol and dimethyl disulfide are derived from a common precursor, methyl methanethiosulfinate, which is a product of the C-S lyase-catalyzed degradation of S-methyl-L-cysteine sulfoxide. The selection of or breeding for cultivars with low S-methyl-L-cysteine sulfoxide content or C-S lyase activity may enable to develop broccoli with fewer undesirable volatile sulfur compounds under anaerobic conditions. Presently, there are no broccoli cultivars with an extremely low production of volatile sulfur compounds under anaerobic conditions⁵). Moreover, in common to *Brassica* vegetables, the production of volatile sulfur compounds is significantly higher in flower buds than in leaves or stems⁵). These findings suggest that the off-flavor is readily generated in broccoli compared with other *Brassica* vegetables, because the main edible portion of broccoli consists of flower buds. Therefore, proper storage and distribution management is presumably the major condition for postharvest handling of *Brassica* vegetables, especially broccoli.

Development of Silk Yarns for Knitted Fabrics

Hiroshi KATO and Tamako HATA

Department of Insect Processing Engineering, National Institute of Sericultural and Entomological Science
(Tsukuba, Ibaraki, 305-8634 Japan)

---Abstract-----

The mechanical characteristics of knitted silk fabrics prepared using salt-shrunk, fiber-dispersed and resin-treated silk yarns were determined based on the Kawabata Evaluation System for Fabrics (KES-FB). These knitted fabrics had a very soft feel and were fluffy and light. The amount of starting material yarn needed to obtain a knitted fabric of the same thickness was smaller in the case of the processed yarns compared with the unprocessed control yarn. Among the mechanical properties determined, the fabrics made from the processed yarns had higher values for the LT, WT, B, 2HB, LC, WC, MMD and SMD parameters, and lower values for the G, 2HG and 2HG3 parameters than fabrics made from the control yarn. These changes in mechanical characteristics suggest that knitted fabrics made from the processed silk yarns are flexible and elastic, have a higher resilience, and are soft and stretching. Although the primary hand feel (HV) parameters like 'Koshi' (stiffness), 'Fukurami' (fullness and softness), and 'Numeri' (smoothness) of the knitted fabrics made for winter outer garments from the processed silk yarns were about the same as those of knitted fabrics made from the control yarn, the former had a higher total hand feel value (THV) which is used for assessing fabric quality. Based on the determination of the various mechanical properties and the results of evaluation by users who wore the silk sweaters, it is considered that the salt-shrunk, fiber-dispersed and resin-treated silk yarns after a good potential as yarns for knitted fabrics.

---Introduction-----

Larger amounts of apparel fibers are currently used for making knitted fabrics than woven fabrics. However, in the case of silk yarns, more than 80% is used as material for Japanese dresses which are made of woven fabrics. Only several percent of the total is used for the manufacture of western style woven or knitted products like dresses, women's undergarments, ties, etc. Various attempts have been made to produce silk yarns with a crimped shape, as in the case of cotton, wool, and synthetic spun yarns, in order to expand the use of silk yarns for making knitted products³⁾.

The present author attempted to develop a crimped silk yarn with good fiber dispersion characteristics by applying the salt-shrinking technique¹⁾. By immersing twisted silk yarn with a twist coefficient of 1,500-2,500 in a hot (80) concentrated solution of calcium nitrate with a specific gravity about of 1.42 for about 1 min, the fiber shrank by 10-40%. Then, by applying the fiber dispersion treatment and resin treatment to the surface, very fine irregular crimping could be obtained in the yarn provided that the fibers were well dispersed. Knitted silk fabrics made from these processed yarns were bulky and showed a high resilience against deformation, while being flexible and elastic.

---Materials and methods-----

1) Materials

- (1) Raw silk (27d x 6, Z200T/m) x 5, S150T/m, first twist coefficient= 2,546
- (2) Raw silk (27d x 4, Z200T/m) x 3, S150T/m, first twist coefficient= 2,078, 25 skeins
- (3) Raw silk (27d x 4, Z150T/m) x 3, S100T/m, first twist coefficient= 1,559, 16 skeins

Samples (2) and (3) consisting of a total of 41 skeins of raw twisted yarn, were placed in a cotton fabric sack and degummed in the sack, in a 10 g/L solution of Marseille soap. The degumming was performed at 95 to the boiling temperature, for 60 min, and the degumming operation was repeated twice. Thereafter, the silk yarn samples were soaped and washed in warm water. The degumming loss was 24.2%. Sample (1) was used as unprocessed yarn (control) for making knitted fabrics. This yarn was also boiled in a sack for degumming, under the same conditions.

2) Preparation of salt-shrunk, fiber-dispersed and resin-treated yarn

The degummed twisted yarn samples (2) and (3) were soaked and treated for about 30 to 60 sec at 80 in a concentrated calcium nitrate solution with a specific gravity of 1.415 to obtain a shrinkage scatter in the range of 30-50%. Thereafter, the yarn samples were washed, subjected to fiber dispersion, surface-treated with resin, and treated with an anti-static agent, in that order. Processed yarns Nos. 2 and 3 with salt shrinkage values of 32.3 and 48.8%, respectively, were prepared from sample (2) and processed yarn No. 4 with a salt shrinkage of 39.0% was prepared from sample (3) ([Table 1](#)). The shrinkage level was calculated from the original length of the yarn and the yarn length after the treatment, i.e. after soaking in the calcium nitrate solution, washing with warm water to remove the calcium nitrate, washing, and drying, according to the formula given below.

$$\text{Salt shrinkage (\%)} = [(\text{Original yarn length} - \text{Yarn length after treatment}) / \text{Original yarn length}] \times 100$$

Table 1.
Salt shrinkage, resin uptake of yarns and weight of knitted silk fabric used for making measurements

Yarn	Degumming loss (%)	Salt shrinkage (%)	Resin uptake (%)	Gauge No.a) (Rows x stitches)	Wale No.	Course No.	Weight (g)
No.1 (Raw silk,27d x 6,Z200) x 5 ,S150	25.4	--	--	48 x 36	56	36	13.74 (5.50) ^{b)}
No.2 (Raw silk,27d x 4,Z200) x 3, S150	24.2	32.3	9.5	50 x 36	60	36	6.27
No.3 (Raw silk,27d x 4, Z200) x 3, S150	24.2	48.8	9.1	48 x 36	52	36	7.31
No.4 (Raw silk,27d x 4, Z150) x 3, S100	24.2	39.0	10.8	52 x 38	60	38	6.13

a): Gauge No., and course No. refer to a 10 x 10 cm area of fabric.

b): The weight given inside the parenthesis for the yarn No.1 is the value after conversion to the size (324d) of the processed yarns Nos.2 and 4.

3) Electron micrographs

The processed silk yarn was coated with gold and observed at an acceleration voltage of 15 kV using a scanning electron microscope JXA-733S (Nihon Denshi).

4) Preparation of knitted fabrics

The fabric samples were machine-knitted and set by applying a steam iron for several minutes after placing a piece of cotton cloth over the fabric. The processed yarn samples Nos. 2-4 listed in Table 1 were used for making the knitted products. Two lady's sweaters were prepared from each type of yarn, with a total of 6 sweaters, and evaluated by wearing. Separately, one piece of knitted fabric each, with about the same thickness, was made from the processed yarns Nos. 1-4 ([Table 1](#)) for determining the mechanical properties.

To maintain uniform knitting conditions, it is generally desirable to keep the same gauge number for all the yarns (Nos. 1-4). However, since the thickness of the processed yarns varied depending on the extent of shrinkage, for measuring the Kawabata Evaluation System (KES) hand values, it was seemed necessary to obtain fabrics with about the same thickness, rather than using the same gauge number for knitting. Therefore, the person who operated the knitting machine set the gauge number (yarn density) at 48 to 50 rows x 36 to 38 stitches (10 cm x 10 cm), by observing the processed yarn ([Table 1](#)). The knitting machine operator had a high level of professional skill and a long experience.

5) Determination of mechanical properties of the knitted fabrics

Five groups of mechanical properties were determined, each 3 times, with a sample of the knitted fabric, using the "KPM-3-M" program for knitted fabrics(4,5,8). The means of the values along the wale direction and the course direction were used to express the tensile, bending, shearing, and surface characteristics of the knitted fabrics.

6) End use tests with the knitted products

Four ordinary consumers in their 30's and 40's were asked to evaluate the knitted sweaters. They used the sweaters for about 4 months after which they were asked to evaluate their performance by answering a questionnaire. Resistance to washing was examined with the sweater samples that were worn and washed repeatedly. The questions included in the questionnaire and the method of testing adopted followed the "Testing of commercial washable silk products" manual prepared by Kokumin Seikatsu Center(7).

Washing and handling were performed as follows: washing for 2 min in warm water by repeatedly pressing down; squeezing out the water by pressing, rinsing for about 2 min, removing the water by placing the sweater in a net and spin drying for 10 sec, and drying by hanging in the shade on a rod. The neutral detergent Acron manufactured by Lion K.K. was used for the washing.

The initial quality evaluation was performed before the first washing, through a questionnaire on the quality and wearing comfort of the sweaters. For quality evaluation after washing, the users were asked to give their opinion about wearing comfort after 5 washings, through a questionnaire. The shrinkage due to washing was measured and the fading of color and gloss was determined using a color computer SM-3-SCH manufactured by Suga Shikenki K.K. For determining the shrinkage, the length and bust size of the sweater before and after washing were measured following JIS L 1018(2) and calculated according to the formula given below.

Shrinkage after washing (%) = [(Size before washing - Size after washing) / Size after washing] x 100

---Results and discussion-----**1) Properties of knitted fabrics**

Electron micrographs showing the surface morphology of salt-shrunk, fiber-dispersed and resin-treated yarn are shown in [Fig. 1](#). The yarns had a very good fiber dispersion and the fibers did not stick together. The twisting and bending of the yarn became more extensive with increased salt shrinkage. The trial products knitted from this type of processed yarn had a very soft hand feel and touch and were very light with good bulkiness and heat retention ([Fig. 2](#)).

*[Fig.1.\(81 KB\)](#), [Fig.2.\(19 KB\)](#)

Table 1 gives the values for the degumming loss, salt shrinkage and resin uptake of the processed yarns, the gauge number, the actually observed wale number and course number of a 10 x 10 cm area; and the weight of a 20 x 20 cm piece of the knitted fabric.

The weight and thickness of the knitted fabric were closely related to the denier and yarn density. The weight of the fabric knitted from the unprocessed yarn (No. 1) was, on the average, 2.1 times larger than that of the fabric samples made from the processed yarns (Nos. 2-4). This is a reflection of the fact that the total denier of the raw twisted yarn used for making the unprocessed yarn was 810 d (27 d x 30), while it was 324 d (27 d x 12) in the raw untwisted yarn used for making the processed yarns. Thus, the former showed a 2.5 times larger weight, to begin with.

In the case of the processed yarns, because of the resin treatment of the yarn surface, about 10% of the weight is due to resin uptake. [Fig. 1](#) clearly indicated that the yarn structure is crimped and not straight. Even though the structure of the crystalline region of the silk fiber was destroyed and became amorphous during the salt shrinkage treatment, and the degree of molecular orientation in the amorphous part, which is considerably higher in silk compared to other fibers, was also lowered by the salt shrinkage treatment, leading to a reduction of the specific gravity of the silk, the 2.1 times larger weight of the knitted fabric made from the unprocessed yarn was within an acceptable range.

In spite of the 2.5 times difference in denier to begin with, when the initial pressure of 0.5 g/cm² was applied to the knitted fabric and its thickness was measured using the KES-FB4 device, the thickness of the knitted fabric made from the unprocessed yarn was 1.91 mm and that made from the processed yarns was in the range of 1.85-2.03 mm. The difference between the two types of fabrics was very small, being only 0.03-0.12 mm (1.6-6.3%) ([Table 2](#)), presumably because after salt shrinkage, fiber dispersion and resin treatments, the silk fiber became slightly thicker, the twisted yarn itself became well-dispersed, crimped and bulky, and the knitted fabric made from it was very fluffy and light. Therefore, although the processed yarn experienced a salt shrinkage of about 40%, a much smaller amount of processed yarn was needed for preparing a knitted fabric that was quite bulky.

Table 2. Mechanical properties of test-made knitted silk fabrics

Group	Parameter	Unit	No.1	No.2	No.3	No.4

a): T is the thickness if the fabric when 0.5gf /cm² pressure was applied, calculated from the compression characteristics.

2) Mechanical properties

Only in very few cases has the fabric quality been evaluated through the measurement of the primary hand values, which is considered to be an objective method of quality evaluation (12). If the warp and weft directions of woven fabrics are considered, respectively, to be equivalent to the wale and course directions of knitted fabrics, the primary hand values calculated from the mechanical properties determined in feel testing may enable to evaluate the performance of the fabric (4). On the basis of this assumption, we determined the

mechanical properties of knitted fabric samples, all having about the same thickness ([Table 2](#)).

(1) Tensile characteristics

Tensile energy (WT) of the fabric was higher in the processed fiber, i.e. the salt-shrunk, fiber-dispersed and resin-treated yarn fabric, compared with the unprocessed fiber. The greater the shrinkage and the lower the number of twists in the yarn, the higher was the WT value of the fabric. The resilience (RT), i.e. the force of recovery from a deformative load, was more affected by the number of twists than by the processing of the yarn. When we compared the processed yarns Nos. 2 and 3 (Z200/S150) with the processed yarn No. 4 (Z150/S100), the former showed about the same RT value of the fabric as the unprocessed yarn, while the latter had a clearly lower fabric RT value. Apart from this, the value of the LT parameter which is a measure of tensile rigidity, was slightly increased by the processing of the yarn. Therefore, the fabric knitted from the processed yarn had smaller spaces in the knitted structure, with increased inter-fiber and inter-yarn contact, compared with the fabric made from unprocessed yarn. In spite of this, the fabric knitted from the processed yarn showed a high EMT (elongation or strain) against tensile force and therefore could be easily stretched. The results suggest that tensile recovery and tensile elasticity can be retained at the same levels as in the fabrics made from the unprocessed yarn, if the number of twists is not very low and the salt shrinkage is about 40%. All these findings suggest that soft, flexible and stretching knitted fabric can be prepared from the processed yarns.

(2) Bending characteristics

The values of the B and 2HB parameters were higher in the fabric made from processed yarn No. 3, which exhibited a greater salt shrinkage, than in the fabric made from yarn No. 2. Crimping induced by processing was optimum when the silk yarn had a twist coefficient of 1,500-2,500 and a salt shrinkage of 30-40%. Even when the original yarn had the same twist coefficient, the degree of twisting increased with increased salt shrinkage and resulted in greater final twisting, which affected the crimping and the processed yarn became somewhat hard in hand feel and lacked fluffiness and bulkiness. These characteristics may account for the increased resistance torque against the bending deformation and the increased bending strength and hysteresis in this type of fabric.

On the other hand, fabrics made from the processed yarns Nos. 2 and 4 showed about the same values for the B and 2HB parameters, which were lower than in the fabric made from the unprocessed yarn. These results suggest that knitted fabrics made from the processed yarns displayed a greater ease of bending and bending recovery. Therefore, if salt shrinkage and the twist number are controlled in a suitable range, well-crimped processed yarn can be obtained. It was found that processing enabled the fiber and yarn to move easily in response to bending deformation and the fabric had a flexible and smooth feel during bending. Based on these results, salt shrinkage of 48.8% for the yarn No. 3 appears to be excessive.

(3) Shearing characteristics

The values for the parameters G, 2HG and 2HG3, which reflect the shearing characteristics of fabrics, all showed a similar response to processing. Compared with the fabric made from the unprocessed yarn, these values were generally lower in processed yarn fabrics, although some of the values were comparable in the 2 types of fabrics ([Fig. 3](#)) (14 KB). Shearing deformation which is determined by factors like yarn pressure and slipping at the crossing points, bending deformation of the yarn, etc. is generally considered to be closely related to the bending characteristics⁹). In the present study, the fabric samples were produced under the same knitting conditions, to obtain the same knitted structure. Therefore, the effect due to the difference in the knitted structure is considered to be minimal.

The fabric made of unprocessed yarn had a high value of G. It showed a high yarn density and very close contact between yarns. Therefore, when a shearing deformative force was applied, the contact area between the yarns at the crossing points increased and the resistance torque increased making it difficult to change the angle of crossing¹⁰). Therefore, the knitted fabric was very hard, with little space within the fabric. In contrast, since the processed yarn fabrics had smaller hysteresis values (2HG and 2HG3), the fabric was resilient and fabrics made from yarn with high salt shrinkage had a small G value and the shape easily changed in response to shearing deformation force. In short, from the point of view of shearing characteristics also, knitted fabrics made from the processed yarns were soft and flexible.

(4) Compression characteristics

In the processed yarns, the values for the WC and RC parameters of the fabric tended to be higher. When we compared the fabrics made from Nos. 2 and 3 processed yarns, the No. 2 yarn fabric which had a lower salt shrinkage showed lower LC and higher RC values, compared with the No. 3 yarn fabric. The WC value was slightly higher in all the processed yarns, including No. 4 which had a small twist number. These results suggest that knitted fabrics made from the processed yarns could be easily compressed and showed a good recovery from compression also. This is believed to be due to fiber intertwining and the increased space in the yarn because of the crimping. However, as discussed in the section on bending characteristics, processed yarn with large salt shrinkage (No. 3 yarn) had high LC and low RC values because it had less crimping, and the fabric was not resilient.

It is known that woven wool fabrics made wholly from untwisted yarn, or in which untwisted yarn is mixed, show smaller LC and greater RC and WC values with an increased proportion of untwisted yarn in the fabric because the untwisted yarn is bulkier and has more space. It is however interesting to note that some of the compression characteristics of the fabrics made from processed yarns in the present study were similar to those of woven wool fabrics.

(5) Surface characteristics

In the surface characteristics of the processed yarn knitted fabrics, the values of both the MIU and MMD parameters (the mean deviation of MIU) were higher than in the fabric made from unprocessed yarn. This increase in the MIU and MMD values in the processed yarn fabrics was ascribed to the fact that the processed yarns had a crimped shape and dispersed fibers and therefore, knitted fabrics made from them did not have a uniform surface. The space within the yarns, the intertwining or misalignment of fibers, fluff formation, etc. all enhanced the surface unevenness of the knitted fabrics.

The results obtained suggest that soft fluffy and resilient knitted fabrics can be produced from salt-shrunk, fiber-dispersed and resin-treated yarns. This is because the twisted silk yarns acquire irregular and minute crimping and good fiber dispersion so that the intertwining of fibers and space in the yarns are increased, giving flexibility and bulkiness to the fabric.

3) Hand feel

The primary hand value (HV) which is a quantified feel parameter calculated based on the determination of the mechanical properties, reflects the stiffness, fullness and softness, crispness, and the anti-drape stiffness. HV is considered to be closely related to the fabric characteristics⁵⁾. We obtained 3 of the HV parameters, 'Koshi' (stiffness), 'Fukurami'(fullness and softness) and 'Numeri'(smoothness), and the total hand value (THV) using the mechanical values > HV and the HV > THV conversion formulae of Kawabata. We used the "KPC-5-N" program for the KES-FB system to carry out these conversions and for preparing the knitted fabric snake charts. [Table 3](#) gives the results of calculations using the criteria for outer winter garments (A) and winter undergarments (B). In the case of undergarments, the thermolab measurements could not be performed because of the limitations of the KES system. We therefore ignored the heat and moisture transfer characteristics that are obtained from thermolab measurements, and calculated HV and THV from the values of the mechanical characteristics KES-FB1 to KES-FB4.

Table 3. Primary hand values of test-made knitted silk fabrics

<u>Hand values</u>	<u>Criteria</u> ^{a)}	<u>No.1</u>	<u>No.2</u>	<u>No.3</u>	<u>No.4</u>
'Koshi'	A	1.7	1.8	2.1	1.1
	B	5.8	5.4	3.8	2.7
'Fukurami'	A	5.0	3.1	3.2	3.2
	B	16.3	16.3	16.6	18.8
'Numeri'	A	8.6	7.9	7.7	7.9
	B	9.6	8.8	9.7	10.9
THV	A	2.2	3.2	3.4	3.2
	B	6.0	2.2	2.2	1.5

a): A; For winter outer garments, B; For winter undergarments.

With the criteria for outer winter garments, the values for the 'Koshi' , 'Fukurami' and 'Numeri' parameters of the processed yarn fabrics were all about the same as in the unprocessed yarn knitted fabric. However, the values of THV, which is a parameter used for evaluating the fabric quality, were in the range of 3.2-3.4 in the processed yarn fabrics, compared with 2.2 in the unprocessed yarn fabric. The hand feel values were not affected by the salt shrinkage and number of twists. It became clear from these results that fabrics knitted from the processed yarns were superior in terms of THV, although they were not appreciably different from the unprocessed yarn fabric in terms of 'Koshi', 'Fukurami' and 'Numeri'.

The THV and mechanical properties determined above suggest that knitted fabrics made from processed yarns in the present study had the characteristic properties and good feel of the processed yarns and such yarns have the potential of becoming attractive silk yarns for knitted fabrics, which would expand the range of application of silk products and satisfy the requirements of consumers.

4) End use tests

(1) Evaluation of initial quality

Four users were asked to evaluate the wearing comfort of the sweaters made from the processed yarns before washing. The users answered "Difficult to say" or "Somewhat poor" when asked about the flexibility of the garment. But regarding the feel of the fabric and wearing comfort, 3 out of 4 users answered "Fairly good". No users stated that the initial wearing quality of the sweaters was poor ([Table 4](#)). The knitted fabric made from processed yarns with 32.3 to 48.8% salt shrinkage lacked the silky gloss and was more like wool in external appearance. Therefore, all the users thought that the sweaters were made of wool, before they were told that they were made of silk. But after wearing them, many of the users said that they were "Very light and easy to wear" compared to woolen sweaters which are generally considered to have just the opposite characteristics⁶⁾. In fact, one of the users suggested that

3) Hand feel

perhaps the material was suitable for undergarments like slips and summer blouses because it was light, soft to touch, moisture absorbing, and not stuffy. The "light feel" of garments is an important feature for summer wear. This is an impression about the fabric which is closely related to the "cool touch".

Table 4. Evaluation of users after wearing the new (unwashed) sweater

	Poor (-2)	Somewhat (-1)	Difficult to say (0)	Moderately good (+1)	Good (+2)
Touch			2a)	2a)	
Flexibility		3a)	1		
Wearing comfort			3	1	

a): The figures refer to the number of users.

In one study on the evaluation of knitted fabrics for undergarments involving a group of 18 expert technologists having 1-20 years of experience in undergarment manufacture and a group of 9 ladies consumers in the 22-38 age group, the 2 groups showed no significant difference in the perception of hand feel, with a high inter-group correlation, the evaluation rather differing from person to person¹²⁾. The 4 users in the present study had a high level of knowledge about garments and acquired a wide experience from managing households. If we take into consideration the report of Sakaguchi et al.¹²⁾, according to which the judgement of consumers was quite reliable, it is clear that the knitted fabrics made from the processed yarns in the present study had a good fabric quality while they were new.

(2) Evaluation of quality after washing

Shrinkage caused by washing of the knitted garments is shown in [Fig. 4\(35 KB\)](#). There was a considerable scatter in the values, perhaps because of slight variations in the method of taking measurements by the users. However, the overall trend showed that the shrinkage varied depending on the extent of salt shrinkage of the yarn. In sweaters made from yarn with a low salt shrinkage (32.3%), after one washing, the length decreased by 5.0 cm while the bust size increased by 4.0 cm, resulting in the change of the shape of the garment. However, after repeated wearing and washing, the dimensions became more or less similar to those of the new sweater. Thus, there was no problem of shrinkage caused by washing. The sweaters made from yarn with a high salt shrinkage (48.8%) showed a reduction in both length and bust size as the garments were washed repeatedly. After 5 washings, the average shrinkage of the 2 sweaters was 7.9% for the length and 2.0% for the bust size, showing significantly higher shrinkage in the length direction. Thus, it may be necessary to improve the quality.

The opinion of the users about the qualities of the garments, such as the feel, flexibility, wearing comfort, etc. after 5 washings was that the sweaters were not appreciably different from the new sweaters with respect to shrinkage, color fading, gloss, hand feel, fluff formation, feel, flexibility and wearing comfort ([Table 5](#)).

Table 5. Evaluation of 4 users for the sweaters after 5 washings

3) Hand feel

	Poor (-2)	Somewhat poor(-1)	Not different from when the sweater was new (0)	Moderately good (+1)	Good (+2)
Shrinkage			4 ^{a)}		
Color fading			4		
Gloss		2 ^{a)}	2		
Hand feel		2	2		
Fluff formation		2	2		
Touch	1 ^{a)}		2	2 ^{a)}	
Flexibility		2	1		
Wearing comfort			3	1	

a): The figures refer to the number of users.

It has been reported that the value of silk blouses and undergarments decreased after washing because of shrinking, yellowing, and changes in gloss and hand feel⁷⁾. In one report¹⁾, it was stated that knitted garments made from spun silk yarns shrank after hand washing with a neutral detergent, their color faded, and the gloss and hand feel were poor, the flexibility characteristic of silk disappeared and the hand feel of the garments became similar to that of garments made from low quality cotton. However, knitted garments made from processed silk yarn in our study showed a lower decrease in quality than anticipated.

The results shown in Figs. 5 and 6 suggest that the sweaters were resistant to washing. However, when asked to give their overall opinion about the sweaters after 5 washings, some users gave comments like "It does not slip well", "It sticks to the body", "It got slightly stretched after repeated use", "It lacks stiffness", "It has a coarse feel", "It lacks smoothness", etc.

There were opinions like "Overall, I do not like the sweater" and "I do not wish to wear this type of sweater". We do not think that all these negative comments can be attributed to the quality of the processed yarns. The sweaters were rather thickly knitted, did not have much gloss which made them look like wool, and had a design that was not very sophisticated. Thus, the fact that samples had just the opposite image to the generally held delicate image of silk garments may have exerted an adverse effect.

---Abstract-----

Bacteriocin-like activity (BLA) was screened in 50 and 30 strains of thermophilic lactic acid bacteria (LAB) isolated from silages and fermented vegetables, respectively. The BLA of the isolates against some bacterial strains was hardly detected by the paper disk method, while in the isolates of 50 strains (62.5% of all) it was clearly detected by the spot-on-lawn method. Only one strain K-4 isolated from grass silage showed a clear BLA against *Enterococcus faecium* in both methods. The strain belonging to the genus *Enterococcus* produced BLA in the logarithmic growth phase in MRS medium. The BLA was completely inhibited by treatment with trypsin, remained stable under boiling conditions and the molecular weight was about 20,000 based on SDS-PAGE analysis. The BLA produced by this strain was due to bacteriocin and positive against only *Ec.faecium* and *Ec.faecalis*.

---Introduction-----

We have a long history of association with lactic acid bacteria (LAB) and hardly experience any damage due to LAB. Therefore, it is considered that LAB and bacteriocins produced by LAB are generally safe (10). Actually, a typical bacteriocin "nisin" has already been used in the food industry as a bacteriocidal additive in more than 50 countries of the world. However, the actual use of nisin is limited because of its low solubility in water and lower activity in neutral pH solution. Information on other bacteriocins produced by LAB is limited and bacteriocin except for nisin has not been applied to the food industry.

Therefore, many research groups^{2,3,5}) have attempted to screen new bacteriocins produced by LAB. In these screenings, LAB were mainly isolated from dairy products in the temperate and frigid zones. However, screening in the tropical zone has not been conducted although some LAB isolated from tropical fermented vegetables and silages may produce new bacteriocins with properties suitable for adaptation to a tropical niche. Therefore, LAB strains that can produce bacteriocin-like activity (BLA) were screened in Thailand, a tropical country.

In this paper, the results of screening conducted in Thailand together with the production of BLA by a selected strain and some of the properties of BLA are described.

---Materials and methods-----

1) Microorganisms

The bacterial strains used in this experiment as target strains and their culture conditions are listed in Table 1.

b): Both media were purchased from Difco Laboratories, USA. MRS; Lactobacilli MRS broth, NB; Nutrient broth.

2) Screening

Fifty LAB strains from silages prepared by using plastic bags¹⁴) in Khon Kaen and Bangkok, Thailand, and gathered in Chiang Mai, Thailand, were subjected to the screening. Thirty LAB strains from fermented vegetables bought in the market in Bangkok, Thailand, were also subjected to the screening. These strains were anaerobically isolated by an ordinary plate culture method using an agar plate with Lactobacilli MRS broth (MRS: Difco, USA) containing 1.6% agar and 0.5% CaCO₃ at 43. For each isolate, the ability to produce BLA was examined by the spot-on-lawn method and the paper disk method.

Spot-on-lawn method⁴): Each isolate was inoculated onto the MRS agar plate to form a colony less than 8 mm in diameter and cultured at 43 for 24 h, an-aerobically. After the culture, the surface of the agar plate (surface with colony formation) was overlaid with a suspension of a target strain at the concentration of ca. 10⁶ cfu/mL¹ in soft agar medium and then incubated to grow the target strain for 24 h under favorable conditions as shown in Table 1. Thereafter, the BLA of the isolate was evaluated based on the formation of a clear zone around the colonies. The medium containing 0.7% agar which is suitable for the growth of the target strains ([Table 1](#)) was used as a soft agar medium.

Paper disk method⁴⁾: A paper disk (diameter 8 mm, thin type, Toyo Roshi, Japan) with adsorbed 30¼L of cell-free culture filtrate was put on an agar plate containing a target strain at the concentration of ca. 10⁶ cfu/mL. Then, the agar plate was incubated under conditions suitable for the growth of the target strain ([Table 1](#)). After incubation for 24 h, the BLA of each isolate was evaluated based on the formation of a clear zone around the paper disk. Each isolate was cultured in the MRS broth at 43 for 20 h and the culture filtrate was adjusted to pH 6.0 with a NaOH solution before adsorption onto the paper disk.

3) *Partial purification of the BLA*

Partially purified BLA was obtained by ultra-filtration, ammonium sulfate precipitation and ion exchange chromatography. The culture filtrate of strain K-4 using 1 L of MRS broth at 43 for 12 h under anaerobic conditions was subjected to ultra-filtration by using a Diaflow YM-10 membrane (MW cut off, 10,000) (Amicon Inc., USA), the same operation was repeated after the addition of 200 mL of 20 mM acetate buffer (pH 4.0) and the sample was concentrated to 50 mL after the addition of 20 mM of the same buffer. Thereafter, solid ammonium sulfate was added step-wise for more than 60 min to the concentrate to reach 75% saturation at 4 and allowed to be stirred for 1 h on a magnetic stir plate. The precipitated suspension was centrifuged for 20 min at 10,000 x g at 4 and decanted. The pellet was dissolved in 50 mL of the same buffer and dialyzed against distilled water using a Spectra/por 1 tube (MW cut off, 6,000-8,000) (Funakoshi Co. Ltd., Tokyo). The dialysate yielded about 2 g of powder by freeze-drying. The powder was dissolved in 10 mL of the same buffer and used for column chromatography (1.6 cm diameter x 40 cm length) with CM Sephadex C-50 (Amersham Pharmacia Biotech Ltd, Sweden) equilibrated with the same buffer. After adsorption of the solution onto the gel, the column was washed with 100 mL of the same buffer and eluted with the same buffer containing 0.8 M sodium chloride. The fraction eluted with the sodium chloride solution was dialyzed against distilled water and yielded 650 mg of powder by freeze-drying. The powder was used for SDS-PAGE analysis and the test of characteristics of BLA.

4) *SDS-PAGE*

The BLA was analyzed by sodium dodecyl sulfate polyacrylamide gel electro-phoresis (SDS-PAGE) on a high cross-linked gel (15%T, 3 x 51 x 58 mm)⁸⁾ at 30mA for 2 h. Calibration proteins (Combithek, Boehringer Mannheim Biochemica, Germany) were used as molecular weight markers.

5) *Sensitivity to heat, pH and trypsin*

The partially purified powder was dissolved in 20 mM acetate buffer (pH 4.0), the pH of the solution was adjusted to 5.0, 6.0 and 7.0 with a NaOH solution and the activity of each pH solution was assayed. The solution prepared in the same manner (pH 6.0) was heated at 100 for 20 min and the remaining activity was assayed. Furthermore, the same solution was treated with trypsin (Sigma Chemical Co., USA) at a final concentration of 0.5 mg/mL. Samples with or without trypsin were filter-sterilized and incubated at 37 for 12 h. The remaining activity was assayed. All the BLA was assayed by the paper disk method.

6) *Standard line for determining bacteriocin activity*

The bacteriocin activity was quantitatively determined by the paper disk method using nisin (1,000 IU/mg, Aplin & Barrett Co., UK) as standard bacteriocin and *Ec.faecium* IFO 13712 as a target strain. The logarithmic concentration of nisin between 500-10,000 IU/mL gave an essentially straight line against the diameter of the clear zone formed around the paper disk by the target strain. This straight line (referred to as standard line) showed in [Fig. 1](#) (13 KB) was used for determining the bacteriocin activity.

-----Results-----

1) BLA of isolates

Table 2 shows the BLA of typical isolates obtained by the spot-on-lawn method and the paper disk method. Among 50 LAB strains isolated from silages, 20 strains (40% of all) displayed a BLA against some target strains when the spot-on-lawn method was used. All the LAB strains isolated from fermented vegetables displayed a BLA against some target strains when the spot-on-lawn method was used. However, strains found positive by the spot-on-lawn method hardly showed a BLA when the paper disk method was used except for strain K-4. Only the culture filtrate of strain K-4 showed a clear BLA against *Ec. faecium* IFO 13712. Strain K-4 was used for further experiments.

Table 2. BLA of typical isolates

a): Each strain was deposited in the culture collection of TISTR as described in **Table 1**.

b): Target strains used were as follows; (1)*Ec. Faecium* IFO 13712, (2)*Ped. Acidilactici* TISTR 952, (3)*Leuc. mesenteroides* TISTR 473. Symbols denote the diameter of the clear zone as follows: + + + ; more than 15 mm, ++; 15-12 mm, +; 12-8 mm, ±; indistinct, -; not detected.

c): (+) denotes Gram-positive reaction.

2) Identification of selected strain K-4 at generic level

Bacteriological properties of strain K-4 were examined and the results are summarized in **Table 3**. The strain was Gram-positive with a typical long chain. The strain grew at 45 in MRS broth and did not produce gas. The strain also grew in MRS broth with the pH adjusted to 9.6 and NaCl concentration to 6.5%. Based on a manual⁶⁾, the strain was tentatively assigned to the genus *Enterococcus*. Therefore, this strain was designated as *Enterococcus* sp. K-4.

3) Spectrum of BLA produced by *Enterococcus* sp. K-4

The spectrum of BLA produced by *Enterococcus* sp. K-4 against 11 bacterial strains is shown in [Table 4](#). The BLA of this strain was positive to only the strains of the genus *Enterococcus* such as *Ec.faecium* IFO 13712 and *Ec.faecalis* IFO 12964 and negative to another strains of the genera *Lactobacillus*, *Pedio- coccus*, *Leuconostoc*, *Staphylococcus*, *Salmonella*, *Escherichia* and *Klebsiella*.

a): +; Positive, - ; Negative.

4) Culture conditions of *Enterococcus* sp. K-4 for the production of BLA

Culture temperature: The effect of the culture temperature on the production of bacteriocin in MRS broth was examined as shown in [Fig. 2.\(16 KB\)](#). The maximum bacteriocin activity during 20 h of culture was observed at 42-45 and the activity was 2 times higher than that at 37 while the maximum lactic acid production was observed at 37-38.

Time course of production of BLA: The production of bacteriocin in MR broth at 43 was associated with the logarithmic growth of the strain. The highest activity was observed in the maximum growth phase and then the activity gradually decreased as shown in [Fig. 3.\(20 KB\)](#).

Inoculum size: The effect of the inoculum size at the levels of 10^5 , 10^6 and 10^7 cfu/mL was examined for maximum production of bacteriocin in MRS

broth at 43. As shown in [Fig.4.\(25 KB\)](#), the culture time for maximum production of the activity decreased with the increase of the inoculum size. The viable cells by inoculation at 10^7 cfu/mL reached maximum counts of 10^9 cfu/mL within 4 h of culture and required only 7 h for maximum bacteriocin activity. Regardless of the inoculum size, the maximum cell counts and bacteriocin activity showed almost the same level (10^9 cfu/mL and 6,200 IU/mL).

5) Properties of BLA produced by *Enterococcus* sp. K-4

The BLA produced by *Enterococcus* sp. K-4 was stable under boiling conditions (100 for 20 min) and the level was almost the same at pH 5.0 to 7.0. However, the activity was completely inhibited by treatment with trypsin. The partially purified powder showed a clear BLA zone in the area with an Rf-value of about 0.4-0.5 in SDS-PAGE. The area corresponded to the Rf-value of trypsin inhibitor (MW 20,100) as a standard protein.

---Discussion-----

Strain K-4, which was isolated from tropical grass silage and belonged to the genus *Enterococcus*, was selected as a bacteriocin-producing strain. When the paper disk method was used, only one strain K-4 showed a clear BLA while 62.5% of the strains among the isolates showed some BLA when the spot-on-lawn method was used in this screening. It is well known that the BLA detected by the spot-on-lawn method can not be reproduced when the paper disk method [10,12](#)) is used. In liquid culture, proteolytic enzymes are released from the producing strain into the culture broth and bacteriocin might be digested by the enzymes. For further detailed studies, the production of BLA in liquid culture is an important and essential factor from the view-points of isolation in large quantity and purification of bacteriocin.

The production of bacteriocin by this strain was activated by the temperature during the culture and 42-45 was the optimum temperature while maximum lactic acid production occurred at 37-38 as shown in [Fig. 2](#). Generally for the strains of the genus *Enterococcus*, a temperature of 42-45 during the culture is rather high for bacteriocin production [7,11](#)) The production of bacteriocin by the current strain at such high temperatures may be due to the origin of the strain which appeared to be a thermophilic strain isolated at 43 in Thailand. It is possible that the bacteriocin produced by this strain showed properties suitable for adaptation to a tropical niche. The production of bacteriocin by this strain occurred during the logarithmic growth phase and the inoculum size did not increase the amount of bacteriocin production, while the culture time was shortened for maximum production. When the inoculum size increased, maximum bacteriocin production and viable cell counts were 6,200 IU/mL and 10^9 cfu/mL, respectively. To increase the bacteriocin production, it is necessary to increase the cell density in the medium together with the modification of the medium composition.

The BLA produced by strain K-4 was positive against only the strains of the genus *Enterococcus*. Usually, bacteriocins show a narrow inhibitory spectrum and give a positive reaction to the same and/or related genus species [9](#)). This tendency was also observed in the current study since strain K-4 which belonged to the genus *Enterococcus*, was active only against *Ec. faecium* and *Ec. faecalis*. The BLA of this strain was thermotolerant and was detected in solutions with a neutral and acidic pH. The apparent molecular weight of main bacteriocin was about 20,000 in SDS-PAGE (data not shown). Some bacteriocins produced by the strains of the genus *Enterococcus* have been reported by several research groups [1,7,11,13,15](#)). These bacteriocins had a molecular weight of less than 10,000 and were active against *Listeria monocytogenes*. Further studies should be carried out for the purification and analysis of the chemical properties of the new bacteriocin produced by this strain.

Cloning and Identification of the Lactococcin A and M Gene Cluster from *Lactococcus lactis* subsp. *lactis* biovar *diacetylactis* DRC1

Yasuhito FUJITA and Takashi OKAMOTO

Department of Animal Products, National Institute of Animal Industry
(Tsukuba, Ibaraki, 305-0901, Japan)

---Abstract-----

The bacteriocin genes from the plasmid pDR1-6 of *Lactococcus lactis* subsp. *lactis* biovar *diacetylactis* DRC1 were cloned into pGKV21 and pGKV259 as 4.0 kb *HindIII* and 9.5 kb *EcoRI* fragments, and expressed in plasmid free and bacteriocin-non-producing strain *L.l.lactis* DRC1021. The nucleotide sequences of the genes were identified as a part of operons of lactococcins A and M.

Discipline: Biotechnology

Additional key words: bacteriocin, lactococcin, dricin

Received for publication, October 8, 1998

The nucleotide sequence data reported in this paper will appear in the DDBJ, EMBL and GenBank nucleotide sequence databases with the following accession numbers D86737 and D86738.

---Introduction-----

Bacteriocins are proteinaceous bactericidal compounds that are produced by some microorganisms, including lactic acid bacteria. The best-known bacteriocin of lactic acid bacteria origin is probably nisin, which is an antibiotic type bacteriocin produced by certain strains of *Lactococcus lactis*. A large number of new bacteriocins in the group of lactic acid bacteria have been characterized mainly biochemically due to the development of efficient protocols for purification of these hydrophobic and cationic peptides in recent years. In several cases it has been demonstrated that bacteriocin production is associated with plasmid DNA. However, only a few genetic determinants for these substances have been cloned and sequenced^{8,10}.

Previously, Powell et al. reported that *L. lactis* DRC1 (Commonwealth Scientific and Industrial Research Organization, Dairy Research Laboratory collection) produced dricin which is a heat-stable proteinous bacteriocin and suggested that the gene involved in dricin production is carried on a conjugative plasmid¹¹. We also found that an antagonistic substance against other lactococci was produced by *L.l.lactis* biovar *diacetylactis* DRC1 in our laboratory collection, formerly designated as *Streptococcus lactis* subsp. *diacetylactis* DRC1 originally obtained from the National Institute for Research in Dairying (now AFRC Institute of Food Research)⁵.

In this report, we demonstrated that the inhibitory activity is due to the concerted action of at least 2 bacteriocins, lactococcins A and M in *L.l.lactis* DRC1 by cloning and sequencing of the genes coding for bacteriocin production.

---Materials and methods-----

The bacterial strains and plasmids used in this study are listed in [Table 1](#) (36 KB). Thirty-eight lactococcal strains in our laboratory collection [5](#)) were examined for cross-antagonistic activity using the agar spot test. Colonies of bacteria that could produce bacteriocin were grown on M17G agar plate overnight [14](#)). A lawn of 4mL of M17G soft agar (0.7%) containing 100 $\frac{1}{4}$ L of a fresh culture of the indicator organism was poured over a plate. After incubation overnight at 30, the colonies were examined for zones of growth inhibition.

Plasmid DNA was isolated from lactococcal strains by the method of Anderson and McKay [1](#)). Transformation of plasmid free strain *L.l.lactis* DRC1021 was performed by electroporation, with a Bio-Rad gene pulser (Bio-Rad Laboratories, Richmond, Calif.) according to the method of Holo and Nes [7](#)). Recombinant DNA analysis was performed as described by Sambrook et al. [12](#)). DNA was sequenced by Taq Dye Deoxy Cycle sequencing on an Applied Biosystems 373A DNA sequencer (Applied Biosystems, Foster City, Calif.). For sequencing, stepwise deletion derivatives of cloned DNA fragments were constructed with ExoIII/Mung Bean deletion kit from Stratagene. The GENETYX-MAC program (Software Co., Japan) was used to analyze DNA sequences. For Southern hybridization, DNA was transferred to Hybond N (Amersham, Buckinghamshire, United Kingdom), using Vacu-gene (Pharmacia, Uppsala, Sweden) according to the manufacturer's specifications. Nonradioactive DNA probes were prepared using a random-primed labeling and detection kit (Boehringer Mannheim, GmbH, Germany). Hybridization and immunological detection were performed as recommended by the supplier.

---Results and discussion-----

As a result of the cross-antagonistic test, *L.l.lactis* DRC1 and ATCC13675 inhibited the growth of the majority of the lactococcal strains such as *L.l.lactis* 527 and 1061. These strains exhibited a cross-immunity to each other and the antagonistic agent was heat-stable under acidic conditions and inactivated by incubation with pronase E, protease K, subtilisin and trypsin. These properties suggested that the strains produced the same polypeptide bacteriocin.

Several plasmid-cured derivatives from *L.l.lactis* DRC1 were isolated after growth in broth containing acridine orange and compared with their plasmid profile and phenotype. *L.l.lactis* DRC1 harbored 6 distinct plasmids originally. Plasmid-free derivatives *L.l.lactis* DRC1021 and *L.l.lactis* DRC104, which contained a cryptic 7.9 kb plasmid pDR1-1, were unable to inhibit the growth of the indicator strain *L.l.lactis* 1061, and were sensitive to the bacteriocin produced by *L.l.lactis* *L.l.lactis* DRC1. Since *L.l.lactis* DRCg4, which contained the large (more than about 60 kb) plasmids pDR1-6 and pDR1-1, still displayed a bacteriocin activity, it was suggested that the presence of pDR1-6 was required for bacteriocin production and its immunity. Plasmid pDR1-6 extracted from *L.l.lactis* DRCg4 was digested with *Bam*HI, *Eco*RI, *Hind*III, *Pst*I and *Sal*I, respectively. These fragments were ligated into the multiple cloning sites of the pWV01-derived cloning vectors pGKV21 [16](#)) and pGKV259 [17](#)), and transformed into *L.l.lactis* DRC1021.

Erythromycin-resistant transformants were overlaid with indicator cells to screen the bacteriocin activity. Plasmid pDR405 (4 kb *Hind*III fragment in pGKV21) which contained the transformant inhibited the growth of the indicator strain but did not inhibit the growth of the bacteriocin-producing strains DRC1 and ATCC13675.

The restriction endonuclease map and nucleotide sequence of the 4 kb *Hind*III fragment specifying antagonistic activity were determined (Fig. 1A). The 4093 bp nucleotide sequence was identical with the lactococcin A gene cluster described by Stoddard et al. (13), including 3 complete open reading frames, *lcnD*, *lcnA* and *lciA*. Incomplete open reading frame of *lcnC*, interrupted by the *Hind*III site, was also present upstream of *lcnD*. Downstream of *lciA* the sequence was identical with the promoter and N-terminal regions of *lcnB*, which was described by van Belkum et al. (4).

[*Fig. 1.\(33 KB\)](#)

Complete lactococcin A gene cluster contained *lcnC* and *lcnD* genes as well lactococcin A structural and immunity genes. It is now generally accepted that *lcnC* and *lcnD* are required for the secretion via a system oriented to bacteriocin export. In this experiment, *L.l.lactis* DRC1021 was able to produce externalizing active lactococcin A in the absence of the plasmid-encoded *lcnC* gene. It was suggested that the chromosomal *lcnC* gene may be present in *L.l.lactis* DRC1021 as in the case of *L.l.lactis* IL1403 (15). A 1.6 kb *Hind*III-Sau3AI fragment encompassing internal *lcnC* was used as the probe in Southern hybridization. A signal was indeed found on the chromosomal DNA of *L.l.lactis* DRC1021.

Lactococcin A which belongs to class II bacteriocin, was purified from *L. l.* subsp. *cremoris* LMG2130 by Holo et al. (6) and is produced by several strains of *L.l.lactis*. The conjugative 60 kb plasmid p9B4-6 isolated from *L. l. cremoris* 9B4 contained 3 operons coding for lactococcins A, B, and M as well as for the corresponding immunity proteins (2-4). Recently, Morgan et al. have reported that the genes encoding lactococcins A, B, and M are located on a 72- and a 78- kb nonmobilizable plasmid in *L.l.lactis* DPC938 and DPC3286, respectively (9). This finding prompted us to determine whether *L.l.lactis* DRC1 carries genes homologous to the other lactococcins. By using pDR403 encompassing incomplete *lcnA* operon as a probe, 2 signals, 9.5 kb and 24 kb, were obtained in *Eco*RI fragments of pDR1-6.

The 9.5 kb *Eco*RI fragment was cloned into competent *E.coli* XL-1 Blue by using the vector pBluescript II, designated as pDR413, and the 9.5 kb fragment was then religated into the *Eco*RI site of pGKV259 and transformed into *L.l.lactis* DRC1021. Resultant transformants also exhibited bacteriocin activity. This recombinant plasmid was designated as pDR430 (9.5 kb *Eco*RI fragment in pGKV259). However, *L.l.lactis* DRC1021 harboring pDR430 did not confer a resistance against *L.l.lactis* DRC1. The restriction map of 9.5 kb *Eco*RI fragment presented in Fig. 1B revealed a similarity to the restriction map of pMB200, which encoded the low antagonistic activity of p9B4-6 described by van Belkum et al., and it was shown that the lactococcin M operon was located on the internal 1.8 kb *Sca*I-*Cla*I fragment (2,3). Therefore, pDR413 was subcloned in *E.coli*, and the following 1.8 kb *Sca*I-*Cla*I fragment was obtained as pDR422. The nucleotide sequence of this 1782bp fragment was determined and identified with lactococcin M operon completely including a part of *lcnD* and 3 open reading frames of *lcnM*, *lcnN* and *lciM* (Fig. 1B) (2,3).

In this experiment, we were not able to clone the 24 kb *Eco*RI fragment of pDR1-6, which contains the operons of lactococcins A and B. *LcnB* operon was located near *lcnA* operon on p9B4-6 (4) and pSM72 (9).

The nucleotide sequence analysis showed that downstream of *lciA* on pDR403 a sequence was present which was identical with the N-terminal sequence of *lcnB*. These findings suggest that pDR1-6 also encoded the third bacteriocin gene.

Initially, it was considered that the inhibitory activity of *L.l.lactis* DRC1 was due to the action of a single bacteriocin(dricin) as described by Powell et al. [11](#)). However, cloning and sequencing revealed that the observed activity was probably due to the combination of at least two different bacteriocins, namely lactococcins A and M

We thank Dr. Jan Kok of Groningen University for kindly providing the vectors.

---Abstract-----

Acute necrotizing mastitis in a cow was investigated pathologically. The udder was firmly enlarged to twice the size of a basketball. Histologically, the epithelium of the interlobular duct of the mammary glands was displaced by necrotic debris and bacterial clumps (Gram-positive cocci). The intralobular ducts were also necrotic. The alveoli showed scattered necrotic foci varying in size and containing bacterial clumps. The vascular walls of the interlobular stroma exhibited fibrinous necrosis with fibrinous thrombi. The liver showed centrolobular fatty and droplet degeneration of the hepatocytes. Extramedullary hematopoiesis was observed in the liver, spleen, adrenal glands, lungs and kidneys. The bacteria observed in the lesions of the mammary glands were stained positively with immunoperoxidase using an antibody against *Staph.ylococcus aureus*. Ultrastructurally, the bacteria were round or oval in shape and had thick cellular walls. Capsule-like fibrous material was present around the surface of the bacteria. Bacteriologically, *Staph.aureus* was isolated in pure culture from the mammary gland. These findings suggest that *Staph.aureus* caused the acute necrotizing mastitis. The pathogenesis of the disease was examined.

Discipline: Animal health

Additional key words: bovine mastitis

---Introduction-----

Bovine mastitis is caused by various bacteria (*Streptococcus*, *Staph. ylococcus*, *Corynebacterium*, *Pseudomonas*, *Pasteurella*, *Brucella* and *Escherichia coli*), *Mycoplasma* and fungi (*Candida*) [2,3,7](#). Gangrenous mastitis is caused mainly by *Staph.aureus* [2,3](#) and *E.coli* [1-3](#). *Staph.aureus* and *Clostridium perfringens* were isolated from gangrenous mastitis [6](#). *Staph.aureus* and *E.coli* are often present in the cow's skin and in the environment around the cow. Therefore the localization of these bacteria in the mammary lesions should be investigated in order to determine the relationship between the bacteria and the lesions. Although there are some reports concerning the bacteriology [4,6](#) or histology of the disease [1,5](#), there are no reports on histological, immunohistochemical and ultrastructural features of gangrenous (necrotizing) mastitis.

This paper describes the histological, immunohistochemical and ultrastructural features of acute necrotizing mastitis caused by *Staph.aureus* in a cow.

---Materials and methods-----

An adult Holstein cow delivered a calf uneventfully. A few days after the delivery, the cow developed swelling of the udder, bloody diarrhea, pyrexia, difficulty in standing, and a positive reaction for the complement-fixation test of Johne's disease. Ten days after the delivery, the cow was sent to our laboratory for pathological examination.

The cow was euthanized with anesthesia for necropsy. The udder, liver, spleen, kidneys, lungs, heart, adrenal glands, stomach, small intestine, large intestine, and other tissues were collected, and fixed in 10% neutral-buffered formalin. The tissues were processed routinely and stained with hematoxylin and eosin (HE). Selected sections were stained with Azan stain, Gram stain and phosphotungstic acid hematoxylin (PTAH). The paraffin sections were stained using an avidin-biotin-peroxidase complex (ABC)-immunostaining kit (Vector Lab., U.S.A.). A rabbit antibody against *Staph.aureus* was used at 1:2,000 dilution. Mammary gland tissues were fixed in 2.5% glutaraldehyde and post-fixed in 1% osmic acid, dehydrated with alcohol, and embedded in epoxy resin. Thin sections were stained with 1% uranyl acetate and Reynold's lead citrate, and examined with a transmission electron microscope (TEM). Attempts to isolate bacteria from the mammary glands, the granuloma in the liver and the colon of the cow were made by aerobically culturing the samples on sheep blood agar plates and desoxycholate-hydrogen sulfide-lactose (DHL) agar plates.

---Results-----

The udder (all 4 quarters of the udder) was firmly enlarged to twice the size of a basketball. Cheese-like material oozed from the lactiferous ducts of the teat papilla and the cut surface of the parenchyma. Encapsulated abscesses (about 2 cm in diameter) were observed in the omentum

and in the peritoneum in addition to pathological findings such as, nutmeg liver, stagnation of the bile in the gall bladder, subcutaneous gelatinous infiltration and jaundice, and congestion and hemorrhages in the small and large intestines. *Staph.aureus* was isolated in pure culture from the mammary glands of the cow.

In the mammary gland, interlobular ducts were severely affected. The epithelium of the interlobular duct was displaced by necrotic debris and bacterial clumps (Gram-positive cocci) ([Fig. 1](#)). The intralobular ducts of most of the lobules of the mammary glands were also necrotic. The alveoli shows scattered necrotic foci varying in size and containing bacterial clumps. In the small necrotic foci, bacterial clumps were surrounded by the alveolar epithelial cells showing necrosis. Fusion of such necrotic foci led to the formation of larger foci. The intact area of the parenchyma revealed hyperemia. The interlobular stroma showed edematous loosening with some neutrophils and mononuclear cells. The vascular walls of the interlobular stroma showed fibrinous necrosis with fibrinous thrombi (PTAH-positive) ([Fig. 2](#)).

[*Fig.1.&Fig.2\(87 KB\)](#)

In the liver, the hepatocytes underwent fatty and droplet ([Fig. 3](#)) degeneration. Occasionally, megakaryocytes, erythroblasts and granulocytes migrated into the sinusoids ([Fig. 4](#)). The spleen showed a marked congestion with megakaryocytes and granulocytes migrating into the red pulp. Severe migration of megakaryocytes, erythroblasts and granulocytes was observed into the blood capillaries of the cortex of the adrenal gland. Occasionally, megakaryocytes were seen in the alveolar walls of the lung and in the blood capillaries of the kidney. Granulomatous nodules, consisting of eosinophilic debris surrounded by multinucleated giant cells and macrophages with proliferation of the fibrous connective tissue, were noted in the pleura on the rib. Gram-positive, small, rod-shaped bacteria were seen in the debris which were present in the granuloma. The cocci observed in the lesions of the mammary glands were stained positively with ABC stain using an antibody against *Staph.aureus* ([Fig. 5](#)), unlike the rods in the granuloma of the pleura. In the mammary glands, the bacteria which were round or oval in shape and had thick cellular walls showed the characteristics of Gram-positive bacteria ([Fig. 6-a](#)). The size of the bacteria ranged from 0.8 to 1.0 μm in diameter. Ruthenium-red-positive fibrous material (capsule) was present around the surface of the bacteria ([Fig. 6-b](#)).

[*Fig.3.&Fig.4.\(79 KB\)](#), [Fig.5.&Fig.6.\(65 KB\)](#)

---Discussion-----

In the present case, the lesions of the mammary glands consisted of vascular necrosis with fibrinous thrombosis. These changes had been reported previously in Staphylococcal mastitis³. This vascular damage may have played a role in the acute coagulative necrosis of the mammary gland parenchyma observed in our case also. Acute Staphylococcal mastitis occurs shortly after parturition³. Extramedullary hematopoiesis in the liver, spleen, adrenal glands, lung, and kidney observed in the present case suggests that the cow may have been anemic, presumably due to parturition. The cow showed a positive reaction to the complement-fixation test of Johne's disease and had small nodules of encapsulated abscesses in the omentum and in the peritoneum. The stresses of parturition, anemia, and infection with another bacterium may have led to a higher sensitivity to Staphylococcal infection.

Previously, researchers had examined histologically 47 cows from an abattoir, and mastitis was recorded in 36 cows⁵, of which, two showed necrotizing mastitis. Bacteriological investigation was not performed, but cocci were observed in the alveoli in that report⁵. Necrotizing mastitis in cows from which *E.coli* were isolated has been reported¹. Although the etiological bacteria of mastitis have been usually identified by bacterial isolation from mastitis, there have been no immunohistochemical demonstrations of bacteria in mastitis. Etiological agents of mastitis are usually present in the skin of cattle and in the environment in which the cattle are housed. Immunohistochemical demonstration of the bacteria in the mastitis lesions is important to evaluate the pathogenicity of the bacteria isolated from the lesions. In our present study, the immunohistochemical detection of *Staphylococcus* in the necrotic foci of the mammary gland indicates that necrotizing mastitis may be caused by *Staph.aureus* infection.

We observed capsular materials (ruthenium-red-positive) in *Staph. aureus* within the necrotic lesions of the mammary glands. Encapsulated strains of *Staph.aureus* from bovine milk were isolated by Yokomizo & Isayama⁸). Their report suggests that encapsulated *Staph.aureus* may play a role in the pathogenesis of bovine mastitis. Further studies on the relationship between necrotizing mastitis and encapsulated *Staph.aureus* should be carried out.

Abstract

Weak plants were found in the BC₁F₁ generation in a backcrossing program aimed at introducing the *wx* gene from a Thai cultivar, Col.No.15, into a Japanese cultivar, Sasanishiki, in Asian cultivated rice. These weak plants were characterized by poor growth and discoloration at the tillering stage, but they were fertile. Hybrid breakdown, which is defined as hybrid weakness and sterility detected in the F₂ and later inbred generations from varietal crosses, is controlled by a pair of complementary recessive genes, *hwd1* and *hwd2*, at unlinked loci. Two dominant genes at either the same or different loci, *Hwd1/Hwd1 hwd2/hwd2*, *hwd1/hwd1 Hwd2/Hwd2* or *Hwd1/hwd1 Hwd2/hwd2* are needed for normal growth. Using tester lines homozygous for a pair of complementary recessive genes selected in the BC₁F₃, the genotypes for hybrid breakdown of 100 Asian rice cultivars were tested based on the phenotype of F₁ plants. Clinal variation for hybrid breakdown was observed. Cultivars with 2 dominant alleles at either *hwd1* or *hwd2* locus, were mainly found in insular Asia (Japan, Philippines and Indonesia), while the frequency of cultivars with 4 dominant alleles was more common in cultivars from continental Asia. Linkage analysis using RFLP markers mapped over 12 rice chromosomes indicated that *hwd1* from Col.No.15 was located between RFLP markers, C701 and R2309, on chromosome 10, and *hwd2* of Sasanishiki was tightly linked to 4 RFLP markers on chromosome 7. Role of hybrid breakdown in genetic differentiation of Asian cultivated rice is discussed.

Discipline: Plant breeding/ Genetic resources

Additional key words: reproductive barrier, hybrid weakness, geographical differentiation, RFLP markers

Introduction

Isolating mechanisms prevent or restrict the exchange of genes between and within species and may be either external or internal in type¹⁸. External barriers include eco-geographical isolation of interspecific and intraspecific variation and result in unique genotypes adapted to distinct environments. Internal barriers restrict gene flow between plants growing sympatrically and play an important role in plant speciation and genetic differentiation.

In addition to partial cross-incompatibility¹⁴⁾, different types of reproductive barriers have been found in varietal crosses of Asian cultivated rice, *Oryza sativa* L. These post-hybridization reproductive barriers include, hybrid weakness or F₁ lethality^{1,8,16)}, hybrid sterility^{9,10)}, hybrid breakdown^{3,6,8,11-13,19)}, hybrid chlorosis¹⁷⁾ and distorted segregation⁷⁾. Among these post-hybridization reproductive barriers, hybrid breakdown which is defined as weakness and sporophytic sterility found in the F₂ and later inbred generations, is distinct from F₁ weakness or lethality. F₁ weakness and hybrid breakdown have been detected in remote crosses of Asian cultivated rice. Whereas a pair of complementary dominant genes causes weakness and lethality in F₁ plants^{1,8,16)}, a pair of complementary or duplicate recessive genes is responsible for weakness in the F₂ and later generations^{3,8,13)}. These characters are free from direct artificial selection and are useful for research into evolution and differentiation in plants. The geographical distribution of genes conferring reproductive barriers reflects the phylogenetic relationship of the varietal groups of rice.

In a breeding program aimed at producing isogenic lines for the wx genes, 30 glutinous cultivars from different Asian countries were used for crosses to introduce the wx gene into the Japanese cultivar, Sasanishiki. When a Thai glutinous cultivar of upland rice, Col.No.15 was used for the cross, weak plants appeared among BC₁F₁ plants backcrossed to Sasanishiki.

In this report, the genetic basis of hybrid breakdown found in the above cross, the geographical distribution of the genes responsible for hybrid breakdown, mapping of genes using RFLP markers and the role of hybrid breakdown in genetic differentiation of Asian cultivated rice will be discussed.

Inheritance of hybrid breakdown^{13,15)}

To analyze the mode of inheritance of weakness, various populations were produced. Reciprocal crosses were made between Sasanishiki and Col.No.15. F₁ plants were backcrossed to both cultivars and were also self-pollinated. Weak BC₁F₁ and BC₂F₁ segregants were crossed to Sasanishiki. Seeds from self-pollinated spikelets of weak BC₁F₁ plants were bulked to detect segregation in the BC₁F₂ generation. Each BC₁F₂ plant was separately harvested to analyze segregation in the BC₁F₃ generation. All the materials were transplanted in the field at the same time and observed for their growth and morphology. BC₁F₂ bulked populations originating from weak BC₁F₁ segregants were planted in the field and investigated for heading time, culm length and the number of panicles per plant.

The segregation for hybrid weakness in different generations is shown in [Table 1](#). F₁ plants of reciprocal crosses between Sasanishiki and Col.No.15 showed vigorous growth and were fertile. BC₁F₁ plants backcrossed to both cultivars segregated into 3 normal : 1 weak types. Weakness did not appear at the seedling stage. The weak BC₁F₁ segregants became yellow at the tillering stage and stunted. Weak plants produced one or a few panicles with fertile seeds. When weak BC₁F₁ and BC₂F₁ segregants were backcrossed to Sasanishiki, BC₂F₁ and BC₃F₁ plants segregated into 1 normal : 1 weak plants. BC₁F₂ bulked populations derived from weak BC₁F₁ plants segregated into 1 normal : 3 weak plants. BC₁F₃ lines derived from a random sample of BC₁F₂ plants segregated into 1 normal : 2 heterozygous : 1 weak lines. F₂ plants from reciprocal crosses between Sasanishiki and Col.No.15 segregated into 11 normal : 5 weak plants. Also, F₂ plants of reciprocal crosses between Sasanishiki and weak BC₁F₃ segregants showed a good fit to the segregation ratio 1 normal : 3 weak plants.

[Table 1. Segregation ratios for hybrid weakness observed in each generation\(32KB\)](#)

The frequency distribution for heading time, culm length and number of panicles per plant in the BC₁F₂ bulked population is shown in [Fig. 1](#). Heading time occurred from August 5 to August 30 (99 to 124 days after sowing) and no relation between heading time and weakness was detected. Three-fourths of BC₁F₂ plants had a very short culm and few panicles and the others showed normal growth, reflecting segregation for hybrid weakness.

[Fig.1:Frequency distribution for heading time, culm length and number of panicles per plant on BC₁F₂ population from weak BC₁F₁ plants of the cross, Sasanishiki/Col.No.15//Sasanishiki\(17KB\)](#)

The genetic basis of hybrid breakdown found in the progeny of the cross between Sasanishiki and Col.No.15 could be elucidated by assuming the presence of a pair of complementary loci in the same manner as postulated by Oka⁸). The segregation ratio for weak and normal plants in all the generations analyzed fitted well to the expected ratios in each population for this mode ([Table 1](#)). Based on this model, if Sasanishiki and Col.No.15 have the genotypes, AAbb and aaBB, segregants with only one or no dominant gene, Aabb, aaBb and aabb, are likely to express the weakness. At least 2 dominant genes at either the same or different loci, AAbb, aaBB and AaBb, are necessary for normal growth.

Based on the results obtained in this study, a pair of complementary loci causing hybrid breakdown in Asian cultivated rice was symbolized as *hwd1* and *hwd2*. Col.No.15 and Sasanishiki carry recessive alleles at the *hwd1* and *hwd2* loci, respectively.

Distribution of a pair of complementary genes for hybrid breakdown¹⁵⁾

Early maturing and fertile BC₁F₃ lines in which double recessive homozygotes express weakness, were selected as tester lines. Using BC₁F₃ lines lacking dominant genes, *hwd1/hwd1 hwd2/hwd2*, for hybrid breakdown, a total of 100 Asian rice cultivars were tested for complementary genes at a pair of unlinked loci. Five to 10 F₁ plants from each of the crosses were grown in the field and analyzed for weakness based on their growth pattern and morphology. F₂ plants from reciprocal crosses between Sasanishiki and one of the tester lines were also investigated.

When the F₁ plants between a tester line and a given cultivar show vigorous growth, the cultivar is likely to carry 2 pairs of dominant genes, *Hwd1/Hwd1 Hwd2/Hwd2*. When the F₁ plants show weakness, the cultivar is likely to carry one pair of dominant genes, *Hwd1/Hwd1 hwd2/hwd2* or *hwd1/hwd1 Hwd2/Hwd2*. When the F₁ plants were intermediate between normal and weak plants, their F₂ progeny was further tested to determine the genotype for hybrid breakdown of cultivars.

Geographical distribution of a pair of complementary genes causing hybrid breakdown in Asian cultivated rice is presented in [Fig. 2](#). Clinal variation was observed in the frequency of genotypes for hybrid breakdown among Asian cultivars. A majority of cultivars with 2 dominant genes, *Hwd1/Hwd1 hwd2/hwd2* or *hwd1/hwd1 Hwd2/Hwd2*, was found in insular Asia, Japan, Philippines and Indonesia. On the other hand, the frequency of cultivars with 4 dominant genes, *Hwd1/Hwd1 Hwd2/Hwd2* was more common in continental Asia, China, Vietnam, Laos, Thailand and Myanmar. All the Nepalese cultivars analyzed in this study carried four dominant genes.

[Fig.2: Geographical distribution of a pair of complementary genes responsible for hybrid breakdown in Asian cultivated rice\(23KB\)](#)

Mapping of complementary genes using RFLP markers²⁾

The location of the complementary genes causing hybrid breakdown was analyzed using RFLP markers. Two cultivars with 2 dominant genes at either locus were used for one of the parents to produce mapping populations. Nepalese cultivar Siborunauli 1 is dominant for *hwd1* and recessive for *hwd2*. Thai cultivar Col.No.15 is dominant for *hwd2* and recessive for *hwd1*. Crosses between these cultivars and one of the tester lines (W26) which is recessive homozygote for these 2 loci were made to produce F₂ mapping populations. F₁ plants from both cross-combinations had only one dominant allele and showed weakness. Two hundred and twenty-five F₂ plants from the cross between W26 and Siborunauli 1 and 184 F₂ plants from the cross between Col.No.15 and W26 were analyzed for segregation into weak and normal plant types.

Total DNA was isolated from the leaves of each F₂ plant using standard procedures and was digested with restriction enzymes. Southern hybridization and signal detection were conducted using ECL direct nucleic acid labeling and a detection kit (Amersham). RFLP markers mapped on the rice linkage map⁴⁾ were used for mapping. Segregation patterns of RFLP markers and plant types in F₂ populations were analyzed with MAPMAKER/EXP 3.0⁵⁾. The map position of 2 loci controlling hybrid breakdown was determined by multipoint linkage analysis.

F₂ plants from the cross between W26 and Siborunauli 1 segregated into 52 normal : 173 weak types. F₂ plants from the cross between Col.No.15 and W26 segregated into 56 normal : 128 weak types. These data fitted to the expected ratio of 1 : 3. Linkage analysis using F₂ population from the cross between W26 and Siborunauli 1 revealed that the gene *hwd1* was located in the proximal region on chromosome 10. The gene, *hwd1*, was linked between RFLP markers C701 and R2309 at a distance of 0.9 centiMorgans (cM) and 0.6 cM, respectively ([Fig. 3](#)). In the F₂ population from the cross between Col.No.15 and W26, 4 RFLP markers (C796B, R1382, C145, C492) co-segregated with plant types, indicating that *hwd2* was located in the central region of chromosome 7 ([Fig. 4](#)).

[Fig.3:Linkage map showing the position of *hwd1* responsible for hybrid breakdown in rice\(17KB\)](#)

[Fig.4:Linkage map showing the position of *hwd2* responsible for hybrid breakdown in rice\(19KB\)](#)

Role of hybrid breakdown in varietal differentiation of Asian cultivated rice

Hybrid weakness in F₁ and hybrid breakdown including weakness in F₂ and later generations have been observed in particular crosses among Asian rice cultivars. The former occurs under a complementary dominant gene system and F₁ plants heterozygous for 2 complementary loci are not viable^{1,8,16}. The latter occurs under a complementary or duplicate recessive gene system and F₂ progeny segregates into weak^{8,3,13}, partially sterile^{6,11,12,19} or chlorotic¹⁷ plants according to Mendelian segregation ratios.

Hybrid weakness analyzed in this study was detected in F₂ and later generations in the cross between a Japanese and a Thai cultivar. Therefore, this weakness is categorized into hybrid breakdown and is controlled by a pair of complementary recessive genes with a segregation ratio of 11 normal : 5 weak plants in the F₂. These results are the same as those reported in the F₂ of a cross between an Indian cultivar and a Japanese cultivar⁸). On the other hand, a duplicate recessive gene system with a segregation ratio of 15 normal : 1 weak or chlorotic plants in the F₂ has also been reported^{3, 17}). If hybrid breakdown contributes to promoting *indica-japonica* differentiation of Asian cultivated rice, these complementary or duplicate genes causing hybrid breakdown must be distributed independently in *indica* and *japonica* rices. In this study, one of the complementary genes for hybrid breakdown, *hwd1*, was carried by the indica cultivar, Col.No.15, and the other gene, *hwd2*, the *japonica* cultivar, Sasanishiki. These findings suggest that the genes may have caused or accelerated *indica-japonica* differentiation. However, to gain a better understanding of the role of hybrid breakdown in varietal differentiation, the distribution pattern of *hwd1* and *hwd2* in rice cultivars with the genotypes, *Hwd1/Hwd1 hwd2/hwd2* and *hwd1/hwd1 Hwd2/Hwd2*, will be further analyzed.

Abstract

The influence of dairy wastes stored in an unlined lagoon on the total nitrogen concentration of shallow groundwater was investigated in western Hokkaido. The lagoon was constructed in a meadow consisting of an Andosol with a high water table. Increase of the total nitrogen concentration in groundwater was observed at a distance of 75 m from the lagoon within 4 days after a low concentration dairy slurry was loaded into the lagoon. At a distance of 15 m from the lagoon, higher total nitrogen concentration was still observed 85 days after slurry loading. These facts clearly indicate that groundwater contamination by cattle slurry stored in the unlined lagoon occurs very quickly and persists for a very long period of time.

Introduction

In Japan, the largest dairy farming areas are located in the eastern and the northern parts of Hokkaido. The farms are getting larger and the number of dairy cattle is increasing in these areas. Dairy wastes were usually separated into solid and liquid materials. However, increasing volume of dairy wastes recently has tended to be handled as slurry. Slurry is sometimes stored in unlined earthen pits, namely lagoons, for economic reasons. Lagoons have already been used in more concentrated animal industries such as swine production in Japan.

Obviously, the utilization of such lagoons is associated with the risk of groundwater contamination. Ozaki et al.⁶⁾ observed an increase in the concentration of nitrate in shallow groundwater at a distance of 50 m from a swine waste lagoon. Shimura and Tabuchi⁸⁾ pointed out that the nitrate concentration of the river increased in proportion to the livestock density of the catchments where lagoons are used.

On the other hand, there are conflicting reports on the influence of lagoons^{1, 3)} because the infiltration rates of slurry vary depending on the experimental conditions^{2, 7)}. In a test conducted under drastic conditions, using a 2 ha lagoon filled with relatively dilute beef cattle manure, Miller et al.⁵⁾ observed the rapid self-sealing of the lagoon within 2 weeks. They concluded that the lagoon had no effect on the downstream groundwater quality. However, Culley and Phillips³⁾ concluded that lagoons were not effectively sealed in an experiment covering a 5-year period using 3 lagoons constructed in areas with different soil types.

In this study, the objective was to examine the risk of utilizing an unlined lagoon. Influence of dairy wastes stored in a lagoon on the total nitrogen concentration of shallow groundwater was investigated. In order to observe the influence clearly, an experiment was conducted under drastic but possible conditions in actual farms. In the experimental design, special attention was paid to both areal expansion and temporal changes of groundwater contamination. Detailed process of contamination is described and its magnitude was analyzed.

Materials and methods

1) Site description

The experiment was conducted at Hokkaido National Agricultural Experiment Station, Sapporo (43° 0' N., 141° 24' E.). A cylindrical lagoon, 10 m i.d.x1.8 m depth, was excavated in a meadow in June 1995. The experimental field was located on a gentle slope on Tsukisamu terrace. Inclination of the slope was 1.7° (Fig. 1).

[Fig. 1. Contour map of experimental site\(40KB\)](#)

The soil belonged to Cumulic Andosols⁹⁾. Tsukisamu terrace is composed of the Tsukisamu clay Formation of Late Pleistocene, covered with volcanic ashes. Soil survey revealed that volcanic ashes could be divided into a humus accumulation layer and Eniwa loamy layer. A transitional layer was observed beneath the Eniwa loamy layer. The upper part of the Tsukisamu clay Formation was divided into 3 layers based on structural differences, namely upper, middle and lower Tsukisamu clay layers (Fig. 2). Based on properties such as texture of soil layers or spurting out of groundwater, the transitional layer and middle Tsukisamu clay layer were considered to be the main paths of

groundwater flow, although their hydraulic conductivity was not appreciably different from that of the Eniwa loamy layer. Lower Tsukisamu clay layer was an impermeable layer, whose hydraulic conductivity was the lowest. Middle Tsukisamu clay layer was an aquifer because it was underlain by an impermeable layer.

[Fig. 2. Soil profile at the location of the lagoon\(33KB\)](#)

2) Operation

One hundred two tons of dilute dairy cattle slurry, with a concentration of 0.8 gN/L total nitrogen, were loaded into the lagoon on June 14, 1995. Since the slurry was rapidly depleted within a few days, additional 23 t were applied on June 21, 1995 in order to keep sufficient loads of slurry.

Groundwater samples were collected from 38 monitoring wells surrounding the lagoon during the period of June 8 and September 7, 1995 ([Fig. 1](#)). Thereafter, the lagoon was overflowed by heavy rainfall, and groundwater sampling was discontinued. Sampling of groundwater was carried out almost every day in the first week after slurry loading, and every 1 or 2 weeks, thereafter. A polyvinyl chloride pipe 26 mm in diameter was used as monitoring well. The pipe was perforated in the lower part up to 60 cm from the bottom, and was set at a 2 m depth from the soil surface ([Fig. 3](#))

[Fig. 3. Profile of survey line along the slope\(26KB\)](#)

3) Analysis

Total nitrogen concentration of the groundwater samples was analyzed chromatically after potassium peroxosulfide degradation⁴⁾. Samples contained a large amount of suspended solids, and they were allowed to stand for a week before analysis in order to induce the precipitation of the suspended solids. Nevertheless, the groundwater samples could not be analyzed by ion chromatography because of the residual suspension.

Soil samples were analyzed for water soluble inorganic ions. Analysis was carried out using 0.45 mm filtrate of water : soil = 5 : 1 extracts by ion chromatography (DX-AQ, Nippon Dionex K. K., Osaka, Japan). Results were expressed as ion concentrations in soil water.

Results

1) Effect of slurry application on total nitrogen concentration of shallow groundwater

Highly contaminated groundwater was observed immediately after the first slurry loading. Contamination spread rapidly. Expansion of contaminated groundwater occurred mainly along the slope inclination (Fig. 4). After 9 days of the first loading, the contaminated area decreased. However, contamination still persisted at 85 days after the first loading in the vicinity of the lagoon

Fig. 4. Expansion of groundwater containing a high concentration of total nitrogen(43KB)

In order to analyze the temporal changes of the total nitrogen concentration in detail, data of 8 monitoring points on line A (Fig. 1) are shown in Table 1. Based on the background level, 1.2 mgN/L at most, the data over 2 mgN/L were considered to indicate the contamination of groundwater by the slurry (depicted in shadowed boxes). On the next day of the first slurry loading, the total nitrogen concentration exceeded the background level at a distance of 50 m from the lagoon. On the 4th day, 75 m point was also contaminated. After 9 days, the concentration decreased at most of the monitoring points. However, contamination still persisted at 85 days after the first loading at 15 m point.

Table 1. Temporal changes in total nitrogen concentration of groundwater

Distance from lagoon	Total nitrogen concentration (mgN/L)									
	Days after slurry loading									
	-6 d	1 d	2 d	4 d	7 d	9 d	15 d	22 d	43 d	85 d
5 m	0.6	142.6	180.7	217.1	208.7	184.8	210.9	87.6	113.7	17.2
10 m	0.7	82.8	127.9	143.0	112.2	96.0	69.4	46.3	41.5	10.6
15 m	0.6	50.5	19.4	91.3	80.4	64.5	38.1	28.9	26.9	3.5
20 m	0.5	33.3	10.5	30.9	43.4	44.2	29.6	19.8	7.5	1.9
25 m	0.5	3.5	11.5	17.5	19.2	21.1	20.4	3.3	2.5	1.5
50 m	0.5	2.0	3.0	11.1	11.8	7.9	1.8	3.8	2.2	1.1
75 m	0.1	0.3	0.6	2.6	3.9	4.1	4.2	2.9	1.4	0.7
100 m			0.2	0.3	0.0	0.5	0.5	0.3	0.3	0.6

Samples were collected from wells on survey line A (Fig.1).

Values over 2 mgN/L are shadowed.

2) Contamination path

After monitoring of the total nitrogen concentration in the groundwater, the slurry was removed and the surrounding soils were analyzed for water-extractable inorganic ions.

In order to analyze the running path of contaminated groundwater, soil samples were collected from every 20 cm layer at 5 sites on line A (Fig. 1). Influence of slurry was obvious at 5 m point down the lagoon (Fig. 5). Ammonium, potassium and chloride were mainly detected in the middle Tsukisamu clay layer. This fact corresponded to the observation that the middle Tsukisamu clay layer was an aquifer, suggesting that most of the contaminated water moved through this aquifer. Interestingly, the nitrate distribution was very different for unknown reasons.

Fig.5.Distribution of water-extractable ions in soils(along the slope)(31KB)

Downward seepage of slurry was examined using soils beneath the bottom of the lagoon. Ammonium, potassium, nitrate and sulfate were mainly distributed within a 20 cm area under the bottom. Chloride was detected slightly deeper, but most part remained within the 50 cm zone (Fig. 6). These facts indicate that downward seepage of the slurry was negligible in this study compared to the horizontal expansion of the contamination.

Fig.6.Distribution of water-extractable ions in soils(25KB)

Discussion

We examined the influence of slurry stored in an unlined lagoon on the total nitrogen concentration of groundwater. Experimental conditions were drastic. The lagoon was constructed where a continuous flow of shallow groundwater was expected, and the slurry which had a very low viscosity would easily percolate into soils. These conditions allowed us to clearly demonstrate the areal expansion, temporal changes and running path of groundwater contamination.

Through an aquifer, an immediate leakage of slurry was observed. On the other hand, decrease of contamination was also observed at the early stage, suggesting that self-sealing effect of the lagoon had occurred. However, this fact may not rule out the risk of continued leakage of slurry because the contamination of groundwater was still detectable at 85 days after the first loading. Moreover, although we constructed a lagoon as large as possible, it was even smaller than those used in actual dairy farms. With 50 cows, our model lagoon might be filled up in approximately 40 days, only half of the period during which the influence of slurry on the contamination of groundwater was still observed. Persisting contamination was also detected in a swine farm in Japan⁶, where a lagoon kept polluting the groundwater at a distance of 50 m

even after 20 years of use which should have been long enough for self-sealing to occur.

Special attention must be paid to the presence of macropores. They largely contribute to the groundwater flow, but precise evaluation of their contribution is difficult. We detected a contamination at a distance of 50 m on the next day of slurry loading, which suggests that contaminated water moved down through some paths with a 10^{-0} cm/s order hydraulic conductivity. Average hydraulic conductivity was 10^{-3} cm/s order in permeable layers, and even the highest value of all the data obtained was 10^{-2} cm/s order. Contribution of a considerable number of macropores was ruled out in the estimation of hydraulic conductivity despite repeated tests. Therefore, it is unlikely that the velocity of the groundwater flow can be predicted based on the hydraulic conductivity.

Evaluation of the slurry loss is important to consider the risk of a lagoon. In this study, the depth of stored slurry was monitored ([Fig. 7](#)). It decreased rapidly at the earlier stages and gradually at the later stages. Increase after 54 days was due to heavy rainfall. Precise estimation of slurry loss was impossible because precise estimation of evaporation and dilution of slurry was uncertain. Therefore only a rough estimation was carried out by comparing the monitored slurry depth and the calculated one, assuming the absence of leakage, dilution and maximum evaporation (5 mm a day) from the lagoon. Calculated depth surpassed the monitored one, and the difference between the two increased throughout the period until 54 days after slurry application to the lagoon, when the monitored depth was only 77% of the calculated one. As the slurry had actually been diluted by rainfall during the experiment and the evaporation rate used for the estimation is maximum in this region, more than 23% of total nitrogen in the slurry initially stored in the lagoon was lost within 85 days.

[Fig.7.Temporal changes in depth of slurry\(21KB\)](#)

Dotted line shows calculated depth of slurry. Line with closed circles shows observed depth (refer to text). Average air temperature was 18.8 °C during the experiment (June 14 - September 7, 1995).

This study demonstrated the risk of using an unlined lagoon for dairy waste storage although experimental conditions were drastic. Environmental problems around livestock farms are a major cause for concern in Japan as they may become more serious in the absence of proper measures. In particular, for the storage of animal excreta, further caution should be paid and risky constructions should be avoided.

Present address:

*Upland Agriculture Research Center, Hokkaido National Agricultural Experiment Station(Memuro, Hokkaido)

Abstract

Growth response to organic nitrogen application was observed among various crops. We used rice bran mixed with rice straw as organic nitrogen source with a C/N ratio of 20. Nitrogen was not readily released from the organic matter because of the high C/N ratio. Organic nitrogen was applied with chemical fertilizers in an upland field to various crops such as upland rice, maize, potato, sugar beet and soybean. Inorganic nitrogen level in fallow soil was lower until the middle of the growth stage when organic nitrogen and chemical N-P-K fertilizers were applied, compared to the application of chemical fertilizers, only. In contrast to the inorganic nitrogen level in soil, upland rice grew better with organic nitrogen than chemical fertilizer, and took up more nitrogen than other crops during the first 100 days after amendment with organic nitrogen. These results can be attributed to 2 factors. (1) Higher mineralization rate in the rhizosphere of upland rice compared with other crops. Upland rice may enhance nitrogen mineralization in soil by the secretion of some enzymes such as protease and/or materials promoting microorganism activity. (2) Upland rice has a greater ability to take up organic nitrogen directly. If a crop is capable of taking up organic nitrogen in the form of amino acids, peptides and protein, the crop could absorb nitrogen with less competition for nitrogen with microorganisms compared with a crop which absorbs nitrogen mainly as nitrate. The protease activity in the soil planted with maize and sugar beet was higher than that in the soil planted with upland rice and in fallow soil. These results show that the enhancement of nitrogen mineralization is not essential for upland rice. In relation to hypothesis (2), upland rice took up more amino acids than maize in a solution culture containing some kinds of amino acids. The amino acid and protein contents in the soils from the rhizosphere and non-rhizosphere zones of upland rice (hereafter referred to as "rhizosphere and non-rhizosphere soils") were lower than those in the case of maize, soybean and fallow soil. We also observed that upland rice took up nitrogen before mineralization based on a ^{15}N -labelled rice bran application test. These results suggest that upland rice may take up organic nitrogen preferentially compared with other crops. We examined on the nitrogen uptake mechanism of upland rice and maize. Upland rice takes up nitrogen preferentially in the organic form rather than as nitrate which is the favorite form for maize. Endocytosis is one of the mechanisms for organic nitrogen uptake by upland rice.

Introduction

Sustainability of agriculture became a major issue of global concern during this decade. Agronomic practices aimed at reducing the dependence on inputs such as chemical fertilizers can contribute to sustainability. Nitrogen is the most limiting and commonly applied nutrient for crop production. The development of nutrient-responsive cultivars especially during the past 3 decades led to an intensive use of nitrogen fertilizers in many agricultural systems. Environmental and economic problems associated with such a practice have, however, generated an interest in alternative management systems, including the exploitation of beneficial biological functions and substitution of chemical fertilizers with farm-generated products.

Application of organic matter has long been known to improve the soil physical properties besides providing several nutrients including nitrogen. Nitrogen fertility of soils is determined by the amount of inorganic nitrogen released from soils during incubation in the laboratory⁴). In fact, the nitrogen fertility measured by this method is positively correlated with the nitrogen uptake by plants¹⁰). There are several arguments, however, against the use of this method. The amount of nitrogen uptake by plants does not always correspond to the amount of nitrogen released from soils, but depends on plants under the same growth conditions. This does not occur if plants take up inorganic nitrogen formed from organic nitrogen in soils through natural mineralization. It is thus suggested that some crops take up nitrogen in a special form.

Nitrogen uptake response of crops to organic nitrogen application

Growth response to organic nitrogen application has been studied in upland rice and maize in a field experiment using an inorganic nitrogen source (ammonium fertilizer) and an organic nitrogen source, consisting of a mixture of rice bran and rice straw as amendments. [Fig. 1](#) shows the nitrogen mineralization pattern from soils with rice bran and/or rice straw application.

[*Fig.1:Changes in the amount of nitrogen released from soil amended with rice bran and rice straw singly or in combination \(RBS\) at 30o C\(25KB\)*](#)

1) Field experiment

In 1992, maize (*Zea mays* L. var. DK250), potato (*Solanum tuberosum* L. var. Toyoshiro), soybean (*Glycine max* Merr. var. Tachinagaha), sugar beet (*Beta vulgaris* L. var. Beetmonobar) and upland rice (*Oryza sativa* L. var. Toyohatamochi) were grown in an Andosol (41.7 g C kg⁻¹, 3.4 g N kg⁻¹ dry soil) field at the National Institute of Agro-Environmental Sciences, Tsukuba, Japan. All the cultivations were performed under upland field conditions. Organic nitrogen was supplied as a 4:1 mixture of rice bran and straw (RBS). The C/N ratio of this mixture was 20. In 1993, only maize and upland rice were cultivated to confirm the reproducibility.

Nitrogen uptake by upland rice, soybean and potato supplied with organic nitrogen was higher than that of the control ([Fig. 2](#)). However, the amount of inorganic nitrogen in the fallow plot amended with organic nitrogen was lower than in the control ([Fig. 3](#)). These facts indicate that nitrogen uptake by some crops did not reflect the nitrogen levels in soil, and that they displayed a nitrogen uptake ability in the presence of organic nitrogen sources¹¹).

[*Fig.2:Nitrogen uptake response of various crops to organic nitrogen at various inorganic nitrogen rates applied as ammonium sulfate under field conditions\(32KB\)*](#)

[*Fig.3:Changes in inorganic nitrogen content at each depth of the fallow plot amended with ammonium sulfate at 80 kg ha-1 nitrogen rate\(25KB\)*](#)

2) Pot experiment

Pot experiments were conducted to study this phenomenon more precisely by avoiding the effect of root spread. In 1992 and 1994, maize, soybean (non-nodulated cultivar, var. T201) and upland rice were cultivated in pots (vol 3.8 L) containing approximately 3 kg dry soil (Andosol). Organic nitrogen was supplied with RBS at a rate of 0.1 g kg⁻¹ soil.

Nitrogen uptake by upland rice was higher than that by the other crops, and showed a positive relationship with the amount of organic matter applied ([Fig. 4](#)). In contrast, maize took up nitrogen actively in the ammonium sulfate plot, indicating that the nitrogen uptake response to organic nitrogen does not depend on the root spread but on crop properties.

[*Fig.4:Nitrogen uptake by various crops at two growth stages following the application of rbs and ammonium sulfate in a pot experiment in 1992\(25KB\)*](#)

We proposed 2 hypotheses for the higher nitrogen uptake of upland rice compared with maize as follows:

Upland rice (1) accelerates nitrogen mineralization from organic nitrogen, by secreting some enzymes⁹⁾ or by stimulating the activity of microorganisms³⁾, and (2) takes up nitrogen as protein, amino acids and ammonium preferentially with little competition with microorganisms before mineralization¹²⁾.

Factors for differences in nitrogen uptake among crops

1) Differences in nitrogen uptake derived from ^{15}N -labelled rice bran among crops

Upland rice, maize, and soybean were cultivated with ^{15}N -labelled rice bran in pot trials. The crops and soils were sampled to determine the nitrogen and ^{15}N contents at 3 stages. The total nitrogen content in the plants and inorganic nitrogen content in the soils were determined by a calorimetric method following Kjeldahl digestion and KCl extraction, respectively. The content of ^{15}N was measured by emission spectrometry.

The ^{15}N content of upland rice was highest among other crops ([Table 1](#)), suggesting that upland rice is more likely to take up nitrogen in the form of ammonium, amino acids and peptides than nitrate which would reduce ^{15}N concentration in a plant, because nitrate would be diluted by the nitrate presence in soil¹⁵). This assumption was supported by the fact that no differences were detected in the ammonium chloride plot.

Table 1. ^{15}N Concentration (atom%) of nitrogen taken up by various crops using ^{15}N -labelled rbs and ammonium, chloride

<u>^{15}N-labelled source</u>		<u>Days after sowing</u>		
		56	69	82
RBS	Upland rice	1.44±0.04	1.53±0.01	1.54±0.02
	Maize	1.39±0.06	1.36±0.01	1.38±0.03
	Soybean	1.26±0.03	1.33±0.03	1.38±0.01
Ammonium chloride	Upland rice	3.11±0.10	3.05±0.02	3.02±0.04
	Maize	3.06±0.06	3.09±0.03	2.90±0.04
	Soybean	2.80±0.06	2.90±0.02	2.89±0.02

2) Differences in protease activity in rhizosphere among crops

Protease activity in the soil planted with crops was measured to determine how much the so-called "rhizosphere effect" contributed (xcm) containing Andosol in 1995. We sampled the soils in the rhizosphere and non-rhizosphere zones separately at 26 and 34 days after sowing, and measured the protease activity of these soils using both casein and Z-phe-leu as substrates⁵).

[Table 2](#) shows the protease activity in whole pot soil for each crop including rhizosphere and non-rhizosphere soils. The activity in the case of maize was higher than that of upland rice, while in the case of soybean an intermediate activity between these 2 crops was detected for both substrates. These results suggest that the rhizosphere effect involved in nitrogen mineralization is not related to the high nitrogen uptake by upland rice¹⁴).

Table2. Protease activity in pot soil planted with various crops in rbs plot at original pH

<u>Crops</u>	<u>Protease activity ($\mu\text{mol h}^{-1} \text{g}^{-1}$ dry soil)</u>			
	<u>Caseine method</u>		<u>Z-phe-leu method</u>	
	<u>26 days</u>	<u>34 days</u>	<u>26 days</u>	<u>34 days</u>
Upland rice	1.62	1.64	1.57	1.78
Maize	2.67	2.11	1.56	1.96
Soybean	1.52	1.78	1.71	1.90
Fallow	2.19	1.31	1.48	1.67

3) Amino acid application in solution culture

Rice and maize seedlings were initially grown for 30 days in perlite pots without any addition of nutrients. After sterilization in an ampicillin solution, the seedlings were supplied with a nutrient solution consisting of 1 M nitrogen solution of nitrate, ammonium,

aspartate, glutamate and arginine, individually. These amino acids are considered to be the major components of rice bran protein⁸).

Nitrogen uptake efficiency of ammonium, aspartate and arginine in upland rice was much higher than in maize with the exception of glutamate (Fig. 5). These results suggest that upland rice could directly take up amino acid nitrogen more effectively than maize.

[Fig.5:Nitrogen uptake efficiency in the form of ammonium and amino acids in upland rice and maize expressed as ratio to nitrate uptake \(=100\) in solution culture\(27KB\)](#)

4) Contents of various forms of nitrogen in pot soil

Upland rice and maize were grown in an Andosol. The contents of protein in the rhizosphere soils of upland rice at all sampling dates after sowing were the lowest among other crops (Fig. 6). The fractionated protein contents of all the rhizosphere soils at 62 DAS were lower than those of fallow soil (Fig. 7). The protein content in fallow soil without RBS was lower than that in fallow soil with RBS, but still higher than that in the rhizosphere soil of crops. These facts indicate that upland rice took up protein over a wide range of molecular weights from the soil, exceeding the amount of protein derived from RBS. As the protease activity in the rhizosphere soil of upland rice was lower than that of maize, the lower concentration of protein in the rhizosphere soil of upland rice did not result from the hydrolysis of protein by the rhizosphere protease¹³).

[Fig.6:Protein content in rhizosphere soil of upland rice and maize in a pot trail with rbs](#)

[Fig.7:Content of protein fractionated into molecular fractions followed by extraction with phosphate buffer in rhizosphere and fallow soil amended and not amended with rbs at 62 days after sowing\(36KB\)](#)

Differences in nitrogen uptake between upland rice and maize

Fig. 8 shows the nitrogen dynamics in the rhizosphere soil and differences in nitrogen uptake between upland rice and maize. In this scheme, protein originating from organic matter was decomposed into amino acids via peptides, changed to ammonium and transformed into nitrate. There was a strong competition with microorganisms for nitrogen.

[Fig.8:Scheme of nitrogen mineralization-immobilization cycle in soil and utilization of various nitrogen forms by crops and microorganisms\(22KB\)](#)

In the previous section, we proposed 2 hypotheses for the high nitrogen uptake by upland rice. Hypothesis (1) was ruled out, because the rate of organic nitrogen degradation to amino acids was not essential for the high nitrogen uptake by upland rice. Hypothesis (2) was supported based on ¹⁵N-labelled RBS application, amino acid supply test and the analysis of the cultivated soils. We concluded that upland rice preferentially takes up ammonium, amino acids and protein, whereas maize takes up nitrate mainly.

Mechanism of organic nitrogen uptake in crops

Plants take up amino acids to incorporate them with less energy compared to nitrate because amino acids can be directly incorporated into metabolic processes. In fact, sedge grass in tundra soils preferentially took up amino acid nitrogen to inorganic one compared with barley²). Also birch growing in moist land took up amino acids rather than nitrate¹). We estimated that similar phenomena may occur in the rhizosphere of upland rice under upland field conditions when organic materials such as RBS were applied.

There are several reports on the absorption of protein by plants. For example, upland rice and barley also absorbed proteins such as albumin and hemoglobin and grew well in solution culture, while naked barley grew better in RNA solution than in nucleotides derived from the decomposition of RNA⁶). A mechanism of "heterophagy" for direct protein uptake has been reported in upland rice⁷). Hemoglobin molecules were taken up by the cell membrane in upland rice through PL-invagination, then moved to vacuoles to be digested for nitrogen nutrition. This mechanism suggests that direct protein uptake by upland rice under upland field conditions may occur. This mechanism can be attributed to the strong response of upland rice to organic nitrogen, since nitrogen in the protein form would be taken up with less competition for soil nitrogen.

Abstract

Results obtained in a special project on insect-borne virus/virus-like diseases of tropical fruit trees implemented during the period 1991-1995 are presented. Incidence of papaya ring spot virus (PRSV), papaya leaf-distortion mosaic virus (PLDMV), banana bunchy top virus (BBTV), cucumber mosaic virus (CMV), citrus greening and citrus tristeza virus (CTV) was examined by ELISA tests for virus diseases of papaya, banana and citrus, and by DNA probes for citrus greening. The FFTC survey teams visited countries in the Asia and Pacific region including Fiji, Guam, Indonesia, Japan (Okinawa), Korea (Cheju), mainland China, Peninsular Malaysia (West Malaysia), Sabah and Sarawak (East Malaysia), New Caledonia, Palau, the Philippines, Pohnpei, Saipan, Taiwan, Thailand, Tonga, Vietnam and West Samoa. The distribution of PRSV and PLDMV diseases is expanding. A large area covering East Malaysia, Mindanao, Fiji, Indonesia, New Caledonia, Palau, Pohnpei, Tonga, Western Samoa was found to be free from these diseases. In Okinawa, Taiwan and Saipan which are located in the northern marginal area of distribution of PRSV, the incidence of PLDMV was also observed. BBTV used to occur together with CMV. BBTV had a wider distribution than had been previously assumed, because banana plants did not show lesions when infected with the symptomless mild strain of BBTV. Except for some Pacific islands including those in Micronesia and New Caledonia, all the countries visited were found to be infected with both BBTV and CMV. Citrus was affected by the greening disease and CTV except for some islands in Micronesia. The distribution of a new greening strain which infects pomelo is now expanding. In addition to Taiwan and Mainland China, Okinawa, Mindanao, Palau and Thailand, citrus trees including pomelo are likely to be destroyed unless appropriate control measures are taken. Integrated management system of insect-borne diseases of fruit trees was analyzed in terms of the development of a production system for virus-free seedlings, protection of seedlings from attacks of viruliferous vectors and the elimination of virus sources.

Discipline: Plant disease/Insect pest

Additional key words: insect-borne diseases, IPM, fruit tree, aphids, citrus psyllids

Introduction

The Food and Fertilizer Technology Center for the Asian and Pacific Region (FFTC/ASPAC) conducted a Special Project on insect-borne virus (-like) diseases in the tropics and subtropics. This project was funded by the Japanese Government, but some activities conducted in Taiwan were supported by the Council of Agriculture (COA), Taiwan.

Emphasis was placed on fruit trees, because there is no international research institute dealing with tropical fruits except for banana, and because the control of insect-borne diseases requires inter-disciplinary cooperation between e.g. entomologists and virologists. Furthermore, perennial crops such as fruit trees are likely to be exposed for a relatively long period of time to infection with viruses, making the control of the diseases extremely difficult.

The FFTC organized survey teams, composed of entomologists and virologists, on insect-borne diseases of citrus, papaya and banana to be conducted in countries of the Asia and Pacific region. Since 1988, when the first survey was conducted in the Philippines and Thailand, survey teams have visited many countries in the Asia and Pacific region, including Fiji, Malaysia (East and West), New Caledonia, Palau, the Philippines, Pohnpei, Saipan, Taiwan, Thailand, Tonga, Vietnam and Western Samoa.

The incidence of fruit tree diseases in the Asia and Pacific region is reported in this paper, i.e. diseases caused by banana bunchy top virus (BBTV), papaya ring spot virus (PRSV), papaya leaf distortion mosaic virus (PLDMV), citrus tristeza virus (CTV) and greening (GO), and strategy for the application of IPM for the control of these diseases is also outlined.

Papaya ring spot virus (PRSV) and papaya leaf-distortion mosaic virus (PLDMV) diseases

1) Expansion of papaya virus diseases

PRSV disease was first detected in Kaoshung, Taiwan in 1975, and in Luzon, the Philippines in 1982. In Taiwan, 44% of a total of 2,100 ha of papaya orchards were not able to produce fruits in 1978 due to PRSV disease, which spread all over the island in 1980¹⁵⁾.

The FFTC survey team confirmed the incidence of PRSV disease in Johore, Malaysia based on serological diagnosis in 1991. We also confirmed the occurrence of PRSV disease in Southern China (1990), Central Thailand (1990), Vietnam (1992), Luzon, the Philippines (1993), Saipan, Commonwealth of the Northern Marianas (1994) and Guam (1994). No infection had been detected in Northern Thailand, Mindanao and Cebu (Philippines), Sabah and Sarawak (East Malaysia), Java (Indonesia), New Caledonia, Fiji, West Samoa, Tonga, Palau and Pohnpei (Table 1).

[Table 1. Distribution of virus \(like\) diseases of fruit trees in the Asia and Pacific region\(42KB\)](#)

Papaya trees infected with PLDMV display symptoms characterized by rosettes on leaves with slender stems on the crown top, and swellings around the ring spots on the fruit. Neither of these symptoms are observed in plants infected with PRSV. PLDMV disease was first identified in Okinawa island in 1954¹⁰⁾. During the 1960s it spread to the adjacent Miyako and Yaeyama islands, but it has not yet been detected on nearby Minami-Daito or Kita-Daito island¹⁰⁾. In 1993, collaborative studies between scientists in Taiwan and Japan confirmed that these 2 virus diseases occurred in both Okinawa and Taiwan, i.e. PLDMV also occurs in Taiwan, and PRSV in Okinawa¹⁶⁾. However, the symptoms of PLDMV had not been observed in Taiwan until the mid-1980s.

2) Control of papaya virus diseases

More than 60 species of aphids are considered to be able to transmit PRSV. Both PRSV and PLDMV are mainly transmitted by *Aphis gossypii* and *Myzus persicae* in a non-persistent manner. They are the "transit visitors or itinerant vectors" of papaya plants and do not colonize papaya ([Table 2](#)). These virus diseases are currently spreading throughout the Asian tropics and Pacific islands.

Table 2. Characteristics of papaya ring spot virus (prsv), banana bunchy top virus (bbtv), and citrus greening diseases

	PRSV	BBTV	Greening
Host plant	Papaya	Banana	Citrus
Country of origin	South America	S. E. Asia	Asia
Resistance gene/cultivar	No	No	No
Cropping system	Annual/Perennial	Annual/Perennial	Perennial
Disease-free planting material	Seeding	Tissue culture of meristem	Shoot-tip grafting
Pathogen	Virus	Virus	Fastidious bacteria
Culture of inoculum	Possible	Possible	Impossible
Indexing techniques	ELISA	ELISA	DNA probe
Transmission type	Semi-persistent	Semi-persistent	Persistent
Cross-protection	Not dependable	Not dependable	Not available
Chemical therapy	No	No	Antibiotics
Vector	Polyphagous aphids No, transit visitors	Banana aphid	Citrus psyllid
Colonization of host plants	as winged forms Difficult in open fields	Yes, attended by ants	Yes
Biological control		Failed (interference by ants)	Not successful (hyperparasitism)
Chemical control	Difficult to control disease vectors with a low control threshold		

A great variety of control methods has been used in order to protect young seedlings from the aphid vectors. These include the selection of planting time to avoid the peak incidence of winged aphids, intercropping with barrier crops such as corn, the use of silver mulch to prevent winged aphids from visiting young seedlings, and covering the plants with netting.

A basic part of any control program is to promote the eradication of infected plants in order to eliminate the source of virus. The cultivation of cucurbits, which are important hosts for PRSV and PLDMV should be avoided in the vicinity of papaya plantations. Once PRSV and PLDMV diseases occurred in a papaya orchard, they spread very rapidly within the orchard by winged aphids, usually in February and March in Taiwan¹⁴⁾, and December to April in Okinawa¹⁰⁾. Roguing infected plants away from the orchard is effective to reduce the rate of infection.

Since there is no PRSV resistance gene, the breeding of tolerant cultivars such as Taichung No. 5 has been attempted. These varieties, however, have not been widely accepted by consumers because of their poor eating quality.

Difficulty encountered in controlling non-persistent aphid-borne virus like PRSV is due to the fact that many of the available pesticides do not kill incoming vectors before they transmit the virus to the crop.

Cross-protection with attenuated virus strains was widely practiced in Taiwan. Since this protection is strain-specific, it often breaks down within half a year and loses its effectiveness. The high level of mutability of PRSV might be another reason for the loss of cross-protection¹⁴.

3) Losses

Concerning the losses due to PRSV, the occurrence of the disease was compared between papaya orchards in Fengshan, Taiwan for which netting was used and those left uncovered. Netting was so effective in preventing PRSV transmission that the production was 10 times higher compared with that of the uncovered trees¹⁵. In Taiwan, papaya is planted each year as if it were an annual crop. Therefore, protecting young papaya plants from vector aphids by netting is effective in producing marketable fruits, because late infection, which occurs when the net is removed after fruiting, causes little damage to the yield. The economic gains, however, have to be evaluated taking into account the cost of building the structure, labor-consuming operation for pollination and the risk of damage caused by typhoons. Another added cost is the annual planting of papaya, which used to be a perennial crop grown for 3-4 years before 1975, when the incidence of PRSV was first observed in Taiwan.

The areas where papaya is free from these virus disease should be protected by restricting the importation of infected plants. These viruses, however, are not vertically transmitted through seeds. Since the seeds of papaya are free from virus, they can be used in plant nurseries without risk of infection.

Banana bunchy top virus (BBTV) disease

1) *Ubiquitous potential infection with mild strains*

BBTV is transmitted semi-persistently by a single vector, the banana aphid, *Pentalonia nigronervosa* ([Table 2](#)). Sometimes the damage caused by BBTV disease is overlooked due to the apparent losses due to Fusarium wilt and Sigatoka disease, and banana plants are considered to be free from BBTV.

However, the FFTC surveys demonstrated that BBTV has a wider distribution than had previously been assumed. BBTV is widespread in tropical and subtropical Asia ([Table 1](#)). It was first reported in Fiji in 1889 and Taiwan in 1900¹⁹). It was also reported in Okinawa, Japan by Nohara in 1968 and was serologically confirmed by the FFTC survey team in 1992¹¹). In almost all of the countries except for the islands located in Micronesia, banana plants were found to be infected with BBTV. The existence of BBTV was newly confirmed by ELISA tests in Indonesia (1989), Thailand (1991), West Malaysia (1991), South China (1992), Okinawa (1992), Vietnam (1992), East Malaysia (1993), Mindanao, the Philippines (1993), Fiji (1994), Tonga (1994) and Western Samoa (1994). On the other hand, we have not found BBTV in Micronesian islands including Saipan/Northern Marianas, Guam, Belau/Palau, and Pohnpei.

Why has BBTV remained undetected for so long in so many countries? There are 2 main reasons for this. First, no serological tests had ever been attempted, because of the lack of suitable techniques and equipment for indexing. Secondly, BBTV occurring in Malaysia and Thailand produces either mild symptoms or no symptoms in banana plants. An overall abnormality such as dwarf growth habit caused by infection with the virus has often been mistaken for a normal characteristic of the cultivar or for a nutritional disorder due to deficiency of nutrients.

Although a certain level of cross-protection with naturally occurring mild strains takes place inadvertently, this latent infection with BBTV is probably causing significant losses in terms of both banana yield and general fruit quality.

A field survey using ELISA tests for banana plants which was conducted in several locations in southern Taiwan revealed that mixed infection with BBTV and cucumber mosaic virus (CMV) was observed at a rate as high as 70% in symptomless plants²³). Asynchronized maturation of fingers in a bunch of bananas grown for export seems to be caused by a mixed latent infection of the viruses. Almost the same situation was also observed in the South Pacific islands including Fiji, Western Samoa and Tonga, in that only one-fifth of the banana samples was free from both virus diseases. Imada et al.⁸), based on ELISA tests, showed that both BBTV and CMV are widely distributed in Thailand and samples with double infection accounted for more than 10% of the total.

2) *Control of BBTV*

To control BBTV disease, a system of virus-free seedling production is highly recommended ([Table 2](#)). The occurrence of BBTV was the lowest in plants produced by tissue culture at 0.2% followed in increasing order by plants grown from suckers and ratoons (Su et al. unpublished).

No plant resistance to BBTV has been identified, which limits conventional breeding approaches to this problem⁹). In fact, propagation of virus-free seedlings by tissue culture is commonly attempted in almost

all the banana-growing countries. In some cases, however, all of the seedlings assumed to be virus-free were found by ELISA tests to be infected with BBTV. Supplying virus-free plantlets grown by tissue culture to growers for planting is the best measure currently available for control.

Various methods of protection of seedlings from infection in the field should then be applied, including cross-protection, though this technique has not been effective against BBTV. In order to promote the control of the banana aphid by naturally occurring biological control agents, farmers should be instructed to use in their banana plantations selective insecticides, which are less toxic to natural enemies of banana aphids.

Biological control of *P. nigronervosa* is being attempted in Tonga introducing a braconid, *Aphidius colemani*, native to Australia. Through the reduction of the total population of aphids, a reduction in the number of alate aphids moving between plants may occur, resulting in a decrease of the rate of spread of the BBTV^{21,22}). Although the presence of *A. colemani* on Tongatapu island was confirmed when it was recovered from *Aphis gossypii* on taro, no evidence of parasitism has been obtained from *P. nigronervosa*. The intensive attendance of *P. nigronervosa* colonies by ants may have significantly reduced the opportunity for this parasitoid to attack *P. nigronervosa* in Tonga²²).

Citrus greening disease and citrus tristeza virus (CTV) disease

1) Citrus groves are being devastated by the greening disease in the tropics

Citrus is most widely grown next to grape in the world. Citrus originated in southern China, India and Indochina peninsula. However, countries in Southeastern Asia are not included in the major citrus production countries, due to the epidemics of the greening disease in this area. Indonesia has experienced complete destruction of its citrus industry due to greening in northern Bali. The citrus-growing area of 12,000 ha in the early 1950s decreased to 4,000 ha in 1988 due to the disease in Thailand. In the Philippines, the area planted to mandarins and sweet oranges covered 25,000 ha in 1961-1962. By 1965 the area had been reduced to 17,300 ha and by 1974 to only 8,300 ha mainly due the greening disease^{1,18}).

Except for some islands located in Micronesia and New Caledonia, all of the countries and areas were found to be affected by this disease. The incidence of CTV was also commonly observed in all of the countries except for the islands in Micronesia, i.e. Saipan, Pohnpei and Palau. Development of the citrus industry in tropical and subtropical Asia, therefore, largely depends on the extent to which the control of greening disease is successful.

The causal agent of the greening disease is a fastidious bacterium, which is transmitted persistently by the Asian citrus psyllid, *Diaphorina citri*, while CTV is vectored non-persistently by aphids, mainly *Toxoptera citricidus* and *Aphis gossypii*¹³).

2) Development of strains attacking pomelo

An important finding from the surveys was that pomelo, which was considered to be resistant to both greening and CTV diseases, has become susceptible recently in some areas. Greening was first noticed in the beginning of the 1950s in Taiwan by A. Sasaki^{5,20}), but the incidence of this disease in Mainland China can be traced back to 1919 in northeastern Guangdong¹²). Although pomelo began to be affected by greening disease in the beginning of the 1970s in Taiwan, in other countries it was yet free from this disease until the 1990s. Currently, greening disease is affecting pomelo in southern China and the

Philippines, while pomelo grown in Vietnam and Thailand still seems to be free from this disease. It has been reported, however, that the infection of pomelo with symptoms of greening in Thailand was observed in a pomelo orchard in Chiang-Rai in 1994 (Bauman, personal communication, Koizumi, personal communication).

Surveys conducted in 1994 in some islands in the North Pacific revealed that greening did not occur in Saipan/North Marianas and Pohnpei, but that a pomelo-infective strain of greening was found in Palau/Belau which is located close to Mindanao, the Philippines. The islands in the South Pacific were considered to be free from greening, because of the absence of the vector insects. The survey teams, however, observed citrus trees with greening disease in Fiji, Western Samoa and Tonga. Since fruit trees normally reproduce vegetatively by grafting and layering, it is likely that all the scions and nursery stocks derived from an infected mother plant, which was introduced outside of the island, are congenitally infected with the greening pathogen.

In Japan, greening was first discovered by electron microscopy in Iriomote island, Yaeyama islands, Okinawa Prefecture by Dr. Miyagawa in 1989 when he was working for the FFTC Special Project. Since the incidence was limited to this particular island, an eradication program was successfully carried out. The FFTC organized a second survey to follow-up the status of greening in Okinawa in 1993. The survey team again found citrus trees affected by greening in this island. The causal agent was confirmed by DNA probes for greening prepared by Su and his colleagues at the National Taiwan University. In 1994, it was also detected in Okinawa island, suggesting that the distribution had expanded. Greening was found to be due to the strain which affects pomelo. Further inspection and eradication of the greening pathogen are recommended in order to prevent the spread of this disease to the other southern islands of Japan where the vector psyllids are common insects.

3) *Control of greening disease and CTV*

Greening is responsible for economic losses of entire citrus orchards within 5 or 6 years following an initial spread of epidemics²⁾. Eradication is an essential measure. Trees already affected by greening disease should be cut down and destroyed to ensure that they do not act as sources of inoculum.

So far, no plant resistance has been identified. Treatment with tetracycline reduces the population of bacteria, but symptoms usually reappear after 1 to 2 years. Heavy pruning and top-working of diseased trees and cutting off of infected branches for corrective control are often only useful for the elimination of potential inoculum of the greening.

Providing farmers with disease-free planting stock at a reasonable price is at the basis of any program to control virus disease in perennial crops. In Taiwan, since 1985, citrus planting stock, which is free from virus and greening, has been produced either by shoot-tip grafting with heat therapy or by nucellar line selection. There is also a budwood certification program, which ensures that the young seedlings distributed to farmers are free from diseases.

The feeding site of *D. citri* is confined to the flush or fresh shoots triggered mainly by rainfall in wet areas and irrigation in dry areas. Chemical control is applied at 10- to 20-day intervals in order to control psyllids which act as vectors during the sprouting period. Pesticides are commonly applied 36-48 times a year by Indonesian farmers¹⁷⁾. Spray or trunk injection of systemic insecticides, such as dimethoate and monocrotophos, has been suggested without any adverse effect on the fauna of natural enemies in the

citrus grove¹⁸). The use of IGRs (insect growth regulators) could be suggested for this purpose.

An ornamental plant often used as a hedge in Taiwan, jasmine orange, *Murraya paniculata*, does not harbor the pathogen of greening but is a favorite host plant of the psyllids. For this reason, jasmine orange should not be planted near citrus orchards. Biological control of the psyllids is carried out in Taiwan using an eulophid parasitoid, *Tamarixia radiata*, which was introduced from Reunion Island during the period 1984-1988. This parasitoid in association with an indigenous parasitoid, *Diaphorencyrtus diaphorinae*, is considered to contribute to the suppression of *D. citri*, particularly in jasmine orange³).

When citrus orchards are to be established, the site of new orchards should be far enough from the old orchards to avoid or retard the infestation with psyllids. Shifting of planting areas from warm lowlands to cool highlands is also practiced to avoid the attack of psyllids in Taiwan. The CTV is spread by aphid vectors mainly by *Toxoptera citricidus* and to a lesser extent by *T. aurantii* and *Aphis gossypii* in a semi-persistent manner¹³) and by propagation with infected buds. The control strategy of CTV disease is similar to that of other insect-borne virus diseases. The use of attenuated CTV for cross-protection has been applied for navel orange, *Citrus sinensis*, in Japan⁶). The CTV is not readily transmitted between trees even in the presence of a fairly large number of vector aphids in a grove^{4,7}). In fact, greening spreads more rapidly than CTV in newly planted orchards in Taiwan.

[Continue to:\[Conclusion\]](#)

[Contents](#)

Conclusion

Systems for the integrated control of virus diseases of fruit trees have 3 basic objectives: (1) the development of a production system for virus-free seedlings, (2) the protection of seedlings from the attack of viruliferous vectors, and (3) the elimination of virus sources. Various techniques are currently available for achieving these objectives and are applied in a number of countries in this region, partly as a result of the work of the FFTC survey team ([Tables 2 and 3](#)).

Table 3. Difference in IPM strategy in relation to the occurrence of insect-borne diseases

	Area with diseases	Area without diseases
Quarantine	Less important	Important to restrict the importation of infected plants Not necessary
Disease-free planting material	Should be developed by mass production system Annual planting or with the shortest vegetative growth	Perennial
Cropping system	Young plants must be protected from vectors ^{a)}	Control only when vectors may cause direct damage
Protection measures from infection	Good yield with healthy fruits for the first cycle of fruiting	Sustainable yield with high/standard quality of fruits for a number of years
Objective		

a): Because the earlier the infection with diseases, the heavier the damage.

A very important problem identified by the members of the survey is the widespread incidence of fruit trees which showed multiple infections with different viruses or diseases. Many banana plants were infected with BBTV and CTV, while papaya was often simultaneously infected with PRSV and papaya mosaic virus (PMV), or with PRSV and PLDMV, and citrus with greening disease and CTV.

Simultaneous multiple infections of this kind often give rise to more severe symptoms than single infection. Presently, control is limited to the use of the integrated system mentioned above to prevent plants from being simultaneously affected by multiple virus diseases.

It was considered that the lack of techniques and expertise for precise indexing of the diseases for plant quarantine and production of disease-free planting materials were one of the major constraints on the implementation of IPM strategy for the insect-borne virus and virus-like diseases of fruit trees.

An IPM strategy has been suggested for the control of insect-borne diseases of tropical fruit trees as follows: (1) Distribution of disease-free planting material to growers. (2) Control of vectors; Planting time, use of barrier crops, silver mulch, netting, insecticides and biological control. (3) Shift of cropping system from perennial to annual crops. (4) Eradication of virus sources. Roguing and avoidance of cultivation of potential host plants close to orchards, e.g. cucurbits for PRSV and jasmine orange for greening. (5) Cross-protection techniques are not dependable or not available. The use of tolerant cultivars or antibiotics may often result in an increase of inoculum sources.

In conclusion, the difference in the IPM strategy between areas with and without disease is shown in [Table 3](#). It should also be emphasized that some islands in the Pacific are now free from these devastating diseases, suggesting the importance of quarantine in preventing these diseases from invading the disease-free areas.

Raising and Transplanting Technology for Long Mat with Hydroponically Grown Rice Seedlings

Kohei TASAKA*

Department of Farm Mechanization, National Agriculture Research Center (Tsukuba, Ibaraki, 305-8666 Japan)

Present address:

*Department of Integrated Research for Agriculture, Kyushu National Agricultural Experiment Station (Chikugo, Fukuoka, 833-0041 Japan)

Abstract

Long mat with hydroponically grown rice seedlings (hereafter referred to as LMHS) with a mat size of 6 m in length and 28 cm in width, was designed to develop a labor-saving rice transplanting system. The rice seedlings were grown in a newly developed nursery device for about 2 weeks and the plant length reached 10 to 15 cm. The seedling mat was composed of entangled plant roots and nonwoven cloth and it was strong enough to be handled. LMHS were transformed into roll type seedlings by rolling up. The weight of a mat with roll type seedlings was about 12 kg and approximately 1/5 of that of a conventional mat with young seedlings raised in a soil bed (hereafter referred to as CMSS). A rice transplanter was designed and tested to transplant the roll type seedlings in paddy fields. The rate of damaged seedlings immediately after transplanting was 30 to 50%. However, the minimum rate of missing hills after rooting was 3%, when the number of plants per hill ranged from 7 to 8. Working rate of the transplanter was approximately 0.5 ha/h for a working speed of 1.13 m/s and a working width of 1.8 m. Rice yield in the case of LMHS was assumed to be equal to that of CMSS.

Discipline: Agricultural machinery

Additional key words: nonwoven cloth

Received for publication, January 11, 1998

Introduction

In Japan, the percentage of transplanting in rice production exceeds 99%. Most popular seedlings used for rice transplanting are referred to as mat type seedlings and they are grown on soil in a seedling box (58 cm long, 28 cm wide and 3 cm deep). The carriage of the seedling boxes is laborious and is associated with major problems for the following reasons: (1) the weight of one seedling box is approximately 6 kg, (2) 2,000 seedling boxes are necessary for paddy fields with an area of 10 ha, and (3) during the period from seeding to transplanting, the seedling boxes must be carried from the seeder to the nursery chamber, greenhouse, truck and rice transplanter.

The objective of this study was to reduce the weight and the carriage frequency of the seedling boxes. Specific objectives were: (1) to raise rice seedlings with long mat (6 m long) by hydroponics in a nursery device, (2) to roll up the seedlings to a small size, and (3) to develop a rice transplanter to transplant the seedlings in paddy fields.

Materials and methods

1) *Outline of nursery device*

The nursery device developed to raise LMHS is illustrated in [Fig. 1](#). The nursery device which consists of a nursery bed, a liquid fertilizer tank and a liquid fertilizer pump was fixed on the ground in a vinyl house. The nursery bed fixed horizontally on the ground comprised 4 nursery trays. A nursery tray (6.5 m long, 28 cm wide and 6 cm deep) made of stainless steel was developed. The height of the nursery tray from the ground surface was set at 60 cm to work without bending the waist. Liquid fertilizer circulates in the tank and on the tray of the nursery device through a pump.

[Fig.1:Hydroponic nursery device\(25KB\)](#)

2) *Seeding method*

A nonwoven cloth was spread on the dry nursery tray and fixed at both ends on the tray with 2 plates like a comb. Liquid fertilizer was circulated in the nursery device and then germinated rice seeds were scattered on the tray with a self-propelled seeder as shown in [Fig. 2](#). Mass of the seeds ranged from 100 to 250 g per unit area corresponding to the size of a conventional seedling box (28x58 cm). The nonwoven cloth was made of cotton and it was used to obtain a seedling mat sufficiently strong to be rolled up and transplanted.

[Fig. 2. Nursery device and self-propelled seeder\(30KB\)](#)

3) *Supply of fertilizer and air temperature in the vinyl house*

Water without fertilizer was circulated in the nursery device for several days after seeding. Fertilizer commercially available for hydroponically grown vegetables, Otsuka No. 1 and No. 2, was dissolved in the water in the liquid fertilizer tank on the 5th day after seeding. Electric conductivity (EC) of the liquid fertilizer was adjusted to reach values ranging from 1.3 to 1.4 mS/cm every day.

Water temperature in the nursery device was adjusted to be compatible with the raising of the seedlings by controlling the air temperature in the vinyl house with heaters or ventilators.

4) *Rolling up of seedlings*

Tests of rolling up of LMHS on the 6 m long mat were conducted for transfer to the paddy fields and loading on a rice transplanter.

5) *Development of a rice transplanter for LMHS*

A riding type rice transplanter currently manufactured was remodeled to transplant the roll type seedlings in paddy fields. The basic performance of the rice transplanter was as follows: working width of 1.8 m (6-row planter with 30 cm row spacing) and maximum working speed of 1.4 m/s.

6) *Experimental methods*

Experiments for raising the seedlings were conducted to investigate the relationship between plant length, root length and number of roots of the seedlings and temperature. Varieties of rice used were Koshihikari, Kinuhikari, Akitakomachi and Himenomochi. In this test, air temperature, water temperature, EC and pH of liquid fertilizer were measured in addition to the examination of the plant conditions.

Field experiments were conducted to determine the working accuracy and working rate of the

transplanter in paddy fields. In the experiments, more attention was directed to determine the rate of damaged seedlings and missing hills after transplanting and rooting. Field tests were also performed to evaluate the rice yield in the case of the LMHS from 1996 to 1997 in 3 prefectures, i.e. Ibaraki, Saitama and Iwate.

[Contents](#)

Fig.1.
Hydroponic nursery device

 [BACK](#)

fig.2 Nursery device and self-propelled seeder

[BACK](#)

Results and discussion

1) Raising of seedlings

Rice seeds and seedlings on the nursery tray immediately after seeding and 2 weeks after seeding are illustrated in [Fig. 3](#). Roots of the seedlings became entangled after penetrating into the nonwoven cloth on the nursery tray. The mat composed of the entangled plant roots and the nonwoven cloth was strong enough to be handled. Appearance of the seedlings on the tray on the 10th day after seeding is illustrated in [Fig. 4](#).

[Fig.3:Cross-section of seeds and seeding on the nursery tray\(51KB\)](#)

[Fig.4:Appearance of the seedlings on the tray at 10 days after seeding\(25KB\)](#)

2) Relationship between plant length, root length and number of roots of the seedlings and temperature

The relationship between accumulated lowest water temperature and the plant length is depicted in [Fig. 5](#) and then the relationships between accumulated lowest water temperature and the maximum root length or number of roots are depicted in [Fig. 6](#). These data were obtained when the highest water temperatures ranged from 30 to 34°C. The plant length as well as the maximum root length reached values of 10 to 12 cm at the accumulated lowest water temperature of 20°C. The number of roots increased from 5 to 7 at the accumulated lowest water temperature of 16°C.

[Fig.5:Relation between accumulated lowest water temperature and plant length\(47KB\)](#)

[Fig.6:Relation between accumulated lowest water temperature and maximum root length or number of roots\(47KB\)](#)

3) Roll type seedlings

Method of rolling up the LMHS on the 6 m long mat was eventually developed. Method of rolling up the seedlings was as follows: (1) pushing down the seedlings with a cylinder of approximately 15 kg, (2) putting a steel plate of 60 cm long, and 27.5 cm wide and a mass of 3 kg on the seedlings, (3) rolling up the seedlings on the circumference of a pipe with a diameter of 15 cm and (4) wrapping the seedlings in a cloth. These operations are illustrated in [Fig. 7](#) and the mats with roll type seedlings are shown in [Fig. 8](#). Diameter and weight of the mats with roll type seedlings ranged from 40 to 45 cm and 12 kg per 6 m, respectively. Comparison between the seedlings subjected to the new and conventional methods for the same length of the mat showed that the mass of the roll type seedlings was approximately 1/5 of that of the CMSS.

[Fig.7:Method of rolling up of the lmhs\(38KB\)](#)

[Fig.8: Roll type seedlings\(33KB\)](#)

The number of seedling boxes for the CMSS shown in [Fig. 9](#) was approximately 60 and the 6 mats with roll type seedlings shown in [Fig. 8](#) corresponded to the seedling boxes shown in [Fig. 9](#). Based on the data described above, the use of the mats with roll type seedlings enabled to reduce the weight and carriage frequency of seedling boxes.

[Fig. 9. Conventional mat type seedlings\(34KB\)](#)

4) Development of a rice transplanter for LMHS

A 6-row riding type rice transplanter currently manufactured was remodeled to transplant the roll type seedlings in paddy fields as shown in [Fig. 10](#). Some equipment was developed to attach the roll type seedlings to 6 seedling platforms of the transplanter. Ability of feeding belts of seedlings increased for reliable and steady feeding by the use of a driving roller in addition to the top and bottom rollers. Two seedling racks were fixed to carry 8 extra mats with roll type seedlings on both sides of the operator's seat. The capacity of the hopper of fertilizer was twice as high and enabled to reduce the frequency of supply of fertilizer to the transplanter.

[Fig.10:Rice transplanted for roll type seedlings\(27KB\)](#)

5) Working accuracy of the rice transplanter

In the field experiments conducted in 1996 to 1997, the working accuracy of the rice transplanter resulted in a 30 to 50% rate of damaged seedlings immediately after transplanting and the minimum rate of missing hills after rooting was 3% when the number of plants per hill was 7 to 8. Working speed did not affect significantly the working accuracy.

The rate of damaged seedlings was not related to the working speed of the transplanter but was related to the strength of the seedling mat depending on the mass of seeds per unit area, days of raising of seedlings and variety of rice. In particular, the strength of the seedling mat depended on the mass of seeds per unit area: the larger the latter, the stronger the former. As a result, the rate of damaged seedlings increased. However, a seed mass less than 150 g per unit area (28x58 cm) led to a reduction of the volume of the seedling mat, resulting in the increase of the rate of missing hills. Therefore, optimum mass of seeds was considered to be 180 to 200 g per unit area.

6) Working rate of the rice transplanter

Working rate of the transplanter with one operator was approximately 0.5 ha/h for a working speed of 1.13 m/s. It took 12 min to supply 6 mats with roll type seedlings to the transplanter.

Although one operator and one helper are required, working rate of a transplanter with the same size under the same conditions when a conventional seedling box was used was nearly 0.3 ha/h. Supply of conventional seedlings to a transplanter requires a helper in addition to the operator and reduces the working rate. Therefore, the use of the transplanter for the roll type seedlings resulted in a considerable saving of labor.

7) Yield of LMHS

Rice yield in the case of the LMHS and the CMSS in 1996 to 1997 is shown in [Fig. 11](#). Rice yield in the 2 kinds of rice seedlings varied with the years and the locations but did not show a particular tendency. As a result, rice yield in the case of LMHS was assumed to be equal to that of CMSS, although more detailed comparison will be needed in future.

[Fig.11:Rice yield in the case of LMHS\(36KB\)](#)

Conclusion

Studies were conducted to develop a long mat with hydroponically grown rice seedlings(LMHS). The rice seedlings were grown in a newly developed nursery device for about 2 weeks, and the plant length reached 10 to 15 cm. The seedling mat composed of entangled plant roots and nonwoven cloth was 6 m long and 28 cm wide. The seedling mat was strong enough to be handled by using a nonwoven cloth.

Roll type seedlings were obtained by rolling up the LMHS. The weight of the mat with roll type seedlings was about 12 kg per 6 m and approximately 1/5 of that of a conventional mat with seedlings raised in a soil bed (CMSS).

A rice transplanter was remodeled to transplant the roll type seedlings in paddy fields. Working accuracy of the transplanter was as follows. Damaged seedling rate immediately after transplanting ranged from 30 to 50% and the minimum rate of missing hills after rooting was 3% when the number of plants per hill was 7 to 8. Working rate of the transplanter was approximately 0.5 ha/h for a working speed of 1.13 m/s and a working width of 1.8 m.

Rice yield in the case of the LMHS was assumed to be equal to that of CMSS, although more detailed comparison will be needed in future.

Abstract

A new steering control method for wheel systems of agricultural machinery to enhance the follow-up performance with a tractor was developed to improve the operability of semi-trailed agricultural machinery. The basic concept of this control method is the alignment of the turning radius of the tractor and machine for a constant turn, and a formula was derived for expressing this geometrical relationship. Based on this formula, a control method was developed which uses the steering angle of the wheel system of an agricultural machine as a variable for the steering angle of the tractor's front wheels and the angle of traction. Thereafter, this control method was applied to the in-line type prototype test trailer and a commercially available roll baler and running tests were conducted. The results showed a significant improvement in the follow-up performance of the trailer and roll baler attached to the tractor. However, since the need to measure the steering angle of the tractor's front wheels is difficult for practical application, the steering angle of the tractor's front wheels was estimated and the estimated values were used for the control for application to the commercially available roll baler. The results of this test showed that the same level of follow-up performance could be achieved as when the steering angle measured for the tractor's front wheels was used and that applications were possible. It was also confirmed that by the addition of a compensation coefficient for a slope to the estimated figures, a high follow-up performance could be achieved even on sloped grassland.

Introduction

Semi-trailed agricultural machinery is widely used for forage harvesting and transport. This system is selected because part of the agricultural machine mass can be supported by the wheel system of the machine. As a result, large mass machines can be easily handled and attachment to a tractor is relatively simple. However, the follow-up performance of this type of machine with the tractor is inadequate as

seen in the off-tracking when turning and improvements in operability and maneuverability are necessary.

In recent years, mechanisms for steering the wheel systems of agricultural machines in accordance with the angle of traction (refraction angle at the hitch point) have become commercially available to improve the operability of manure spreaders and sugar beet harvesters. The so-called link method enables to obtain uniform tracks of the tractor and the machine for a constant turn. However, for driving states in which the turning radius changes constantly, such as zigzag driving or a 90° turn (referred to as the non-constant turning state), no significant improvement is expected in the follow-up performance because the control is passive. Since ordinary agricultural machines often perform this type of non-constant turning, it is necessary to solve this problem in order to improve the operability of semi-trailed agricultural machinery.

Under these circumstances, examination of an active steering control method (referred to as active precision control method) for a single axle, 2-wheel agricultural machine using the actual steering angle of the tractor's front wheels in addition to the angle of traction was initiated to develop a method for high-precision follow-up by semi-trailed agricultural machinery of a tractor's driving track even in a non-constant driving state. In this report the method for deducing the basic equality to control the system and the results of driving tests for a test trailer, used as a model of agricultural machine are presented. A commercially available roll baler to which this control method was applied for a driving system with the agricultural machine attached in the straight rear of the tractor (referred to as the in-line format) is described.

Deducing the basic equality to control the system²⁾

1) Turn under constant radius circle

The conditions of the tractor and agricultural machine state when the machine is steered so that the constant turning radius is aligned are shown in [Fig. 1](#) as the 2-wheel model. The A and B points in Fig. 1 are arbitrary points on the central line of the tractor and machine and the system is designed to make the tracks of these 2 points uniform for a constant radius circle.

[Fig.1: Concept of development of steering method\(22KB\)](#)

The following equation is derived when a perpendicular line is drawn from the central point T of the machine wheels to OP and a triangular shape is formed by point T, point P and the perpendicular line.

$$\tan(\phi + \theta) = \frac{l_h + l_t \cos \phi}{R_r - l_t \sin \phi} \dots\dots\dots (1)$$

In this equation, ϕ is the angle of traction, θ is the steering angle of the machine wheels, l_h is the distance from the center of the tractor's rear wheels to the hitch point, l_t is the distance from the hitch point to the machine wheels and R_r is the turning radius.

When $\tan(\phi + \theta) = (\tan \phi + \tan \theta) / (1 - \tan \phi \tan \theta)$ is used to rearrange this equation, the following equation is derived.

$$R_r(\cos\phi \tan\theta + \sin\theta) = l_t + l_h(\cos\phi - \sin\phi \tan\theta) \dots\dots\dots (2)$$

Also, since points A and B are located on the perimeter of the same circle with the radius $(R_r^2 + l_a^2)^{1/2}$, when the distance from point A to the tractor's rear wheels is defined as l_a , the following equation is derived.

$$l_a^2 - l_b^2 - l_h^2 = 2 l_b (l_h \cos\phi - R_r \sin\phi) \dots\dots\dots (3)$$

When R_r is eliminated using equations (2) and (3), the equation showing the relationship which provides the alignment of the tracks of points A and B for a constant radius circle is derived.

Furthermore, when the equation is simplified using the approximations of $\sin\theta \approx \theta$ and $\cos\theta \approx 1$, the following is derived.

$$\theta = \frac{(l_a^2 - l_b^2 - l_h^2 + 2 l_b l_t) \phi}{(-l_a^2 + l_b^2 + l_h^2 + 2 l_b l_h)} \dots\dots\dots (5)$$

In this equation, l is the wheel base of the tractor and is defined as $l = -R_r \tan\delta$. Now, δ is the steering angle of the tractor's front wheels.

2) Non-constant turning state

The plane movement of the tractor and agricultural machine is considered assuming the absence of side slip of the wheels. In [Fig. 2](#), when the line which connects the hitch point and the T point, in the center of the machine wheels, is the base, since the traveling speed of the tractor and the machine in the direction of this line is aligned, the following is derived.

[Fig.2: Model used for the tractor and trailed machine\(18KB\)](#)

$$V_t \cos(\phi - \theta) = V \cos(\phi - \beta) - (l_r + l_h) r \sin\phi \dots\dots\dots (6)$$

Next, when the speed element which intersects the base line is considered and the drawing angle β representing the change of speed V is determined, the following is derived.

$$\dot{\phi} = \frac{V_t \sin(\phi - \theta) - (l_r + l_h) r \cos\phi - V \sin(\phi - \beta)}{l_t} - r \dots\dots\dots (7)$$

In this equation, V_t is the traveling speed of the agricultural machine, V is the tractor driving speed, r is the tractor yaw angular velocity, β is the side slip angle at the tractor's center of gravity position and l_r is

the distance from the tractor's rear wheels to the center of gravity.

l and r in the absence of side slip of wheels are represented by $\tan^2 \delta = lr \tan^2 \phi / l$ and $r = V \tan^2 \phi \cos^2 \delta / l$. Then the equation is rearranged by deriving V_t from equation (6) and substituting it in equation (7) and the following is derived.

$$\dot{\phi} = V \{ -l\phi - (\ell_h + \ell_t)\delta - \ell\theta \} / \ell\ell_t \dots\dots\dots (8)$$

Meanwhile, by substituting $R_r = -l/\tan \phi$ in equation (2), further simplifying and determining the relationship between the target angle of traction δ and the tractor front wheels' steering angle necessary for obtaining identical trajectories of points A and B, the following is derived.

$$\phi_t = \{ (\ell_b + \ell_h)^2 - \ell_a^2 \} \delta / \ell \ell_b$$

At this point, in order to provide a control for aligning δ with δ_t , a feedback technique is applied in which the δ changing speed ($\dot{\delta}$) is expressed by the following equation.

The target steering angle θ_t of the agricultural machine necessary for achieving this feedback is indicated by the following equation.

$$\theta_t = (\alpha - k_2)\phi / k_2 - (\alpha k_1 + k_3)\delta / k_2 \dots\dots\dots (9)$$

In this equation,

Based on the equation, the target steering angle of the machine wheels for aligning the track in a non-constant turning condition is determined. The machine wheels should be controlled for steering to meet the target steering angle.

Test trailer overview and driving test 2,3)

1) Test trailer overview

[Fig. 3](#) shows the test trailer prototype attached to the tractor. The sizes of the steering angle of the tractor's front wheels, the angle of traction and the steering angle of the trailer's wheels are measured by potentiometers installed at relevant positions. Based on the values of the angles determined by potentiometers, **ON-OFF** of the electromagnetic, hydraulic direction control valve is controlled via a relay and the hydraulic cylinder expands and becomes contacted to drive the trailer wheels. In the test, a control program was run which uses interruptions every 10 ms based on an interval timer built into the control computer in order to maintain a constant control interval. The cylinder used for steering the trailer wheels is a bilateral rod type cylinder with an internal diameter of 30 mm, a rod diameter of 16 mm and a stroke of 250 mm.

[Fig.3:Test trailer and tractor\(24KB\)](#)

2) Driving test results using the test trailer

In the driving test, drops of water are left on the surface at set points to draw the track and the tracks are compared to align the tracks of the tractor and trailer. Tests of a constant radius circle with the tractor side point set in the rear wheel center and the trailer side point set in the trailer wheel base center when the control was applied, were carried out. Based on the results obtained, while a track offset of 8.5 cm and 26 cm occurred for steering angles of 18° and 31°, respectively for the tractor's front wheels, there was almost no off-tracking when the control was applied. [Fig. 4](#) shows a comparison with the calculated values for cases in which a constant radius circle is driven with different actual steering angles for the tractor's front wheels and measurements of the angle of traction and the steering angle of the trailer's wheels are taken. The link indicated in the figure corresponds to the case when the link method is used for control with the target steering angle based on equation (5) being determined and applied for actual control. The wavy line and alternate long and short dash line in the figure show the results of driving when the trailer side setting point position changed in the active precision control method and in both cases, the calculated values and the measured values agreed well.

[Fig.4: \$\delta_e\$ / \$\delta_r\$ characteristic diagrams\(30KB\)](#)

Next, [Fig. 5](#) shows a comparison between the active precision method and absence of control and steering control by the link method for a turning track when a 90° angle turn is performed through an abrupt turn of the handle by the operator driving the tractor on a flat concrete street surface. The driving speed at this time is 0.38 m/s, the points at which the system attempts to align the track when the control is applied correspond to the center of the tractor's rear wheels for the tractor and the center of the machine wheels for the machine and a neutral zone of $\pm 1^\circ$ is set for the angle of traction when control is applied. When there is no control, once the 90° turn begins, the trailer cuts to the inside and the track for the setting point goes way off course. Furthermore, the trailer track is not aligned with the tractor track even after reverting to a straight course. When the link method control is applied, the track is not as far off as without any control, but even though the control is set to align the tracks for a constant radius circle, in the first part of the circle, the trailer crosses outside of the tractor's track and for the latter half of the circle, it crosses inside of the tractor's track. In contrast, when the newly developed active

precision control method is used, while there is a slight amount of crossing on the inside by the trailer initially, the follow-up performance is excellent afterwards. The return to a proper track after the tractor reverts to a straight course is also quick. The reason why some crossover to the inside at the beginning of the turn is observed with the active precision control method is that since the tractor and the trailer are controlled to follow the same turning circle with the same turning point, when the tractor's front wheels are adjusted, the trailer's wheels are turned to be on the turning track which matches the angle of the tractor's adjustment although the trailer is still on the tractor's straight course track.

[Fig.5:Top view of trajectories in 90° turn\(22KB\)](#)

These results show that the introduction of the active precision control method significantly improves the follow-up performance of a semi-trailed agricultural machinery attached to a tractor.

Application of control system to a middle-sized commercialized roll baler and tests⁴⁾

Based on the results obtained with the test trailer and in order to study the suitability of the active precision control method, a middle-sized roll baler available in the market with a pick-up width of 1 m and a bale-forming chamber diameter of 90 cm was retooled for steering control and used in driving tests as well as field work. The tractor selected for these tests had an engine output of 22 kW, a wheel base (l) of 1.79 m, a distance from the rear wheels to the hitch point (l_h) of 0.96 m, a distance from the baler hitch point to the wheels (l_t) of 1.76 m and a distance from the hitch point to the center of the baler pick-up device (l_b) of 0.995 m. Also, steering of the baler wheels was handled by a hydraulic cylinder and oil was supplied by a hydraulic unit (with an output of 2.4 L/min when the tractor PTO base rotation is 540 rpm) built in the baler. The points at which the control system attempted to align the track corresponded to the center of the rear wheels ($l_a = 0$) on the tractor side and to the center of the pick-up device on the baler side.

In [Fig. 6](#), a comparison of the results is shown for the absence of control and a model of link method control for the track when a 90° turn is performed at a speed of 1.65 m/s on a flat concrete surface. As in the case of the test trailer, the track alignment is off to the greatest extent for the absence of control and the amount of dislocation decreases in the link method and then in the active precision control method. Even when bales weighing nearly 140 kg are loaded in the bale-forming chamber and a 90° turn is performed, the follow-up performance using the active precision control method shows almost no change. In field work as well, excellent follow-up performance is achieved. Furthermore, by applying a control process, since the risk of interference of the tractor with the baler is reduced even with larger angles of traction and a smaller turning radius, the turning performance is also enhanced in addition to the better follow-up performance.

Improvement of the control method and effect¹⁾

The active precision control method as described thus far involves the measurement of the steering angle of the tractor's front wheels using a potentiometer and applying control based on the results of measurement. This method requires that sensors be attached to the tractor for measurement of the steering angle of the front wheels or the rotary angle of the handle, and this requirement is not suitable for practical use. Therefore, instead of a method which measures the steering angle, a method which uses estimates of the actual steering angle from the angle of traction and the angular velocity of the angle of traction was examined.

In equation (8), the angular velocity of the angle of traction was determined from the angle of traction and the steering angle of the tractor's front wheels or the steering angle of the machine wheels. This equation (8) can be derived as follows.

$$\dot{\phi} = -k_2\phi - k_3\theta - k_3\delta$$

Note that $k_2 = V/l_t$ and $k_3 = V(l_h + l_t)/ll_t$. In this case, θ and δ are determined and $\dot{\phi}$ can be calculated as the change in ϕ measured over time. Therefore, the actual steering angle of the tractor's front wheels necessary for control can be estimated by the following equation.

$$\delta = -(\dot{\phi} + k_2\phi + k_3\theta)/k_3 \dots\dots\dots(10)$$

When the relationship expressed in equation (10) is substituted in equation (9), it is assumed that the target steering angle corresponds to the measured steering angle ($\theta_t = \theta$) and the equation is simplified. As shown in the following equation, it is possible to determine the target steering angle from the angle of traction and the angular velocity of the angle of traction.

$$\theta_t = \frac{l_a^2 - l_b^2 - l_h^2 + 2l_b l_t}{-l_a^2 + l_b^2 + l_h^2 + 2l_b l_h} \phi - \frac{l_t}{V} \times \left[1 - \frac{2l_b(l_h + l_t)V'}{\alpha l_t \{ (l_b + l_h)^2 - l_a^2 \}} \right] \dot{\phi} \dots\dots(11)$$

Here, \pm is the feedback gain, V is the actual driving speed and V' is the fixed speed value input in advance.

This revised control method is referred to as the "new active precision control method" in contrast to the original "active precision control method", and [Fig. 7](#) shows a comparison of this method applied to the previously described roll baler for a track resulting from zigzag driving over a flat concrete surface with the absence of control, link method control and active precision control. For this control application, the feedback gain is set at 0.84 and V' at 1.2 m/s with a driving speed of 1.7 m/s. Also, the angle of traction neutral zone for control is set at $\pm 10^\circ$, and the driving speed is set by inputting a value which is compatible with the defined driving zone in order to simplify the control device. Without any control, the dislocation is 52 cm (maximum) and for the link control method, the maximum track dislocation is 23 cm with phase delay. By comparison, the active precision control method and the active precision control method based on the estimation of the steering angle gave a maximum dislocation value of 10 cm and 7 cm, respectively. It is thus obvious that the track follow-up performance can be achieved at the same levels as

with the active precision control method, and considering the lack of requirement for special work on the tractor itself, this method is highly suitable.

[Fig.7:Top view of trajectories in zig-zag running test\(36KB\)](#)

When work is being conducted on sloped grassland, since the agricultural machinery slips towards the valley side of the slope, the work performance deteriorates compared to flat land. To alleviate this shortcoming, a sensor which detects the slope angle is attached to the machine and if this angle is used as compensation to equation (11) for the application of steering control to the machine wheels, it is possible to achieve an excellent follow-up performance and work results even on sloped grasslands. Specifically, the following equation is used to determine the steering angle.

$$\theta_t = F_1 \phi - F_2 \dot{\phi} - F_3 \omega \dots\dots\dots(12)$$

In this equation, F_1 and F_2 are the coefficients of ϕ and $\dot{\phi}$ in equation (11), $\dot{\phi}$ is the slope angle and F_3 is the compensation coefficient based on the slope.

When a driving test was conducted on an 8° slope using a roll baler (with a bale diameter of 100 cm) to which this slope compensation had been applied, the results showed that while a dislocation of about 7 cm occurred in the absence of control or without slope compensation, there was practically no dislocation when slope compensation with F_3 fixed at 0.3 was applied. Also, when a zigzag traveling test was applied to the same land, while the track dislocation between the tractor and the baler was nearly 20 cm without any control, a maximum value of about 5 cm was maintained when the control was applied. These results emphasize the value of this technique for improving the follow-up performance of the machine on sloped land.

Conclusion

- (1) For semi-trailed agricultural machinery, a method for controlling the steering of the machine wheels based on the angle of traction and the steering angle of the tractor's front wheels was developed in order to improve the follow-up performance with the tractor.
- (2) The basic approach for the control technique was to obtain identical values for the turning radius of the tractor and the machine wheels for a constant radius circle and a theoretical equation was introduced. Furthermore, the effectiveness of this approach was verified using a test trailer.
- (3) To align the tracks for a non-constant radius turn, the active precision control method which provides a steering control based on the following equation using the angle of traction and the steering angle of the tractor's front wheels was developed, and this control method was applied to a test trailer and a commercially available roll baler for driving tests. The results showed that this control method improved the follow-up performance of the machine with the tractor.

$$\theta_t = (\pm k_2) \dot{\phi} / k_2 - (\pm k_1 + k_3) \dot{\phi} / k_2$$

- (4) The active precision control method was further improved by estimating the steering angle of the tractor's front wheels and using these values in the following equation to determine the steering angle for the machine wheels based on the angle of traction and the angular velocity of the angle of traction. This improved method which is referred to as the active precision control method based on the estimation of

the steering angle was applied to the roll baler for driving tests. The results showed that the follow-up performance reached levels similar to those obtained with the active precision control method. Also, this control method was suitable for practical use because it does not require the installation of sensors for measuring the actual steering angle of the tractor's wheels or other changes.

$$\theta_t = \frac{l_a^2 - l_b^2 - l_h^2 + 2l_b l_t}{-l_a^2 + l_b^2 + l_h^2 + 2l_b l_h} \phi - \frac{l_t}{V}$$

$$\times \left[1 - \frac{2l_b(l_h + l_t)V'}{\alpha l_t \{ (l_b + l_h)^2 - l_a^2 \}} \right] \dot{\phi}$$

Additionally, the follow-up performance can be further enhanced by applying a compensation coefficient for sloped grassland.

Abstract

In savanna and tropical monsoon areas where the dry and rainy seasons can be clearly distinguished, it is important for farmers to secure as much irrigation water as possible in the dry season in order to produce fruits and vegetables. Though the Department of Land Development, Ministry of Agriculture and Cooperatives, Thailand recommends that farmers excavate small farm ponds for the purpose mentioned above, the irrigation water stored in the farm ponds in the rainy season is not effectively used in the dry season because of evaporation from the surface of water and percolation from the bottom and lateral parts of the ponds. Therefore, the authors developed methods to control the evaporation and percolation in small farm ponds. They selected 4 methods mentioned below, based on the results of experiments carried out in the eastern region of Thailand by Kobayashi. They developed low cost and sustainable methods which farmers can apply themselves as follows: (1) Covering the surface of water with floating materials. (2) Management of irrigation water using several ponds. (3) Changes in the pond shape. (4) Compaction of the bottom of the pond after crushing. The authors confirmed the effectiveness of the 4 methods through field experiments and model calculations.

Discipline: Irrigation, drainage and reclamation

Additional key words: floating materials

Received for publication, April 6, 1998

Introduction

The climate of Thailand can generally be classified into 2 main types, savanna and tropical monsoon. For example, the major part of the eastern region in Thailand has a savanna climate where the dry and rainy seasons can be clearly distinguished by the amount of rainfall. Consequently, rainfall in the eastern region of Thailand is concentrated during the rainy season from May to October and the amount is very small during the dry season, especially from December to March.

Presently the authorities concerned have attempted to promote crop diversification including the development of orchards in order to improve the standard of living of the farmers. To achieve this objective, the farmers must secure water resources for the dry season. For example, since some of the tropical fruits in the eastern region of Thailand pollinate from January to February, irrigation water must be preserved at least until February through the utilization of farm ponds, groundwater, etc. However, water resources in this region are mainly derived from surface water with some supply from groundwater.

Construction of farm ponds is one of the measures to alleviate these shortcomings. However, valuable irrigation water in farm ponds gradually evaporates and percolates under the strong sun in the dry season. Therefore, it is important for the authorities concerned to implement sustainable measures to preserve farm pond irrigation water as much as possible.

The authors studied and conducted some experiments related to the development of methods to control evaporation and percolation in small farm ponds for

2 years (1995~1996), based on experiments carried out by Kobayashi in 1994²⁾. In the current report, the results of this study are described.

Selected measures

In this study the authors aimed at implementing water conservation measures in small farm ponds, especially in standard-type small farm ponds ([Fig. 1](#)) recommended by the Department of Land Development (DLD), Ministry of Agriculture and Cooperatives, Thailand. Moreover, the authors aimed at implementing practical water conservation measures which farmers can apply themselves.

[Fig.1:DLD standard-type small farm pond \(excavated type\)\(21KB\)](#)

The following 4 methods were selected: (1) Covering the surface water with floating materials (hereafter referred to as Floating cover method). (2) Use of several ponds (hereafter referred to as Compartment method). (3) Changes in pond shape (hereafter referred to as Pond shape method). (4) Crushing and compaction of the bottom of the pond (hereafter referred to as Crushing and compaction method) ([Fig. 2](#)).

1) *Floating cover method*

The authors carried out 2 experiments in the 1995 and 1996 dry seasons. The results of these experiments are shown in Table 1.

Table1:Floating cover experiments

Method	<u>1995 Experiment</u>			<u>1996 Experiment</u>		
	77-day-cumulative evaporation total (mm)	Daily average evaporation (mm/day)	Evaporation reduction rate (%)	77-day-cumulative evaporation total (mm)	Daily average evaporation (mm/day)	Evaporation reduction rate (%)

Control	494.57	6.42(100%) ^{a)}	-	433.02	4.98(%) ^{a)}	-
Polystyrene foam	304.85	3.96(62%)	38	-	-	-
Bamboo	370.64	4.81(75%)	25	-	-	-
Drinking water bottles	331.97	4.31(67%)	33	-	-	-
Duckweed	450.00	5.84(91%)	9	379.75	4.13(83%)	17

a): Rate taking "Control" as 100%

Based on the 1995 experiment, though the results showed that polystyrene foam was most effective in reducing evaporation from farm ponds, the authors selected duckweed (a kind of floating weed) as the most suitable and sustainable floating material in taking account of the cost and load on the environment.

In the 1996 experiment, the authors confirmed again the effectiveness of duckweed for evaporation control. Based on these experiments, the authors observed that duckweed used as floating cover reduced the evaporation by about 10%.

2) *Compartment method*

(1) Method1)

A schematic diagram illustrating the method is shown in Fig. 3. The ponds were operated as follows:

Fig.3:Schematic cross-section diagram of 3-compartment ponds(37KB)

- 1.They were full of water at the end of the rainy season (Stage 1).
- 2.Water for consumptive use was pumped from pond 1 until the evaporation and percolation losses from pond 2 and pond 3 were equal to the amount of water remaining in pond 1 (Stage 2).
- 3.A pump was used to transfer the water remaining in pond 1 to fill the unused capacity of pond 2 and pond 3 (Stage 3), which eliminated further evaporation and percolation losses from pond 1.
- 4.Water was withdrawn as needed for consumptive use from pond 2 until the amount of water remaining in pond 2 was equal to the unused capacity in pond 3 (Stage 4).
- 5.A pump was used again to transfer the remaining water from pond 2 into pond 3 (Stage 5). At this stage, pond 3 was filled and pond 1 and pond 2 were empty, which eliminated further evaporation and percolation from pond 2.

(2) Results

Based on a computer calculation, it was observed that this method was effective for the control of evaporation and percolation.

When the method is applied to DLD standard-type small farm ponds, it is considered that there are 2 systems. In one, a pond is divided into various compartments, and in the other some standard-type small farm ponds are used with water consumption corresponding to the number of ponds. Therefore, the authors examined 7 cases as shown in [Table 2](#). Case-A corresponded to the DLD standard-type small farm pond. In Case-B1 to Case-B3 the former system was used and in Case-C1 to Case-C3 the latter system was employed.

[**Table 2. Calculation of water reduction in the Compartment method\(42KB\)**](#)

The assumptions for the calculations were as follows: evaporation amounted to 5.0 mm/day, percolation to 5.0 mm/day, there was no rain and the daily water consumption per standard-type pond was 5.0 m³/day.

The results of calculation are shown in Tables 2, 3 and Fig. 4. The conclusions were as follows:

[**Fig.4: Effectiveness of Compartment method in reducing evaporation and percolation\(19KB\)**](#)

- In the Case-C series, consisting of some DLD standard-type small farm ponds which were used with water consumption corresponding to the number of ponds, evaporation and percolation control of farm ponds was effective.
- The more farm ponds were used in Case-C series, the greater the effectiveness.
- Using the figures listed above in the calculation, farmers could reduce evaporation and percolation from ponds by 13% and secure irrigation water for 16 days more in Case-C3 (use of 4 ponds) than in Case-A (DLD standard-type small farm pond).
- The effectiveness based on the number of ponds was almost the same in all 3 cases of the Case-C series. Since the reduction of evaporation and percolation per pond in Case-C3 was about 1.6 times greater than in Case-C1, 4 ponds should be used in the Case-C series.

3) Pond shape method

Based on the computer calculation, it was observed that the steeper the slope, the greater the effectiveness for evaporation and percolation control. Furthermore, round farm ponds were more effective for evaporation and percolation control than rectangular farm ponds, based on the same calculation method.

Sixteen cases were analyzed as shown in Table 4. In Case-A to Case-L the rectangular ponds were used and in Case-M to Case-T round ponds were used. Four patterns of slopes were examined = 1:2.0, 1:1.5, 1:1.2 and 1:1.0.

[**Table 4:Calculation of water reduction on the ponds \(pond shape method\)\(62KB\)**](#)

The assumptions for the calculations were as follows: evaporation rate was 5.0 mm/day, percolation rate was 5.0 mm/day, there was no rain and the daily water consumption per pond was 5.0 m³/day.

The results of the calculations are shown in [Table 4](#) and [Fig. 5](#). The conclusions were as follows:

[**Fig.5:Role of pond shape in reducing evaporation and percolation\(27KB\)**](#)

- The steeper the slope, the greater the effectiveness for evaporation and percolation control.
- Round ponds were more effective for evaporation and percolation control than rectangular farm ponds.
- Steeper slopes and round shape resulted in greater effectiveness when the compartment method was applied than when it was not applied.

- Using the figures mentioned above in the calculation, farmers could reduce evaporation and percolation from ponds by 23% and secure irrigation water for 28 days more in Case-P (slope 1:1.0, round shape, application of the compartment method using four ponds) than in Case-A (DLD standard-type small farm pond).

4) *Crushing and compaction method*

The authors carried out a percolation control experiment in December 1996 using a simulated farm pond. The results of the experiment are shown in [Table 5](#). The soil of the bottom of the simulated farm pond consisted of gravelly sandy loam soil.

Table 5. Percolation control experiment

Case	Percolation						Average of 1st to 4th trials
	1st trial	2nd trial	3rd trial	4th trial	5th trial	6th trial	
Unimproved(A)	5.7×10^{-2}	5.7×10^{-2}	4.9×10^{-2}	5.1×10^{-2}	3.7×10^{-2}	3.1×10^{-2}	5.3×10^{-2}
Crushing and compaction(B)	1.5×10^{-2}	1.0×10^{-2}	8.9×10^{-2}	7.4×10^{-2}	--	--	9.8×10^{-2}
Ratio of (B)to(A)	26.3%	17.5%	18.2%	14.5%	--	--	18.5%

Based on the results of the experiment, the crushing and compaction method was effective in reducing percolation from farm ponds. At the bottom of the simulated pond where the crushing and compaction method was used, the percolation rate decreased to about 20% compared with the rate in the unimproved area.

Though we observed that the crushing and compaction method was able to cut the percolation rate by 80% on gravelly sandy loam soil, we could not determine whether the same phenomenon occurred on clay soil which is suitable for the bottom of the ponds. Therefore, similar experiments should be conducted on clay soil, at the bottom of several actual farm ponds, especially, to confirm the effectiveness of the method.

Fig.5. Role of pond shape in reducing evaporation and percolation

[BACK](#)

Integrated application of the 4 methods

The authors studied the effectiveness in each case where all or some of the 4 methods described above (Floating cover method, Compartment method, Pond shape method and Crushing and compaction method) were integrated, based on the computer calculations. [Table 6](#) shows the 16 calculation cases. In Case-a, none of the methods listed above were used. In Case-b to Case-e we used only one method, in Case-f to Case-k we combined 2 methods, in Case-l to Case-o we used 3 methods together and in Case-p we integrated all of the 4 methods.

[Table 6: Calculation of water reduction in the ponds \(integration of methods\)\(56KB\)](#)

The assumptions for the calculations were as follows:

- Evaporation was assumed to be 5.0 mm/day.
- Evaporation was assumed to be 4.5 mm/day when the floating cover method was employed because the experiments showed that this method reduced evaporation by about 10%.
- Percolation was assumed to be 5.0 mm/day.
- Percolation was assumed to be 2.0 mm/day at the bottom of the farm ponds when the crushing and compaction method was applied because the experiments showed that the method was effective in reducing percolation and the reduction rate was about 80% in the case of gravelly sandy loam soil.
- There was no rain.
- The daily water consumption per pond was assumed to be 5.0 m³/day.

The results of the calculations are shown in [Tables 6, 7](#) and [8](#). The conclusions were as follows:

- When only one method was applied, the Compartment method was the most effective in reducing evaporation and percolation, followed by the Crushing and compaction method and the Pond shape method, while the Floating cover method (duckweed) was the least effective.
- The more methods we applied, the greater the effectiveness, except for Case-c and Case-i where the Compartment method was employed.
- We could expect greater effectiveness by applying the Pond shape method together with the Compartment method and/or the Crushing and compaction method. For example, in Case-i, the reduction rate of "evaporation + percolation"(21.7%) was higher than the total (16.6%) of the rate when the Compartment method was applied (12.9%) and the rate when the Pond shape method was applied (3.7%).
- Using the figures mentioned above in the calculation, farmers could reduce evaporation and percolation from ponds by 31% and secure irrigation water for 38 days more in Case-p (the 4 methods were integrated) than in Case-a (DLD standard-type small farm pond).

[Table 7: Degree of effectiveness\(55KB\)](#)

[Table 8: Effectiveness of Pond shape method when combined with another method\(36KB\)](#)

Conclusion

Though the experiments on the Floating cover method and the Crushing and compaction method should be continued, and the degree of effectiveness of these methods in reducing evaporation and percolation should be

- Considerable reduction of evaporation and percolation could be expected by employing only the

Floating cover method (duckweed) and the Crushing and compaction method. These methods should be disseminated among farmers because they are cheap and easy to apply by farmers under the support of the government.

- When new ponds are excavated, the shape of the ponds should be round. Furthermore, the lateral parts of the ponds should be as steep as possible.

- The use of several ponds (Compartment method) was very effective for evaporation and percolation control. Therefore, the DLD should ask the farmers to form small groups, excavate several farm ponds and let them manage water use by employing the Compartment method.

Summer-Sown Cultivation of Forage Oats and Breeding in Japan

Masaaki KATSURA

Department of Grassland, Kyushu National Agricultural Experiment Station
(Nishigoshi, Kikuchi, Kumamoto, 861-1192 Japan)

Abstract

Oats are mainly used as forage in Japan. A new cultivation type, in which oats are sown in late summer and harvested as silage or hay in December or later, has been adopted in the warm region of Japan. This type which is referred to as "summer-sown cultivation" enables to make good use of the field from late summer to early winter. However, this system is not satisfactory for oats, because high temperatures persist until mid-September, the day-length shifts from long to short, and the temperature from high to low. We have been engaged in the breeding of oats for summer-sown cultivation to overcome such adverse conditions. Therefore we focused on early heading habit in fall. Based on the evaluation of introduced varieties and lines for heading habit, we observed that some Mexican varieties headed early in summer-sown cultivation. Then we released 'Haeibuki' which is a progeny from a cross between a Mexican cultivar, 'Guelatao' and an old Japanese one, 'Hayate'. Haeibuki is characterized by very early heading in summer-sown cultivation and a high dry matter percentage at harvest. Through field trials in the breeding process, we observed differences among cultivars in germination under summer-sown conditions, presumably associated with high temperature.

Discipline: Plant breeding

Additional key words: *Avena sativa* L., heading, germination

1~8):[References](#)

Introduction

Oats, *Avena sativa* L., are mainly used as forage in Japan, while as grain and for grazing in other countries. The total area of forage crops in Japan was estimated at 980,200 ha in 1995, of which the seeding area covers 188,582 ha. The seeding area of oats is estimated at 10,500 ha and oats rank third after maize and sorghum except for grasses, including Italian ryegrass. Oats are mainly distributed in Kyushu, which is located in the southwestern part of Japan, with an area accounting for about 65% of the total oats area.

Oats have been sown in fall in the southwestern part of Japan and harvested in the next spring for many years. This system is referred to as "fall-sown cultivation". When oats are used as forage, another cultivation type has been adopted in the warm region of Japan, which is referred to as "summer-sown cultivation". In this type, oats are sown in late summer and harvested as silage or hay in December or later. We have been engaged in the breeding of forage oats for summer-sown cultivation since 1988. In this review, various aspects relating to the breeding of oats for summer-sown cultivation will be described along with the characteristics observed through our breeding process.

Summer-sown cultivation of oats and breeding objectives

The main forage crops in Japan are summer crops such as corn and sorghum. They are sown in spring and harvested in summer and fall. Farmers try to get high yield with high nutritive value by growing them. Therefore, some farmers implement double cropping of corn. In this case, since the interval between the first harvest and second seeding is very short, the system is very laborious.

In the warm region of Japan, corn tends to be sown earlier for avoiding typhoons in late summer while paddy rice is transplanted in early spring. Therefore, it is necessary to make good use of the field from late summer to early spring after harvesting rice or corn by mid-August because the area of arable land in Japan is small. Oats are an important crop for producing feed in early winter and next spring as well as Italian ryegrass. In the case of summer-sown cultivation of oats, in which oats are sown in late summer and harvested in early winter, farmers have enough time to make preparations for the growth of the next crops. As stated above, to save labor and avoid risk, summer-sown cultivation of oats is an important alternative. Then, the weather from fall to early winter is mild in the southwestern part of Japan, particularly in southern Kyushu, i.e. Miyazaki and Kagoshima ([Fig. 1](#)). There is enough rain and the weather is mild in fall. Therefore, this cultivation type enable to make the best use of the climatic conditions.

[Fig.1: Monthly total precipitation and average temperature\(29KB\)](#)

However, the conditions of summer-sown cultivation are not favorable for oats which are a long-day plant. High temperature persists until mid-September, and this period corresponds to the germination stage. The day-length shifts from long to short and the temperature from high to low ([Figs. 1 and 2](#)). These conditions influence panicle emergence and subsequent growth. In order to overcome such shortcomings, we developed the following breeding objectives: (1) stable germination under high temperature conditions, and (2) early heading in fall to reach a stage beyond the milky stage at harvest. Particularly, we focused on early heading in fall to obtain a high dry matter percentage at harvest. Then the high dry matter percentage may decrease the labor for prewilting in the field before harvesting at a low temperature.

Evaluation of germplasm for heading habi

Many studies on heading habit have been performed. Peterson⁵⁾ pointed out in his review that the time required for inflorescence development and emergence is affected by the temperature and photoperiod in oats. While the optimal temperature for the most rapid development varies among studies, both warmer and cooler temperatures were found to delay heading. Griffiths³⁾ reported that panicle emergence was entirely suppressed under photoperiods of 12 h and less in some varieties. In addition, he dissected the growing points of plants which failed to emerge under short days. As a result, he observed that floral differentiation had not been inhibited by short days, but that the full elongation of the internodes, especially the upper internodes, had been suppressed.

As stated above, the day-length shifts from long to short, and the temperature from high to low in summer-sown cultivation (Figs. 1 and 2). Considering the climatic conditions and the results mentioned above, panicle emergence may be affected. In order to head under such unfavorable conditions, cultivars should be characterized by a low chilling requirement and low sensitivity to day-length. Ueyama⁸⁾ evaluated 28 introduced cultivars and lines for heading habit in summer-sown and fall-sown cultivation ([Table 1](#)). He divided these cultivars and lines into 5 groups. The panicle emergence of group I was early in summer-sown cultivation and very early in fall-sown cultivation. Heading in group II was earlier than that in group I in summer-sown cultivation and later than that in group I in fall-sown cultivation. Heading in group III was later than that in group I and as early as that in group I, respectively. Heading in group IV was later than that in group I in both types of cultivation. Group V did not reach the heading stage within a year in summer-sown cultivation. Many Japanese commercial varieties belonged to group I and group III. Group II included Mexican cultivars and their progenies. As a result, he pointed out that the characteristics of group II were important to develop a new cultivar for summer-sown cultivation.

Development of a new cultivar 'Haeibuki'

We released a new cultivar 'Haeibuki' for summer-sown cultivation in 1996⁴⁾. Haeibuki is a progeny from a cross between 'Guelatao' and 'Hayate'. Guelatao, released by the National Institute of Agriculture Research in Mexico, is able to head in early fall. Hayate, introduced from Australia, has been used in summer-sown cultivation for many years. The cross, Guelatao x Hayate, was made in the greenhouse in 1988. The F₁, F₂ and F₃ were advanced in the greenhouse without selection. The F₄ plants were grown from late summer to winter in 1989, and individual selection was performed for early heading in fall. The F₅ lines derived from the selected F₄ plants were selected for early heading in fall again in 1990. The F₆ plants were multiplied by removing abnormal plants in the spring of 1991. The F₇ lines were evaluated for yield and the other agronomic characteristics in summer-sown cultivation in 1991. As a result, 2 lines were selected, and named Kyushu-1 and Kyushu-2. After the F₈ generation, Kyushu-1 and Kyushu-2 were examined in the local adaptability tests. Lastly, we chose Kyushu-2, and it was registered as Haeibuki. The characteristics of Haeibuki are shown in [Table 2](#). The significant characteristics were early heading in summer-sown cultivation and high dry matter percentage at harvest. Moreover, the dry matter yield was slightly higher than that of other leading cultivars.

Table 2. Characteristics of Haeibuki in summer-sown field test^{a)}

Germination habit of oat cultivars for summer-sown cultivation

Throughout breeding process, we observed differences among cultivars and lines in germination in the summer-sown field test. Our experimental lines showed good germination, while some cultivars displayed poor germination. Then we carried out the germination test using the seeds harvested in 1994 and 1995 at constant temperatures of 20 and 30 on the date corresponding to the seeding time in summer-sown cultivation, because we considered that poor germination was due to high soil temperature. Mean maximum/minimum soil temperatures in the fields in Kumamoto at a depth of 2 cm were 32/23 in 1995 during the seeding and germination period from August 31 to September 10, and at a depth of 5 cm in 1996 the values were 30/22.

Table 3. Influence of temperature on the germination percentage on the date corresponding to the seeding time in summer-sown cultivation

<u>Cultivar</u>	<u>Year when harvested</u>	<u>Temperature (°C)</u>
-----------------	----------------------------	-------------------------

Haeibuki	1994	<u>20</u>	<u>30</u>
	1995	98	100
Guelatao	1994	95	94
	1995	94	88
Hayate	1994	96	89
	1995	88	62
Early Queen	1994	84	21
	1995	90	45
Enducks	1994	93	24
	1995	84	6
Super Hayate Hayabusa	1994	85	0
	1995	86	46
Sabitsuyoshi	1994	89	0
	1995	89	60
	1995	97	78

Germination test was started on September 12, 1994 and August 29, 1995. Seeds were harvested in the spring 1994 and 1995, and stored at room temperature after threshing and cleaning. Seeds of Super Hayate Hayabishi in 1994 were bought from a seed company. Fifty seeds were placed in a petri dish (9 cm in diameter) with 2 sheets of filter paper imbibed with distilled water at the constant temperatures of 20 and 30 C. A seed was considered to have germinated when the radicle protruded through the seed coat. Germination counts were expressed as mean germination percentage obtained from 2 replications.

[Table 3](#) shows the results of the germination test. There was a significant difference among cultivars at 30, while all of them showed a germination percentage of more than 80% at 20. The germination percentages of Haeibuki and Guelatao were very high, and those of 'Enducks' and 'Super Hayate Hayabusa' were very low. Radford and Key⁶⁾ determined how the temperature affects germination, mesocotyl length and coleoptile length in 16 oat (*Avena* spp.) genotypes. They defined germination as the emergence of the shoot from the seed, and observed that the critical temperature for the differentiation of genotypic effects on germination was 30. Our results were in agreement with those findings. Observation of the state of germination in the field test of summer-sown cultivation in 1995, revealed a difference similar to the results mentioned above. That is, cultivars except for Super Hayate Hayabusa and Enducks reached the germination stage within 5 days after seeding, while in the former 2 germination was delayed. [Fig. 3](#) shows the state of germination of Haeibuki and Super Hayate Hayabusa in the test in summer-sown cultivation in 1997. Apparently the germination of Super Hayate Hayabusa was delayed compared with that of Haeibuki. Then, we performed germination tests at a constant temperature of 30 in 1995 using the seeds stored at room temperature, which were harvested in 1994 ([Fig. 4](#)). As a result, all the cultivars germinated with a percentage of more than 80%, because the non-germination habit decreased during the storage, as stated by Corbineau et al.¹⁾ They examined the dormancy of cultivated oat (*Avena sativa*) seeds, and its elimination during dry storage at 30. They showed that the longer the dry storage at 30, the more easily the coated caryopses germinated at high temperatures. Therefore, the new cultivar Haeibuki was able to germinate at high temperatures better than the other cultivars and the non-germination habit at high temperature could be removed more rapidly than in the other cultivars. In addition, regarding the relation between germination and high temperature in oats, Radford and Key⁶⁾ reported that high temperature induced a temporary dormancy or state of "suspended animation". Corbineau et al.²⁾ also studied the induction of thermodormancy using dormant seeds and non-dormant ones in oats, and showed that the incubation of imbibed dormant seeds at 30 induced a thermodormancy. The results obtained and observations may be related to the induction of a temporary dormancy or a thermodormancy and studies on this phenomenon are currently in progress.

[Fig.4: Effect of storage period on the germination percentage at constant 30°C\(34KB\)](#)

Perspectives

In the breeding of forage oats for summer-sown cultivation, we focused on early heading in fall. We were able to develop Haeibuki and other very early heading lines. However, new problems related to early heading should be addressed. Nagatani (pers. comm.) observed that some diseases spread after heading stage in the field tests, suggesting that the early type may be readily affected, and special attention was paid to crown rust and Helminthosporium leaf blotch. There are many descriptions about crown rust resistance, but very few about Helminthosporium leaf blotch resistance. Tsukiboshi et al.⁷⁾ evaluated 56 cultivars and lines including *A. strigosa* and *A. byzantina* for their resistance to Helminthosporium leaf blotch based on seedling tests using spore spray inoculation, and they examined the mechanism of plant reaction. They could not detect any cultivars with true resistance. However, they classified the cultivars into 4 categories according to the level of susceptibility to the disease. Therefore we plan to introduce the seedling test of Helminthosporium leaf blotch into individual selection schemes.

Lodging resistance is also an important characteristic for summer-sown cultivation. Lodging leads to damage of growing plants and consequently the quality and yield decrease. Actually, we developed an experimental line with a strong lodging resistance which is currently undergoing in local adaptability tests.

In this way, in order to make the best use of the period from late summer to early winter, oat cultivars can be improved. The major purpose of summer-sown cultivation is to achieve stable yield every year. However, the yield of forage oats in summer-sown cultivation seems to be largely affected by the weather conditions. Breeding work can play a very important role in stabilizing the yield of forage oats.

Abstract

A non-cooking fermentation system for shochu spirit production was evaluated using both small-scale and bench pilot-scale equipment. This system employed a commercially available fungal enzyme preparation as saccharifying agent together with citric acid. The fermentation products from bench-scale equipment were distilled under vacuum or atmospheric conditions and the distillates were evaluated by a taste panel. Distillates produced under atmospheric conditions by the non-cooking fermentation method compared favorably with those produced by the cooking fermentation method. This method of production could result in significant savings of labor and energy if operated on a production scale. A case study and an analysis of economic aspects were carried out in a medium-scale shochu spirit factory.

Discipline: Food

Additional key word: atmospheric and vacuum distillation, flavor and aroma components, economic aspects

Received for publication, May 13, 1998

Introduction

Economic pressures on many small to medium-sized shochu spirit distilleries require a reduction in the labor force. In spirit production in Japan, pretreatment of cereal raw materials by cooking and preparation of "koji" for saccharification are the most labor-intensive operations and account for 30% of the total work load.

Recently, because of the trend toward milder tasting spirits, distillers have concentrated their attention to the development products that will meet this trend, by use of vacuum distillation or ion exchange treatments. Investment in the equipment needed for these processes will lead to unavoidable increases in costs. Investigations have therefore been carried out on systems based on a non-cooking method and employing exogenous saccharifying enzymes. These are designed to produce a mild spirit while saving labor and energy. A "non-cooking fermentation" method²⁾ was developed by the addition of citric acid,

and the fermentation progression depended on the commercial enzyme preparations used. It was also evident that the aroma and flavor compounds were derived from the cereal mash, especially higher fatty acid esters.

This paper describes investigations on the practical applications of these results. A bench-scale pilot plant was then used to follow the changes in the concentrations of the flavor and aroma compounds with time. Finally, sensory tests were carried out on the products obtained by atmospheric and vacuum distillation. In the case study, attempts were made to determine whether this non-cooking fermentation system could be introduced into a shochu spirit factory. From the economic point of view, this system may enable to reduce of cost for manufacturing by about 10% .

Materials and methods

1) *Bench-scale fermentation test*

The production of spirit by non-cooking and cooking fermentation methods was investigated using the bench-scale plant shown in [Fig. 1](#). The stainless steel fermentation tank had a 130 L capacity and the temperature was controlled at 25. Crushed rice grains (50 kg) were steeped in tap water overnight and filtered for 1 h; 75 L of mashing water (mashing water rate 150%) containing 0.2% (w/v) of citric acid and 100.6 g of enzyme preparation E (0.1 g protein/100 g crushed rice) were added to the fermentation tank, followed by 4.5 L of suspended yeast. The temperature was controlled at 25. A cooking fermentation test was conducted as a control using cooked rice that had been boiled for 30 min. The mashes were stirred 2-3 times a day with a paddle. The yeast inoculum used in this fermentation test was prepared as follows: 100 mL of seed prepared as in the small-scale fermentation test was added to a 30 L fermenter containing 18 L of sterilized medium and cultured at 25 for 20 h at an aeration rate of 0.1 v/v min.

[Fig.1: Scheme of non-cooking and cooking fermentation systems in the bench-scale plant\(28KB\)](#)

2) *Distillation method*

After the completion of the fermentation, the 120 L mash was divided into 2 equal parts, and one-half was subjected to distillation in a 100 L vessel that could be adapted to either atmospheric or vacuum distillation. Distillation at atmospheric pressure was carried out at 99 for 60-70 min, whereas vacuum distillation was carried out for 75-90 min until the temperature had risen from the starting temperature of 35 to a final temperature of 43. The distillates were stored at 2 for 10 days and then filtered through No. 2 filter paper. Tap water was added to the filtrates to obtain products with an ethanol concentration adjusted to 25% (v/v).

3) *Analytical methods*

The acidity of the mash was analyzed according to the analytical method stipulated by the National Tax Administration Agency¹⁾. The concentration of ethanol in the mash was estimated using a gas chromatograph (GC-7A Shimadzu, Kyoto). The column (3x1 mm) was packed with Porapak Q and equipped with a flame ionization detector. Isopropanol was used as an internal standard. Flavor components with a low boiling point other than isoamyl acetate and ethyl caproate, were analyzed by the direct injection method according to Nishiya's method⁵⁾. The contents of isoamyl acetate and ethyl caproate were determined by gas chromatography based on the head-space method. One mL of the internal standard solution (10₃mg/L *n*-isoamyl alcohol solution) was added to a 30 mL vial containing 5

g of mash or 5 g of the product. The vial was hermetically sealed with a septum and an aluminum cap, and heated at 50 for 20 min, then 1 mL of the head-space gas from the vial was subjected to gas chromatography (14A, HHS-2A, Shimadzu, Kyoto). The temperature gradient employed was 5/min from 50 to 120. The detailed analytical conditions were described in the previous report ²⁾. The flavor components with a high boiling point in the mash after distillation were extracted by the addition of 60 mL of ether to 5 mL of the distillate and assayed by gas chromatography. The products obtained by distillation were also analyzed in the same way. The concentration of glucose in the mash was analyzed according to the gluco-stat method using an F-kit (Yamanouchi Seiyaku K. K., Tokyo), and organic acid components were analyzed by the post-label method³⁾ using a high-speed liquid chromatograph.

Results and discussion

1) Production of spirit based on the bench-scale fermentation test

The conditions of the bench-scale fermentation test were established based on the results from the small-scale fermentation test, i.e. 3% seed inoculum and a fermentation temperature of 25 were used. The time course of fermentation is shown in [Fig. 2](#). Fermentation was completed on the 10th day in the non-cooking fermentation method, which is only slightly different from the 9 days required for the completion of the fermentation process in the case of the cooking fermentation method. The difference was due to the initial concentration of glucose in the mashes; this concentration for the cooking fermentation method was 22.3 g/L, whereas 1.3 g/L for the non-cooking fermentation method. The rate of saccharification therefore limited the fermentation rate in the non-cooking fermentation methods. A clear advantage of this system, however, was the lower level of bacterial contamination.

[*Fig.2:Time course of ethanol and glucose concentrations in mash in 2 types of fermentation using the bench-scale plant\(32KB\)*](#)

2) Flavor and aroma components during the fermentation

The changes in the concentrations of the aroma and flavor components during the fermentation are shown in Figs. 3-5. Isoamyl alcohol concentration increased in both the cooking and non-cooking fermentation systems at the early stage of fermentation, but decreased in the latter period. The concentration of isoamyl acetate derived from isoamyl alcohol increased during the latter period of fermentation in the non-cooking fermentation system ([Fig. 3](#)). The amounts of b-phenethyl alcohol and b-phenethyl acetate formed in both the cooking and non-cooking fermentation systems are shown in [Fig. 4](#). Both components were present at different concentrations in the cooking and non-cooking fermentation systems but the concentrations increased with the progression of the fermentation and then reached a constant level ([Fig. 4](#)).

[*Fig.3:Time course of isoamyl alcohol and isoamyl acetate concentrations in mash during batch fermentation using the bench-scale plant\(23KB\)*](#)

[*Fig.4:Time course of ²-phenethyl alcol and²-phenethyl acetate concentrations in mash during batch fermentation using the bench-scale plant\(23KB\)*](#)

Since the changes in the concentrations of ethyl myristate, ethyl oleate and ethyl linoleate showed almost the same behavior, the increase of the concentration of ethyl linoleate is shown in [Fig. 5](#). The amount of ethyl linoleate reached the highest level during the middle stages of fermentation in the cooking fermentation system and decreased in the latter period of fermentation, whereas the ethyl linoleate concentration increased during the latter period of the fermentation in the non-cooking fermentation system. The analytical values of the flavor components with a high boiling point therefore confirmed the data from the small-scale fermentation test, the values being 11/32 as high as the values obtained in the conventional method (small-scale fermentation test²). A system using the enzyme preparation E was therefore considered to be suitable for the production of mild spirit.

[*Fig.5:Time course of ethyl linoleate concentrations in mash during batch fermentation using the bench-scale plant\(19KB\)*](#)

The above results suggest that the concentrations of all the aroma and flavor components formed with low, medium and high boiling points were high in the non-cooking fermentation system. These results are similar to those obtained in the small-scale fermentation test as described in the previous report²⁾, because the free fatty acids contained in the raw materials were volatilized by cooking⁷⁾.

3) Effect of distillation method on aroma and flavor product components

The mashes from the non-cooking and cooking fermentation systems were subjected to atmospheric and vacuum distillations using the same still. The sensory test for the products was carried out according to a 5-point method by 14 panelists.

The ratios of the principal aroma and flavor components in the distillate produced by vacuum distillation are shown in [Fig. 6](#). In the sensory test, the value for the product obtained by the non-cooking fermentation method was satisfactory, 2.64 compared with 2.86 for the product obtained by the cooking fermentation method. As mentioned above, these results were due to the high concentration of the flavor components of the products obtained by distillation, and the higher concentrations of the flavor components from the mash in the non-cooking fermentation system compared with the mash in the cooking fermentation system. The product obtained by the cooking fermentation system was of a dry type because the aroma was weak and almost no higher fatty acid esters were detected. In contrast, the product obtained by the non-cooking fermentation system had a good aroma and mild taste because the concentrations of flavor components with low and medium boiling points were higher. The A/B ratio was as high as 2.6 but the taste was rather dry because of the low concentration of higher fatty acid esters.

[Fig.6:Sensory test of spirit \(25% \(v/v\)\) made by the application of the non-cooking and cooking fermentation with the saccharifying enzyme preparation E\(42KB\)](#)

The ratios of the principal aroma and flavor components of the products obtained by atmospheric distillation are also shown in [Fig. 6](#). Generally, both aroma and flavor components are present in large quantities in spirits distilled under atmospheric pressure, but a product with well-balanced A/B, A/P (isoamyl alcohol/*n*-propyl alcohol) and B/P (isobutyl alcohol/*n*-propyl alcohol) ratios of higher alcohols is preferable⁴⁾. Spirit obtained by the cooking fermentation method had a low A/B ratio (1.34 and 1.32 under vacuum and atmospheric distillation, respectively) because isobutyl alcohol was present in large quantities. However, spirit obtained by the non-cooking fermentation method had a high A/B ratio (2.6 under both vacuum and atmospheric distillation) because isoamyl alcohol was present at higher concentrations. As the product obtained by atmospheric distillation had a slightly increased higher fatty acid ester content than that obtained by vacuum distillation, it was superior to the product obtained by vacuum distillation in terms of roundness to receive an evaluation point of 2.28. This product therefore could satisfy the taste of the public.

It has been stated that the characteristics of the raw materials are well developed in the product obtained by the non-cooking fermentation method⁶⁾. In this study, the product obtained by the non-cooking fermentation method was superior to that obtained by the cooking fermentation method in terms of both aroma and flavor components. The product had a milder taste than that obtained by atmospheric distillation from the second mash in the conventional method. This was due to the low fatty ester content, as shown in [Fig. 6](#) in this paper and Table 5 in the previous report²⁾. Therefore, this product received a high evaluation point from the panelists.

4) Conditions used in the case study in the shochu spirit factory

4) Conditions used in the case study in the shochu spirit factory

The shochu spirit factory surveyed this time used 630 kg of rice per fermentation, and the proportion of raw materials and water is shown in [Table 1](#). Two workers were engaged in the factory's manufacturing process: 650 L of crude shochu was manufactured from 630 kg of raw materials with an alcohol percentage of 43.5%. Considering that the ordinary percentage of alcohol of distributed shochu is 25%, the value can be converted to 1,131 L of commercialized shochu. Although the case study was carried out under these conditions, the cost calculation will be based on the conversion of actually measured figures 1,131 L into 1,000 L (1,131 L/1,000 L).

Table 1. Proportion of raw materials and water

	<u>First fermentation</u>	<u>Second fermentation</u>	<u>Total</u>
Rice koji	180 kg		180 kg
Rice (main raw material)		450 kg	450 kg
Water	216 L	792 L	1,008 L

Regarding the energy aspect, the amount of water in the boiler, exhaust gas temperature, oxygen concentration in exhaust gas, the amount of heavy oil used, the amount of drain of the koji-making machine and the amount of drain of the distillation machine were measured, and the energy consumption was examined. The total energy consumption required to manufacture 1,000 L of 25% shochu is shown in [Table 2](#). The steam amount in a shochu factory using 630 kg of rice was 656 kcal/kg, and 172 L as A-grade heavy oil.

Table 2. Ratio of working process and workers^{a)}

<u>Manufacturing process</u>	<u>Ratio of process</u>	<u>Workers</u>	<u>Note</u>
Raw material treatment	11.0 (%)	0.22(person)	Saving of labor 0.75 person x 20,000yen = 15,000 yen
Koji process	19.1	0.38	
First fermentation	7.7	0.15	
Second fermentation	32.0	0.64	
Distillation	18.0	0.36	
Refining & blending	3.6	0.02	
Others	8.1	0.16	
----- Total	100.0	2.00	-----

Two workers were engaged in the manufacturing process and the number of worked hours depending on each process is shown in [Table 3](#). By introducing an automatic koji process machine, the ratio of the koji process which is the most time and labor-consuming process during the manufacture process, decreased to 19.1%. The characteristics of the non-cooking fermentation system removed the processes of rice steaming, koji-making and the first fermentation stage. Without these processes, 0.75 manpower could be saved. If the daily wage for 1 person is 20,000yen, 15,000yen can be saved.

Table 3. Consumption of energy for working process an cost

<u>Current manufacturing process(A)</u>	<u>Manufacturing process in non-cooking fermentation system(B)</u>	<u>(A-B)/(A)</u>	<u>A-B</u>
---	--	------------------	------------

4) Conditions used in the case study in the shochu spirit factory

Amount of energy	Amount of steam	1,851.1 L	1,352.8 L		
		-----	-----	26.8%	2,259 yen
	A heavy oil	172.0 L	125.9 L

		2.00 persons	1.25 persons		
Saving		-----	-----		
		20,000yen x 2.00 persons = 40,000yen	20,000yen x 1.25 persons = 25,000yen	37.5%	15,000 yen
		-----	-----		
			--		32,230 yen

The manufacturing cost per 1 kg of koji, including the raw material cost was 299yen, and in this factory the koji cost was 53,800yen. The koji manufacturing cost excluding the raw material cost was therefore 24,155yen. In the non-cooking fermentation system, as mentioned before, enzyme and citric acid were used. The cost of the enzyme was 4,504yen (1,126 g x 4yen) and that of citric acid was 4,680yen (1,800 g x 2.6yen).

5) Economic aspects of the introduction of the non-cooking fermentation system into a rice shochu factory

In taking account of the energy consumption and labor force, the present conditions of a medium rice shochu factory were examined. Thereafter the economic effectiveness of the introduction of the non-cooking fermentation system into this shochu factory, was estimated. Since the non-cooking fermentation system is characterized by the elimination of the rice steaming process, energy can be saved and thus manpower in the manufacturing process can also be reduced. Due to the possibility of reducing labor to 38.8% and eliminating the first fermentation stage in the manufacturing process, it was possible to reduce the whole process to half. Based on the results obtained, a comparison between the existing manufacturing system and the non-cooking fermentation system is shown in Table 3. In terms of energy, 2,259 yen could be saved and this figure represented 26.8% of the whole energy cost. Since the koji process could be eliminated, 24,173 yen could possibly be saved. However, a sum of 4,504 yen for enzyme treatment and 9,184 yen for citric acid is necessary in the non-cooking fermentation system. Based on the figures listed above, a total sum of 14,471 yen could be saved. Due to labor-saving, 15,000 yen could be saved resulting in an economic benefit of 32,248 yen in terms of cost-saving. In addition, since the non-cooking fermentation system can be applied to the existing facility, new plant and equipment investment is not necessary. As a result, in the process of manufacturing 1,000 L of 25% alcohol shochu, it was evident that 32,248 yen could be saved, suggesting that 58 yen per bottle of ordinarily distributed 25% shochu could be saved, which amounted approximately to 10% of the cost of shochu production.

Isolation of Individual Quantitative Trait Loci Causing Long Grain in Rice

Tsuneo KATO

School of Bioresources, Hiroshima Prefectural University (Shobara, Hiroshima, 727-0023 Japan)

Abstract

To evaluate the gene action and interaction of quantitative trait loci (QTLs) as a single Mendelian factor, attempts were made in this study to isolate individual QTLs causing long grain in a large-grain rice cultivar 'BG 1', in other words, to establish a series of near-isogenic lines which had long-grain alleles derived from BG 1 at only one QTL and the short-grain alleles at the other QTLs. In the course of developing recombinant inbred lines from the cross between BG 1 and a short-grain cultivar Koshihikari, the lines were surveyed through backcrossing of the recombinant inbreds and by progeny test. Until the BC₂F₂ generation, a total of 8 lines, which obviously showed monogenic segregation within the respective progenies in which a single QTL was involved, were obtained. All of the long-grain alleles at the isolated QTLs were recessive to the short-grain alleles. The process of isolation of 2 different QTLs was described in detail as an example of the strategy adopted in this study. These isolines for isolated QTLs should contribute significantly not only to the characterization of individual QTLs and their combinations but also to breeding programs as gene sources to be used directly.

Discipline: Plant breeding

Introduction

Most of the agronomic traits exhibit continuous variations in populations consisting of different genotypes, like genetically segregating populations after crossing. These traits are referred to as quantitative traits, and their genetic control is attributed to a number of loci which are designated as quantitative trait loci (QTLs), or polygenes. Generally, each of the QTLs is assumed to affect the trait cumulatively and less dominantly compared with non-genetic factors. As a result, it is very difficult to evaluate QTLs individually for their locations along chromosomes as well as their gene actions and interactions.

Some efforts have been made to localize the individual QTLs along chromosomes by detecting linkage relationships between QTLs and some suitable genetic markers^{7,11}). Recent advances in molecular biology have provided many kinds of molecular markers which can cover all the chromosomes with a high density. Using these high-resolution molecular linkage maps with an adequate software, a large number of QTLs controlling various complex agronomic characters have been located in limited chromosomal regions in many crops^{1,10}). Several kinds of software for the QTL mapping can also estimate some of the gene effects for each QTL, the interaction of QTL with the environment, etc., from the same mapping population^{6,12}).

From a plant breeder's standpoint, on the other hand, it is very important to evaluate the gene actions of individual QTLs as single Mendelian factors which can actually show monogenic segregation, and not as

regions estimated on the linkage map by calculations under some assumptions. To achieve this kind of QTL evaluation, it is essential to isolate the individual QTLs through recombination and selection. This QTL isolation so far has not been sufficiently carried out, because it is a time-consuming procedure.

In this study special attention was paid to the grain length of rice as an example of quantitative trait, because this trait was generally considered to be controlled by a number of QTLs, as well as a single major gene, and had agronomic significance in determining the grain size and finally the grain yield in this crop. In the current study, then, attempts were made to isolate the individual QTLs causing long grain length in a large-grain rice cultivar 'BG 1'. The final objective is to establish a series of near-isogenic lines with long-grain alleles derived from BG 1 at only one QTL and short-grain alleles at the other QTLs in relation to grain length. Although this objective has not been fully achieved yet, in this paper, the progress made and some of the results obtained are reported.

Materials and methods

A rice (*Oryza sativa* L.) cultivar BG 1 showing an extremely large (long) grain size⁸ was crossed as a female parent with a cultivar 'Koshihikari' showing a small (short) grain size (or a standard grain size in Japanese cultivars). Fifty F₂-derived F₅ progeny lines, which corresponded nearly to a set of recombinant inbred lines, were developed by the single-seed descent method from randomly selected F₂ plants of this cross-combination. In the F₅ population, several recombinant inbred lines showing different grain lengths were selected and crossed as a male parent with a cultivar 'Gimbozu' which showed a nearly equal or shorter grain length compared with Koshihikari. The crosses between recombinant inbreds and Gimbozu aimed at estimating the number of QTLs related to grain length involved in these inbreds. In each F₂ population of these crosses, F₂-derived progeny lines were developed from several F₂ plants with different grain lengths. Among these F₂-derived lines, the candidates which seemed to have only one QTL carrying the allele for long grain from BG 1 were crossed with Gimbozu recurrently until monogenic segregation in grain length was clearly confirmed within the respective progeny lines. Allelism test for long grain length was conducted when different lines of interest were obtained in the course of the study.

Grain length of a plant was determined as the average length of 5 unhulled grains collected from the basal parts of the 3rd, 4th, and 5th primary branches from the top of a typical panicle of this plant. The length of an unhulled grain was measured as the distance between the top of the apiculus except for awn and the bottom of the glume up to the F₅ generation after the crossing of BG 1/Koshihikari. From the F₁ generation of the crosses between recombinant inbreds and Gimbozu, the distance between the base of the apiculus and the bottom of the palea was defined as grain length.

(Received for publication, January 5, 1998)

Results and discussion

Fig. 1 shows the changes in the frequency distribution for grain length with generation advancement after the crossing of BG 1/Koshihikari. In the F₂ and F₃ generations, typical continuous distributions were observed for this trait, indicating that the genetic difference in grain length between these 2 parents was due to a number of QTLs and not to a single locus. In the F₄ and F₅ generations, on the other hand, several peaks emerged in the distribution, resulting in a multimodal distribution. In addition, several F₂-derived lines appeared to show within-family segregation in a monogenic manner in the F₃ and F₄ generations (data not shown). This monogenic-like segregation within a derived line had already been observed by Takita⁹⁾ in his materials. In all the generations, no plant exhibited extreme transgressive segregation beyond the range between the 2 parents.

[Fig.1: Frequency distribution of grain length in F₂, F₃, F₄, and F₅ populations from the cross of BG 1/Koshihikari, developed by the single-seed descent method \(23 KB\)](#)

These results suggest that every QTL for grain length converged into either of the parental genotypes, a large-grain homozygote (BG 1 type) or a short-grain homozygote (Koshihikari type). The population thus consisted of several and not numerous kinds of recombinant homozygotes showing different grain lengths by F₄ and F₅ generations. Among these homozygotes, there were genotypes where only one or a few QTLs carried the alleles for long grain derived from BG 1. Several recombinant inbred lines with different grain lengths were selected and crossed with a cultivar Gimbozu to estimate the number of QTLs carrying the long-grain allele in their genotypes and to initiate backcrossing. The use of Gimbozu instead of Koshihikari as a recurrent parent aimed at comparing other kinds of near-isogenic lines involving major genes for long grain under the same background as that of Gimbozu⁴⁾. As an example of the following processes, the progenies of the cross between Gimbozu and a recombinant inbred T34 are described hereafter.

A part of **Fig. 2** shows the distribution of grain length in the F₂ population of Gimbozu/T34. Apparently, a bimodal-like distribution was observed in this population, in contrast with the distribution in the F₂ population of BG 1/Koshihikari (**Fig. 1**). A total of 20 F₂ plants with different grain lengths was selected and F₂-derived F₃ progeny lines were developed for the progeny test of grain length. The other part of **Fig. 2** shows the distributions in 7 F₃ lines out of 20, as examples. In this figure, several types of F₃ lines could be distinguished: non-segregating lines whose single modes of grain length were similar to that of either of the parents, Gimbozu (line *a* in Fig. 2) or T34 (*g*); non-segregating lines whose single modes showed either of the 2 intermediates between the 2 parents (*c* and *e*); and segregating lines which showed discontinuous distributions with 2 modes or more (*b*, *d*, and *f*). In the segregating F₃ lines, each of the modes in the distribution roughly corresponded to one of the modes of the parents and intermediates.

[Fig. 2: Frequency distribution of grain length in the F₂ population and F₂-derived F₃ lines from the cross of Gimbozu/T34 \(a recombinant inbred from BG1/Koshihikari\)\(23 KB\)](#)

These results imply that a recombinant inbred line T34 received the alleles for long grain from BG 1 at 2 different QTLs, and the alleles for short grain from Koshihikari at the other QTLs. Each of the F₂-derived

F₃ lines showing an intermediate grain length, i.e. line c and line e in [Fig. 2](#), should have either of the 2 QTLs as above where the long-grain allele from BG 1 occurred under a homozygous condition, whereas the segregating lines, lines b, d, and f, had these QTLs under heterozygous conditions. These lines of intermediate grain lengths, therefore, might indeed be the final objectives in this study. After checking homozygosity for grain length in the F₄ generation, each F₄ progeny of these lines was crossed as a female donor parent with Gimbozu.

[Fig. 3](#) shows the segregation of grain length in the BC₁F₂ populations (Gimbozu/T34//Gimbozu). The donor parents of the populations depicted in Fig. 3-a and -b were the progenies of line c and line e shown in Fig. 2, respectively. Obviously, a bimodal distribution in grain length was observed in each population. In Fig. 3 the results of the progeny test using BC₁F₃ families derived from individual BC₁F₂ plants were superimposed. The ratio of the short-grain, segregating, and long-grain families fitted well to the expected ratio of 1:2:1 ($\chi^2 = 1.51$ and 0.08 in Fig. 3-a and -b, respectively). The range of grain length of the short-grain group considerably overlapped with the range of Gimbozu in each population. These results strongly suggest that in both populations only one QTL should be involved in the segregation of grain length, and the short-grain allele at this QTL was dominant over the long-grain allele. Consequently, it is concluded that, in the long-grain segregants of each BC₁F₂ population, a single QTL should be isolated as a monogenically segregating factor from a number of QTLs causing long grain in BG 1. In each population, one of these segregants was subjected to successive recurrent backcrossings with Gimbozu, and also to allelism tests between these 2 QTLs.

[Fig. 3: Frequency distribution of grain length in the BC₁F₂ populations \(Gimbozu/T34//Gimbozu\)\(21 KB\)](#)

[Fig. 4](#) shows the segregation of grain length in the BC₂F₂ populations. Apparently, typical monogenic segregation with a ratio of 3 short- to 1 long-grain group was observed ($=\chi^2 1.63$ and 0.01 in Fig. 4-a and -b, respectively), confirming that only one QTL carried the recessive allele for long grain in the long-grain segregants in each population. The average grain length of the long-grain group in Fig. 4-a was obviously shorter than that of the long-grain group in Fig. 4-b. Also, as observed in [Fig. 2](#), the average grain length of line c, was shorter than that of line e. These results suggest that in the 2 isolated QTLs gene expression showed different magnitudes.

[Fig. 4: Frequency distribution of grain length in the BC₂F₂ populations \(Gimbozu/T34//2*Gimbozu\) \(13 KB\)](#)

[Fig. 5](#) shows the results of the allelism test between the 2 isolated QTLs as indicated above, where a continuous distribution with a wide range was observed in this F₂ population, although no transgressive segregant in the direction of shorter grain length was recorded. The results of the allelism test confirmed that the 2 isolated QTLs for long grain were different from each other. The isolated QTLs in the populations shown in Fig. 4-a and -b were, thus, tentatively designated as 'QTL-A' and 'QTL-B', respectively. As shown in Fig. 5, there were many transgressive segregants beyond the grain length of the parent with longer grain (a long-grain segregant shown in Fig. 3-b) which should include the QTL-B. This fact indicates that QTL-A and QTL-B induced long grain in an additive manner. Hence, the genetic variation of grain length depicted in Fig. 5, and also in Fig. 2, might be attributed mainly to the

segregation in QTL-B and partly to that in QTL-A.

[Fig. 5: Frequency distribution of grain length in the F₂ population from the cross between a long-grain segregant of BC₁F₂ shown in Fig. 3-a and that in Fig. 3-b \(13 KB\)](#)

Until the BC₂F₂ generation, 6 QTLs for long grain were isolated besides the QTL-A and QTL-B via other recombinant inbreds than T34, although allelism test among them has not been completed. In all of the isolated QTLs, the short-grain alleles were dominant over the corresponding long-grain alleles. Kato³) conducted a diallel analysis of rice grain length using 6 cultivars including BG 1 and Koshihikari, the parents of the progenies used in this study. In this analysis, the genes conferring long grain were considered to be recessive, and BG 1 and Koshihikari were assigned to a completely recessive parent and a completely dominant parent, respectively. These results from the diallel analysis agreed well with the present results.

A series of isolines involving every single QTL, the final objective of the attempt as described above, corresponded to the "substitution lines" for chromosomal regions which are expected to be a very suitable tool for analyzing QTL action and location^{5,13}). In rice, several QTLs related to heading date¹³) and one QTL related to grain width²) had already been isolated as a form of near-isogenic lines through backcrossing by monitoring the graphical genotypes of the progenies. The actions and interactions were evaluated also for the QTLs of heading date using these isolines¹⁴). The present attempt will be continued until every QTL causing long grain, at least with sufficient gene action to be detected, is isolated. The tagging of individual QTLs with molecular markers should certainly facilitate the enumeration and handling of the QTLs in this study, whereas the detection of suitable markers has not fully progressed because of insufficient polymorphisms among the present materials. In any case, these isolines for individual QTLs may raise various issues about the nature of a quantitative trait. In addition, plant breeders could directly utilize these materials themselves as gene sources in their breeding programs. A larger number of QTLs should be isolated as a monogenic Mendelian factor in various agronomic traits for achieving these purposes.

Optimizing the Particle Bombardment Method for Efficient Genetic Transformation

Takashi HAGIO

Department of Biotechnology, National Institute of Agrobiological Resources
(Tsukuba, Ibaraki, 305-8602 Japan)

Abstract

Particle bombardment method has evolved into a useful tool for biotechnologists, allowing direct gene transfer to a broad range of cells and tissues over the past several years. Some of the important applications of the process include the production of fertile transgenic crops including maize, soybean, rice, wheat, barley, sorghum, etc. Recent results have extended the range of gene transfer to animal and bacterial cells. In this article the method of particle bombardment is reviewed and discussed, and practical suggestions for improving transformation efficiency are presented.

Discipline: Biotechnology

Additional key words: biolistic, particle gun, direct gene transfer

1~49): [Click here for References](#)

Introduction to particle bombardment method

Particle bombardment method which is one of the technologies for introducing foreign genes into cells was developed by John Sanford and co-workers^{23, 37)} at Cornell University in the United States. This technique involves accelerating DNA-coated particles (microprojectiles) directly into intact tissues or cells. The research was conducted with a view to avoiding the host-range restrictions of *Agrobacterium tumefaciens*, and the regeneration problems of protoplast transformation.

In the early system, DNA-coated tungsten powder (spherical particles 4 μ m in diameter) was placed, as a suspension in a small aqueous volume, at the front end of a bullet-like plastic macroprojectile ([Fig. 1](#)). The macroprojectile was accelerated by a gunpowder charge. Upon impact with a plastic stopping plate at the end of the acceleration tube, the macroprojectile extruded through a small orifice. This extrusion further accelerated the microprojectiles. Although the gunpowder model was found to be successful for genetic transformation of various plant species in several laboratories, lack of control over the power of the bombardment as well as physical damage to target cells limited the number of stable transformations^{22, 37)}.

[Fig.1: Schematic diagrams of the gunpowder-driven particle gun developed by Klein et al.25\) \(18KB\)](#)

The current model, PDS-1000/HeTM, which is now marketed by BIO RAD Laboratories, represents a significant technical improvement over the gunpowder device. The basic design was developed by Sanford et al.³⁷⁾. The PDS-1000/HeTM device is powered by a burst of helium gas that accelerates a macrocarrier, upon which millions of DNA-coated microcarriers have been dried ([Figs. 2 and 3](#)). Compared to the gunpowder device, it is cleaner and safer, allows better control over bombardment parameter, distributes microcarriers more uniformly over target cells, is more gentle to target cells, is

more consistent from bombardment to bombardment, and yields several fold more transformations in the species tested²²).

[**Fig.2: Schematic diagrams of the helium-driven particle gun\(from the catalog of BIO RAD PDS-1000/HeTM\) \(14 KB\)**](#)

[**Fig.3 Helium-driven particle gun \(BIO RAD PDS-1000/HeTM\)\(15 KB\)**](#)

Sanford et al.³⁸) suggested the term "biolistic" which is a coined word derived from "biological and ballistic", though the terms particle gun or particle bombardment are becoming generic terms. This method has also been called the microprojectile bombardment method, the gene gun method, the particle acceleration method, etc. Therefore, one must pay attention to the choice of key words when searching for literature.

Since the development of the first particle bombardment system, several different types of bombardment devices have been developed, including an electrically triggered discharge gun²⁹), pneumatic particle guns³²), helium, nitrogen and carbon dioxide-powered devices^{13,43}) and a micro-targeting gun³⁹). These devices have been developed toward the same goals: more simplicity, safety, accuracy, and a lower cost for DNA delivery⁵). The basic principle of all these devices is the same as that originally developed by Sanford and co-workers^{23,25,37}).

This method was originally developed as a means of delivering foreign genes into the nuclear genome of higher plants and successful transformation of a wide range of tissues in a wide range of plant species was reported ([**Table 1**](#)). Tested plant tissues include cell suspensions, calli, immature embryos, microspores, etc. Transformed species include those for which transformation was otherwise impossible or very difficult.

[**Table 1: Production of transgenic plants by particle bombardment \(focused mainly on cereals\) \(46 KB\)**](#)

This method has also been found to be effective in microbial species, including *Bacillus megaterium*, *Pseudomonas syringae*, *Agrobacterium tumefaciens*, *Erwinia amylovora*, *Escherichia coli*, etc.³⁸). It first made possible the transformation of organelles. Chloroplasts of *Chlamydomonas*³) and mitochondria of yeast and *Chlamydomonas*²¹) can be transformed. In 1990, Svab et al.⁴²) reported the transformation of animal cells using particle bombardment.

In 1996, the advanced design of the hand-held particle gun was released in the U.S.A. It has become commercially available in Japan since March 1997. This device called "HeliosTM Gene Gun System" is marketed by BIO RAD ([**Fig. 4**](#)). In contrast to the conventional particle guns where the overall size of the target to be transformed is limited by the size of the chamber and the target tissue is subject to a vacuum during bombardment, the new device does not require vacuum and any target accessible to the barrel can be transformed. It may be used in a much wider variety of gene transfer applications and provides a tool for both *in vitro* and *in vivo* transformations.

[**Fig.4: Hand-held particle gun \(BIO RAD HeliosTM Gene Gun System\) \(16KB\)**](#)

In this article the method of particle bombardment is reviewed and discussed, and practical suggestions for improving transformation efficiency are presented. Most of the discussion will relate to BIO RAD

PDS-1000/He™ which was developed by Sanford et al.(23,37) and is most widely used in the world. Basic principle of the particle bombardment method is the same regardless of the device used.

Characteristics of the method

This method has become the second most widely used vehicle for plant genetic transformation after *Agrobacterium*-mediated transformation⁹). The number of researchers using particle gun has been increasing in spite of the availability of protoplast transformation because the protoplast-to-plant method of obtaining transgenic plants is laborious and time-consuming⁹).

This method of genetic transformation offers both advantages and disadvantages over *Agrobacterium* or protoplast-mediated transformation as follows.

1) Advantages

(1) Almost any kinds of cells or tissues can be treated.

(2) Device operation is easy.

Transformation protocols are simplified. A large number of samples can be treated within a short time by technicians once the method has been routinized by researchers.

(3) Plasmid construction is simplified.

DNA sequences essential for T-DNA replication and transfer in *Agrobacterium* are not required. Furthermore, the introduction of multiple plasmids (co-transformation) is routinely accomplished.

(4) False positive results arising from the growth of *Agrobacterium* in host tissues are eliminated.

(5) Small amount of plasmid DNA is required. Only 0.8 μ g DNA is required for one bombardment in BIO RAD PDS-1000/HeTM.

(6) Transient gene expression can be examined within a few days.

It is conveniently used for evaluating transient expression of different gene constructs in intact tissues.

2) Disadvantages

(1) Generally, transformation efficiency is still low.

Even though this method has become one of the most widely used vehicles for plant genetic transformation, transformation frequency is still low compared with *Agrobacterium*-mediated or protoplast transformation.

(2) Consumable items are expensive in some models.

The cost of one bombardment is 260 yen in the case of BIO RAD PDS-1000/HeTM using standard pressure kit (130,000 yen for 500 bombardments).

(3) One must consider patent royalty in commercial use.

This is a very delicate and complicated issue. One should consult with a specialist in patent issues.

Basic operation of the device

BIO RAD PDS-1000/HeTM is routinely used in our laboratory. The protocol we currently use to prepare DNA-coated microcarrier (tungsten or gold particles) is as follows. The method is generally applied by following the instruction manual but some modifications were made by the author to enhance the transformation efficiency. This is one of the most important sources of variation affecting the transformation efficiency³⁸). One should strive to make the precipitation reaction mixture as homogeneous and reproducible as possible.

(1) Vortex the microcarrier suspension prepared in 50% glycerol (60 mg/mL) for at least 5 min on a platform vortex (Fig. 5) to resuspend and disrupt agglomerated particles. [Fig.5: Platform vortexTM \(23 KB\)](#)

(2) Remove 5 μ L (3 mg) of microcarrier suspension and put it into a 1.5 mL microfuge tube. It is important to vortex the tube containing the microcarriers continuously in order to maximize uniform sampling. In the previous manual, it was recommended that particles be sonicated to maximize uniform sampling. From the author's experience this is not beneficial and under certain conditions can make particle agglomeration worse rather than better, especially when gold particles are used.

(3) While vortexing vigorously, add in order:

5 μ L DNA (1 μ g/ μ L),

50 μ L CaCl₂ (2.5 M),

20 μ L spermidine (free-base, 0.1 M).

(4) Continue vortexing for 3 min.

(5) Allow the microcarriers to settle for 3 min.

(6) Pellet microcarriers by spinning 2 sec in a micro-centrifuge. (approx. 5,000 rpm)

(7) Remove liquid and discard.

(8) Add 150 μ L of 70 % ethanol without disturbing the pellet.

(9) Remove liquid and discard.

(10) Add 150 μ L of 100 % ethanol without disturbing the pellet. 99.5 % ethanol can also be used.

(11) Remove liquid and discard.

(12) Add 55 - 60 μ L of 100 % ethanol. 99.5 % ethanol can also be used.

(13) Resuspend the pellet by tapping the side of the tube.

(14) Remove 6 μ L aliquots of microcarriers and transfer them to the center of a macrocarrier.

Spread microcarriers over the central 1 cm of the macrocarrier ([Fig. 6](#)).

Wait until microcarriers dry.

[Fig.6: Coating microcarriers \(DNA-coated particles\) over a macrocarrier. \(13 KB\)](#)

If fewer bombardments are needed, prepare enough microcarriers for 3 bombardments by reducing all volumes by one-half.

The operation of the device is as follows. The method is generally applied by following the instruction manual but some modifications were also made by the author. Regardless of the apparatus used the basic

principle of how to bombard the target is the same.

- (1) Turn on the vacuum pump and the power switch.
- (2) Set the helium regulator roughly at 200 psi above the selected rupture disk.
- (3) Load the rupture disk.
- (4) Load the stopping screen.
- (5) Load the microcarrier assembly.
- (6) Place the target cells or tissue.
- (7) Press the VAC switch.
- (8) When the vacuum gauge registers the desired vacuum level (above 27.5), put the VAC switch on the HOLD position.
- (9) Turn off the vacuum pump to prevent overheating.
- (10) Keep pressing the FIRE button until the rupture disk automatically bursts.
- (11) After the bombardment is completed, put the VAC switch on the VENT position.
- (12) Remove the sample.
- (13) Remove the microcarrier assembly. Stopping screen may be used a few more times.
- (14) Remove the rupture disk. If you continue the work, repeat the process from (3).
- (15) Clean the chamber with 70% ethanol.
- (16) Close the valve of helium tank.
- (17) Release the helium from the device.
- (18) Turn off the power switch.

[BACK](#)

Improvement of the method for more efficient gene transfer

In some research articles the authors stated that "Particle bombardment is an efficient method for delivery of DNA into plant cells. This method is especially beneficial for those plants which appear to be a poor host for *Agrobacterium*."5), "Particle bombardment offers a rapid method for delivery of DNA to plant cells for both transient gene expression and stable transformation studies."13), or "These advances have given us the opportunity to create, characterize and select plant cultivars which could not be obtained by traditional breeding methods."11).

Although such optimism is understandable and gives a reader hopes for the future, my experience in working towards genetic transformation using particle gun convinces me that we still have problems to overcome. Success requires more than occasional gene transfer into experimentally well-suited varieties of some species. It requires routine and efficient gene transfer into any desired variety of any species34).

Some suggestions for improving transformation efficiency which are presented below are based on our accumulated experience and are still more empirical than scientific, in the author's laboratory.

(1) Water:

Use autoclaved ultra pure water when preparing buffers and solutions.

(2) Spermidine:

After adjusting the concentration to 0.1 M, pour the solution into 1.5 mL microcentrifuge tubes. Keep them in a deep freezer (- 80°C). At the start, when the solution is being used, keep the tube in an ordinary freezer (- 20°C) and finish using it within 2 weeks. Discard it even if some solution is left after 2 weeks.

(3) Ethanol:

Use fresh ethanol. When using 70% ethanol, prepare it just before the experiment. Absolute ethanol is better than commercially available 99.5% ethanol. Molecular sieve(SIGMA, M-9882) is recommended to absorb water in ethanol.

(4) Particle wash:

Remove the supernatant as much as possible. After the second wash with absolute ethanol, one more ethanol wash is recommended to remove the residues of spermidine and water. Once particles have been coated with DNA they should be used as soon as possible.

(5) Centrifuge:

The particles must be gently pelleted. Lower speed is recommended (3,000-5,000 rpm for 1-2 sec is enough). Higher speed enhances particle agglomeration.

(6) Plasmid DNA:

Plasmid DNA must be very pure. Do not use the sample containing RNA sometimes derived from miniprep extraction method.

(7) Carrier DNA:

Do not use carrier DNA. Carrier DNA is often used in electroporation of protoplasts but carrier DNA is also absorbed by the particles.

(8) Microcarrier (particle) coating on the macrocarrier:

Uniform coating is very important. For more reproducible coating procedures one needs some practice to master the uniform coating method. DNA-coated macrocarrier should be used within 2 h.

(9) Osmoticum (Osmotic treatment):

Addition of an osmoticum (mannitol or sorbitol) to the bombardment medium increases the rates of transient and stable transformation 44). The author has observed that this holds true for some plant species, although the optimum concentration for each species varies. Increased osmoticum concentrations may enable to protect the cells from leakage and bursting, and may also improve particle penetration itself. The optimum osmotic concentration for tobacco BY-2 cell is approximately 0.4-0.5 M mannitol, however, the cells grow slowly.

(10) Routinize:

Operation of the particle gun device itself is easy. The method can be routinized once the researcher sets up the bombardment parameters.

(11) Bombardment of the sample in which there are no references about the bombardment parameters:

The following conditions are applied in the author's laboratory.

Microcarrier : 1.6 μ m gold particles.

Target position : 9 cm from the stopping screen to the target cells or tissues.

Helium gas pressure : 1,100 psi and 1,300 psi.

Bombardment time : 2 times per sample.

Promoter gene : Dicot ; 35 S,

Monocot ; 35 S, Adh, or rice actin.

Reporter gene : *Gus*.

If there are no blue spots, another method of gene transfer or construction of the new promoter suited to the sample is strongly recommended. If there are one or more blue spots, it is suggested that the experiment should be continued to identify optimum conditions.

Conclusion

It is not necessary to rely on the particle bombardment method if *Agrobacterium* or a protoplast transformation system is available because the transformation frequency of particle bombardment is still low. The method is sometimes too labor-intensive and rather expensive to obtain large numbers of independently transformed plants.

The author considers that the protoplast transformation system is most appropriate. The advantage of isolated protoplasts is that they represent a true single cell system because each protoplast is completely separated from other cells and gene transfer can be performed by a relatively simple method without using specialized equipment like a particle gun. An electroporator device is easily constructed and is also commercially available. The PEG method does not require any special device.

Particle bombardment is certainly not a panacea. There are still major technical and scientific obstacles that need to be overcome in order to bring the technology to its full potential¹¹). However, in the past few years the author learned a great deal about how to make the process more effective. Some research

groups including ours are still trying to determine how to optimize the process with its diverse fields of application.

In the near future this method will become a tool for wider application of molecular and genetic approaches to crop improvement.

Development of Automatic Fog Culture System for Year-Round Rice Production in Greenhouse

Yuichi NAGAYA*1, Takeshi MATSUOKA*2, Takanori KOBAYASHI*2 and Tetsuro TANIYAMA*1

*1 Faculty of Bioresources, Mie University (Kamihama, Tsu, Mie, 514-8507 Japan)

*2 Matsuoka Sangyo K. K. (Nakamura, Nagoya, Aichi, 450-0003 Japan)

Abstract

Though there are some drawbacks in the design of this rice culture system, the results showed that these can be alleviated. The culture system was set up in a glass greenhouse to avoid yield loss due to typhoon and heavy rain which led to an inadequate amount of solar radiation even during the summer. Inclining the seeding bed southwards at 30° did not enable to improve the light absorption. Some favorable aspects of this fog culture system, however, are worth considering. Subsoil water temperature particularly in winter became more manageable. Carbon dioxide concentration in a particular growth phase could be enhanced. Nutrients could be replenished in the most suitable growing period and with the most appropriate amount. The oxygen supply to the root system was provided adequately during atomization. With all these advantages, year-round production increased 3 times or more due to the absence of seasonal effect. This experiment also indicated that the apparent photosynthetic rate could be enhanced by increasing the amount of insolation and solar energy conversion. This should certainly exert a beneficial effect on the panicle number, ripening efficiency and grain-straw ratio or total grain yield in general. Lastly, our group aims at redesigning the set-up in order to increase the production. In Japan, we are focusing on a stable, high-yielding and automatic year-round rice production while aiming at the same time at preserving the environment by reducing the consumption of expendable energy. To some extent, this study provides a basis for the development of a technology for desert or arid areas and subfrigid zones to increase productivity.

Discipline: Crop production/Agricultural facilities

Additional key words: apparent photosynthetic rate, grain-straw ratio, root system, solar radiation

Introduction

More than half of the 5.8 billion world population is eating rice as staple food. Though rice is usually produced in the tropical zone, Japan has been cultivating rice which is genetically resistant to cold temperature. Moreover, through recent varietal improvement studies, high-yielding cultivars with good quality have been developed. Nowadays, among the rice-producing countries, Japan is considered to be the world's northernmost area.

With the progress in farming technology and varietal improvement, Japanese rice can now withstand cold weather injury^{2,4}). The cold summer in 1993 caused the greatest postwar rice shortage in Japan which led to emergency rice importation. Another factor which is a cause for concern regarding the future supply of rice, the staple food in Japan, is the ageing population of rice farmers with no successors

to continue rice farming. Recently, for rice culture as well as for the production of other crops, heavy input of chemicals and other practices causing environmental pollution have become a global problem^{5,6}).

The objective of this study was to develop a rice culture system that would: 1) minimize yield losses due to natural disasters, 2) reduce environmental pollution, and 3) lead to sustainable year-round production.

This paper reports partial results obtained during several years of research on the development of an automatic fog culture system for rice production.

Automatic fog culture system set-up

A system similar to that shown in [Fig. 1](#) was set up in a glass greenhouse. The cultivation area was 172 cm long and 235 cm wide. To obtain satisfactory sunlight penetration within the rice population and during the winter season, seeding beds were inclined southwards at 30°. A vinyl chloride culture room was constructed inside the glass greenhouse. Room temperature was controlled by an air-conditioner to maintain the most suitable temperature for paddy production. A small scale fan was set up over the paddy so that the leaves would sway constantly to a certain degree. This ventilation helped to secure a satisfactory CO₂ diffusion and a high canopy photosynthetic rate. It was reported that under lowland field conditions, root respiratory activity decreases as the paddy develops and reaches the reproductive phase, causing a remarkable decrease in yield, mainly due to an inadequate oxygen supply in the rhizosphere³. The special characteristic of our rice fog culture set-up is that the root system is aerated. The nutrient solution is atomized intermittently such that the O₂ supply is satisfactory and root growth is optimum. Plant growth decline due to root rot can be avoided using this culture system.

[Fig.1: Automatic fog culture system \(34 KB\)](#)

The composition of the basic nutrient solution (Kasugai A) is shown in [Table 1](#). The concentration of the solution was renewed weekly to compensate the plant nutrient uptake. The nutrient solution temperature, pH and EC were monitored regularly. The pH was adjusted automatically with a NaOH solution using a peristaltic pump to pH 5.0-5.5 which is the optimum pH for rice. The temperature was maintained at 25°C. After noting the difference between the daytime and nighttime temperature, the atomization time was set to be longer during the daytime. During winter the root space and seedbed temperature were kept at 25°C but in the summer planting season the temperature was not regulated.

Table 1. Kasugai A solution used in this experiment

(NH ₄) ₂ SO ₄	188.7 (Unit: mg/L)
Na ₂ HPO ₄	40.0
CaCl ₂	7.9
Fe-EDTA.....	27.4
MnCl ₂	0.75
KCl.....	47.5
SiO ₂	137.3
N.....	40
P ₂ O ₅	20
CaO.....	4
MgO.....	6
K ₂ O.....	30

Foam styrol beads 5.8 mm in diameter were glued onto the bedding material (STIRODOREN, Mitsubishi Chemical BASF Co. Ltd.). With this seeding block, sufficient space is provided between beads so that root elongation becomes easier. Seeding holes were bored as shown in [Fig. 2](#). The orientation of the seed to the seeding box and the space for tillers are illustrated in [Fig. 3](#). The sown seeds were covered with sand up to a thickness of 1 cm to prevent the emerging seeds from moving upwards due to the pressure from the elongating roots. In fact, the permeability of STIRODOREN was quite adequate for the rooting of the rice plant ([Fig. 4](#)). Since rice shows intrinsically a high tillering potential, the sowing holes were oriented transversally to prevent lodging. After heading, when the translocation of photosynthates to the paddy starts, the ear weight becomes heavier and the culm's bending momentum also increases. In the present planting system, however, lodging was not observed because the culm was confined within the walls of the rectangular seeding hole. Moreover, with this bedding material, hill to hill distance and interrow spacing could be manipulated in response to the growth stage such that an optimum leaf area index could be obtained.

[Fig.2: Seeding block and seeding hole \(16 KB\)](#)

[Fig.3: Outline of seeding method \(20 KB\)](#)

[Fig.4: Seeding block, STIRODOREN and rooting of rice \(33 KB\)](#)

In the tropics, the major activity in rice culture is the transplanting of seedlings in the field. In the current system, seeds are sown directly and cultural management is possible from sowing to harvest. Since the seedlings do not undergo transplanting injury, the growing period is shorter⁹). The main advantage of hydroponics is that fertilizer management is considerably easier and can be adjusted depending on the growth stage such that the plant intrinsic photosynthetic capacity can be enhanced.

Furthermore, by using fluorescent lamps and a timer, photoperiodism can be regulated and the plant growth phase modified. The potential of an automatic year-round production scheme is the most remarkable advantage of the current planting system over field cultivation. [Fig. 5](#) illustrates the seeding bed after sowing (vinyl chloride sheets removed). The nutrient solution is sprayed on both top and root sections. This spraying also supplies the water required by the emerging seeds or seedlings. As the seedlings grow, only the underground area is atomized. The time of spraying depends on the elongation of the roots such that nutrient absorption is sufficient for plant growth.

[Fig.5: Seeding bed \(18 KB\)](#)

Materials and methods

Early season variety (*Oryza sativa* L. cv. Koshihikari) and standard season variety (*O. sativa* L. cv. Harebare) were used in this fog culture experiment. After seed treatment to hasten germination, both varieties were sown at a row spacing of 17 cm and hill distance of 12 cm and 14 cm on March 7, 1992. Ordinary tap water was used for the first 6 days before replenishing with the basic nutrient solution (Kasugai A) at gradually increasing concentrations of 0.25, 12.5, 25, 50 to 100%. [Fig. 6](#) clearly shows the relative concentration of the Kasugai A solution in relation to the plant age.

[*Fig.6: Relative concentrations of Kasugai A solution used in fog culture system \(20 KB\)*](#)

Between March 12 - June 1, illumination was provided by fluorescent lamps for 4 h from 6 pm - 10 pm to simulate a long-day environment. Heading was observed on July 10 for Koshihikari, while Harebare headed 8 days later. Apparent photosynthetic rate was measured before heading (July 2). Leaf age, plant length, tiller number, internode length, root length, grain yield and yield components were determined at the harvest stage on August 24, 1992.

Results and discussion

The fluctuations in the maximum, minimum and mean temperatures during the growing period are shown in [Fig. 7](#). The daily maximum temperature exceeded 40°C several times. Moreover, in the second half of the growing period, particularly during the ripening stage, a relatively high temperature was observed. The high temperature after the rainy season affected ripening. Even the daily mean temperature tended to affect the plant growth during the later stage. Tange (1973) reported that for rice growth the optimum temperature is in the range of 30-32°C. Since the present rice culture system was set up inside a glass greenhouse, the temperature build-up was higher than the ambient temperature in the field. The comparatively high temperature was also compounded by the low cooling-off efficiency of the set-up. These observations suggest that the fog culture system could be improved by avoiding the set-up inside a glass or greenhouse with a low cooling efficiency.

[Fig.7: Changes in air temperature during the experiment \(32 KB\)](#)

The concentration of the nutrient solution was adjusted based on the leaf color and growth conditions. Regarding the nutrient balance, a nearly normal transition was observed from the maximum tillering stage to the grain maturation stage. The growing tillers during the active tillering stage are shown in [Fig. 8](#). The changes in the leaf age for both varieties are depicted in [Fig. 9](#). The turning point of the leaf-emergence rate corresponded to the 8th leaf stage. After the 8th leaf had emerged, the leaf-emergence rate was one leaf higher in the Harebare variety. This pattern continued until harvest. Nevertheless, based on the leaf age the growth was considered to be normal. In [Fig. 10](#) the changes in plant length are compared. Harebare grew up to 100 cm while Koshihikari reached 120 cm. Elongated growth was observed in the Koshihikari variety which did not affect significantly the final yield. [Fig. 11](#) shows the changes in the tillering pattern. The Harebare variety continued to develop more tillers during the most active tillering stage. Tiller number was high, as much as 12 tillers per hill which also resulted in a large number of non-productive tillers. On the other hand, non-productive tillers were not observed in the Koshihikari variety. This difference clearly indicates that the tillering potential is a varietal characteristic. In this experiment, the planting density was higher than under the usual paddy field conditions. Based on the response of Koshihikari to dense planting, this variety could be considered to belong to the erect plant type. The changes in the maximum root length are shown in [Fig. 12](#). Both varieties responded similarly and no remarkable differences were observed.

[Fig.8: Active tillering stage of rice \(31 KB\)](#)

[Fig.9: Changes in leaf age during the experiment \(15 KB\)](#)

[Fig.10: Changes in plant length \(12 KB\)](#)

[Fig.11: Changes in the number of tillers \(14 KB\)](#)

[Fig.12: Changes in maximum root length \(14 KB\)](#)

In [Fig. 13](#), the apparent photosynthetic rate of the top 4 leaves was compared at light saturation. The top, most actively developing leaf was designated as Leaf 1 and Leaf 2 was the leaf just below Leaf 1, etc. Data were gathered on a clear, fine day just before heading. The apparent photosynthetic rate in each leaf was highest in Leaf 1 but the rate decreased with the decrease of the leaf position. In Koshihikari the rate of decline was more remarkable. Leaves 2-4 in Harebare tended to display a higher rate than leaves in the same position in Koshihikari. The level of the photosynthetic rate in either variety, however, was only 1/3 of the rate in the rice plants grown under normal field conditions. During the measurement, leaf sampling units were maintained in the vertical position and the leaf surface received sunlight directly. At a normal light intensity, data were not considerably low. The low photosynthetic rate was mainly due to the reduced penetration of sunlight because the system was set up inside a glass greenhouse. The glass wall acted as a twofold screen and decreased the sunlight intensity by as much as threefold. Though some plants show a low light compensation point, lettuce, honewort and other vegetables for instance can yield optimally even at 20,000 lux¹) while rice requires at least 50,000 lux⁸).

[Fig.13: Comparison of photosynthetic rate among leaf positions from top \(19 KB\)](#)

The top and root system at harvest are shown in **[Figs. 14 and 15](#)**, respectively. After harvesting, internode length and yield components were determined. To reduce the experimental error, data obtained from hills with good growth and poor growth were segregated. **[Fig. 16](#)** shows the length of the internode from the top. In both varieties, the topmost internode was the longest while there was an abrupt decline in the second internode. The relative decrease between internodes 2, 3, 4, and 5 was gradual. In Koshihikari, regardless of the internode position, the growth stand did not affect the internode length. In Harebare, however, the length of internodes 1 and 2 from hills with poor growth was considerably shorter, presumably due to mutual shading which led to a large number of non-productive tillers in the Harebare variety. The decline in the over-all apparent photosynthesis was due to the low light transmittance caused by dense tillering and short internodes.

[Fig.14: Panicles at harvest stage](#)

[Fig.15: Root system at harvest stage \(47 KB\)](#)

[Fig.16: Comparison of length of internode from top \(19 KB\)](#)

The grain yield and yield components are listed in **[Table 2](#)**. Sampling was performed in 5 hills with 4 replications. In both varieties, the number of panicles per hill and 1,000 grain weight from rice hills with good growth were generally satisfactory. However, the number of panicles per hill and the percentage of ripened grains were very low. These 2 parameters contributed to the low grain yield. The maximum yield of Koshihikari was 808 kg/10 a and Harebare produced only half of this. The major difference may be attributed to the inefficient ripening in Harebare. Grain yield from hills with poor growth was even much lower mainly due to the small number of panicles and was aggravated by the large number of unfilled grains. One obvious reason for the low maximum yield was the light competition caused by dense planting. The plant density in the paddy field using a transplanting machine is usually 23 hills/m². In this experiment, at a hill distance of 12 cm the rice population was 49 hills/m². A distance of 17 cm then results in a population of 42 hills/m² or almost twice the normal paddy field population. The wide variation in the actual grain weight implies that some hills were dominant and were more efficient in tapping solar energy. Hills with few panicles were undoubtedly poor hills. In this experiment, if the hill distance had exceeded 17 cm (sparse planting density), it is probable that the yield would have been higher because the light competition effect would have been minimal.

Table 2. Comparison of yield components among hills

	<u>Number of panicles per hill</u>	<u>Number of spikelets per panicle</u>	<u>Percentage of ripened grains</u>	<u>1,000 grain weight (g)</u>	<u>Grain-straw ratio</u>	<u>Yield (kg/10 a)</u>
Koshihikari (1) ^{a)}	21.6	60.2	69.7	21.2	0.37	808
Koshihikari (2) ^{b)}	6.8	58.0	48.6	18.9	0.19	108
Harebare (1) ^{a)}	25.0	62.7	32.9	19.8	0.15	463
Harebare (2) ^{b)}	6.4	28.3	17.2	18.2	0.047	23

a): (1); Hill with good growth, b) : (2); Hill with poor growth.

Furthermore, comparison of the grain yield with the straw yield showed that the ratio was very low, suggesting that the plants did not receive enough insolation to sustain the ripening process. In general, low yield was expected because of the low light energy absorption. Our set-up, however, indicated that even when the solar radiation was low, rice production in a fog culture system was possible because the nutrients could be supplied when the plant required them most.

Abstract

Grade judgment is an essential component of a vegetable and fruit sorting system. Judgment of capability should be integrated with the collection of raw data from an object, and classification of algorithm of processed data. Machine vision is a useful tool for collecting raw data and for classification. Recently, machine vision applications for sorting and inspecting some fruit vegetables have been studied by many scientists^{4-7, 10, 12-16}). However, the traditional image recognition and image understanding methods cannot evaluate satisfactorily irregularly shaped fruit vegetables. Thus, in this article a new feature extraction procedure and neural network were applied to the machine vision system to precisely evaluate fruit vegetables. As the newly developed machine vision system has a learning capability, it can evaluate more than one variety of fruit vegetables. The results obtained for 4 kinds of strawberry varieties and 1 variety of green pepper showed a high accuracy, confirming that the system has a great potential for grade judgment^{3, 9}).

Introduction

In Japan, to upgrade the commodity value, fruit vegetables are generally sorted into grades based on shape, damage and color and into grades based on size or weight before marketing. For most of the fruit vegetables, grade sorting according to size or weight has already been mechanized. However, grade sorting based on shape, internal quality, etc., such as in the case of orange, apple, and cucumber, is still in the initial stage and in most cases performed manually. Along with the unprecedented severe shortage of farm labor, the rapid ageing of Japan's experienced growers and producers with few potential successors pose a difficult problem to the industry. Therefore, to eliminate the errors of judgment of producer and inspector, to meet the consumers' demand for strict standardization and to be able to market fruit vegetables uniformly, it is essential to improve the sorting methods.

At present, because of the advances in electronic technology, machine vision can be applied to research on the development of an automatic sorter. Machine vision enables to handle a large amount of raw data and perform remote judgment. It is used extensively in fruit vegetables sorters. On the other hand, there are conventional image recognition methods such as matching, statistical method and logical method of computation. However, they are not suitable for determining the shape of fruit vegetables because of the complexity and ambiguity involved.

This paper describes a general-purpose grade judgment system with high performance rate and capability of evaluating more than one kind of fruit vegetables using image processing technology and multiple-valued neural network theory^{1, 2, 8, 11}). One of the unique characteristics of this system is that it enables to evaluate fruit vegetables according to their standard patterns, which are learned by the software before the actual judging operation is performed. The system also enables to evaluate different kinds of fruit vegetables by learning their corresponding extracted shape characteristics.

Concept of sorting fruit vegetables

1) Shape features of fruit vegetables and representation

The fruit vegetables are biological products. Although vegetables or fruits may be cultivated in the same way, their shape, size, color and other characteristics are different. Moreover, one vegetable or fruit may consist of many varieties, which requires that sorting standardization for each kind be performed. Using machine vision to evaluate the shape of fruit vegetables, expression and extraction of shape features become an important element because compared with an industrial product, the shape standard of vegetables or fruits does not follow quantitative rules. In this article a set of shape features, which are expressed as thickness, length and curve is proposed, and a method of extraction of characteristic patterns from an object of standard shape is described.

2) Sorting of fruit vegetables

After harvest, sorting of many fruit vegetables is still carried out manually. Inspection standard table classified those that have a good shape and color into grade A, while those with inferior characteristics were graded B. The strawberry inspection standard was set up by the Agricultural Cooperative Association in Miyazaki Prefecture, Japan. Accordingly, there are 3 grades based on shape, namely: A, B and C, and 5 grades based on the size: 3L, 2L, L, M, and S as shown in [Fig. 1](#).

[Fig.1: Standard table for strawberry sorting in Miyazaki Prefecture \(38 KB\)](#)

It is important that a machine vision judging system has learning and fuzzy process functions. Such a system enables to overcome the weakness of traditional type systems. Therefore, the researchers have developed an advanced judging system using machine vision, involving image processing, shape feature extraction, neural network and computer technologies. The system can grade various fruit vegetables according to their shape using the learned standard pattern.

 [BACK](#)

Materials and methods

1) Strawberry and green pepper

Four kinds of strawberry varieties, namely 'Reiko', 'Toyonoka', 'Nyoho' and 'Akihime', and one green pepper variety 'Sadowarahikari super' were used in the experiment.

The characteristics of each variety are as follows:

Reiko variety has a large fruit with a circular conical shape and a strong pericarp. The flesh has an excellent taste. It is fragrant and has high sugar and acid contents. Generally, the fruits with deformed shape account for about 4 to 5%, while those with a good shape account for 80%.

Toyonoka variety has a large fruit with a short circular conical shape. The color of the pericarp, which develops more slowly when shaded by other plant parts from sunlight, is cherry-like. The pulp density is high. As the flesh is not porous, the juice content is high.

Nyoho variety shows a circular conical shape and the top is not sharp. The occurrence of an odd shape is low. Its shape resembles that of Reiko because it was produced by cross-fertilization with the Reiko variety. The size of the fruit is medium. Pericarp and pulp are cherry-like in color and hard, and the flesh is not porous. The sugar and acid contents are high and the taste is good.

Akihime fruit is large with a long circular conical shape. The occurrence of an odd shape is very low. The pericarp is lustrous and cherry-like in color.

Sadowarahikari super is well suited to greenhouse cultivation. This variety of pepper has a medium size with a dark green color. Under low temperature and daylight conditions, the flesh is thick and of high quality which makes it highly marketable.

2) Proposed method for shape feature extraction

Reading and writing of image dot data require a long processing time. By decreasing the frequency of readings, length of processing can be reduced. This paper describes a new shape feature extraction method for easy calculation and faster operation.

The 3 parameters, i.e. thickness, length and bend are illustrated in [Fig. 2](#). After preprocessing of the fruit image into a binary form using the image processing technique, 5 horizontal widths, W_1 , W_2 , W_3 , W_4 , and W_{max} ; one vertical height H and a length L of a line which connects the midpoints of W_1 and W_{max} were extracted. H is the perpendicular distance of the topmost point of the image from the maximum horizontal width, W_{max} , while W_1 , W_2 , W_3 , W_4 are $0.1H$, $0.2H$, $0.4H$, and $0.7H$, respectively, from the topmost point of the fruit's binary image. From these measured parameters, K_1 , K_2 , K_3 , K_4 , K_5 , and K_6 were calculated as follows:

[Fig.2: Feature extraction of fruit vegetables \(18 KB\)](#)

$$K_1 = W_1 / W_{max}$$

$$K_2 = W_2 / W_{max}$$

$$K_3 = W_3 / W_{max}$$

$$K_4 = W_4 / W_{max}$$

$$K_5 = H / W_{max}$$

$$K_6 = L/H \text{ ----- (1)}$$

3) Neural network and algorithm

The machine vision system must be able to recognize a vegetable or fruit when it "sees" one and must decide to what grade or class the fruit should belong based on its shape and size. This is essentially the function which the judging component has to accomplish by employing appropriate software.

In this study, the multiple-valued neural network (MVNN) theory, generally accepted as a useful tool for the recognition of various patterns, and image processing technique were used for the development of the desired software. For example, [Fig. 3](#) shows a 3-layer neural network model consisting of an input, a hidden and an output layer. Six input units, K_1 , K_2 , K_3 , K_4 , K_5 , and K_6 , representing a set of features, are fed into the network through the input layer. Each unit is connected to all the nodes of the hidden layer which is in turn connected to the 2 nodes of the output layer. Computation of the value of each unit in the hidden and output layers is then carried out using a piecewise linear operation expressed as:

$$Y = f(X) \text{-----} (2)$$

[Fig.3: Model of multiple-layer neural network \(17 KB\)](#)

where f is the arithmetic function and X is the weighted sum of the units in the previous layer, as shown in [Fig. 4](#).

$$f(X) = \begin{matrix} X & X > 0 \\ 0 & X < 0 \end{matrix} \text{-----} (3)$$

[Fig.4: Basic unit for multiple-valued neural network \(16 KB\)](#)

An algorithm using the back-propagation method was applied to the neural network model to calculate the weight (synapse) values. That is, $K_1, K_2, K_3, K_4, K_5,$ and K_6 were fed to the MVNN as inputs for learning, the weight values were then adjusted until the output value became very close to that of the teaching signal.

4) Machine vision judging system and its software

The machine vision system for grade judgment of fruit vegetables is illustrated in [Fig. 5](#). The turntable moves automatically and draws the position of strawberry exactly under a CCD camera (ELMO EC-202 II lens: 16 mm, $f = 1.5 - 1.0$). The frozen image of fruit could be viewed in the monitor (SONY PVM 9221) through the image digitizer board FDM-4-256. The developed software, loaded into NEC PC 9801 RA analyzes the image of fruit to ascertain its shape and size. Soon after the shape of strawberry is ascertained, the 5-joint robot picks up and transports the fruit to predefined locations. As shown in Fig. 5 (b), the robot arm distributes the fruits subjected to evaluation.

[Fig.5: Machine vision judging system \(50 KB\)](#)

The flowchart of the judging system software is shown in [Fig. 6](#). This software displays learning and judging components as follows:

[Fig.6: Flowchart of machine vision judging system software \(45 KB\)](#)

(1) Learning program

1. The name of the fruit vegetables to be handled and the kind are inputted.
2. Input the standard shape of an object from a CCD camera in order to develop a pattern for learning. (Shape features $K_1, K_2, K_3, K_4, K_5,$ and K_6 are generated from this.)
3. The teaching signal is inputted from the computer keyboard.
4. The numbers of layers in the middle, number of units in each layer, learning coefficients are adjusted to a specific MVNN model.
5. According to the teaching signal, the MVNN model learns a set of standard patterns.
6. If learning succeeds, data are saved then go to end, if not, go to "4", until the learning operation is completed.

(2) Judging program

1. Determine, in interactive style, whether the learning operation for the kinds of fruit vegetables has already been completed for evaluation, if not, the learning program is called upon.
2. Load synapse or weight data to MVNN.
3. Rotate turntable, and the specimen is brought to a location under the CCD camera.
4. Image processing and feature extractions are performed.
5. The MVNN evaluates shape features, and sends control signals to the robot.
6. The robot carries the object evaluated to the correct area in the collection unit.

Results and discussion

1) Shape judging standards and learning patterns

Shape judging standards of fruit vegetables are determined in every producing district. This time, the shape judging standards of Fukuoka, Miyazaki and Tochigi Prefectures were used. The shape grade of 4 varieties of strawberry and 1 variety of green pepper is shown in [Table 1](#). Based on Table1, learning patterns of fruit vegetables used in the experiment were generated and are shown in [Fig. 7](#).

Table 1: Standard shape ranks of 4 varieties of strawberry and 1 variety of pepper

<u>Variety</u>	<u>Shape class</u>				
Reiko	A	B	C		
Toyonoka	A	B	C		
Nyoho	Superfine	LA	2A	3A	B
Akihime	A	B			
Sadowarahikari super	A	B			

Fig.7: Learning patterns of 4 strawberry varieties and 1 variety of green pepper (46 KB)

2) Input and acquisition of learning patterns

According to the learning patterns ([Fig. 7](#)), one by one, the standard pattern is put under a CCD camera and the teaching signal (A=0, 0; B=1, 0; C=0, 1) is inputted accordingly from the computer keyboard in every set of learning patterns. Here, the error limit is defined as 0.01, 5 kinds of learning patterns were acquired, and the learned results all succeeded. Therefore, after learning, the machine vision judging system could evaluate more than 1 variety of vegetables.

3) Judgment and appraisal

Judging system requires attention because the fruit should be placed on the turntable vertically (see Fig. 8) in order to extract features correctly. Experimental judging results were compared with those of manual judging to assess the accuracy rate. Since the judging standard of fruit vegetables is fuzzy, it is likely that different results will be obtained from different persons for the same object. Thus, manual judging results as defined above should be agreed upon by 3 persons aside from an instructor and student, i.e. a total of 5 persons in the laboratory. For example, when 5 persons determined that the strawberry shape is A, A, B, A, B, respectively, the human judging results are taken as A.

In this judging experiment, fresh fruit vegetables were used, including Reiko (122 fruits), Toyonoka (187 fruits), Nyoho (170 fruits), Akihime (167 fruits), and Sadowarahikari super (100 fruits). The agreement rate of human judging results and the machine vision judging system are shown in [Table 2](#).

Table 2. Agreement rates of shape judgment

<u>Variety</u>	<u>Accuracy</u>	<u>Error</u>
Reiko	95%	5%
Toyonoka	97%	3%
Nyoho	98%	2%
Akihime	94%	6%
Sadowarahikari super	89%	11%

The test results of the machine vision sorting system displayed a high degree of precision. Table 2 shows that robotic sorting and manual sorting exhibited only a marginal difference in terms of accuracy. Percentage accuracy ranged from 89 to 98% and the percentage of error in shape judgment for different varieties ranged from 2 to 11%.

4) Future problems

It is important for MVNN to produce learning patterns in the machine vision judging system. Since a given set of precise learning pattern is acquired by MVNN, the accuracy of the machine vision judging system increases. Moreover, it is necessary to increase the number of features and to improve the components of the extracting method, because there is still a difference in the judgment from human. In order to evaluate fruit vegetables such as green pepper that have a complex shape, it is necessary to develop a

judging method that combines fuzzy and MVNN theories to improve the judgment accuracy.

Conclusion

In order to evaluate more than one kind of fruit vegetables, according to the shape, the machine vision system was studied. The shape judgment of fruit vegetables is difficult compared to industrial products of fixed form because of the naturally unique outline. In this study image processing and MVNN technologies were used for the advanced machine vision judging system, which enabled to alleviate the fuzzy judging problem of shape. Due to its learning capability, the system was able to evaluate different kinds of fruit vegetables according to their learned standard pattern. In the judging experiments, 4 varieties of strawberry, Reiko, Toyonoka, Nyoho, Akihime and 1 variety of green pepper Sadowarahikari super were used. The results showed that the judging accuracy for strawberry ranged from 94 to 98% while 89% for green pepper. Therefore, the system has a high potential in grade judging of fruit vegetables which is still in the developmental stage.

Varietal Differences in Female Flower Bearing Ability and Evaluation Method in Watermelon

Keita SUGIYAMA

Kurume Branch, National Research Institute of Vegetables, Ornamental Plants and Tea
(Kurume, Fukuoka, 839-8503 Japan)

Abstract

These studies were carried out to identify varieties with a high female flower-bearing ability among genetic resources and develop a simple method to evaluate the female flower bearing ability of watermelon before transplanting. The results showed that Japanese F₁ varieties bore more female flowers than the other varieties except for those from China and Taiwan. Also varieties with many female flowers among wild species could be used as breeding materials to improve the female flower bearing ability of other watermelon varieties. Watermelon varieties with a high female flower bearing ability bore the first female flower at a lower node than those with a low female flower bearing ability, when sprayed with silver thiosulfate, STS, at the cotyledonary stage. Correlation between the number of female flowers in the F₂ population sprayed with 6 mM STS and the node order of the first female flowers was high. In a progeny selected from the F₂ population, the female flower was borne at a lower node order of the main stem, whereas in another, the first female flower differentiated at a higher node order; the former bore more female flowers than the latter. These results indicate that it is possible to select plants with a high female flower bearing ability by STS treatment before transplanting.

Discipline: Plant breeding

Additional key words: *Citrullus lanatus*, STS, selection

Introduction

Watermelon varieties have fewer female flowers than other cucurbit crops such as cucumber and melon. The formation of female flowers in watermelon is easily affected by the temperature^{8,9,11,12}), day-length^{8,9,11,12}) and fertilizer conditions¹).

A long pollination period is required in watermelon because the species differentiates few female flowers under high temperature and long day-length conditions and when excess nitrogen is applied. Furthermore, abortion of female flowers or low fruit-setting ratio is caused by weather conditions characterized by a low temperature and little sunshine. Also, to set the fruit at the nodes which are convenient for improving fruit quality and reducing cultivation labor, varieties with a tendency to differentiate relatively more female flowers should be used.

A testing method to evaluate juvenile plants with a high female flower bearing ability would be advantageous because much time is required to evaluate the female flower bearing ability of watermelon. There are many reports in testing methods for gynococious line breeding in cucumber³⁻⁶), but only a few in watermelons. Hence, we attempted to develop a simple method to evaluate the female flower bearing

ability of watermelon before transplanting by using silver thiosulfate (STS).

Materials and methods

Experiment 1: Varietal differences in female flower bearing ability in watermelon

Forty-five Japanese watermelon varieties (19 pure-bred varieties, 12 F₁ small-sized watermelon varieties and 14 F₁ large-sized watermelon varieties), 10 watermelon varieties derived from China and Taiwan, 12 watermelon varieties derived from America, Russia, Europe and other countries and 9 wild watermelon varieties were used in this experiment ([Table 1](#)). They were sown on March 21 and transplanted to a greenhouse on April 15, 1994. Four plants per variety were used with 2 replications. The total number of female flowers up to the 30th node on the main stem was recorded. Hermaphrodite flowers and degenerated female flowers were categorized as female.

[Table 1: List of watermelon varieties\(46 KB\)](#)

Experiment 2: Effect of STS on the induction of female flowers

Seedlings of watermelon, 'Red Seeded 3b', 'Koryou 200', 'Beijing Xi C', 'Fujihikari TR', 'Aohanagawa', 'Summit', 'Klekley Sweet' and 'Green Seeded' sown on March 24, 1993, were sprayed with 0 (distilled water, control), 1, 3 and 6 mM STS at the cotyledonary stage (seeds sown on October 5) on October 14. The amount of solution sprayed was about 2 mL per plant. Ten plants per variety were used with 2 replications in all the treatments. The node order of the first female flower and the first male flower and the total number of female flowers up to the 10th or the 20th node on the main stem were recorded. Hermaphrodite flowers and degenerated female flowers were categorized as female.

Experiment 3: Selection effect of female flower bearing ability by STS treatment

F₂ seedlings were derived from the cross between Red Seeded 3b with many female flowers and Green Seeded with a few female flowers. The F₂ progenies (117) were sprayed with 6 mM STS at the cotyledonary stage on April 5, 1994 (seeds sown on March 24). From this population, RG94 and RG33 were selected; the former bore the first female flower at a basal node, whereas RG33 bore its first female flower at a more distal node. These selections were self-pollinated. Seeds of the F₂ population (79) and seeds of the F₃ population of RG94 (58) and RG33 (24) were sown on September 20. These plants were not treated with STS. The number of female flowers up to the 30th node on the main stem was recorded in the F₂ and F₃ seedling populations. Hermaphrodite flowers and degenerated female flowers were categorized as female as above.

Results

Experiment 1: Varietal differences in female flower bearing ability in watermelon

Average number of female flowers up to the 30th node on the main stem was 3.7 flowers ([Fig. 1](#)). Red Seeded 3b bore the largest number of female flowers (7.1 female flowers) followed by Africa 22860 with 6.1 female flowers. It was found that Green Seeded bore the lowest number with 0.5 female flowers. Thus, wild species displayed a wide range of female flower bearing ability.

[Fig.1: Varietal differences in number of female flowers in genetic resources \(20 KB\)](#)

The varieties from America, Russia, Europe and other countries bore fewer female flowers than the Japanese varieties. However, the varieties of China and Taiwan showed almost the same number of female flowers as the Japanese F₁ varieties.

Japanese pure-bred varieties were found to display a wide range of female flower bearing ability. However, small-sized and large-sized watermelons and Japanese F₁ varieties bore about 3 to 4.5 and 4 to 5 female flowers, respectively. Thus, large-sized watermelon and Japanese F₁ varieties were found to bear the largest number of female flowers.

Experiment 2: Effect of STS on the induction of female flowers

Spraying STS at the cotyledonary stage was effective in inducing female flowers ([Table 2](#), [Fig. 2](#)). Treatment with 6 mM STS lowered the node order of the first female flower on the main stem in varieties with many female flowers by 2 nodes compared to that in the control. In Red Seeded 3b treated with 6 mM STS, which showed the highest frequency of female flowers, the mean node order for the first female flower was 3.4, whereas in Koryou 200 and Beijing Xi C, which bear many female flowers, the mean node order was 3.8 and 4.4, respectively. With the same treatment, the basal nodes with the first female flowers of Aohanagawa and Klekley Sweet were 7 and 8, respectively, a value significantly lower than that in the control. Yet, the node order was still higher than for all the other varieties except for Green Seeded. The node order of the first female flower of Green Seeded was lowered by the 1 mM STS treatment, while the application of 3 or 6 mM STS was ineffective.

Table 2: Effect of STS treatment at the cotyledonary stage on sex expression in watermelon

Sowing date: Oct. 5, 1993. STS treatment was applied on Oct. 14, 1993

a): On the main stem, including hermaphrodite.

b): STS concentration.

c): Up to 20th node on the main stem in control.

d): Mean separation within columns by Duncan's multiple range test, at 5% level.

e): Correlation coefficient between node order of the first female flower and total number of female flowers up to 20th node in control.

** Significant at 1% level.

[Fig.2: Effect of STS on first female flower setting \(21 KB\)](#)

Spraying of 1 mM STS was slightly effective in lowering the node order of the first female flower. Differences in the female flower bearing ability among varieties were clearly revealed when seedlings were sprayed with 6 mM STS.

Spraying of seedlings with 3 or 6 mM STS was effective in increasing the number of female flowers; concurrently, the node order bearing the first male flower tended to decrease by STS treatment.

Correlation coefficient between the node order of the first female flower in the STS-treated plants and the number of female flowers up to the 20th node in the nontreated plants was very high.

Experiment 3: Selection effect of female flower bearing ability by STS treatment

A wide range of node orders bearing the first female flower was observed in the F₂ population of the watermelon varieties tested. The lowest node order bearing the first female flower was 3, while the highest node order bearing the first female flower was 14 ([Fig. 3](#)). The watermelon plants bearing many female flowers tended to bear the first female flower at a lower node. In contrast, the watermelon varieties bearing fewer female flowers tended to bear them at a higher node. Correlation coefficient between the number of female flowers up to the 30th node on the main stem and the node order bearing the first female flower was significantly high.

[Fig.3: Relationship between the node order of the first female flower and the number of female flowers after application of 6 mM STS at the cotyledonary stage in F₂ \(17 KB\)](#)

Two plants were selected from the F₂ population: one was RG94 for which the first female flower bearing node order was 4 and the other one was RG33 which bore the first female flower on the 10th node.

The F₃ plants derived from RG94 bore more female flowers than those derived from RG33 and F₂ plants ([Fig. 4](#)).

[Fig.4: Frequency distribution of number of female flowers of F₂, RG33\(F₃\) and RG94\(F₃\) \(19 KB\)](#)

Discussion

Female flower bearing ability in the Japanese F₁ varieties is higher than that of Japanese pure-bred varieties or varieties from other countries except for China and Taiwan. It is assumed that recently Japanese F₁ varieties have been improved to become adapted to greenhouse culture. The varieties were altered with a high bearing ability to stabilize the setting of fruits as well as to advance maturity and reduce the cultivation labor. However, the Japanese F₁ varieties did not bear many female flowers. This problem may have been solved by the application of a training method which enabled to increase the number of female flowers by growing 3 or 4 lateral vines of watermelon plant. However, since the female flower bearing is easily affected by the weather conditions, it is necessary to genetically alter varieties to increase their female flower bearing ability. Red Seeded 3b and Africa 22860 with a high female flower bearing ability are suitable for use as breeding materials.

It is generally recognized that the number of female flowers (including hermaphrodite flowers) of watermelon can be increased by aminoethoxyvinylglycine²⁾, silver nitrate^{2,10)} and maleic hydrazide¹⁴⁾ applications. Triiodobenzoic acid treatment increased the production of female flowers and induced the formation of the first female flower at lower nodes of the main stem⁷⁾. On the other hand, ethephon treatment decreased the number of female flowers²⁾. It was assumed that the use of some methods may enable to carry out selection for female flower bearing ability. In one method, selection involved plants which differentiated female flowers under conditions inhibitory to female flower formation such as long day-length, high temperature, or with treatments with certain plant growth regulators such as ethephon or conversely, the selection involved plants which initiate female flowers under favorable conditions, such as short day-length, low temperature or with some of the above-mentioned substances.

Sugiyama et al.¹³⁾ exposed watermelon seedlings to high temperature and long photoperiod to select plants with a high female flower bearing ability but the method requires a large and expensive phytotron for a long duration.

We applied STS which is more easily absorbed by the plant than silver nitrate. STS was applied at the cotyledonary stage to induce the first female flower at a lower node on the main stem and to increase the number of female flowers. It was assumed that the varieties with many female flowers tended to bear the first female flower at a lower node under STS treatment.

By selecting 2 progenies from an F₂ population bearing female flowers at lower or upper nodes on the main stem, we demonstrated that this bearing habit is heritable. Hence, we were able to select plants with a high female flower bearing ability by STS treatments. This testing method should enable to select plants with a high female flower bearing ability before transplanting, in order to improve the efficiency by shortening the turnover generation in watermelon breeding.

Improvement of Postharvest Life in Several Cut Flowers by the Addition of Sucrose

Kazuo ICHIMURA

Department of Floriculture, National Research Institute of Vegetables, Ornamental Plants and Tea
(Ano, Mie, 514-2392 Japan)

Abstract

Sugars play important roles in keeping the quality of cut flowers because the amount of sugar contained in cut flowers is limited. Effects of sucrose treatment on the vase life of several cut flowers were investigated. Continuous treatment with sucrose markedly promoted floret opening and extended the vase life of cut sweet pea flowers. Pulse treatment with sucrose was also fairly effective in improving the vase life of these flowers. Continuous treatment with sucrose increased anthocyanin concentrations in petals as well as extended the vase life of several cultivars of cut *Eustoma* flowers. This treatment was also effective in improving the vase life of cut snapdragon flowers. Although pulse treatment with sucrose was fairly effective in improving the vase life of cut hybrid Limonium, pulse treatment with sucrose in combination with α -aminoisobutyric acid (AIB), an ethylene biosynthesis inhibitor, was markedly effective in improving the vase life. Role of the application of sucrose to cut flowers was reviewed and discussed.

Discipline: Horticulture

Additional key words: *Eustoma grandiflorum*, hybrid Limonium, snapdragon, sugar, sweet pea
1~36): [Click here for References](#)

Introduction

In Japan, cut flowers have been increasingly distributed in markets along with the increase of flower production in recent years. Furthermore, transportation of cut flowers over long distances has increased. These conditions are unsuitable for keeping the quality of cut flowers. Development of postharvest technology in cut flowers is, thus, being promoted.

Sugars play important roles in plants as substrates for respiration and cell walls as well as osmolytes. Since the amount of sugar contained in cut flowers is limited, the addition of sugars such as sucrose to vase water is effective in improving the vase life of some cut flowers8).

In this report, I described the role of sugars in improving the vase life of cut flowers. Furthermore, here I reported the improvement of the vase life of cut sweet pea, hybrid *Limonium*, *Eustoma* and snapdragon flowers by treatment with sucrose.

Role of sugars in cut flowers

Addition of sugars to vase water not only extends the vase life of cut flowers but also promotes flower opening. Furthermore, the expression of the flower color is improved by treatment with sugars in some cut flowers such as carnation¹⁵⁾ and rose^{7,27)}. Effects of sugars on the extension of the vase life of cut flowers are considered to be associated with the improvement of the water balance. However, since inorganic ions did not extend the vase life more than sugar¹⁹⁾, it is suggested that the effect of sugars on the improvement of the vase life is due not only to the effect of osmolytes but also to that of substrates of respiration and synthetic materials.

1) Promotion of flower opening by sugars

A large amount of soluble carbohydrates is required for flower bud opening as substrates for cell walls and respiration as well as for their osmotic properties. Since the carbon source of cut flowers is limited, addition of sugars such as sucrose and glucose to vase water is highly effective in promoting flower opening^{5,6,18,28)}.

Petal growth associated with flower opening results from cell expansion¹⁴⁾, which is required for the influx of water and osmolytes such as sugars into cells. In hybrid *Limonium* and carnation, the concentration of sucrose in petals decreased, and that of glucose and fructose increased^{23,31,36)}. In *Hemerocallis*, fructans are degraded to monosaccharides during flower opening²⁾. Monosaccharides derived from sucrose or fructans increase the osmotic pressure, which contributes to flower opening. Woodson and Wang (1987)³⁶⁾ showed with carnation that these changes in the sugar composition are accompanied with the increase in invertase activity.

2) Extension of longevity of cut flowers

In many cut flowers, sugars such as sucrose extend the vase life. We observed that sucrose extends the vase life of cut sweet pea flowers.

Flowers of sweet pea are highly sensitive to ethylene^{22,25,35)}, and the vase life is very short. When cut spikes of sweet peas were treated with 40 g L⁻¹ sucrose, the vase life became twice as long¹²⁾. This treatment increased the glucose, fructose and sucrose concentrations ([Fig. 1](#)) and inhibited ethylene production of florets ([Fig. 2](#)). These findings suggest that the sugar concentration increased by the sucrose treatment may lead to the inhibition of ethylene production.

[Fig. 1. Changes in sugar concentrations of petal and the other parts of sweet pea floret with time \(32 KB\)](#)

[Fig. 2. Changes in ethylene production of sweet pea floret with time \(16 KB\)](#)

To further clarify the relationships between ethylene production and the sugar concentration of flowers, cut spikes were treated with sucrose continuously (continuous treatment) or only for 24 h (pulse treatment) after harvest. Vase life of control spikes was about 3 days. The continuous and pulse treatments with sucrose extended the vase life of spikes by 8 and 6 days, respectively. Climacteric ethylene production was advanced by the pulse treatment compared to continuous treatment. Furthermore, the sugar concentration decreased with the time after pulse treatment whereas it remained at a high level by continuous treatment. Therefore, ethylene production was largely affected by the sugar concentration in floret.

To determine whether sucrose inhibits the ethylene action, the effect of sucrose on ethylene production of floret was compared to that of silver thiosulfate complex (STS), an ethylene action inhibitor⁹). Although sucrose inhibited ethylene production more than STS ([Fig. 3](#)), STS extended the vase life more than sucrose. STS is known to suppress autocatalytic ethylene production by inhibiting ethylene action. These findings suggest that sucrose may not inhibit the ethylene action although it remains to be determined whether sucrose directly inhibits ethylene production.

[Fig.3. Changes in ethylene production of sweet pea floret with time \(17 KB\)](#)

3) Improvement of flower color expression by sucrose

Treatment with sugars such as sucrose improved the expression of petal colors in some cut flowers such as rose^{7,27}), sweet pea⁹) and Eustoma¹¹). Pigments of these flowers are mainly anthocyanins.

Anthocyanins are synthesized via several enzymatic steps such as chalcone synthase and chalcone flavanone isomerase⁴). Tsukaya et al. (1991)³²) and Moalem-Beno et al. (1997)²¹) reported that in petunia the gene expression of chalcone synthase, a key enzyme of anthocyanin biosynthesis was induced by sucrose. Similarly, Kusuhara et al. (1996)¹⁶) reported that in *Eustoma* sucrose increased the expression of genes involved in anthocyanin biosynthesis such as chalcone isomerase, dihydroflavone reductase and chalcone synthase. Thus, the stimulation of anthocyanin expression of cut flowers by sucrose may be involved in the promotion of anthocyanin biosynthesis gene expression. Furthermore, this promotive effect is possibly due to the supply of sugars as glycoside residues of anthocyanin because anthocyanins are usually present as glycosides.

To determine whether the amount of other flower pigments such as carotenoid and betacyanins increased by sugar treatment, further studies will be required.

Effects of sucrose treatment on the vase life of various cut flowers

Since sugars such as sucrose are effective in improving the vase life of cut flowers, they are included in preservatives. I describe here that sucrose improves the vase life of several important cut flowers.

1) Sweet pea

Sweet pea (*Lathyrus odoratus* L.) is a very suitable cut flower because of its wide range of colors and exceptional fragrance. The vase life of the cut flowers is very short^{22,25,35}). Since the flower of sweet pea is sensitive to ethylene, STS has been shown to be very effective in prolonging the vase life of sweet pea^{13,22,30}). STS, however, contains silver, a heavy metal, which is a potent environmental pollutant. Therefore, other chemicals will be required. Aminoxyacetic acid³), α -aminoisobutyric acid^{26,29}), aminoethoxyvinyl glycine¹) and 1,1-dimethyl-4-phenylsulfonylsemicarbazide²⁰), inhibitors of ethylene biosynthesis, have been found to be effective in prolonging the longevity of cut carnation flowers. These compounds, however, are only slightly effective in extending the vase life of cut sweet pea flowers³³). On the contrary, diazocyclopentadiene, an ethylene action inhibitor, is fairly effective in extending the longevity of cut sweet peas³⁰).

We therefore investigated the effect of sucrose on the vase life of bud-cut sweet peas. Continuous treatment with sucrose markedly promoted floret opening and extended the floret longevity in cut sweet peas¹²). The vase life of florets treated with 100 g L⁻¹ sucrose was 3 times longer than that of control florets.

Although STS is a potent environmental pollutant, the use of this compound is not prohibited as preservative. We thus examined the effects of pulse treatment with sucrose and STS on the vase life of sweet pea flowers harvested at conventional times for farmers⁹). The cut spikes were treated with 100 g L⁻¹ sucrose for 16 h, 0.2 mM silver thiosulfate complex (STS) for 2 h and 0.2 mM STS for 2 h followed by 100 g L⁻¹ sucrose for 16 h. Treatment with STS followed by sucrose was the most effective in promoting floret opening ([Fig. 4](#)) as well as extending the vase life ([Table 1](#)). Anthocyanin concentrations increased by treatments with sucrose alone or STS followed by sucrose ([Table 2](#)). These results show that the addition of STS followed by sucrose is more effective than that of STS alone in improving the vase life of cut sweet pea flowers.

[Fig.4. Effect of combined treatment with STS and sucrose on floret bud opening \(18 KB\)](#)

[Table 1: Effects of combined treatment with sucrose and STS on the vase life of cut sweet pea flowers](#)

<u>Treatment</u>	<u>Vase life (days)</u>	
	<u>Floret</u>	<u>Spike^{a)}</u>
Control (water)	1.7	2.5
Sucrose (100 g L ⁻¹)	3.0	5.9
STS(0.2 mM)	4.4	7.2
STS (0.2 mM) + Sucrose (100 g L ⁻¹)	6.0	8.7

a): Vase life of spikes was determined as the time from harvest to the time when all the florets wilted. Cut flowers were kept at 23 °C.

Table 2: Effects of combined treatment with sucrose and STS on anthocyanin concentrations of petals in cut sweet pea flowers

<u>Treatment</u>	<u>Anthocyanin</u> (OD530 nm gFW ⁻¹)
Control (water)	0.84
Sucrose (100 g L ⁻¹)	2.62
STS (0.2 mM)	1.11
STS (0.2 mM) + Sucrose(100 g L ⁻¹)	1.76

Cut flowers were kept at 23 °C.

As mentioned above, the use of STS is not recommended. Since the treatment with sucrose alone was also considerably effective in improving the vase life of cut sweet pea, it is assumed that the use of sucrose in combination with ethylene inhibitors, other than STS, may improve the vase life of sweet pea in the same way as STS.

2) Hybrid *Limonium*

Hybrid *Limonium*, cultivar 'Blue fantasia 100', is an interspecific hybrid between *L. bellidifolia* Gouan and *L. latifolium* Kuntzn. The inflorescence has many small florets, which are at various developmental stages between bud and opened floret. In the cut inflorescence, buds seldom open and the floret longevity is short. Thus, the effects of sucrose on the vase life of hybrid *Limonium* were investigated³¹).

The cut flowers were treated with sucrose for 24 h, and thereafter placed in water. Sucrose at 10 and 20 g L⁻¹ significantly increased the percentage of open florets, but did not affect appreciably the floret senescence. Since sucrose alone did not improve the vase life sufficiently, we further examined the effect of combined treatment with 20 g L⁻¹ sucrose and 10 mM α -aminoisobutyric acid (AIB), an inhibitor of 1-aminocyclopropane-1-carboxylic acid (ACC) oxidase on the vase life. The combined treatment with sucrose and AIB promoted floret opening and inhibited floret senescence. This effect is probably due to the promotion of floret opening by sucrose and extension of longevity by AIB. Petal color was expressed well and florets fully opened after the treatment. Therefore, this treatment can be practically used as preservative for farmers.

3) *Eustoma*

Eustoma grandiflorum (Raf.) Shinn., which is native to the southern United States, was introduced into Japan more than 60 years ago. *Eustoma* is widely produced in the world, particularly in Japan. Although the vase life of cut *Eustoma* flowers is relatively long, small buds do not open fully and the color of petals is slightly expressed. We therefore investigated the effect of sucrose with 8-hydroxyquinoline

sulfate (HQS) on the vase life in 6 cultivars of *Eustoma* flowers¹¹).

Continuous treatment with 20 g L⁻¹ sucrose combined with 200 mg L⁻¹ HQS significantly promoted flower opening and extended the vase life of all the cultivars tested ([Table 3](#)). This treatment also increased anthocyanin concentrations of petals, particularly in 'Azuma-no-ginga' and 'Azuma-no-kasumi', both of which show a light color ([Table 4](#)).

Table 3: Effect of sucrose with HQS on vase life in various cultivars of cut *Eustoma grandiflorum*

Cultivar	Vase life ^{a)} (days)	
	Control (water)	Sucrose + HQS
Azuma-no-ginga	9.8	14.4
Azuma-no-kasumi	11.1	16.0
Azuma-no-shirabe	14.4	20.1
Piccolo blue	10.7	19.0
Piccolo blue picoty	11.9	24.0
Piccolo rose	12.4	19.4

a): Vase life was determined as the time from harvest to the time when all the florets wilted. Cut flowers were kept at 23°C.

Table 4: Effect of sucrose with HQS on anthocyanin concentrations in various cultivars of cut *Eustoma grandiflorum*

Cultivar	Anthocyanin concentration (OD530 nm gFW ⁻¹)	
	Control (water)	Sucrose + HQS
Azuma-no-ginga	0.40	4.31
Azuma-no-kasumi	0.17	2.52
Piccolo blue	3.65	10.10
Piccolo rose	1.20	4.85

Cut flowers were kept at 23°C.

Cut *Eustoma* flowers used in this study were transported in a cardboard box without water for 1 day, and then they were immersed in tap water and kept at 23°C for 3 days. In spite of unsuitable conditions for cut flowers, the use of sucrose with HQS improved considerably the vase life of cut *Eustoma* flowers. Therefore, the use of sucrose with HQS could become a practical treatment in improving the vase life for consumers as preservative.

4) *Snapdragon*

The flowers of snapdragon (*Antirrhinum majus* L.) are sensitive to ethylene, and the vase life of the cut flowers is relatively short. Furthermore, most of the buds do not open fully and the color of their petals is slightly expressed^{17,24,34}).

We examined the effects of sucrose application on the vase life of cut snapdragon flowers¹⁰). Continuous treatment with sucrose at 25, 50, 75 or 100 g L⁻¹ in combination with 200 mg L⁻¹ HQS markedly promoted floret opening and extended the vase life of flower spikes ([Table 5](#)). In addition, petal color expression was markedly improved by these treatments. The optimum concentration was 50 g L⁻¹. This treatment increased the sugar concentrations of petals and suppressed ethylene production of florets. These results suggest that the effect of sucrose in promoting bud opening and inhibiting flower senescence is probably due to the increase in sugar concentration and inhibition of ethylene synthesis.

Table 5: Effects of various concentrations of sucrose with HQS on the vase life of cut snapdragon flowers

<u>Treatment</u>	<u>Vase life^{a)} (days)</u>
DW	8.2
0 g L ⁻¹ sucrose + HQS	10.2
25 g L ⁻¹ sucrose + HQS	17.4
50 g L ⁻¹ sucrose + HQS	20.7
75 g L ⁻¹ sucrose + HQS	17.7
100 g L ⁻¹ sucrose + HQS	15.0

a): Vase life was determined as the time from harvest to the time when all the florets wilted. Cut flowers were kept at 23°C.

Conclusion

As described above, treatment with sucrose not only extended the vase life but also promoted flower opening. In addition, sucrose improved the petal color expression. In this paper, I observed that continuous treatment with sucrose is very effective in improving the vase life of cut sweet pea, *Eustoma* and snapdragon flowers. Pulse treatment with sucrose was also effective in cut sweet pea and hybrid *Limonium* flowers. These findings suggest that sugars are effective in improving the vase life of many cut flowers. In addition, sugars are cheap and safe compounds. However, sugars are not much utilized practically in Japan. To keep the quality of cut flowers, the utilization of sugars should be further promoted

Abstract

Efficient plant regeneration system of *Cucumis figarei* and *C. metuliferus* from cotyledon was developed. Excised cotyledon explants from young seedlings after 3 days of germination were cultured on MS medium containing 30 g/L sucrose, 2.5 g/L gelrite and several combinations of phytohormones. In *C. figarei*, the effect of the combination of BA and IAA on shoot organogenesis was investigated. Adventitious shoots were induced from cotyledonary explants and the highest regeneration frequency was 40% on MS basal medium supplemented with 1 mg/L BA. It was demonstrated that the use of IAA decreased the regeneration frequency, and the application of 2 mg/L IAA suppressed shoot organogenesis completely. Subsequently, other combinations of phytohormones were investigated to improve the regeneration frequency. Combination of 1 mg/L BA and ABA (1 or 2 mg/L) increased the regeneration frequency (ca. 60%), while the combination of 1 mg/L BA and Zeatin (0.5, 1 and 2 mg/L) did not enhance shoot organogenesis and the addition of TDZ (0.2, 0.5, 1 and 2 mg/L) inhibited shoot organogenesis. In *C. metuliferus*, the highest regeneration frequency was 92.5% when cotyledonary explants were cultured on MS medium with 1 mg/L BA and 0.2 mg/L IAA. Lower concentration of IAA (0.2 mg/L) stimulated shoot organogenesis, while a higher concentration of IAA (2, 4 and 8 mg/L) exhibited an adverse effect, and especially, shoot organogenesis was suppressed completely by the addition of 8 mg/L IAA. Regenerated shoots were transferred onto MS medium containing 1 mg/L IAA to induce adventitious roots. Elongated shoots with adventitious roots were acclimatized and grew to normal plants in the greenhouse.

Introduction

Melon (*Cucumis melo* L.) is cultivated over a wide area in the world, and up to now, breeding of melon had been progressing to improve many characters, especially disease and insect resistance. It was reported that several wild *Cucumis* species display a resistance to diseases and insect pests, including the resistance to viruses, *Fusarium* wilt and greenhouse whitefly of *C. metuliferus*^{5,7,14}, virus resistance of *C. figarei*¹³ and root knot nematode resistance of *C. angria*^{5,7}). However, in most of the wild species, crossability with cultivated melon is limited^{2,9}), and it is very difficult to promote the introgression of the resistance to diseases and/or insect pests of wild

Cucumis species into cultivated melon by cross-pollination. Under these conditions, cell fusion is considered to be a suitable method for the production of hybrids between cultivated melon and wild *Cucumis* species.

To produce somatic hybrids by cell fusion, it is essential that an efficient protoplast culture system be established and reliable selection methods be also developed. Protoplast culture of melon was already reported by several researcher groups^{19,23}). In contrast, attempts at plant regeneration of *C. metuliferus* from protoplasts have been unsuccessful²¹), and protoplast culture of other wild *Cucumis* species has not been reported yet. Although the production of somatic hybrids between melon and pumpkin was reported²²), the production of interspecific hybrids between melon and wild *Cucumis* species by cell fusion has not been successful. In the production of somatic hybrids by cell fusion, it is important to develop an efficient regeneration system from protoplasts and reliable methods for the selection of somatic hybrids. Several selection methods of somatic hybrids in cell fusion had already been reviewed by Bajaj¹). In the review, reliable selection of somatic hybrids by marker genes, e.g. antibiotic resistance genes, introduced into plant through recombinant DNA technology was described. To apply this selection method to the production of somatic hybrids between melon and wild *Cucumis* species, it is essential that selective marker gene(s) be introduced into wild *Cucumis* species. However, the plant regeneration procedure applied to *C. metuliferus*^{15,16}) and *C. angria*¹¹) was found to be ineffective practically while that of *C. figareii* has not been reported yet.

In the present study, the use of phytohormones was evaluated to develop efficient plant regeneration in *C. figareii* and *C. metuliferus*. We succeeded in recovering whole plants from cotyledonary explants in *C. figareii* and improving the regeneration system in *C. metuliferus*.

Materials and methods

1) Plant materials and culture conditions

Peeled seeds of *C. figareii* and *C. metuliferus* were surface-sterilized by dipping in a hypochlorite solution containing ca. 1% active chlorite for 10 min, followed by 3 rinses in sterile distilled water. To ensure uniform germination, seeds were placed in a shallow dish and on a wet filter paper with sterile distilled water for 3 days at 28°C in darkness. Afterwards, each cotyledon dissected from seed was cut into 2 pieces and cultured onto MS medium¹⁰) containing 30 g/L sucrose, 2.5 g/L gelrite and phytohormones. The pH of all the media was adjusted to 5.8 prior to autoclaving sterilization at 121°C for 15 min. All the cultures except for the seed germination period were carried out under cool-white fluorescent lamps (ca. 2000 lux) and 16 h photoperiod and at 25°C.

2) Plant regeneration from cotyledonary explants in *C. figareii*

Media: Combinations of benzyladenine (BA) (0.5, 1 and 2 mg/L) and indole-3-acetic acid (IAA) (0, 0.2 and 2 mg/L) were used to evaluate the effect on shoot organogenesis. Subsequently, effects of 1 mg/L BA combined to several concentrations of abscisic acid (ABA) (0.2, 1, 2 and 4 mg/L), Zeatin (0.5, 2 and 4 mg/L) and thiazuron (TDZ) (0.2, 0.5, 1 and 2 mg/L) on shoot organogenesis were evaluated. The explants were cultured onto the media in plastic petri dishes (ϕ 90x20 mm). At 4 weeks after the initial culture, the regeneration frequency was calculated based on the number of explants forming adventitious shoots to that of total explants cultured. The experiment was replicated 3 times, and 10 explants were used in each treatment. Adventitious shoots were transferred to MS medium containing 30 g/L sucrose, 2.5 g/L gelrite and 1 mg/L IAA to elongate shoots and induce adventitious roots. Plantlets with adventitious roots were acclimatized and grew to normal plants.

3) Plant regeneration from cotyledonary explants in *C. metuliferus*

Media: Combinations of BA (0.1, 0.5, 1 and 2 mg/L) and IAA (0, 0.2, 2, 4 and 8 mg/L) were used to evaluate the effect on shoot organogenesis. At 4 weeks after the initial culture, the regeneration frequency was calculated based on the number of explants forming adventitious shoots to that of total explants cultured. The experiment was replicated 3 times, and 24 explants were used in each treatment. Other conditions were the same as those described above.

Results

1) Production of adventitious shoots in *C. figarei*

Adventitious shoots of *C. figarei* were induced on media containing only BA as plant growth regulator ([Table 1](#) and [Fig. 1-A](#)). Especially, the highest regeneration frequency (43.3%) was achieved at 1 mg/L BA. Lower concentration of BA (0.5 mg/L) was insufficient to promote adventitious shoots, and higher concentration of BA (2 mg/L) slightly decreased the regeneration frequency (36.7%). However, the addition of IAA into the shoot induction media decreased the regeneration frequency remarkably. It was shown that the combination of BA and IAA inhibited shoot organogenesis from cotyledonary explants in *C. figarei*

Table1: Effect of application of phytohormones on shoot oraganogenesis in *C. figarei*

		<u>IAA (mg/L)</u>		
		<u>0</u>	<u>0.2</u>	<u>2</u>
BA	0.5	10.0±5.8	13.3±3.3	0
(mg/L)	1.0	43.3±5.8	10.0±5.8	0
	2.0	36.7±5.8	10.0±5.8	0

The experiment used 10 explants in each treatment and was triplicated.

[Fig.1: Shoot organogenesis and plant regeneration in *C. figarei* and *C. metuliferus* \(42 KB\)](#)

As we considered that the regeneration frequency (43.3%) obtained from these experiments was not satisfactory for practical application, other conditions, including the combination of 1 mg/L BA and other phytohormones (ABA, Zeatin and TDZ), were investigated to enhance the regeneration frequency. Combination of 1 mg/L BA and ABA (0.2 to 2 mg/L) increased the regeneration frequency, and the highest regeneration frequency (63.3%) was achieved when cotyledonary explants were cultured with a combination of 1 mg/L BA and 0.2 mg/L ABA ([Table 2](#)). However, the addition of 4 mg/L ABA did not improve the frequency of shoot organogenesis. The regeneration frequency under the combination of 1 mg/L BA and 2 mg/L Zeatin was the same as that with 1 mg/L BA only, while the combination of 0.5 mg/L Zeatin decreased the regeneration frequency compared to 1 mg/L BA only (Table 2). TDZ exerted adverse effects on shoot organogenesis in *C. figarei*, and the regeneration frequency decreased remarkably (data not shown). These experiments, indicated that the combination of 1 mg/L BA and 0.2 mg/L ABA promoted shoot organogenesis in *C. figarei* efficiently.

Table 2. Effect of addition of Zeatin and ABA on shoot organogenesis in *C. figarei*

<u>Control^{a)}</u>	<u>Zeatin (mg/L)</u>			<u>ABA (mg/L)</u>			
	<u>0.5</u>	<u>2</u>	<u>4</u>	<u>0.2</u>	<u>1</u>	<u>2</u>	<u>4</u>
40.0±5.8	30.0±5.8	43.3±3.3	45.0±5.0	63.3±0	60.0±5.8	60.0±10.0	45.0±5.0

The experiment used 10 explants in each treatment and was tripliated.

a): Explants were cultured on MS medium containing 1 mg/L BA, 30 g/L sucrose and 2.5 g/L gelrite.

Most of the regenerated shoots were elongated and induced adventitious roots on MS medium supplemented with 1 mg/L IAA ([Fig. 1-C](#)). Plantlets acclimatized grew vigorously in the greenhouse.

2) Production of adventitious shoots in *C. metuliferus*

The use of BA only or of a combination of BA and IAA resulted in the induction of adventitious shoots from cotyledonary explants in *C. metuliferus* ([Fig. 1-B](#)). The application of 1 and 2 mg/L BA could induce adventitious shoots, and the frequencies were 84.4% and 80.0%, respectively. However, lower concentrations (0.1 and 0.5 mg/L) of BA induced adventitious shoots less efficiently than higher ones. Moreover, the combination of BA (0.1, 0.5, 1 and 2 mg/L) and 0.2 mg/L IAA enhanced shoot organogenesis, and the frequencies ranged from 78.8 to 92.5%. Especially, the highest regeneration frequency (92.5%) was obtained under combinations of 1 mg/L BA and 0.2 mg/L IAA. However, a higher concentration of IAA decreased the frequencies gradually, and the addition of 8 mg/L IAA suppressed shoot organogenesis completely at all the concentrations of BA in this experiment ([Table 3](#)).

Table 3. Effect of application of phytohormones on shoot organogenesis in *C. metuliferus*

BA (mg/L)	IAA (mg/L)					
	0	0.2	2	4	8	
0.1	47.2±19.6	78.8±5.3	35.4±8.0	49.6±4.4	0	
0.5	50.4±12.3	91.1±5.1	62.5±22.0	25.0±17.6	0	
1.0	84.4±4.4	92.5±10.6	85.4±4.2	50.1±8.8	0	
2.0	80.0±7.1	89.6±14.7	66.7±18.0	6.3±8.8	0	

The experiment used 24 explants in each treatment and was triplicated.

Most of the regenerated shoots were elongated and induced adventitious roots under the same conditions as those for *C. figareii* ([Fig. 1-D](#)). Plantlets of *C. metuliferus* also grew vigorously in the greenhouse.

Discussion

Combination of phytohormones often determines the course of morphogenesis, e.g. shoot organogenesis or embryogenesis. The use of plant growth regulators is essential for the control of morphogenesis in tissue culture. In this report, first of all, the effects of combinations of BA and IAA on shoot organogenesis in *C. figareii* and *C. metuliferus* were analyzed, because BA and IAA have been most often used for shoot organogenesis in melon^{3,8,18}) and cucumber¹⁷). Combination of BA and IAA was also reported to be effective for shoot organogenesis in watermelon^{4,20}).

Shoot organogenesis and embryogenesis in *C. figareii* had not been reported yet, and *C. figareii* was considered to be a recalcitrant plant for plant regeneration from tissues. In this report, the regeneration system of *C. figareii* was investigated and developed as in the case of *C. metuliferus*. When cotyledons 3 days after forced sprouting were cultured in the presence of BA (0.5, 1, 2 mg/L) only or in combination with 0.2 mg/L IAA and BA (0.5, 1, 2 mg/L), several adventitious shoots were induced. Addition of IAA into the shoot induction medium suppressed shoot organogenesis. In some regeneration systems via shoot organogenesis in melon and cucumber, it was reported that the utilization of auxin was not essential^{3,17}). In the tissue culture of *C. figareii*, the combination of cytokinin and auxin had tended to stimulate callus proliferation, and efficient shoot organogenesis was not achieved, because the conditions of shoot induction from dedifferentiated callus and proliferation were not favorable. Subsequently, BA was combined with several kinds of phytohormones to improve the regeneration frequency. It was found that the combination of BA and ABA stimulated shoot organogenesis from cotyledons 3 days after forced sprouting. Recently, it has been reported that the addition of ABA improved the regeneration frequency via shoot organogenesis and somatic embryogenesis^{6,17}). However, the mechanisms of action of ABA in tissue culture have not been elucidated. One of the assumptions was as follows: the induction of ABA when plants experienced several stresses, e.g./low and high temperature, desiccation, microbial infection and injury, conferred a certain degree of tolerance against these stresses⁶). Addition of ABA into the regeneration medium may induce tolerance to tissue culture as a kind of stress.

In *C. metuliferus*, adventitious shoots were induced effectively in the presence of BA only or in combinations of BA and IAA, especially, the highest regeneration frequency was obtained under the combination of 1 mg/L BA and 0.2 mg/L IAA. Orczyk et al.¹¹) attempted to induce plant regeneration from a leaf of *C. figareii* and *C. metuliferus* in the presence of several concentrations of 2,4-dichlorophenoxyacetic acid (2,4-D) and 6(γ , γ -dimethylallylamino)-purine (2iP). Raharjo and

Punja¹⁶⁾ succeeded in the induction of shoot callus derived from petioles in the presence of 2,4-D and BA. Punja et al.¹⁵⁾ also succeeded in the induction of adventitious shoots from cotyledon, leaves and petiole. The highest regeneration frequency of 30% was obtained from leaf cultured on MS medium with 5 μ M IAA and 5 μ M BA. However, Punja et al.¹⁵⁾ failed to achieve plant regeneration when these explants were cultured under a combination of α -naphthaleneacetic acid (NAA) and BA, or 2,4-D and BA. Based on this information, including our results, it was considered that the utilization of IAA and BA was essential for efficient shoot organogenesis in *C. metuliferus*. Although concentrations of BA and IAA reported by Punja et al.¹⁵⁾ and those we used were very close, the regeneration frequency was different between the 2 groups. The difference between these reports was attributed to the difference in the explant used in tissue culture, namely Punja et al.¹⁵⁾ used cotyledon from 8 to 10 days old seedlings and leaves and petiole from 3 to 4 weeks old seedlings, while we used cotyledons 3 days after forced sprouting in our experiment. Cotyledons of mature seed or very young seedlings were used for tissue culture in Cucurbitaceae^{3,4,12,17,18,20)}. Potential for regeneration of several kinds of explants was examined for shoot organogenesis and embryogenesis in melon, and the regeneration ability of cotyledons of mature seeds was found to be higher than that of cotyledons from 7 days old seedlings and leaves and petiole from 3 weeks old seedlings¹⁸⁾. Based on these reports, it was assumed that the ability of cotyledons of melon^{8,18)}, and watermelon^{4,20)} for plant regeneration gradually decreased when the duration of the period after germination increased. For the development of an efficient plant regeneration system in *C. metuliferus*, it is essential to use a combination of BA and IAA as phytohormones for shoot organogenesis and young cotyledons 3 days after forced sprouting were also used as explants.

The results of our study suggest that efficient regeneration conditions for *C. figarei* and *C. metuliferus* may enable to produce transgenic wild Cucumis species, and contribute to the development of a regeneration system of protoplast culture in *C. figarei* and *C. metuliferus*.

Abstract

Acetosyringone, which is one of the phenolic compounds produced by wounding plant tissues, actively induces the transfer of T-DNA from *Agrobacterium* to plant. To produce transgenic calli from tea plant (*Camellia sinensis*), leaf explants of the tea plant were co-cultivated with *Agrobacterium tumefaciens* LBA4404 harboring pBI121 under different acetosyringone concentration conditions. After the infection, these explants were placed on a medium containing 200 mg/L kanamycin and then resistant calli were selected. Although callus differentiation was not observed without acetosyringone at 10 μ M application, resistant calli were obtained from the explants treated with acetosyringone. In particular, the application of 500 μ M of acetosyringone promoted the production of resistant calli. When the fluorogenic assay was carried out to detect the GUS gene expression, one resistant callus showed the activation. In addition, PCR and PCR Southern blot analyses confirmed that the resistant calli were transformants.

Introduction

Plant genetic transformation has been applied to many crop plants and some of the transgenic plants have been used commercially in recent years. Although some transformed woody plants also have been produced, such as apple⁶⁾, kiwi fruit¹⁷⁾, citrus¹¹⁾ and poplar¹⁾, the number of woody plants species giving rise to transformants is limited. Since successful transformation is based on tissue culture techniques, regeneration from plant tissues or protoplasts, cannot be easily established for many woody plants.

Tea plant (*Camellia sinensis*), one of the important crops for beverage, is a woody plant. No stable technique of foreign gene introduction to the tea plant has been developed. For tea plant breeding, transformation technology will be a powerful tool. 'Yabukita', a leading variety of tea which covers 74% of the tea fields in Japan, is susceptible to several pathogens. To alleviate these shortcomings, genetic engineering including a reliable transformation system is required. Several gene introduction methods, such as electroporation, PEG, bombardment and *Agrobacterium*-gene mediation, have been developed up to the present. In tea tissue culture, regeneration from protoplasts to a whole plant is difficult but possible from stem tissues or cotyledons. Although the ratio of infection is low, *Agrobacterium* can infect tea. In addition, *Agrobacterium*-gene transfer method does not require any expensive equipment, such as particle gun. Therefore, the *Agrobacterium*-gene mediated system is considered to be suitable for tea. At first we attempted to improve the ratio by the application of acetosyringone which is one of the phenolic compounds produced by wounding plant tissues and which induces the transfer of T-DNA from *Agrobacterium* to plants^{1,10,16)}. In this study, we demonstrated that the use of acetosyringone is effective for *Agrobacterium*-gene transfer to the tea plant and enables to produce some transformed tea calli.

Materials and methods

1) Plant tissues and co-cultivation

Leaf was cut from *in vitro*-cultured tea plant which was a natural seedling of 'Sayamakaori' and prepared to approximately 10x10 mm fragments as an explant. The plant medium used in this study consisted of Murashige and Skoog¹²⁾ standard 0.8% agar solid medium containing 3% sucrose, 0.5 mg/L IBA, 10 mg/L BA. Co-cultivation media with *Agrobacterium* contained acetosyringone at final concentrations of 10, 100 and 500 μ M. *Agrobacterium tumefaciens* LBA4404 containing a binary vector pBI121 was used. The leaf explants were inoculated with *Agrobacterium* and cultured on the media for 2 days in the dark at 28°C. The leaf explants were washed with water, treated with carbenicillin (500 mg/L) to kill *Agrobacterium* and then transferred to a selective medium containing kanamycin (200 mg/L) and carbenicillin (500 mg/L). These explants were cultured under a 16 h/light, 8 h/dark, regime in a clean room controlled at 25°C and also transferred to fresh selective medium every 2 weeks.

2) Callus proliferation and evaluation

We developed a growth index(G.I.) indicated below and evaluated the degree of differentiation of callus from the explant 2 months after transfer to the selective medium.

0; Callus did not differentiate.

1; Callus differentiation only occurred at the periphery of the explants.

2; Callus covered about less than 30% of the explants.

3; Callus covered about more than 30% of the explants.

3) GUS fluorogenic assay

A binary vector plasmid (pBI121) contained a selective gene, NPTII, and a marker gene encoding the GUS controlled by the CaMV35S promoter. The fluorogenic assay was carried out as described by Jefferson⁷). One resistant callus was ground with sand in lysis buffer (50 mM NaH₂PO₄, pH 7.0, 10 mM EDTA, 0.1% Triton X-100). After centrifugation, 1 mM MUG buffer was added to the supernatant solution and the solution was incubated at 37°C for 2 h. A tube containing the solution was placed on an ultraviolet light box and the blue fluorescence was observed.

4) PCR and PCR Southern blot analyses

DNA was isolated from the resistant or non-resistant calli according to the method of Guillemat³) with modifications and less than 10 ng DNA was used for the PCR template. Primer sequences were 5-GCATACGCTTGATCCGGCTACC-3 and 5-TGATATTCGGCAAGCAGGCAT-3 for the NPTII gene and 5-GAACAACGAACTGAACTGGCA-3 and 5-CTAGTGCCTTGTCAGTTGC-3 for the GUS gene. Length of target DNA fragments of the NPTII or the GUS genes was 221 bp and 291 bp, respectively. Samples for enzymatic amplification were subjected to 30 repetitions of the following thermal cycle: 1 min at 95 °C, 2 min at 55°C and 3 min at 72°C.

The amplified DNAs were electrophoresed in 0.8% agarose gel, stained with ethidium bromide and visualized by illumination with ultraviolet light. Then DNAs were transferred to Hybond N+ (Amersham) membranes and hybridized with fluorescein-labeled probes from the NPTII or the GUS DNA fragments. Hybridization was performed at 65°C overnight. After hybridization, the membranes were washed with 0.2xSSC, 0.1% SDS at 65°C for 15 min twice. Chemical detection was carried out on X-ray film according to the manufacturers' manual (Amersham) .

Results

Results of callus differentiation from tea explants are shown in [Table 1](#). Tea calli differentiated at the periphery of the explants and proliferated on the MS agar solid medium containing BA and IBA without antibiotics after 2 months. Fourteen explants showed a growth index (G.I.) of 2 and calli from 6 explants also proliferated up to G.I. 3. On the other hand, calli on the selective medium containing 200 mg/L kanamycin did not grow even to G.I. 1. Therefore, the selection of kanamycin 200 mg/L was effective for the inhibition of normal differentiation or proliferation from the explants. These results also indicated that acetosyringone did not affect kanamycin selection since no relationship between the concentration of applied acetosyringone and the G.I. was observed.

Table 1. Effect of acetosyringone application on differentiation of resistant callus from tea leaf explants

<u>Concentration of acetosyringone</u>	<u>No Agrobacterium inoculation</u>				<u>Agrobacterium inoculation</u>			
		<u>Growth index</u>				<u>Growth index</u>		
<u>(¼Mm)</u>	<u>0</u>	<u>1</u>	<u>2</u>	<u>3</u>	<u>0</u>	<u>1</u>	<u>2</u>	<u>3</u>
0 ^{a)}	0	0	14	6	20	0	0	0
0	10	0	0	0	17	3	0	0
10	4	6	0	0	9	7	4	0
100	4	6	0	0	5	9	2	5
500	4	6	0	0				

a): No. of differentiated with on a medium without antibiotics.

None of the explants inoculated with *Agrobacterium* on the medium without acetosyringone or application of 10 mM induced calli on the selective medium. When 100 mM acetosyringone was used, 4 of the 20 explants induced G.I. 3 calli, and 5 calli in the 500 mM experiment could proliferate up to G.I. 3. These calli continued to grow on the selective medium and became green. Multiple transfers to the fresh medium were carried out to prevent the loss of antibiotics and contamination of *Agrobacterium*. Elimination may occur since *Agrobacterium* was not detected when part of the resistant calli was placed on LB agar medium. Therefore we attempted to use 5 calli in 500 mM for further analyses to determine whether these calli consisted of transformed cells.

To detect the expression of the GUS gene, we carried out a fluorogenic assay. The intense blue fluorescence of the resistant calli under UV light was stronger than that of the negative control ([Fig. 1](#)). In the PCR analysis, 221 bp (NPTII) and 291 bp (GUS) DNA fragments were detected by staining callus No. 2 ([Fig. 2, lane 5](#)) with ethidium bromide as in the case of the positive control, pBI121, and a weak signal which showed the amplified 221 bp of NPTII was observed in callus No. 1 (lane 6). Hybridized fragments were observed not only in No. 1 and 2 calli but also in No. 5 callus ([Fig. 3](#)). Since the target DNA in a negative control experiment was not amplified, we assumed that calli No. 1, 2 and 5 consisted of transformed cells.

Discussion

Several attempts to produce transgenic tea plants made until now had not been successful. The tea plant is, therefore, considered to be one of the recalcitrant plants for transformation. We selected the *Agrobacterium*-mediated gene transfer system as mentioned above. Tea plant is infected with *Agrobacterium* but shows a tendency to be resistant in the field, because the probability of observing natural crown galls on tea roots is low and even if it occurred, the damage would not reach an economic level. In the process of transformation through *Agrobacterium*, the low efficiency of

the infection is a disadvantage which must be overcome. At first we tried to improve the ratio by using acetosyringone which had been employed to obtain transgenic plants, not only dicotyledonous plants such as Arabidopsis¹⁵⁾, sugar beet⁵⁾ and tomato⁸⁾, efficiently but also monocotyledonous plants including rice⁴⁾. In these reports, acetosyringone was used at final concentrations ranging between 0.1 and 100 mM. The promotion of the expression of *Vir* genes began at 0.1 and reached a maximum level at 100 μ M¹⁶⁾. In this study the resistant calli only emerged by the application of higher concentrations of acetosyringone. Application of 100 μ M also promoted tea callus differentiation and callus grew up to G.I. 2. Since the G.I. 2 callus was resistant to kanamycin, it was considered that it consisted of transformed cells. These results indicated that the application of acetosyringone to the medium was very effective for tea cell transformation using leaf explants and the concentration for tea was higher than that of other plants.

One resistant callus showed the GUS gene expression, and PCR and Southern blot analyses revealed that 3 calli were transgenic. However, we could not confirm that 2 of the 5 resistant calli were transformants by PCR and PCR Southern analyses. The lack of amplification of the target DNA fragments of the 2 calli could not be explained, but may be due to the low concentration of template DNA under the current PCR thermal conditions.

Our final objective is to develop a technique for the introduction of foreign genes in the tea cells and production of transgenic tea plants by practical gene introduction. The tea plant can regenerate from cotyledon¹³⁾ and stem^{9,14)} in *in vitro* tissue culture. To produce a whole transgenic tea plant, it is necessary to combine 2 techniques for foreign gene introduction and regeneration from transgenic cells. We demonstrated that acetosyringone application was effective in the production of transgenic tea cells. These results will be applied in a following study to produce whole transgenic tea plants.

Decontamination of Dry Food Ingredients with "Soft-Electrons" (Low-Energy Electrons)

Toru HAYASHI*

Abstract

Electrons with energies of 300 keV or lower were defined as "soft-electrons". Soft-electrons eradicated microorganisms residing on the surface of grains, pulses, spices and dehydrated vegetables, and reduced their microbial loads to levels lower than 10 CFU/g. Soft-electrons penetrated only into the surface of grains and did not significantly degrade starch molecules inside grains. The use of electrons with a higher energy and with a higher penetration capacity resulted in a higher thiobarbituric acid value (TBA, parameter for lipid oxidation) of brown rice. Milling of rice at a yield of 90% or 88% after exposure to electrons resulted in a TBA value of rice treated with electrons at 65 keV almost the same as that of untreated rice, indicating that the milling process removed the portion of brown rice exposed to soft-electrons. It is concluded that soft-electrons can decontaminate dry food ingredients with few adverse effects on the quality.

Discipline: Food

Additional key words: grains, pulses, spices, dehydrated vegetables

Introduction

Grains, pulses, spices and dehydrated vegetables are frequently contaminated with microorganisms, especially heat-resistant bacterial spores, although they are widely used for food processing. Bacterial spores contaminating these dry food ingredients can not be inactivated completely by heating processes such as steaming and boiling at food processing plants. Thus dry ingredients for food processing should be decontaminated to prevent food spoilage and food-borne diseases. Decontamination techniques including fumigation with ethylene oxide gas (EOG), irradiation with ionizing radiation and treatment with super-heated steam are applied to some of the dry food ingredients. However, these techniques are associated with some drawbacks. EOG fumigation is prohibited in Japan, because of the carcinogenic effect of the residues. Irradiation with gamma-rays or electron beams can effectively inactivate bacterial spores contaminating spices and dehydrated vegetables with minimal quality alteration, and irradiation of spices is practiced on a commercial basis in more than 20 countries¹²). However, irradiation of food products other than potato is not approved in Japan. Irradiation at high doses for decontamination is not applicable to grains such as rice and wheat. Ionizing radiation causes oxidation and degradation of components such as lipid and starch molecules^{1,11,12}), which results in quality deterioration of grain products such as noodles and rice cake in terms of flavor and texture. Treatment with super-heated steam

is the only method widely used for decontaminating dry ingredients in Japan. However, super-heated steam sometimes brings about changes of flavor and color of dehydrated vegetables and herbs. No method has been developed for decontaminating all the dry food ingredients.

It is generally recognized that since most of the microorganisms contaminating dry food ingredients reside on their surfaces, the inner parts do not have to be exposed to heat, gas or radiation for decontamination. The penetration capacity of an electron beam is controlled by the energy; electrons with lower energies display lower penetration capacities²⁾. We have defined low-energy electrons at 300 keV or lower as "soft-electrons". Soft-electrons reach only the surface of food, and the quality changes of food caused by such electrons are expected to be much more limited than those caused by gamma-rays or high-energy electron beams with much higher penetration capacities. We carried out studies on the efficacy of soft-electron treatment to decontaminate dry food ingredients.

Equipment for soft-electron treatment

Dry ingredient samples were treated with soft-electrons under rotation to expose all the sample surfaces to electrons with low penetration capacity. A grain rotator was developed which enabled samples to rotate by shaking and vibrating them simultaneously at variable speeds (*Fig. 1*). The rotator was placed under the window of a Van de Graaff electron accelerator (Nissin High Voltage Engineering Co., Ltd., Kyoto, Japan), which generated electrons at acceleration voltages of 170-300 kV. The distance between the window of the electron accelerator and the plastic tray of the grain rotator was 17 cm.

[*Fig. 1. Grain rotator for treating grains with low-energy electrons \(22 KB\)*](#)

Penetration capacity of soft-electrons

Penetration capacities of soft-electrons at different energies were determined based on depth-dose curves. Several pieces of radiochromic film dosimeter (RCF) (5.94 mg/cm², FWT-60-00, Far West Technology Inc., Goleta, California, USA) were stacked together in layers at the bottom of the plastic tray of the grain rotator (C of *Fig. 1*) which was placed under the window of the electron accelerator at a distance of 17 cm, and irradiated with electrons for 60 min under various conditions (170 kV, 4 μ A; 180 kV, 8 μ A; 190 kV, 10 μ A; 200 kV, 14 μ A). Absorbances at 510 nm of all RCF films before and 30 min after irradiation were measured and the dose absorbed by each RCF film was determined according to the method of McLaughlin et al.⁸⁾.

Energies of electrons at a distance of 17 cm (air) from the window (50 μ m thick titanium) of the electron accelerator were lower than those of the electrons at the window (acceleration voltage). The energies of electrons irradiating samples at 17 cm from the window were estimated to be 60, 75, 90, 100, 130, 160 and 210 keV for acceleration voltages of 170, 180, 190, 200, 225, 250 and 300 kV, respectively, based on the mass stopping power of air and titanium^{7,10)}.

Depth-dose curves of electrons at various energies were developed by plotting all the absorbed doses determined with RCF films (*Fig. 2*)⁶⁾. The penetration capacity of electrons at 60 keV was about 6 mg/cm² and that at 75 keV was about 10 mg/cm², while those at 90 and 100 keV were lower than 17.82 mg/cm² (5.94 mg/cm² x 3 pieces). Doses absorbed by the first RCF film for 1 h were about 30, 58, 70 and 110 kGy at 60, 75, 90 and 100 keV, respectively (*Fig. 2*)⁶⁾.

[Fig. 2. Depth-dose curves of electrons determined with radiochromic film dosimeter \(RCF\) \(25 KB\)](#)

Sterility and viscosity of grains exposed to soft-electrons

Energies of electrons necessary to reduce microorganism levels to less than 10 CFU/g were 75 keV for brown rice, 130 keV for rough rice, 75 keV for wheat and 160 keV for buckwheat ([Table 1](#))⁵. The results suggested that most of the contaminating microorganisms resided in the region that the electrons with such low energies could reach. Gamma-rays at 7.5-12.5 kGy were necessary to achieve the same levels of sterility.

[Table 1: Sterility of grains exposed to low-energy electrons or gamma-rays \(CFU/g\) \(73 KB\)](#)

Viscosity of heat-gelatinized grain suspensions decreased with the energy of electrons ([Table 2](#))⁵. Viscosity of brown rice and wheat treated with electrons at 75 keV was almost the same as that of untreated samples. Viscosity of rough rice and buckwheat exposed to electrons at 130 keV was slightly lower than that of untreated samples, but much higher than that of the samples irradiated with gamma-rays at 10 kGy. The viscosity values of a grain suspension which was heat-gelatinized under an alkaline condition is a parameter for starch degradation^{3,4}. The results suggested that electrons with minimum energy for decontamination did not degrade starch molecules inside the grains.

[Table 2: Viscosity of 7.5% aqueous suspensions of grains exposed to low-energy electrons or gamma-rays \(mPa.s\) \(39 KB\)](#)

The applicability of soft-electrons to wheat depended upon the variety of wheat. Soft-electrons could decontaminate wheat grains of Australian Standard White (ASW), Shirogane and Western White (WW) varieties, but could not decontaminate those of Dark Northern Spring (DNS), Norin No. 61 and No. 1 Canadian White (1CW) varieties ([Table 3](#)). No relationship was observed between the application of soft-electrons and the sensitivity of the contaminating microorganisms to gamma-rays. The difference in the application of soft-electrons was ascribed to the structure of the wheat grain. In varieties such as DNS, Norin No. 61 and 1CW, microorganisms would reside in areas which soft-electrons did not reach.

Quality of milled rice prepared from brown rice treated with soft-electrons

Both Koshihikari and Nihonbare could be decontaminated with soft-electrons even at 60 keV⁶). No significant difference in the viscosity was observed at any milling yield between the control and the rice grains exposed to electrons at 60-90 keV. Milling reduced the effect of electrons on the viscosity; milling of rice grains at a yield of 88% did not result in a significant difference in the viscosity between untreated samples and 100 keV-electron treated samples⁶). However, milling did not affect the viscosity of rice irradiated with gamma-rays. The results suggested that soft-electrons degraded starch molecules near the surface of rice grains, which could be removed easily by milling. On the contrary, gamma-rays degraded all the starch molecules in rice grains most of which could not be removed by milling⁶).

Thiobarbituric acid (TBA) value is a parameter of lipid oxidation. TBA value of brown rice increased with the energy of electrons. TBA values of brown rice samples exposed to electrons at 60-100 keV were significantly higher than that of untreated control ([Table 4](#))⁶). The use of gamma-rays at 7.5 kGy resulted in a higher TBA value than that of electrons with energies of 60-100 keV. Milling decreased the TBA values of all the samples, especially those of electron-treated samples. Accordingly, the differences in the TBA values between the control and the electron-treated rice grains decreased markedly after milling. The difference in the TBA values between the control and the rice samples exposed to electrons at 60 keV was not significant at a milling yield of 90% or lower, and the difference between the values of the control and the rice samples exposed to electrons at 75 keV was not significant at a milling yield of 88%. The results suggested that most of the lipids oxidized by electrons at 60 and 75 keV were removed by milling at yields of 90 and 88%, respectively.

[Table 4: TBA values of rice exposed to low-energy electrons or gamma-rays \(22 KB\)](#)

Hardness and stickiness under low and high compressions of cooked rice grains (90% milling yield) exposed to electrons at 60-75 keV were almost the same as those of the control ([Table 5](#))⁶). Hardness and stickiness under low and high compressions of gamma-irradiated samples were lower than those of the control. Hardness and stickiness under low compression are parameters for rheological properties of the surface of cooked rice grains, and those under high compression are parameters for the properties of overall cooked rice grains⁹). The results showed that rice grains which were exposed to electrons at 60-75 keV and milled at a yield of 90% displayed the same rheological properties as the control. The results shown in Tables 4 and 5 indicate that milling at yields of 88-90% removed the portion of rice exposed to electrons at 60 keV which could eradicate most of the microorganisms contaminating brown rice.

[Table5: Physical properties of cooked rice graina\) \(34 KB\)](#)

Decontamination of other ingredients

Soft-electrons at 100 keV reduced the microbial loads of shredded dehydrated vegetables to levels lower than 10 CFU/g, although the time necessary for electron treatment was different ([Table 6](#)). Longer duration of electron treatment was necessary for dehydrated vegetable samples which required a higher dose of gamma-rays for disinfection. The microorganisms contaminating dehydrated vegetables showed

the same resistance to soft-electrons as to gamma-rays. Black pepper could be decontaminated with electrons at 210 keV, while white pepper, basil and coriander could be decontaminated at 100 keV. Pulses such as soybean, adzuki bean and black soybean could be decontaminated with electrons at 60 keV.

[Table 6: Sterility of dehydrated vegetables exposed to low-energy electrons \(CFU/g\) \(59 KB\)](#)

Conclusion

Soft-electrons can decontaminate dry food ingredients such as grains, dehydrated vegetables, spices and pulses with minimal quality deterioration. The portion of grains exposed to electrons is removed as husk and bran by dehusking and/or milling. Therefore chemical compounds formed by electron exposure are removed by dehusking or milling and no such compounds occur in the edible parts of grains.

Electrons with such low energies do not require a thick shield due to their low penetration capacity, which enables in-line decontamination at food processing plants. Facility to expose all the ingredient surfaces uniformly to soft-electrons on a large scale in a short period of time should be developed to industrialize this decontamination technique.

Abstract

Long-term storage of the tropical forest tree *Guazuma crinita* Mart. following alginate encapsulation technique and cryogenic procedures was attempted. Shoot tips excised from *in vitro* plantlets were encapsulated in calcium alginate beads and stored on different substrates at 12, 20, and 25°C. Viability was retained when encapsulated shoot tips were stored on substrate containing only water solidified with 1% (w/v) agar. Percentage of viability 12 months after storage was 90% at 25°C and 70% at 20°C. For cryogenic experiments, shoot tip, nodal segment, root tip, and adventitious bud cluster explants were stored in liquid nitrogen following 4 cryopreservation methods: (1) simple freezing, (2) rapid freezing, (3) slow pre-freezing, and (4) encapsulation/dehydration method. High survival rates (about 80%) were achieved when the adventitious bud cluster explants were exposed to a cryoprotectant mix solution containing (w/v), 25% glycerol, 15% sucrose, 15% ethylene glycol, 13% dimethyl sulfoxide, and 2% polyethylene glycol (4,000), at 25°C for 15-60 min prior to storage in liquid nitrogen.

Introduction

Bolaina blanca (*Guazuma crinita* Mart., Sterculiaceae) is a useful fast-growing tree endemic in the Amazon forest region⁸). This tree is a light hardwood species with good working properties that has been used for light construction, panelling, interior joinery, mouldings, cases, matches, packing, etc. *G. crinita* has a fast initial growth rate of up to 3 m in height per year (final rotation age of 10 to 15 years) and shows an excellent adaptability to a wide range of sites including areas with poorly drained heavy clay soils which are widespread throughout the tropics. It has been used for reforestation in the Peru-Amazon¹⁷).

Germplasm conservation has become necessary for future sustainable harvesting systems, and as a means of maintaining species diversity to prevent genetic erosion.

The propagation and conservation of this species traditionally take place by seeds. However, propagation and conservation by vegetative means are desirable for better preservation of true-to-type genetic

characteristics. The conservation of desirable genetic materials using conventional *in situ* or *ex situ* methods such as a field genebank is costly and prone to possible catastrophic losses due to diseases and pest attacks, and is liable to environmental and political threats. Although the use of *in vitro* genebanks alleviates these problems, the maintenance of large collections under conventional *in vitro* storage systems requires much handling and is expensive because most cultures need subculturing at regular intervals to prevent browning and loss of viability, hence the increasing risk of contamination.

Alginate encapsulation technique and cryogenic procedures may be reliable methods for long-term storage of plant genetic resources without apparent risk of genetic instability using minimum space and with lower labor and maintenance costs.

This paper describes the storage of shoot tips encapsulated in calcium alginate beads under temperature conditions above freezing (12, 15, and 20°C), and the cryogenic procedures for the long-term storage of *G. crinita* using *in vitro*-cultured plant materials.

Materials and methods

1) Storage following alginate encapsulation technique

(1) Plant material

Shoot tips, about 3-4 mm long, were aseptically excised from *in vitro*-cultured plants regenerated by the method described by Maruyama et al. (1996)¹⁷.

(2) Encapsulation

Calcium alginate beads were produced by encapsulation according to the method of Kinoshita and Saito (1990)¹². Shoot tips were immersed in autoclaved standard woody plant medium (WPM)¹⁵ supplemented with 1 μ M kinetin containing 4% (w/v) sodium alginate and 2% (w/v) sucrose. Next, the shoot tips in the alginate medium were picked up individually with tweezers and dropped into a sterile solution of 1.4% (w/v) calcium chloride where they remained for 30 min. The calcium chloride solution was then decanted and the alginate beads, each containing 1 shoot tip, were rinsed 3 times with the same autoclaved medium.

(3) Storage

Encapsulated shoot tips were transferred to 200 mL Erlenmeyer flasks containing about 75 mL of the following substrates: water, water containing 2% (w/v) sucrose, and sucrose and plant growth regulator-free WPM. All the substrates were solidified with 1% (w/v) agar (Wako Pure Chem. Ind.). Storage lasted for 3, 6, and 12 months at 25 to 20°C (16 h photoperiod under photon flux density of about 35 μ mol m⁻² s⁻¹) and 12°C (in the dark).

(4) Plant regeneration

Stored encapsulated shoot tips were transferred to germination media (WPM with 1 μ M KIN) and incubated in a culture room at 25°C under a photon flux density of about 65 μ mol m⁻² s⁻¹ for 16 h daily. About 60 days after the transfer to the germination media, encapsulated shoot tips regenerated to plantlets were counted.

(5) Data and analysis

Five encapsulated shoot tips were employed for each of 2 replicates per treatment, at 3 storage temperatures, on 3 storage substrates, over 3 storage periods. Data were analyzed quantitatively by

calculating rates of plant regeneration from stored encapsulated shoot tips. The standard error of means was calculated according to Snedecor (1957)25).

2) *Storage following cryogenic procedures*

(1) Plant material

Shoot tips, nodal segments and root tips, excised from 2 to 3-month-old plantlets regenerated in vitro by the method described by Maruyama et al. (1996)17), were cut into segments about 2 mm long.

Adventitious bud clusters obtained from petiole culture by the method described by Maruyama et al. (1997)18) were cut into small (1.0-1.5 mm³) or large (3.0-4.0 mm³) cubic segments.

(2) Cryoprotectant mix

The following cryoprotectant mix solutions, modified from Sakai et al. (1991)23) and Towill (1990)27), were tested containing (w/v), Mix A: 20% glycerol and 15% sucrose; Mix B: 30% glycerol, 15% sucrose, 15% ethylene glycol, and 15% dimethyl sulfoxide (DMSO); Mix C: 25% glycerol, 15% sucrose, 15% ethylene glycol, 13% DMSO, and 2% polyethylene glycol (PEG); Mix D: 35% ethylene glycol, 10% DMSO, and 5% PEG. The aqueous volume added consisted of WPM without sucrose and growth regulators. All the cryoprotectant mix solutions were filter-sterilized.

(3) Cryopreservation methods

a) Simple freezing

Explants were treated with cryoprotectant mix solution A at 25°C for 5, 10, 15, 20, 30, 45, and 60 min and then cooled in a freezer at -30°C for 1 h prior to immersion in liquid nitrogen (LN) and kept there for at least 1 h.

b) Rapid freezing

Explants were treated with cryoprotectant mix solutions A, B, C, D, alone or in succession at 25°C for different periods of time (0 to 90 min) and then directly immersed in LN and kept there for at least 1 h.

c) Slow pre-freezing

Explants were treated with cryoprotectant mix solutions A, B, C, alone or in succession at 25°C for different periods of time (0 to 45 min) and then cooled to -40°C at a rate of 0.5°C/min prior to immersion in LN and held there for at least 1 h.

d) Encapsulation/dehydration

Explants were progressively pre-cultured at 5°C by successive daily transfer onto solidified WPM containing 5, 10, and 20% (w/v) sucrose. Then, they were encapsulated or not, in 3% (w/v) alginate-coated beads containing 20% (w/v) sucrose. Encapsulated (constructed beads about 5 mm in diameter containing one shoot tip or nodal segment by the same method as that described previously) and non-encapsulated explants were treated with the same medium supplemented with 30% (w/v) sucrose for 16 h at 5°C. After treatments with sucrose they were subjected to dehydration at 25°C for 0 to 24 h in the laminar flow cabinet or inside petri dishes (9 cm in diameter) containing about 50 g silica gel sterilized by heating at 110°C for 16 h, and then cooled in LN by the slow pre-freezing or by the rapid freezing method.

(4) Survival and plant regeneration

Explants were thawed by rapid transfer of cryotubes in a water bath at 37°C. After thawing, cryoprotectant mix solutions were drained from the cryotubes and replaced with a medium containing 40% (w/v) sucrose and kept for 20 min. Then, shoot tip and nodal segment explants were transferred onto solidified WPM containing 10 μ M zeatin and cultured at 25°C under a photon flux density of 65

μ mol m⁻² s⁻¹. The root tip and adventitious bud cluster explants were transferred into liquid WPM containing 10 μ M zeatin and cultured on a bio-shaker at 73 rpm under a photon flux density of 25 μ mol m⁻² s⁻¹. All the explants were cultured at 25°C and under a 16 h photoperiod provided by cool white fluorescent lamps (100 V, 40 W; Toshiba Co.). Examination of the explants for survival was performed at weekly intervals. Survival was recorded when explants had turned green and produced leaves or adventitious buds. Plant regeneration was considered to have occurred when explants had developed into plantlets.

(5) Acclimatization of plantlets

Plantlets regenerated from cryopreserved explants were transplanted into plastic pots filled with vermiculite after washing the roots with tap water to free any adhering agar. They were acclimatized in a growth cabinet at 25-30°C at a photon flux density of 35 μ mol m⁻² s⁻¹ under a 16 h photoperiod, and were irrigated with water for the first 2 weeks and then with 0.1% (v/v) Hyponex plant food solution (The Hyponex Co., Inc.) containing (w/v): 5.00% N, 4.36% P, and 4.15% K. During the first 2 weeks plantlets were kept in a closed container with a transparent cover inside the growth cabinet. After that, the cover was opened gradually during another 2 weeks and removed completely about 1 month after transplanting.

Results and discussion

1) Storage following alginate encapsulation technique

Attempts at growth suppression using alginate encapsulation techniques in combination with temperature reduction and/or omission of some nutrients essential for normal growth were made in order to develop an efficient method for germplasm conservation under temperature conditions above freezing. [Table 1](#) shows the results of plant regeneration from alginate encapsulated shoot tips after 3, 6, and 12 months of storage under various conditions. When the encapsulated shoot tips were stored on a water substrate, the growth process was suppressed or reduced at all the storage temperatures tested. However, the percentage of plant regeneration varied with the temperature and period of storage.

[Table 1: Effect of substrates and storage temperature on plant regeneration from stored alginate-encapsulated shoot tips of *G.crinita* \(18 KB\)](#)

Although the addition of 2% sucrose into the water substrate promoted rooting (not shown) in beads stored at 25°C, it did not induce conspicuous growth under the other storage conditions. However, the effect of sucrose on the stored beads was not beneficial because plant regeneration 6 months after storage was only achieved at 12°C. These results suggest that (1) although conspicuous growth did not occur in stored beads, metabolic processes for germination were induced, (2) the addition of sucrose into the agar substrate enhanced the deterioration of stored beads at storage temperatures of 25 and 20°C, and (3) the beads deteriorated least at a storage temperature of 12°C.

The results may be summarized as follows: (1) in general, water was the optimum substrate for suppressing growth in alginate encapsulated shoot tips, (2) the optimum temperature for storage of encapsulated shoot tips was 25°C, (3) 20°C was the lowest temperature recommendable for storage of alginate encapsulated shoot tips of *G. crinita* under temperature conditions above freezing, and (4) shoot tips encapsulated in alginate beads could be stored for more than 12 months without considerable loss of viability ([Fig. 1A](#)).

[Fig.1: Storage of *G_crinia* in vitro cultures \(47 KB\)](#)

Storage of alginate encapsulated shoot tips under temperature conditions above freezing was found to be a suitable method for conservation of *in vitro*-cultured germplasm. After storage for 12 months, the rate of plant regeneration was up to 90%. Development of germplasm conservation techniques, based on the storage of shoot tips under temperature conditions above freezing, is an important alternative for many species that do not tolerate conventional reduced temperature storage systems (generally at about 4°C).

The alginate bead effect on growth immobilization or minimal growth storage may be attributed to a reduction in the respiration process in encapsulated cells⁴). Alginate is one of the most commonly used polymers for immobilization of plant cells and production of manufactured seeds because it is available in large quantities, is inert, non-toxic, cheap, and easily handled⁷). In addition, while the conventional conservation of *in vitro*-cultured germplasm requires about 4 to 6 subcultures in fresh media within a year to prevent browning and loss of viability, with the method of storage using alginate encapsulation techniques, the handling, cost of maintenance, and risk of contamination, can be reduced four to sixfold.

In vitro germplasm conservation methods based on conditions that permit minimal rates of growth, generally achieved by reducing the temperature of culture or using growth retardants, have been published for many species^{6, 9, 28}). However, studies on *in vitro* germplasm conservation using alginate encapsulation techniques have been reported for only a few species. Embryogenic tissues of *Santalum album*²), axillary buds of *Morus indica*¹), and adventitious buds of *Morus alba*¹⁶) have been encapsulated in alginate or agar beads and then stored for 45-80 days at 4°C without loss of viability. Kinoshita and Saito (1992)¹³) reported that the encapsulated axillary buds of *Betula platyphylla* var. *japonica* could be stored at 4°C for more than 80 days without loss of viability. Micro-cuttings of *Eucalyptus grandis* x *E. urophylla*, encapsulated in alginate beads and kept on a nutrient-free agar medium,

were stored for 10 months at 30/25°C with a plant regeneration rate of at least 52% after storage³⁰).

Although more studies to determine the optimum temperature, photon flux density, concentration of alginate in gel matrix, concentration of essential nutrients into substrate, and other conditions for minimal growth storage, are necessary to further improve the efficiency of the system, the method developed here can be used as a good alternative for the germplasm conservation of many tropical forest trees species that do not tolerate conventional reduced temperature storage systems.

2) Storage following cryogenic procedures

The effects of cryopreservation methods on the survival and plant regeneration of different explants are shown in [Table 2](#). Survival of explants after immersion in LN was not achieved in any of the treatments tested by the simple freezing and encapsulation/dehydration method. Only the use of the rapid freezing and the slow pre-freezing method resulted in plant recovery after storage in LN. These results suggest that the explants tested were not suitable materials for cryopreservation by simple freezing since this method had been successfully applied to cultured cells²⁴), and that treatments in media with a high concentration of sucrose by the encapsulation/dehydration method that has been reported as a successful cryopreservation method for some species^{21, 24, 26}), caused damage to explants apparently due to the fact that this species does not tolerate drastic dehydration processes.

Table 2: Effects of different cryopreservation methods on the survival (S) and plant regeneration (PR) rates of *G. crinita* after cooling in

Adv. Bud cluster			85	25				

a): Explants were treated with cryoprotectant mix and then cooled in a freezer at -30°C for 1 h prior to immersion in LN.

b): Explants were treated with cryoprotectant mix and then cooled by direct immersion in LN.

c): Explants were treated with cryoprotectant mix and then cooled to -40°C at a rate of 0.5°C/min prior to immersion in LN.

d): Explants, with or without alginate encapsulation, were treated with a medium enriched with sucrose before dehydration in a laminar flow cabinet or inside petri dishes containing silica gel, and then cooled in LN by slow pre-freezing or by the rapid freezing method.

Shoot tip, nodal segment, and root tip explants were cut into segments about 2 mm long. Adventitious bud cluster explants were cut into about 1.0-1.5 mm³ cubic segments.

Slow pre-freezing was the optimum method for cryopreservation of shoot tip explants ([Fig. 1B](#)). Rates of 50% for survival and 15% for plant regeneration were achieved when shoot tips were treated with cryoprotectant mix A and B for 20 and 10 min, respectively, and then cooled to -40°C at a rate of 0.5°C/min prior to storage in LN. For root tip explants no difference between the rapid freezing method and the slow pre-freezing method was found ([Table 2](#)). As in the case of shoot tip explants, plant regeneration from cryopreserved root tips was obtained through adventitious bud formation ([Fig. 1C](#)) and subsequently shoot differentiation on medium supplemented with 10 and 1 μ M ZEA, respectively. Although this method is time-consuming and laborious, and requires controlled freezing equipment and complicated procedures, it is the most commonly used method for the cryopreservation of meristems/shoot tips, cell cultures and somatic embryos. Several species have been successfully cryopreserved following slow pre-freezing methods^{5, 9-11, 24, 29}).

In the present study, although rapid freezing failed to cryopreserve the shoot tip and nodal segment explants, this method was effective for the cryopreservation of adventitious bud clusters of *G. crinita*. Survival of adventitious bud clusters after storage in liquid nitrogen varied depending on the size of explant, cryoprotectant mix and on the duration of the cryoprotectant mix treatment. High survival rates (73-85%) were achieved for small cubic

segments (1.0-1.5 mm³) pretreated with cryoprotectant mix B or C. In contrast, large cluster explants (3.0-4.0 mm³) and cryoprotectant mix D-treated bud clusters did not survive after storage in liquid nitrogen ([Fig. 2A](#)). These results suggest that (1) the large size of the explants is not favorable for the dehydration-cryoprotective action of the vitrification solution, or that (2) the duration of the cryoprotectant mix treatments for large cluster explants was insufficient and that (3) glycerol and sucrose are necessary as components of the cryoprotectant mix solution for cryopreservation of bud clusters of *G. crinita* by the rapid freezing method. Based on these results, large-sized cluster explants and cryoprotectant mix D were not used for further experiments.

Survival of small cluster explants did not differ when they were treated with either mix B or C at 25°C for various periods of time prior to direct immersion into liquid nitrogen. The highest rate of survival was obtained with the explants treated with mix B for 15-45 min or with mix C for 15-60 min, respectively. In both cryoprotectant mix treatments, a pretreatment of 5 min in a cryoprotectant solution was insufficient, and pretreatment for 90 min was inhibitory to the survival of explants ([Fig. 2B](#)). The original green color of the bud cluster segments was evident immediately following cooling but was lost within 24-48 h after warming. However, the successfully vitrified bud cluster segments regained their green color within 1 to 2 weeks after transfer to recovery growth medium ([Fig. 1D](#)). After 45 days of culture, clumps of numerous bulbous structures about 5 mm in diameter were formed ([Fig. 1E](#)). When transferred onto agar-solidified WPM containing 1 μ M zeatin, after 60 days, about 30% of the surviving cryopreserved explants formed shoots ([Fig. 1F](#)). No differences were observed among the rates of shoot development from untreated control and surviving cryopreserved explants. Regenerated plantlets were successfully acclimatized and all survived and grew well. No morphological abnormalities were observed in the plants regenerated from cryopreserved explants.

[Fig.2: Cryopreservation of adventitious bud cluster explants of *G.crinita* cultured in vitro \(41 KB\)](#)

Rapid freezing is the simplest method of cryopreservation and it does not require sophisticated and expensive controlled freezing equipment and complicated cryoprotective procedures, but allows cells and meristems to be cryopreserved by direct immersion into liquid nitrogen^{14,19,24,27,29}).

Although several authors have indicated that cold hardening and/or pre-culturing with a high concentration of sugar medium are essential to successful cryopreservation of *in vitro*-cultured plant materials^{11,20,22}), adventitious bud clusters of *G. crinita* cryopreserved by the rapid freezing method showed high survival rates without any cold-hardening and/or pre-culturing treatments. Similar results were reported in the vitrified bud clusters of asparagus¹⁴). On the other hand, cold-hardening and/or pre-culturing with sugar-enriched medium were not found to be effective to induce dehydration tolerance in this species. Attempts at using several cold-hardening and/or pre-culturing treatments modified from Niino & Sakai (1992)²¹), Suzuki et al. (1994)²⁶), Matsumoto et al. (1994)¹⁹), and Brison et al. (1995)³), to enhance the survival and plant regeneration rate (data not presented) were not successful.

The results of the cryopreservation experiments may be summarized as follows: (1) slow pre-freezing was the optimum method for cryopreservation of shoot tips, (2) rapid freezing was not effective for the cryopreservation of the shoot tip and nodal segment explants, however this method was found to be effective for the cryopreservation of adventitious bud clusters, (3) for root tip explants, there was no difference between the rapid freezing and slow pre-freezing method, (4) the simple freezing and encapsulation/dehydration method failed to cryopreserve all explants tested, and (5) cold-hardening and/or pre-culturing treatments were not effective in enhancing the survival or plant recovery rate after storage in LN.

Although the plant recovery rates should be improved in the near future for a more effective cryopreservation system, in our opinion, these results can be used at present without inconvenience because, considering that more than 823,000 shoots can be obtained in a year from only one shoot tip explant¹⁷), further propagation of *G. crinita* from a few cryopreserved surviving explants is really possible. Thus, cryopreservation by using both the slow pre-freezing and rapid freezing methods can be considered to be a suitable alternative for the long-term storage of *G. crinita* germplasm. Cryopreserved germplasm of tropical forest tree species will be the major source for planting stocks in the so-called biotechnology-assisted reforestation in the tropics soon.

Storage of selected germplasm following the alginate encapsulation technique and/or cryogenic procedures described here is an attractive possibility for

the conservation of genetically superior tropical forest trees for many decades.

Abstract

A function of the male pheromone of *Leptoglossus australis* (Fabricius) in its migration process was investigated on Ishigaki Is., the southernmost part of Japan. It was observed that the immigration of adults into particular fields of bitter melon or loofah occurred suddenly within a short period of time. Immigrants landed mostly on a male-baited cage placed in a cucurbit field (a host plant of the bug) rather than on crop plants themselves without males, suggesting that cues inducing landing of immigrants are not their host plants, but the pheromone emitted by males. Moreover, an egg parasitoid, *Gryon pennsylvanicum* (Ashmead) (Hymenoptera: Scelionidae), was attracted to the male pheromone of *L. australis*, which may act as a kairomone for host searching of the parasitoid.

Discipline: Insect pest

Additional key words: attraction, *Gryon pennsylvanicum*, immigration, parasitoid

Introduction

It is well known that male adults in some Heteroptera emit a pheromone that attracts conspecific adults of both sexes^{1,2,4,8,12}). Another remarkable performance of Heteroptera is that adult bugs suddenly invade crop fields, including orchards^{6,7,9}) and they gregariously attack crops, often causing severe damage. However, it remains to be determined whether flying adults are attracted to pheromone-emitting males or to the cue of host plants.

The leaf-footed plant bug, *Leptoglossus australis* (Fabricius), is a serious pest of a limited kind of cucurbits and various fruits in the tropics and subtropics³). Outbreaks of adults have been reported from Sri Lanka and Papua New Guinea^{5,11}). On Ishigaki Island, the southernmost part of Japan, the bug breeds mainly on a wild melon, *Diplocyclos palmatus* C. Jefferey, in spring, and ensuing adults disperse in seeking fruits appropriate as food, but scarcely visit cucurbit fields. From late June to July when the wild melon has decayed, substantial immigration of adults to cucurbit fields often occurs^{13,14}).

In order to clarify the role of adult males of *L. australis* in the induction of landing of immigrants, a number of host plant fields were investigated for the relation between the previous presence of males in the field and ensuing adult immigration.

In addition, the attractiveness of male or female *L. australis* to its egg parasitoid, *Gryon pennsylvanicum* (Ashmead), was examined, since a preliminary experiment suggested that the host-searching behavior of the parasitoid is elicited by the presence of *L. australis* adults.

Materials and methods

1) Detection of immigrants in cucurbit fields

To detect the immigration of *L. australis*, adults were visually counted in 17 fields of bitter melon or loofah, both being host plants of the bug. These fields were located within an experimental area 2 km in diameter on Ishigaki Is. and each had enough fruits for bug's food. The census was conducted from June 15 to July 11, 1987 at intervals of 1-3 days after the onset of immigration.

2) Influence of male attraction on immigrants

A cage containing 5 *L. australis* males (male-baited cage) was placed in each crop field (Nos. 14, 16 and 17) on July 4, 1987. Another one was also set on June 15, 1987 in a shrubbery surrounded by non-host plants, i.e. sugarcane, in the experimental area. Adults attracted to the male-baited cages were counted until July 11.

The cage consisted of a plastic basket (21 cm in diameter and 9 cm in height) and a plywood cover, and the confined males were supplied with water and bitter melon seeds in the basket ([Fig. 1-B](#))[17 KB].

3) Ovarian development of females attracted by male-baited cages and of those from crop plants

Some of the adults settling on male-baited cages or on crop plants were collected and all the females were dissected to examine the status of ovarian development. A female which showed fully developed eggs with a chorion or eggs of almost the same size was recorded as a mature one.

4) Attraction of *G. pennsylvanicum* by *L. australis* adults

A trap baited with male or female bugs was used to examine the attractiveness of *L. australis* adults to *G. pennsylvanicum*. The trap consisted of a water pan (35 cm in diameter x 8.5 cm in height) filled with water and of the same type of cage as that used in the male attraction experiment (see the section 2) previously), which was kept ca. at 5 cm above the water surface ([Fig. 1](#))[17 KB]. Three different types of traps were used: a male-baited trap with 5 males in the cage, a female-baited trap with 5 females, and a control trap without bugs. Each cage was provided with a water container and bitter melon seeds.

A group of 4 traps was placed in each of the 3 plots separated by ca. 50 m from a field of bitter melon where *L. australis* naturally occurred. The traps of each plot were arranged in a square with a spacing of 10 m. Trap type was the same in all the 4 traps in each plot, but different among plots. The arrangement of the traps is shown in [Fig. 2](#)[10 KB]. The trap types were rotated among the plots every day. *L. australis* adults and *G. pennsylvanicum* caught by the traps were collected and their number counted daily during 7 days in September 1989.

Results

1) *Detection of immigrants in cucurbit fields*

In some fields, *L. australis* adults already appeared in mid-June when censuses had started, but there was no substantial increase in number until the beginning of July. Hence, only the number of adults in the census fields from July 1 to 11 is shown in [Table 1](#). Numerical figures in parentheses indicate the number of adults removed from the field for the examination of ovarian development.

During the period from July 1 to 8, conspicuous immigration was observed. Average number of adults per census field was 2.9 on July 1-2, then 96.3 on July 7-8. Only 36% (5/14) of the census fields were inhabited by adults on July 1-2, but the proportion of census fields suddenly increased to 88% (14/16) on July 7-8.

There were differences in the number of immigrants among the fields and the immigration occurred within a short period of time to some particular fields. For instance, a sudden increase in number was found in field 8 from July 3-4, whereas no concomitant increase was observed in field 9 which was only 200-300 m apart from field 8. A similar difference in the extent of immigration was observed between fields 10 and 11, 200-300 m apart from each other, in 2 days from July 1-3.

Sex ratio of adults during the census period was about 0.45. Nymphs were hardly observed in any fields.

2) *Influence of male attraction on immigrants*

The number of adults settling on male-baited cages is given in [Table 2](#), with reference to the number of adults on the crop where the cage was placed.

Numerical figures in parentheses indicate the number of adults removed from the fields for the examination of ovarian development.

The male-baited cage set in the shrubbery on June 15 displayed a distinct increase in the number of adults on July 3-5, when immigration simultaneously occurred in other census fields.

On July 4 when male-baited cages were placed in fields 14, 16 and 17, no bugs, 1 female and 11 adults of both sexes were recorded, respectively. In fields 14 and 16 where no males were present, immigrants initially gathered on the male-baited cages and a few on the crop plant. In field 17 with both sexes, immigrants preferred the crop plant to the male-baited cage.

3) *Ovarian development of females attracted by male-baited cages and of those from crop plants*

Sampling sites were divided into 3 groups, that is, crop plants, male-baited cages in crop fields and male-baited cages in the shrubbery. Percentages of mature females in each group were 37, 24 and 9%, respectively. Most of the females seemed to be immature.

4) *Attraction of *G. pennsylvanicum* by *L. australis* adults*

G. pennsylvanicum was primarily caught in male-baited traps, and no wasps were caught in female-baited traps ([Table 3](#)). The control trap (without bugs) captured 2 individuals once, but no bugs on the other 6 days. All the parasitoids trapped were females. *L. australis* adults (15 females and 7 males) were caught only in male-baited traps.

Table 3. Number of *G.pennsylvanicum* and *L.australis* individuals in traps baited with 5 *L.australis* males and those with females

<u>Trap</u>	<u>No.of insects^{a)}</u>	
	<u><i>G.pennsylvanicum</i></u>	<u><i>L.australis</i></u>

Male-baited	5.6+4.1**	3.1+1.8*

Control	0.3+0.7	0.0+0.0

*,** : A significant difference from control at $P < 0.05$ and $P < 0.01$, respectively, by the randomization test.

a) : Values are means (insects / 4 traps / day) with SD (n=7).

Discussion

Male-baited cage was apparently selected by immigrants as a landing place when the crop plants in the surroundings were not inhabited by males, suggesting that the male pheromone emitted from caged males stimulated the landing of flying adults. Therefore concentrated immigration was likely to be induced by a male pheromone released from certain fields. However, this fact does not necessarily imply that immigrants disregard host plants. Pioneer individuals seeking host plants must depend on other materials than male bugs as a cue for landing and host plants may be one of the candidates.

Consequently, the male pheromone of *L. australis* attracts both sexes to develop an adult population on the host plant. However the ecological significance of the male attraction remains to be elucidated. In the case of the brown-winged green bug, *Plautia stali* Scott, one of the fruit-piercing stink bugs in Japan, which exhibits male attraction to the conspecific adults of both sexes, adults attracted to caged males were mostly underfed, sexually immature¹⁰) and did not mate between them⁸). Accordingly, the male attraction in *P. stali* was considered to be effective in the exploitation of temporally and spatially limited food resources rather than in mate-finding¹⁰). Indeed, adults may be able to save their energy and time for searching host plants by using an easily detectable sign which indicates the location of host plants. However the benefit which a pheromone-emitting male on a host plant can obtain by informing the location of the plant to other individuals remains unknown.

Another hypothesis is that a male on a host plant emits its pheromone to call females and simultaneously the other males aggregate to mate with the females attracted to the male pheromone²). In *L. australis*, mating was occasionally observed between the attracted adults (Yasuda, unpublished), suggesting that the male pheromone plays a role in mate-finding. More detailed studies should be conducted to confirm this assumption.

L. australis males attracted the egg parasitoid *Gryon pennsylvanicum*. It was reported that the attracted parasitoids attacked host eggs in the vicinity and eventually caused a high parasitism of eggs¹⁵). When adult bugs concentrate in particular host plant fields, the presence of male bugs rather than host plants may effectively indicate the area where host eggs probably occur.

Some of the chemicals emitted from male bugs certainly function as a kairomone for the parasitoid in its host-searching process. The chemicals may be related to the male pheromone of the bug, although this assumption should be confirmed by experiments using a synthetic pheromone. If so, the development of the synthetic pheromone may enable the effective control of *L. australis* through the manipulation of the host-searching behavior of the parasitoid.

Black Rot of Crucifers and Sources of Resistance in Brassica Crops

Alexandre IGNATOV, Ken'ichi HIDA and Yasuhisa KUGINUKI

Department of Vegetable Breeding, National Research Institute of Vegetables, Ornamental Plants and Tea
(Ano, Mie, 514-2328 Japan)

Abstract

Since the early 1990s, diseases caused by *Xanthomonas campestris* have been spreading on new host plants and in new regions, that had not been previously affected by the pathogen. Still, vegetable crops of *Brassica oleracea* are the most damaged plants by black rot. Recent achievements in the studies on resistance to black rot were reviewed. For the first time resistance genes were identified based on gene-for-gene interaction with different races of the pathogen. Some East Asian cabbage and Portuguese Penca kale cultivars seemed to carry the homologous genes for race-specific resistance. Their origin in Asian cabbages was traced to the Flat Dutch group of varieties and to heading Mediterranean kale. It is suggested that novel non-specific stem resistance found in Chinese kale, broccoli and cabbage might be an alternative means of genetic protection against the pathogen.

Discipline: Plant disease/Plant breeding

Introduction

Incidence of black rot caused by *Xanthomonas campestris* pv. *campestris* on horticultural brassicas is well recognized worldwide. Periodical epidemics of the disease were usually ascribed to the introduction of susceptible cultivars, careless application of contaminated seeds and seedlings and weather conditions favorable for disease development³⁷). Studies on the recent outbreaks caused by *X. campestris* on oilseeds suggested that spreading of new highly aggressive variants of the pathogen was the main reason for these epidemics^{21,23}). However, breeding of *B. oleracea* for resistance to black rot has been undertaken without recognition of the existence of pathogenic variants (races). As a result, control of the disease by the introduction of some resistant cultivars may not be effective.

Characteristics of the pathogen

Table 1. Diseases produced by the pathovars of Xanthomonas campestris on different host plants

<u>Pathovar</u>	<u>Typical symptoms</u>	<u>Race</u>	<u>Reaction of brassicas with genome</u>		
			<u>A</u>	<u>B</u>	<u>C</u>
<i>campestris, aberance</i>	blac rot, leaf blight	1, 4	RS ¹⁹)	RS ^{17,19})	RS ¹⁷)
<i>campestris</i>	leaf blight, black rot	0	NS ^{17,19})	NS ^{17,19})	NS ¹⁷)
<i>raphani</i>	leaf spot, black rot	3	RS ¹⁷)	na	RS ¹⁷)
<i>armoracea</i>	leaf spot	na	Na	na	NS ¹¹)

Na : No available data, RS: Race-specific response, NS : Non-specific response.

The most common races for each group were designated according to the reaction on the Kamoun et al.¹⁹⁾ differential set of varieties.

Xanthomonas campestris pv. *campestris* (Xcc) belongs to the genus that causes diseases on at least 124 monocotyledonous and 268 dicotyledonous plant species including all major crop plants²⁰⁾. According to a recent reclassification based on DNA analysis³⁵⁾, Xcc was assigned to the same genetic group as that of other pathovars infecting a wide range of crucifers as systemic or leaf pathogens (**Table 1**). The clear difference between leaf spot and black rot symptoms was attributed to the expression of a few genes, present in these pathovars¹⁰⁾. Factors responsible for the pathogenicity of Xcc include plant-stimulated proteins produced by pathogenicity genes targeted to plant nucleus³⁹⁾, several enzymes and extra-cellular polysaccharides¹⁰⁾. No highly toxic compounds were detected in association with the pathogenicity²⁶⁾.

It was shown that Xcc is composed of genetic and serologically heterogeneous groups of strains¹⁾. Kamoun et al.¹⁹⁾ reported that isolates of the pathogen could be grouped into 5 races according to the response of *B. rapa* and *B. juncea* cultivars. Race 4 was prevalent in Japan and in Portugal, while race 1 in UK, USA and it was also found on seeds of *B. oleracea* imported to Japan and England^{17,25)}. Race 0 was found in USA and Portugal (**Table 2**). Race 2, represented by only isolate 2D520, did not express pathogenicity in particular varieties of *B. oleracea*, *B. napus* and *Arabidopsis thaliana*^{6,17)}. Race 3, also represented by one isolate, showed the same interaction with differential varieties as isolates of *X. campestris* pv. *raphani* did¹⁷⁾. It is likely that these 2 races were designated by Kamoun et al.¹⁹⁾ based on some other types of interaction with the host plants than avirulence-resistance matching pairs of genes, and further use of these races is questionable.

Table 2. Geographical distribution of *Xanthomonas campestris* pv. *campestris* races

<u>Country</u>	<u>No. tested isolates</u>	<u>Race frequency (%)</u>				
		<u>0</u>	<u>1</u>	<u>2</u>	<u>3</u>	<u>4</u>
Japan ¹⁷⁾	65	0	35.0	0	0	65.0
UK ²⁵⁾	100	0	72.0	0	0	28.0
Portugal ³⁷⁾	61	31.0	18.0	0	0	51.0
USA ¹⁹⁾	na	Present	Present	Present	Present	Present
Europe, Russia ¹⁷⁾	25	0	42.0	0	0	58.0
Total	251	7.8	51.2	na	na	41.0

na: Not available.

Races were designated based on the Kamoun et al.¹⁹⁾ set of differential varieties.

Evidence of new races was suggested on the basis of interaction between worldwide collection of Xcc and new differential varieties in *B. oleracea* and *B. napus*^{16,17)}. The variability of Xcc continuously endangers cultivars with a narrow genetic base of resistance. The spreading of the disease on new host crops

considerably increases the chance of outbreaks on more susceptible vegetables grown in the same locations. Pathotyping of the pathogen populations may be necessary to provide a scientific base for breeding and introduction of resistant varieties in the areas endangered by black rot.

Since the pathogen can remain in soil even in plant debris only for 1 or 2 growing seasons²⁹), survival in contaminated seeds and on weed crucifers is considered to be most essential for the cycle of the disease. In Southeast Asia, although pak-choi, pet-tsai and other oriental brassicas are less damaged by black rot than vegetables of the *B. oleracea* group, they could become a source of inoculum.

(Received for publication, November 26, 1997)

Resistance to black rot in brassicas

The term "resistance" has been sometimes applied to very distinctive events, which results in a reduced damage of plants under natural conditions, including specific morphological characteristics and disease escape due to environmental factors²⁷). Several studies have clearly revealed the ability of plants to decrease their susceptibility to black rot after inoculation with some micro-organisms⁸). Plant morphology and life cycle may play a very important role in the degree of black rot development in the field. The rate of guttation plays a major role in the difference in disease development between susceptible cultivars²⁸). Here, the word "resistance" will be used here only for the genetic factors specific to host-pathogen interaction.

Ability of the pathogen to multiply in the vascular system of plant plays a major role in the expression of black rot symptoms. Vein plugging in plants infected with Xcc seems to be due to the accumulation of fibrillar material in vessels to prevent pathogen spreading inside the vascular system. Due to water deficiency, wilt and death of leaf segments between affected veins are the main reasons for the V-shaped lesions, typical of black rot⁵). It is less known that Xcc can produce some other symptoms. Under common nursery conditions, the disease can appear as yellowing of cotyledons and deformation of first true leaves on seedlings. At low temperatures, after the fall of diseased leaves, plants may remain infected but symptomless until the occurrence of warm weather³⁷). Alternatively, they could recover under cool temperature⁴). Systemic invasion often causes symptoms of "chlorotic spotting" or "pale mottle" on susceptible plants^{1,9}) - local whitish deformation of the epidermis on parts of leaves affected by the compounds produced by the bacteria. The proposed toxic nature of these compounds⁹) has not been confirmed experimentally and other factors like pathogenicity proteins or bacterial hormones should be considered.

Area of pathogen spreading in plant vessels is much more extensive than the area of visual symptoms⁹) and sometimes, typical V-shaped marginal lesions can appear as a result of systemic infection as well as after hydathode infection. Under wet and cool weather conditions, when intercellular spaces in leaves are soaked with water, the bacteria can penetrate into plants through stomata and induce extensive leaf spot lesions without systemic symptoms⁹). In several cases, Xcc caused rapidly expanding lesions referred to as "blight"^{1,15}). Vascular spreading of the bacteria in some other crucifers can be symptomless³⁴).

The resistant reaction in plant occurs in hydathodes, the natural gateway for the pathogen penetration into plant⁹), and in the vascular system, where the pathogen spreads and multiplies⁵). In early studies, a difference between leaf and stem susceptibility of cabbages was noticed. With the same leaf reaction as in European cultivars, the Japanese cultivars exhibited a lower stem susceptibility^{3,32}). This novel stem resistance can be represented as the arrest of the pathogen in the stem vascular system. It was observed that in the progeny of a cross between stem-resistant Chinese kale and leaf-resistant cabbage, these types of plant reaction were controlled by different genes and could be evaluated separately¹⁷). Routine observation of visual symptoms of black rot produced by conventional inoculation methods had ignored the difference between the resistance types and gave data that did not enable to distinguish the different types of resistance. Thus, selection for one type can result in the loss of another.

Race-specific resistance in brassicas was normally associated with hypersensitive response (HR) at the site of inoculation with incompatible race of Xcc¹⁹), but sometimes only partial expression was observed¹⁶). The distribution of the resistance to Xcc among Brassica species displays some interesting similarities ([Table 3](#)). The dominant single gene in plants with B genome^{13,14}) conferred the highest level of resistance to all races except for race 0. The high frequency of dominant resistance to race 4 was found in *B. rapa* of Japanese and Central Asian groups as well as in cultivars of oilseed *B. napus*^{16,17}).

Presently, plants of the *B. oleracea* group, especially cabbage and cauliflower, are most severely damaged by the disease³⁷). The frequency of black rot resistance in *B. oleracea* is very low. Although, there are no true resistant accessions among several hundreds of varieties and landraces of cabbage and cauliflower^{30,32,38}), many additive genes were responsible for the reduced damage by black rot in the field in diallel crosses between varieties or breeding lines of cabbages³³) and cauliflower²⁵). Attempts to introduce into *B. oleracea* the dominant monogenic resistance from *B. carinata* PI199947 (previously designated as *B. napus*) were made via protoplast fusion, but the progeny obtained was more susceptible than the resistant parent, suggesting that some other genes were important as well¹⁴).

Since the first report of resistant cabbage cultivars by Bain²), the existence of resistance has been detected in several other *Brassica oleracea* plants^{11,12,18,30}) ([Table 3](#)). Since plant defense includes several biochemical events, such as synthesis of receptor-like kinase (SRK), defense proteins, chitinase and enzymes of phenylpropanoid metabolism²⁴), several genes should be involved in the phenotypic expression of the resistance. Although, single resistance genes in cabbage varieties Huguénot and cauliflower SN455 were reported, the participation of a larger number of genes could not be ruled out^{3,18}).

Two accessions of *B. oleracea* var. *capitata* Fujiwase and PI436606 have been widely used to breed commercial cultivars. Unfortunately, the resistance of these cultivars showed complex relationships with the genetic background and race-specific action^{11,17,38}). The black rot resistance of variety Fujiwase was controlled by a single recessive factor affected by 2 gene-modifiers³⁸), as well as the resistance of plants selected from line PI436606¹¹). Recently, by the use of quantitative trait loci (QTL) mapping, the resistance in Fujiwase progeny has been found to be associated with several additive loci in different linkage groups and one of them, responsible for the resistance in both adult and young stages was dominant, while the other was recessive⁷).

In the progenies of Chinese kale, cabbage line PI436606 and the Penca kale, a homologous recessive gene was responsible for the race-specific resistance to the newly designated race 5 of Xcc and a dominant gene provided resistance to race 1. Several cabbage lines of Japanese origin and Penca kale landraces displayed similar patterns of race-specific reaction and inheritance of resistance to races 1 and 5 of Xcc17) ([Table 4](#)).

Table 4. *Brassica oleracea* accessions grouped according to their postulated resistance genes¹⁷⁾.

<u>Subspecies</u>	<u>Accession</u>	<u>Postulated resistance genes (R)</u>
alboglabra	S1	1
trachuda	ISA55, ISA454	1, 2
Capitata	Badger Inbred 16, Kinkei DH01, Reiho DH01 Fujiwase 1; Fujiwase DH01, 02, 05; Harukei DH01	1, 2
	PI436606; DH M9606; Aichi dai Bansei DH01, 02	2
	Reiho DH01, 03; Fujiwase DH 03, 04; Matsunami DH22	2, 4
	Matsunami DH77; DH M9602, 9603	4

If an accession showed a variable reaction, single plant selection was made prior to the test; DH, doubled haploid lines, obtained from Japanese cultivars resistant to black rot.

The genes of resistance were proposed on the basis of both resistance-avirulence matching pairs in the gene-for-gene interaction between the resistant varieties and Xcc races and the resistance inheritance. Gene R1 conferred the resistance to race 1, gene R2 - to race 5, gene R4 - to race 4.

Cabbages have been introduced to Japan relatively recently and in most of them the pedigree included some varieties of the Flat Dutch group³¹⁾ This group was selected from heading Mediterranean kale related to the landrace Penca de Mirandella, which is also resistant to black rot^{12,22)}. As tested by Bain²⁾, all open-pollinated varieties related to Flat Dutch contained a large number of resistant plants in bulk. In the same experiments, suggesting a similar race composition of the applied inoculum, the frequency of resistance in the Fujiwase stock was about 95%. Since Fujiwase has a documented origin from Flat Dutch, it is highly probable that its resistance was inherited from Flat Dutch or from heading Mediterranean kale. We can assume that the race-specific resistance to black rot in Asian cabbages did not appear *de novo* under the pressure of the disease, as suggested by some researchers³⁷⁾, but probably was inherited from the plants related to heading Portuguese kales. Only the use of genetic markers in the analysis of race-specific HR will enable to determine whether the genes studied in one cultivar are the same as in others.

After these recent achievements, sources of race-specific leaf and non-specific stem resistance among *B. oleracea* became available for plant breeding. The discovery of the race structure of Xcc populations for the first time enabled to design a breeding program based on the recognition of different genes and different mechanisms of resistance to black rot.

Abstract

A microcomputer-controlled unmanned air blast sprayer was developed to avoid the operator's exposure to agricultural chemicals or mechanical noise, and to improve the work efficiency during application for pest control in orchards. The developed sprayer moves automatically without a driver along a guiding cable, which is set up along the work course between the tree rows of the orchard. Unmanned application system developed controls automatically steering gears of the sprayer by detecting a magnetic field, which was generated by feeding an alternating current to the guiding cable. The cable can be installed underground (at a depth of less than 30 cm), on the ground surface, or at a height of 150 to 200 cm from the ground along the work course. The maximum total length of the cable is about 1,000 m. During unmanned application, the machine sprays agricultural chemicals automatically along the work course. However, if it is unnecessary to spray outward at the end of the tree rows where the sprayer turns, the machine is able to stop spraying outward while turning, due to a special system. All the functions of the sprayer stopped automatically when the sprayer reached the end point of application work. The sprayer has several safety devices controlled by the unmanned application system to avoid any accidents during unmanned application work. As a result of the performance test, deposition of sprayed chemicals on the fruit trees and work efficiency by this sprayer were as good as in any conventional manned air blast sprayers.

Discipline: Agricultural machinery

Additional key words: guiding cable, unmanned pest control, unmanned traveling, orchard

Introduction

Since the application of chemicals for pest control in orchards involves upward spraying, exposure of the operators to agricultural chemicals during the application has become a cause for concern. Protective wear, therefore, is used, but it is extremely unpleasant during hot months. A cabin may be attached to an air blast sprayer to avoid exposure, but for trellis fruit trees, for example, where the space is limited between the upper part of the equipment and the overhead branches, cabins may not be practical. Also the blower and other mechanical noises cause problems for the operators. As a result, a safe and comfortable work environment should be created.

The microcomputer-controlled unmanned air blast sprayer was developed to alleviate these shortcomings. In addition, this type of sprayer is the first unmanned air blast sprayer for orchards ever to be commercialized in Japan.

Purpose of development

Various systems of unmanned traveling can be used. In the current studies, we installed a guiding cable along the work course in the orchard, and when an electric current was fed to this cable, it generated a magnetic field around, which then could be detected by an electromagnetic sensing system^{1,2}).

Magnetic field is generated around the cable in which the current runs and around the coils placed within the magnetic field where the magnetic flux varies. As a result, electromotive force is generated according to the change of speed of the flux. These basic principles of electromagnetics were applied in this system.

The unmanned application system in the sprayer controls automatically steering gears of the sprayer depending on the degree of deviation from the guiding cable detected by an electromagnetic sensor, which is referred to as "guiding sensor" described later in this paper.

Compared with the standard application of chemicals with a conventional manned air blast sprayer, the application procedures for the unmanned sprayer are as follows:

- (1) The sprayer is brought manually to the starting point for the spraying operation.
- (2) Electric current is fed to the guiding cable.
- (3) The unmanned operation system of traveling and spraying is activated.
- (4) Unmanned operation continues until the liquid tank becomes empty.
- (5) The sprayer is then transported by an operator to an area where the chemicals may be replenished and then to the area where the application is to resume.
- (6) At the end of the entire application work, all the functions of the sprayer should come to an automatic stop.

We expected that the sprayer would be as efficient as the current manned air blast sprayer used for pest control in orchards.

Guiding cable

The guiding cable is laid along the work course. Examples of cable installation are shown in [Fig. 3](#).

[Fig. 3 Examples of guiding cable installation\(59 KB\).](#)

The depth at which the cable should be buried is either right under the surface or up to 30 cm beneath the surface for apple or other upright fruit trees, or the cable may be installed overhead at a height of 150 to 200 cm from the ground for trellis fruit trees such as pears and grapes.

Any parts of the cable should be about 1.5 m apart, considering the distance between dwarfed apple trees. Although the standard-specification cable is an automotive

Specifications of the unmanned sprayer

low-voltage wire (JIS cord: AV3), any electric cable larger than 3 mm² in cross-section can be used.

The length of the cable to be installed is limited by the capacity of the signal generator or electric resistance of the cable, and in the present stage of technology, the maximum length of the cable is about 1,000 m. A cable of this length is capable of covering 30 to 40 a, including turning radii, in the case of dwarfed apple orchards where the trees are planted 4 to 4.5 m apart from each other.

The guiding cable is fed with an AC current of 1.5 kHz and 185 mA as the guiding signals from the signal generator. This signal generator is powered with a rechargeable battery that can be recharged in 5 h, using an exclusively built charger, and then it may be used for 8 consecutive hours. The signal generator provides 2 output-terminals, and the machine may be used for 2 cable systems by changing the switch.

Unmanned application system^{3,5)}

[Fig. 4\(Block diagram of unmanned application system\[44 KB\]\)](#) shows a block diagram of the unmanned application system of the sprayer. The major sensing devices of the system consist of a guiding sensor ([Fig. 1 Major part of unmanned sprayer\[61 KB\]](#)) and [Fig. 5 Guiding sensor and main controller\[30 KB\]](#) and steering angle sensor (Fig. 1).

The guiding sensor has 2 sensing heads placed on both right and left sides of a radiator in the forward portion of the sprayer. This sensor detects the degree of deviation of the sprayer from the guiding cable by sensing the magnitude of the magnetic field generated around the guiding cable.

The steering angle sensor installed in the steering gear detects the angle of steering, i.e. the direction of the wheels.

An oil hydraulic cylinder actuated by an electromagnetic valve actuates the 4-wheel steering gears, traveling clutch and brake of the sprayer.

Based on the output of the sensors, the microcomputer (CPU: 20 MHz/16 bits, ROM: 32 Kbytes, RAM: 1 Kbytes) inside the unmanned traveling and spraying control device (referred to as "main controller" shown in [Fig. 5](#)) calculates the target steering range, in other words, the angle of turning for the steering in the case of a manned operation, based on which the steering gear is controlled just as the human operator would steer his/her wheels. Thus the unmanned sprayer may travel without any human attendance along the work course where the guiding cable is installed.

Algorithm of automatic steering control^{3,4)}

If variable V_d is the output of the guiding sensor, variable V_{dm} is the moving average of V_d , variable V_{off} is the offset value from V_{dm} to the center of the sprayer body, ΔV_d is the displacement of V_d , ΔV_s is the control variable of steering, displacement of the body from the target position is represented by variable (1), and the direction of the body is represented by variable (2), as follows:

$$V_d - (V_{dm} + V_{off}) \dots\dots\dots (1)$$

$$\Delta V_d \dots\dots\dots (2)$$

Then, ΔV_s was obtained using those variables with the following 6 rules of fuzzy reasoning.

Rule 1: If the body is on the right side and the direction is right, steer left.

Rule 2: If the body is on the right side and the direction is straight, steer left.

Rule 3: If the body is on the right side and the direction is left, don't steer.

Rule 4: If the body is on the left side and the direction is right, don't steer.

Rule 5: If the body is on the left side and the direction is straight, steer right.

Rule 6: If the body is on the left side and the direction is left, steer left.

Then, variable V_{sr} is the actual steering angle and variable V_{sg} is the target steering angle, V_{sg} is expressed as follows:

$$V_{sg} = V_{sr} + \Delta V_s \dots\dots\dots (3)$$

The actuators for automatic traveling control of the unmanned application system are controlled by V_{sg} .

Auxiliary remote control system^{3,4)}

The start of the unmanned operation (onset of the application work) is controlled by the transmitter ([Fig. 2](#))[13 KB] of the auxiliary remote control system so that the operator may be protected from any exposure to the chemicals or noise. Radio waves of the system are in the range of specific low-power radio waves, requiring no particular license, and the accessible distance of radio waves is guaranteed at 150 m in common orchards. This system is capable of starting or stopping the traveling, blowing and spraying functions of the sprayer, as well as application work.

In addition, a single operator can control simultaneously more than 2 unmanned sprayers with this system in every adjoining orchard. Application work is more efficient and labor-saving than in any of the conventional manned air blast sprayers.

Functions during unmanned operation³⁻⁵⁾

Functions during unmanned operation are as follows:

(1) During application by unmanned operation, chemicals are sprayed in all directions between the tree rows (right, left and upward of the sprayer). However, when the sprayer turns at the end of a tree row, it is designed to automatically stop spraying chemicals unnecessarily outside of the turning area without trees. In this instance, the steering condition is constantly monitored by the unmanned application system. The system proceeds straight or turns based on the output of the sensors for steering angle, for velocity, etc. and controls the spraying device of the sprayer. Automatic spray stopping function may be disengaged when spraying is desired even during turns.

(2) When the chemicals in the tank run out during the unmanned operation, traveling, blowing and spraying stop automatically through the effect of the pressure sensor ([Fig. 6 Pressure sensor for sensing when the tank is empty\[29 KB\]](#)) installed with the spraying pump built inside the sprayer. This device detects the reduction in the discharge of the pump, signaling the depletion of the chemicals, thus automatically halting traveling, blowing and spraying.

(3) When the application work is complete, the cable installed is bent at a certain sharp angle, which allows the magnetic fields to interfere with each other. As a result, the guiding sensor is unable to detect the specific magnetic field at this spot, and all the functions stop automatically.

It may be noted that the release of the unmanned application system enables manned operation of the sprayer as required, just as in any other conventional manned air blast sprayers.

Safety devices

Since emphasis must be placed on safety in unmanned operation, unmanned application system of the sprayer incorporates safety devices as follows:

(1) A couple of obstacle-detecting sensors (2 ultrasonic sensors shown in [Fig. 1\[61 KB\]](#) and [Fig. 4\[44 KB\]](#)) built in the front bumper, upon detecting an obstacle about 1 m ahead, halts traveling, blowing and spraying.

(2) A touch sensor ([Fig. 1](#) and [Fig. 7](#)) built in the bumper, in the case of an obstruction, stops all functions of the sprayer including the engine automatically.

(3) Should the system be out of control in emergency, the engine may be stopped by all-function-stop switches ([Fig. 1](#)) which are located on both sides of the bonnet (hood) of the sprayer body.

(4) In case of the interruption of the transmission of radio waves because of the exhaustion of the battery in the transmitter of the auxiliary remote control system, or due to trouble or accidental switch-off, traveling, blowing and spraying come to a halt automatically.

(5) When the guiding sensor is unable to detect the magnetic fields generated around the guiding cable, since the battery of the signal generator is exhausted (battery exhaustion is indicated through a gauge set in the signal generator), the cable is broken, or the sprayer is derailed from the cable, the engine is automatically put to a stop, i.e. all functions of the sprayer come to an end.

Fig.7 Ultrasonic sensors and touch sensor

Performance tests and results³⁻⁵)

1) Functional confirmation tests

Functional confirmation tests in which the range of velocity was 0.9 to 2.7 km/h were conducted on flat ground in several test courses and orchards. An example of the results of the functional confirmation tests is shown in [Table 2 . Results of tests for function confirmation \(45 KB\)](#).

The unmanned sprayer could travel smoothly along the guiding cable on the work course. It was confirmed that the system stopped spraying outward outside of the tree rows while turning, stopped traveling, blowing and spraying when the tank became empty, and stopped all functions at the end point of the work course. Moreover, each safety device was functioning during the unmanned operation.

2) Deposition performance

Deposition performance tests based on IAM test code No.12-1989 were conducted in a range of application velocities of 1.8 to 2.5 km/h, and the application rates ranged from 310 to 450 L/10 a in an orchard of dwarfed apple trees (variety: “Fuji”, age: 18 years, height: 4 m, width: 3 m, planting pattern: 4x2.5 m). The results of the tests were satisfactory and similar to those with a conventional manned air blast sprayer.

3) Work efficiency

Work efficiency tests were also conducted in several orchards of dwarfed apple trees ([\(Fig. 8\)Unmanned application test \[44 KB\]](#)), trellis pears and trellis grapes ([\(Fig. 9\)Unmanned application test \[44 KB\]](#)).

According to the test results, the rate of work with the unmanned sprayer was almost the same as or higher than that with any conventional manned air blast sprayers.

However, the application work with the unmanned sprayer was more labor-saving and efficient than that with a conventional manned air blast sprayer, because the operator himself/herself of the unmanned sprayer could prepare agricultural chemicals to replenish the empty liquid tank during the unmanned operation without any assistant.

Conclusions

Advantages of the unmanned sprayer developed are as follows:

- (1) This newly developed sprayer prevents operator's exposure to agricultural chemicals, noise or danger involved.
- (2) During the operation of the unmanned sprayer, the operator may carry out himself/herself other activities such as preparation of agricultural chemicals, hence the reduction of labor and enhancement of work efficiency.
- (3) Theoretically, a single operator can manipulate simultaneously more than 2 unmanned sprayers, thus contributing to labor-saving and timely pest control.

In consequence, introduction of the unmanned air blast sprayer ensures efficient and labor-saving application work of chemicals for pest control in a comfortable environment.

Water Hyacinth Control Program through Community Development Approach: A Case Study in a Bangladesh Village

Haruo UCHID*1 and Kazuo ANDO*2

*Department of Hilly Land Agriculture, Shikoku National Agricultural Experiment Station
(Zentsuji, Kagawa, 765-0053 Japan)

*Center for Southeast Asian Studies, Kyoto University (Sakyo-ku, Kyoto, 606-8304 Japan)

Abstract

A Village Committee was established for the organization of the rural development activities in a village, Dakshin Chamuria, in Bangladesh under the JICA (Japan International Cooperation Agency) Project of JSRDE (Joint Study on Rural Development Experiment). The committee consists of so-called traditional village leaders 'matabbors', who are mostly active in enhancing the villagers' unity and devoted to the village public affairs. The authors outline the Community Development Approach to establish the Village Committee and its performance to control an aquatic weed (water hyacinth) in order to protect deep water rice in the study village. The paper describes the procedure adopted to establish the Village Committee representing all the villagers, as a key part in the Community Development Approach of JSRDE. Secondly, the water hyacinth control program as a study case under the Community Development Approach was also evaluated. Overall, the results of this study indicate that the Community Development Approach may contribute significantly to the solution of the rural development problems in Bangladesh.

* This paper is based primarily on our previous study entitled "Rural Development Program by Community Approach in a Bangladesh Village" (in Japanese) submitted to the Journal of Agricultural Development Studies. However, a large part of the paper has been revised and newly added.

Discipline: Irrigation, drainage and reclamation/Agricultural environment

Additional key words: rural development, village community, village committee, matabbor

1~4): [Click here for References](#)

Background

The target group approach is presently the main approach for the rural development programs in Bangladesh. Although the target group approach organizes landless farmers, women, the poor, etc., they are supervised and controlled by non-villagers who provide the services of loan, job training, etc. Although the supplied goods and services reach target groups, most of the time, this approach enhances the dependency of the groups in the program. Consequently, the villagers become passive and dependent, which is not favorable for sustainable rural development¹⁾.

We consider that it is difficult to achieve sustainable rural development without the Community Development Approach. Thus, we introduced rural development programs in a village, 'Dakshin Chamuria' (D village) in Bangladesh, to involve the whole village community and include indigenous technologies under the Joint Study on Rural Development Experiment (JSRDE) from 1992 to 1995. The project was funded by the Japan International Cooperation Agency (JICA) and jointly implemented by JICA and the Ministry of Local Government and Rural Development & Cooperative, Bangladesh. This paper describes the establishment of the Village Committee which played a key role in the community development approach of the JSRDE, including the water hyacinth control program proposed by the Village Committee. The paper also briefly indicates why such an approach may contribute significantly to sustainable rural development in Bangladesh.

'Matabbors' and the Village Committee

'Matabbors' are the traditional village leaders, some of whom are active and devoted to the village public affairs, village court for example. These leaders are not necessarily rich or educated. Some of them have a small land holding even less than 1 acre and are illiterate. However, the villagers recognize them as leaders because of their eloquence and ability to collect information.

In addition to acting as mediators in the village court, matabbors also contact organizations outside the village such as the government agencies and NGOs interested in implementing new programs in the village. According to the survey conducted in 1988, more than 70% of the matabbors indicated that they usually go to the 'Thana' office (local administrative office) more than once a month⁴). Thus matabbors are active persons of a village who usually gather useful information from the government agencies, NGOs, etc. On the other hand, when outside organizations attempt to initiate some programs in the village, matabbors are also a good source of information about the village. By such connection, matabbors always receive various types of and new information earlier than the other villagers. This situation is sometimes misused by the matabbors for monopolizing profitable information. It has been often observed in villages that the tricky matabbors are selfish and may not serve the interests of the village people. Such characteristics of matabbors have been often criticized and matabbors are considered as 'touts' by the officials concerned with the rural development programs. Therefore, it is important that the matabbors' activities/performance related to the village public affairs including building of a village school and development of 'hat' (regular market in the village) be evaluated²).

Usually, the matabbor acts as a leader when villagers face problems and unite the villagers for possible solutions. On such occasions, matabbors become significant for the community interest of the villagers. Against this background, the JSRDE project adopted the Community Development Approach aiming at utilizing the leadership qualities of matabbors but, at the same time, at supplying everybody with useful information that tended to be monopolized by the matabbors. For this purpose, the Village Committee was established in D village.

A village in Bangladesh usually consists of several small communities called 'para'. The village under the study, D village, has 4 paras and each of these paras has several matabbors. To set up a Village Committee, a general meeting was held in the classroom of the primary school in D village on January 2, 1993. The selection of the matabbors was carried out during this meeting by about 200 people from all paras. Matabbors from each para were selected according to the number of households in each para. The committee had 18 members including 4 female, 1 from each para. Other procedures included the selection of the executing body, a chairman and secretaries on the basis of the villagers' recommendation (Fig.1).

[Fig.1. Village Committee Meeting\(21 KB\)](#)

The Village Committee is assumed to fulfill the following 3 main functions: (1) To hold a monthly meeting for discussing the common problems. (2) To prepare programs for possible solutions. (3) To hold a coordination meeting with the field workers of the rural development agencies, the government and NGOs.

It is important to mention that 6 months after the start of the Village Committee, there was a distinct gap in information flow between the Village Committee and the common villagers. To fill this gap, the Para Meeting was started within each para between the project staff and the common villagers including the Village Committee members of the para. As expected, the Para Meeting also played an important role in encouraging the villagers' participation in the project. Therefore, the Para Meeting was deemed indispensable for the Community Development Approach in D village.

In the following part of the paper, the aquatic weed(water hyacinth) control program designed and implemented by JSRDE and the Village Committee is outlined.

Action program for water hyacinth control

1) Background

During the rainy season, all of the land except homesteads and roads in D village were usually inundated to a large extent. The water flowing from the neighboring village carried water hyacinth and deep water rice growing in the flooded fields was damaged. In September 1993, a Village Committee member, Mr. Rahman who is a primary school teacher introduced this problem for discussion during the Village Committee Meeting. He suggested that laborers should be hired by the local government aid program, namely Test Relief, to control the water hyacinth problem. However the Village Committee could not obtain this assistance, because the program had a shortage of wheat as wages for laborers. However, the committee discussed some of the measures that should be adopted to address this problem as the damage caused by water hyacinth occurs frequently and is severe.

In order to solve this problem, JSRDE suggested the introduction of 'African Doncha' (*Sesbania rostrata*) which is a plant used to stop the invasion of water hyacinth into rice fields.

African Doncha was cultivated during the late dry season to obtain the seedlings (stem cuttings). Firstly, at the beginning of the rainy season, the seedlings were planted in the field, which remained fallow during the rainy season and was located just in front of 'Chinamura Doch' (water depression in the neighboring village) from where water hyacinth flows out. Secondly, the seedlings were also planted on the drainage sides of water hyacinth in the deep water rice growing area in order to guide water hyacinth to 'Ronger Doch' (water depression in D village) directly. Thirdly, at the same time, African Doncha was cultivated on the levees around the rice fields to prevent the invasion of water hyacinth to the deep water rice growing fields ([Fig. 2](#)).

[Fig.2: Water hyacinth control program \(26 KB\)](#)

In addition to the water hyacinth control program, African Doncha, as described later, was newly introduced to Bangladesh for use as green manure, forage, fuel, fence and article for sale. Before 1993, the seeds of African Doncha had not been readily available to common villagers even though, as told by the counterparts of JSRDE from the Bangladesh Agriculture University (BAU), a large quantity of seeds was produced in their experimental farm. Therefore, suggestions were made to the Village Committee that this plant should be introduced to D village in cooperation with the BAU counterparts. The cultivation of African Doncha was successfully promoted by the effective coordination of the Village Committee and motivation at the Para Meeting in D village.

2) African Doncha

Professor Altaf Hossain, one of the BAU counterparts, introduced for the first time African Doncha, an annual legume, to Bangladesh in 1986 from the International Rice Research Institute. The plant grows up to a few meters. 'Deshi Doncha' (*Sesbania aculeata*), a local variety of Doncha (*Sesbania* spp.), had grown traditionally in Bangladesh for the same use as that of African Doncha. However, nowadays, dry season's modern rice varieties (high-yielding varieties) are cultivated to a large extent in the fields where Deshi Doncha used to be broadcasted at the end of the dry season, March to April. Unfortunately, these rice varieties are usually harvested in May. Thus, Deshi Doncha had disappeared gradually along with the introduction of these rice varieties. On the other hand, African Doncha can be cultivated using seedlings (young plants and stem cuttings) under waterlogged conditions. Therefore, it can be cultivated at any time even during the rainy season if the seedlings are available. There is no competition for land between the modern rice varieties and African Doncha, unlike in the case of Deshi Doncha. Research has revealed that African Doncha is more effective than Deshi Doncha as green manure and that rooting occurs 2-3 days and leafing 5-6 days after planting of a stem cutting 50 cm high for normal cultivation and 1 m for deep waterlogged conditions, respectively³). For use as a green manure, the appropriate timing of incorporation of African Doncha in soil is 40-60 days after planting ([Fig. 3](#)).

Fig. 3 African Doncha

Since 1989, after the initiation of the field experiment, BAU has started to distribute the seeds to the research organizations and the Agricultural Extension Department. Based on the activities of BAU, JSRDE decided to introduce this plant for one of the development programs as mentioned earlier.

3) Performance of the program

It was eventually decided to implement the water hyacinth control program during the meeting of the Village Committee held in November 1993, in agreement with the suggestion made by Mr. Rahman in September. During the same meeting, it was also decided to rent a piece of land, 31 decimals in size (1 decimal is about 40 m²) to cultivate African Doncha in the village. At the end of February 1994, the seeds of African Doncha were broadcasted on the rented land and cuttings were planted tentatively in the rented rice field in April, at the end of the dry season. On June 1, the stem cuttings were planted in the field located in front of Chinamura Doch as mentioned before. During the meeting of the Village Committee held on June 6, the villagers were informed that the stem cuttings would be supplied to them upon request. The villagers who thought that African Doncha was the same as native Doncha (*Sesbania aculeata*) were skeptical and reluctant to plant the stem cuttings. They pretended that the stem cuttings and also the young plants of Doncha would not take root. They did not agree with the program. On the other hand, many villagers took the stem cuttings and realized that African Doncha was different from Deshi Doncha. Moreover, some villagers stole the stem cuttings from the rented rice field without permission and all the stem cuttings disappeared. During the meeting of the Village Committee held on June 24, 1994, it was decided that the program would be discontinued.

Although the program was discontinued, the villagers continued to grow African Doncha and harvested it

at the end of the rainy season for home consumption or to sell seeds and stems. Three, 9, 6 and 11 villagers cultivated African Doncha in the fallow fields, on levees of the aman rice growing fields, around the homesteads and the ponds, respectively. Sixty-four villagers cultivated African Doncha in total and 35 of them used the plant to control water hyacinth in their deep water rice fields. Eighty villagers could not obtain the stem cuttings although they wanted to get them.

Fortunately, in 1994, the water hyacinth did not overflow from Chinamura Doch as in a normal flooding year. On the contrary, the unexpected large flood washed away the planted stem cuttings of African Doncha in the following year. Therefore, the efficiency of the water hyacinth control program could not be substantiated. The program was successful, nevertheless, from the viewpoint of introduction of a new plant as well as the spontaneous response of the villagers. African Doncha was cultivated in the next year.

4) Role of the Village Committee

The water hyacinth control program was initiated after the proposal of a member of the Village Committee. This type of problem, damage by water hyacinth, was considered to be an individual problem formerly. However, when the problem was raised at the Village Committee Meeting, it became a common issue to the villagers. In this sense, the committee considered that the problem could be solved and asked the villagers to implement the program.

The main function of the Village Committee is to control the matabbors who exclusively keep the information by holding discussions with the villagers and invite them to make decisions about matters relating to the village public affairs. Moreover, the Village Committee played the role of contact outside of the village. The chairman and the chief secretary, after the decision of the Village Committee, went to Chinamura and other villages as the representatives of the village to negotiate some issues. And, in some cases, they took formal letters to the matabbors of other villages upon the request of their Village Committee. Such negotiations had been traditionally conducted after consultation among matabbors, but the common villagers were seldom involved in the process until a decision was made. However, the villagers were informed of all the actions taken such as negotiations during the Village Committee Meeting. The Village Committee can be expected to benefit from the services from organizations outside the village.

JSRDE and the committee members explained frequently the purpose and use of African Doncha to the villagers in order to obtain their agreement on the program in the Village Committee. Especially during the Para Meeting, ease of cultivation of African Doncha in the fallow fields by planting the stem cuttings and use as green manure and fuel were emphasized in order to disseminate it even to villagers whose fields had not been damaged by water hyacinth. It is considered that, without the Para Meeting, African Doncha would not have been introduced to the village so actively and widely.

Discussion

The ecological characteristics of African Doncha as well as the Village Committee and the Para Meeting contributed significantly to the promotion of the program. The matabbors became active in the program when they were formally recognized as the authority of the village. Information was given to all the villagers through the Village Committee and the Para Meeting. The matabbors did not act as touts and

their original function in the community was fulfilled by the villagers. Thus, they could not monopolize the benefit from new information as previously. The power of the community increased by the introduction of the new Community Development Approach. The Village Committee and the Para Meeting paved the way for the awareness of the villagers of common problems and the villagers' unity increased during the programs.

Results of the JSRDE programs are highly significant for people's participation in FAP (Flood Action Plan), National Development Program and some rural development programs in Bangladesh. It is essential to evaluate and utilize the local village system and indigenous knowledge of villagers to promote people's participation.

The authors are grateful to colleagues of the JSRDE Tangail project site and the villagers of Dakshin Chamuria for their cooperation. They especially thank Dr. Niaz Ahmad, JSPS Research Fellow at the Center for Southeast Asian Studies, Kyoto University for his valuable comments and cooperation in this report.

Abstract

To analyze the structural modifications of forage grass lignin during digestion in ruminant animals, dioxane-soluble lignin fractions were isolated from the feces and rumen digesta of ruminants that received forage grasses, without any pretreatments such as ultragrinding, acid and alkali hydrolysis, and their physico-chemical characteristics were compared with those of undigested original lignin preparations of forage grasses. Both dioxane-soluble lignin fractions from the feces and rumen digesta were composed mostly of guaiacyl-syringyl lignin with *p*-hydroxyphenylpropane units and contained only small amounts of non-lignin constituents. When compared with the undigested original lignin preparations, the dioxane-soluble lignin fractions contained a larger amount of syringylpropane units, and a much smaller amount of bound phenolic acids and showed a lower molecular size. Dioxane-soluble lignin fractions from the *in vitro* rumen-digested residues of forage grass contained a smaller amount of bound phenolic acids and associated carbohydrates and showed a lower molecular size than those from the cellulase-treated residues. These results indicate that soluble lignin fragments, which are likely to be degradation products of grass lignins or lignin-carbohydrate complexes involving bound phenolic acids, are released in the rumen and then excreted in feces.

Introduction

Lignin is a complex macromolecular substance composed of 3 phenylpropanoid residues, guaiacyl-, syringyl- and *p*-hydroxyphenylpropane units, and their ratios vary depending on the plant species, organs, tissues and maturity. It has been widely recognized that lignin in forages is virtually undigested and inhibits rumen fermentation of forage cell wall poly-saccharides, thereby reducing the utilization of forage by ruminant animals. The inhibitory effect of lignin is closely related to its structure and thus probably affected by modifications which lignin undergoes in the digestive tract of ruminants^{3,11}). Research on the fate of lignin in the digestive tract demonstrated that some part of lignin fed to ruminants is solubilized as a complex with carbohydrates in the rumen^{6,7}) and, after leaving the rumen, the complex is excreted as solid matter in the feces¹⁸). Evidence for the solubilization or degradation of grass lignins by rumen microorganisms was provided by *in vitro* experiments^{1,16,19}). In addition, rumen digestion has been reported to lead to the decomposition of lignin model dimers into monoaromatic compounds and their metabolites^{4,5}) and demethylation of the syringyl units of grass lignin¹⁷). However, little is known about the composition and structure of solubilized or degraded lignin fractions. Characterization of the lignin fractions may provide further information not only on the nutritional effect of forage lignin but also on the biodegradation of plant lignins in an anaerobic environment.

We conducted a series of studies on the structural characteristics of lignin fractions solubilized or degraded during digestion in ruminant animals¹²⁻¹⁵). We found that an organic

solvent-extractable lignin fraction was present in the rumen digesta and feces of ruminants fed on forage grasses, and characterized the soluble lignins by chemical analysis, nitrobenzene oxidation, UV, IR and ¹³C-NMR spectroscopy and gel permeation chromatography, compared with undigested original lignin preparations of forage grasses.

Isolation and partial characterization of soluble lignin fractions from feces of sheep

1) Isolation procedure of soluble lignin fractions from feces

Orchardgrass (*Dactylis glomerata* L.), timothy (*Phleum pratense* L.) and Italian ryegrass (*Lolium multiflorum* Lam.) were grown as pure swards, harvested at the heading stage of the first growth and, after wilting for a half-day, dried in an air-forced drier to give grass hays. Hay of each type of grasses was offered to 4 sheep at a maintenance level during a 7-day adaptation period and a 7-day collection period. Feces were sampled during the collection period and representative samples were dried at 55°C and ground with a Wiley mill to pass a 1 mm screen.

The fecal samples from 4 different sheep were bulked and pre-extracted with ethyl ether. After air-drying, the pre-extracted residue was extracted with 90% (v/v) aqueous dioxane for 48 h at room temperature, and the dioxane extract was dried under reduced pressure to give a crude dioxane-soluble lignin fraction. The crude lignin fraction was dissolved in 90% (v/v) acetic acid and precipitated in ethyl ether. After drying, the precipitate was suspended in water to remove water-soluble contaminants. The insoluble material was collected by centrifugation and purified by re-dissolution in acetic acid followed by re-precipitation in ethyl ether.

2) Composition, UV and IR spectra of soluble lignin fractions from feces

Table.1

Yield and composition of the dioxane-soluble lignin fractions isolated from feces of sheep fed on orchardgrass, timothy and Italian ryegrass

	<u>Orchardgrass</u>	<u>Timothy</u>	<u>Italian ryegrass</u>
Yield (g kg ⁻¹ feces)	12.4	15.6	9.5
Elemental Composition (g kg ⁻¹ soluble lignin)			
C	581	574	585
H	56	59	61
N	8	7	12
Chemical composition (g kg ⁻¹ soluble lignin)			
Klason lignin	875	844	818
Carbohydrate	18	23	20

The yield of dioxane-soluble lignin from the feces was in the range of 9.5-15.6 g kg⁻¹ dry feces ([Table 1](#)).

The forage grass samples did not contain any significant amount of dioxane-soluble lignin. The dioxane-soluble lignin fractions contained only small amounts of non-lignin constituents such as nitrogenous compounds and carbohydrate, and most part of the lignin was converted into an acid-insoluble residue (Klason lignin) by 72% sulfuric acid hydrolysis for all the grasses. The 3 soluble lignin fractions showed similar UV absorption spectra with a maximum at 278 nm and a shoulder peak at around 320 nm (Fig. 1).

[Fig.1 UV spectra of the dioxane-soluble lignins from feces of sheep fed on forage grasses\(22 KB\)](#)

The absorption maximum was attributed to hydroxylated aromatic nuclei and the latter shoulder peak to bound phenolic acids. No appreciable differences were found in the absorption coefficient among the 3 soluble lignin fractions. IR spectra showed distinct bands at 1,600, 1,510 and 1,425 cm⁻¹ attributable to aromatic nuclei of lignin (Fig. 2).

[Fig.2 IR spectra of the dioxane-soluble lignins from feces of sheep fed on forage grasses\(28 KB\)](#)

Bands associated with guaiacylpropane units were observed at 1,030 and 1,270 cm⁻¹, and a band assigned to syringylpropane units appeared at 1,330 cm⁻¹.

Physico-Chemical Characteristics of Soluble Lignin Fractions Released from Forage Grasses by Ruminant Digestion

The present analytical and spectral data revealed the presence of soluble lignin fractions consisting mostly of lignin components in the feces of sheep fed on forage grasses. The dioxane-soluble lignin fractions were insoluble in water but soluble in 80% ethanol, neutral and acid detergents; fibrous residues prepared with these reagents from feces were free of dioxane-soluble lignin. Consequently, the presence of dioxane-soluble lignin in feces of ruminants accounted partly for the incomplete fecal recovery of dietary lignin, which has often been reported.

Structure of lignin fractions isolated from forage grasses and from feces of sheep fed on them

1) Isolation procedure of lignin fractions from forage grasses and from feces

Two undigested original lignin preparations (ball-milled lignin, BML and ball-milled and cellulase-treated lignin, CTL) were isolated from orchardgrass and timothy hay samples harvested at the heading stage. The grass hay samples were boiled with 80% (v/v) ethanol under reflux for 1 h, the residues collected by filtration and dried. The dried residues were ultraground with a vibratory ball mill in the dry state under N₂ atmosphere with external cooling by water for 24 h. The ultraground sample was extracted with a 90% dioxane solution for 24 h at room temperature, and the extract was dried under reduced pressure to give a crude lignin fraction (BML). The ultraground and dioxane-extracted residue was treated with cellulase at 40°C for 24 h under a toluene atmosphere. The resultant insoluble residue was collected by centrifugation and washed with water. Crude lignin (CTL) in the insoluble residue was obtained by extraction with 90% dioxane. The crude soluble lignin fractions were dissolved in 90% acetic acid and then precipitated in water. The precipitated lignins were further purified by re-dissolution in 90% acetic acid followed by re-precipitation in ethyl ether.

Dioxane-soluble lignin fractions (fecal soluble lignin, FSL) in feces of sheep fed on forage grasses were prepared by the same method as that described above.

2) Characteristics of different soluble lignin fractions

[Table 2. Chemical composition, neutral sugar composition, and nitrobenzene oxidation products of the 3 dioxane-soluble lignin fractions from forage grasses \(38 KB\)](#)

BML and CTL, extracted from the ball-milled grasses, were relatively rich in associated carbohydrates ([Table 2](#)). The major neutral sugars of associated carbohydrates in BML and CTL were D-xylose and L-arabinose. In contrast to BML and CTL, FSL from the feces of sheep contained much less carbohydrate, which was poor in D-xylose. The analytical data agreed with the ¹³C-NMR spectra ([Fig. 3](#)). In the spectra of BML and CTL, signals derived from ²-1, 4-linked xylan chains were observed at 63.2-63.7 (C-5), 74.6-75.0 (C-3), 75.5-75.8 (C-4) and 101.4-102.1 (C-1) ppm, together with those of the acetyl group in the xylans at 20.7-21.3 ppm. In the spectra of FSL, on the other hand, NMR signals from the xylan backbone were below the background noise level. These results suggest the occurrence of marked degradation of the lignin-associated xylans by digestion in sheep.

Grass lignins are characterized by high levels of ester-linked *p*-coumaric acid⁸). The undigested original lignin preparations of forage grasses, BML and CTL, contained 10-21 g kg⁻¹ ester-linked *p*-coumaric acid while the *p*-coumaric acid ester content of FSL from the feces was very low ([Table 2](#)). This difference was confirmed by the ¹³C-NMR spectra ([Fig. 3](#)). A prominent signal at 130.2-130.5 ppm originating from C-2 and C-6 in *p*-coumaric acid ester was observed in the spectra of BML and CTL, whereas the corresponding signal was virtually absent in the spectra of FSL.

[Fig.3. ¹³C NMR spectra of the dioxane-soluble lignins from ball milled orchardgrass\(BML\),ballmilled and cellulase-treated orchardgrass\(CTL\),and feces of sheep fed on orchardgrass\(FSL\)\(37 KB\)](#)

The major phenolic aldehydes produced by nitrobenzene oxidation were *p*-hydroxybenzaldehyde, vanillin and syringaldehyde ([Table 2](#)), which were derived from *p*-hydroxyphenylpropane, guaiacylpropane and syringylpropane units, respectively. The yield of *p*-hydroxybenzaldehyde decreased in the following order: CTL, BML and FSL. Although no large differences were found in the yields of vanillin and syringaldehyde among the 3 lignins, the molar ratio of syringaldehyde (S) to vanillin (V) was higher for FSL than for BML and CTL. In the ¹³C-NMR spectra ([Fig. 3](#)), FSL showed higher relative intensities of a signal originating from C-2 and C-6 in syringyl units (104.0-104.7 ppm) to those of C-2 (111.3-111.9 ppm) and C-6 (119.1-119.7 ppm) in guaiacyl units than for BML and CDL. The increased molar ratio of S to V in FSL and the ¹³C-NMR data indicate that the dioxane-soluble lignin fractions from feces of sheep were richer in syringyl units. Based on a microscopic study, plant tissues with syringyl type lignin are more readily degraded by rumen microorganisms than tissues with other types of lignin²). A recent study using ¹⁴C-lignin cell wall preparations of wheat has revealed a more extensive solubilization of syringyl units by *in vitro* rumen fermentation¹⁷).

[Fig.4. Gel permeation chromatograms of the dioxane soluble lignin fractions from ball-milled grasses \(BML, ___\), ball-milled and cellulase-treated grasses\(CTL, ___\), and feces of sheep fed on grasses \(FSL,---\)\(20 KB\)](#)

The gel permeation chromatograms of BML, CTL and FSL are shown in [Fig. 4 \(17 KB\)](#). For both grasses, FSL contained a larger amount of low molecular size fractions than CTL and BML; CTL contained higher molecular size fractions that eluted at the void volume. Similar differences were observed with the saponified lignin preparations. Ball milling breaks bonds in the lignin-carbohydrate complex and causes depolymerization of lignin macromolecules due to the cleavage of ether bonds⁹) and thereby part of native lignin is converted to an organic solvent-extractable form. The elution profiles of gel permeation chromatography show that FSL was composed of lignin fragments with lower molecular sizes, compared with BML and CTL, and hence it is likely that the soluble lignin fragments released by digestion in sheep corresponded to depolymerization products of the forage grass lignins.

[BACK](#)

Comparison of soluble lignin fractions from rumen digesta and feces of heifer

1) Isolation procedure of soluble lignin fractions

Orchardgrass hay harvested at the pre-heading stage was offered to a heifer (Japanese Black Cattle) fitted with a rumen fistula during a 14-day adaptation period and a 2-day collection period. A rumen digesta sample was taken prior to 09:00 feed for 2 days, freeze-dried and bulked. Feces collected during the 2-day period were mixed thoroughly and a representative sample of the feces was freeze-dried. Soluble lignin fractions were extracted from the rumen digesta and fecal sample with 90% dioxane and purified as described above.

2) Physical and chemical characteristics of soluble lignin fractions

[Table 3. Chemical composition, nitrobenzene oxidation products and molecular size on of the dioxane-soluble lignin fractions from rumen digesta and feces of heifer fed on orchardgrass\(24 KB\)](#)

The yields of the dioxane-soluble lignin were 3.3 g kg⁻¹ for the rumen digesta and 8.2 g kg⁻¹ for the feces. It was preliminarily confirmed that the orchardgrass hay sample did not contain any significant amounts of dioxane-soluble lignin. Most of the dioxane-soluble lignin was recovered as Klason lignin by 72% sulfuric acid hydrolysis ([Table 3](#)). There were no considerable differences in the levels of bound phenolic acids and the yields of phenolic aldehydes produced by nitrobenzene oxidation between the rumen digesta and feces samples ([Table 3](#)). Both dioxane-soluble lignin fractions showed a wide molecular size distribution ranging from monomer up to 15,000. Elution maxima appeared at a molecular weight of 1,500 for the rumen digesta and at a molecular weight of 1,480 for the feces. The rumen and fecal dioxane-soluble lignin fractions had similar number-average molecular weights (Mn) and weight-average molecular weights (Mw) ([Table 3](#)).

The presence of dioxane-soluble lignin fractions in the rumen digesta indicates that, part of the orchardgrass lignin fed was released in the rumen as soluble lignin fragments. The chemical and physical properties of the fecal dioxane-soluble lignin were similar to those of the rumen dioxane-soluble lignin, suggesting that the soluble lignin fragments did not undergo any significant modifications after leaving the rumen.

Characteristics of soluble lignin fractions formed by in vitro rumen digestion of forage grass

1) Isolation procedure of soluble lignin fractions

Timothy hay harvested at the seed setting stage, supplemented with soybean meal, was offered to a heifer (Japanese Black Cattle) fitted with a rumen cannula during a 7-day adaptation and a 3-day collection period. Hay and feces were sampled during the collection period and their representative samples were dried, ground to pass a 1 mm screen. The hay sample was boiled with 80% ethanol under reflux for 1 h. The ethanol-extracted and dried residue was ultraground with a porcelain ball-mill for 10 days and then pre-extracted with 90% dioxane. The dioxane-extracted and air-dried residue was divided into 2 parts: one was subjected to enzymatic treatment and the other subjected to in vitro rumen digestion.

One part was treated with cellulase at 40pC under a toluene atmosphere for 72 h. The insoluble residue after the enzymatic hydrolysis was collected by centrifugation, washed with water and freeze-dried. The dried residue was extracted with 90% dioxane. The dioxane extract, after drying by evaporation, was dissolved in 90% acetic acid and then precipitated in water. The precipitated lignin was further purified by dissolution in 90% acetic acid followed by precipitation in ethyl ether to give cellulase-treated lignin (CTL).

The other part was digested in rumen liquor in vitro for 72 h. The rumen liquor used was taken from the fistulated heifer that received the timothy hay and soybean meal. The in vitro rumen-digested residue was collected by centrifugation, washed with water and freeze-dried. A soluble lignin fraction in the residue (rumen-digested lignin, RDL) was extracted with 90% dioxane and purified by re-dissolution and re-precipitation.

Dioxane-soluble lignin (heifer-digested lignin, HDL) in the fecal sample of the heifer was extracted and purified in the same way as described above.

2) Physical and chemical characteristics of soluble lignin fractions

[Table 4. Chemical composition of the 3 dioxane-soluble lignin fractions from timothy](#)

[CTL](#)

[RDL](#)

[HDL](#)

(g kg⁻¹ soluble lignin)

Klason lignin	708	887	889	CTL: extracted from ball-milled and cellulase-treated timothy, RDL: extracted from ball-milled and rumen-digested timothy, HDL: extracted from feces of heifer fed on timothy.
Carbohydrate	189	50	37	
<i>P</i> -Coumaric acid				
Ester-linked	15.0	3.7	3.4	
Ester-linked	2.3	1.5	1.5	
Ferulic acid				
Ester-linked	2.1	0.4	0.6	
Ester-linked	6.5	2.3	3.4	

Although CTL and RDL were prepared from the same timothy sample, the 2 lignin fractions differed considerably in chemical and physical properties. RDL contained less carbohydrate, ester- and ether-linked *p*-coumaric and ferulic acids than CTL ([Table 4](#)). The lower levels of the bound phenolic acids in RDL than in CTL suggest the removal or degradation of the bound phenolic acids from timothy lignin by rumen fermentation. This assumption does not conflict with the similarity in the composition between RDL and HDL. Phenolic acid ethers are reported to form a cross-linking unit between lignin and polysaccharides in grass cell walls^{10,20}). The decrease in the carbohydrate and phenolic acid ether contents in RDL may be indicative of ruminal degradation of a lignin-carbohydrate complex involving cross-linking phenolic acid ethers.

[Fig.5 Gel permeation chromatograms of the dioxane-soluble lignin fractions from ball-milled and cellulase-treated timothy\(CDL, _____\), ball-milled and rumen-digested timothy\(RDL,.....\), and feces of heifer fed on timothy \(HDL, _____\)\[20 KB\]](#)

Appreciable differences were observed in the molecular size distribution among the 3 lignin fractions ([Fig. 5](#)). CTL was distributed in a higher molecular size region than RDL and HDL. About 30% of CTL, based on the area ratio of the chromatogram, was eluted at the void volume. Saponification did not substantially affect the differences in molecular size distribution among the 3 lignin fractions ([Fig. 5](#)), although saponification reduced the carbohydrate content of all the soluble lignin fractions extensively and liberated ester-linked phenolic acids. Consequently, it is considered that RDL consisted of lignin fragments with lower molecular sizes than CTL. This finding suggests that rumen microorganisms are able to modify the macromolecular structure of forage grass lignin.

Estimation of Fine Root Production in Coniferous Forests in Japan

Nobuhiko KASUYA

Faculty of Agriculture, Kyoto Prefectural University (Sakyo-ku, Kyoto, 606-8522 Japan)

Abstract

It is well documented that fine root production (FRP) in forest ecosystems is large due to rapid turnover in spite of the small standing crop. Several methods have been applied to measure FRP: sequential coring, ingrowth core, nitrogen budget, soil carbon budget, and mini-rhizotron methods. The processes as well as advantages and disadvantages of each method were briefly reviewed in this report. The soil micromorphological method applied in a Japanese coniferous forest was described. This method enables to determine the fine root distribution and microstructure of the organic layer where fine roots are mostly concentrated. The ability to observe root cross-sections may improve the classification of the physiological status of the roots. The data obtained by this method at one time indicated that those fine and active roots were distributed mostly in the superficial litter layer of the soil. In the fermentation layer below, a smaller number of active types of roots were found. Periodical collections of samples may enable to study seasonal changes of fine roots and supply additional information on root ecology. The most difficult problem in the study of fine root dynamics is still the methodology. Over- and underestimation should be corrected to acquire more accurate information on forest production ecology and the role of forests in carbon and nutrient balance.

Discipline: Forestry and forest products

Introduction

Fine roots (including mycorrhizae) play an important role in the carbon and nutrient economy in temperate forest ecosystems. In many cases, more than 50% of annual net primary production (NPP) is allocated belowground^{9, 10, 17}), and nutrient return to the soil by fine root death may exceed that by aboveground litterfall³²). However, there had been discrepancies in the methods of measuring the fine root production (FRP) and turnover in the past decades^{7, 8, 19, 23-26, 29, 31}). Hendricks et al. (1993)¹⁴) raised an important question: Is belowground NPP positively or negatively correlated to aboveground NPP? They concluded that a positive correlation was more likely, despite many conflicting data.

This review compares several methods used to estimate FRP, examines the contribution of belowground components to the forest productivity, and offers a new approach, that is, micromorphological method of studying the fine root dynamics in a coniferous forest in Japan.

Methods of estimating fine root production

Several methods have been developed to estimate fine root production^{27, 33, 36}). In this paragraph, I will describe each method and the results obtained. First of all, in the "sequential coring" method attempts are made to detect seasonal fluctuations by the following procedures: a certain number of small volumetric soil samples are collected at regular intervals, and the differences in the mean root biomass are summed to represent fine root production. Unexpectedly a large fine root production was first reported by Edwards and Harris (1977)⁵) in a mixed deciduous forest. They measured fine root biomass several times over a period of 2 years and found distinct seasonal changes expressing bimodal peaks each year. Persson (1978)²⁴) suggested that the supply of dead fine root materials to the soil was considerably higher than that conventionally expected. Here it must be noted that some types of calculations give a wide range of values^{7, 8, 29}). In the simplest way, production is estimated by subtracting the minimum from maximum fine root standing crop, while in other cases either all differences or only significant differences are summed. McClaughy et al. (1982)²⁰) developed a decision matrix to account for the simultaneous occurrence of production and death, assuming rapid fine root turnover. They compared some values from different calculations plus decomposition data and suggested that lower estimates of production were more accurate.

In the "ingrowth core" method soil cores are taken, the roots are removed from them and the soil samples are buried after packing them into meshbags so that the roots can penetrate into the root-free soil cores through the mesh from the surrounding soil^{27, 33}). The advantage of this method is that it enables to compare different experimental treatments and it is less laborious than sequential coring. However it is difficult to convert the data on an area basis³³). Persson (1983)²⁶) actually compared FRP estimates based on "sequential coring" and "ingrowth core" method in boreal forests, and found only small differences in magnitude. My preliminary experiment with this method¹⁵) in a Japanese cedar (*Cryptomeria japonica* D. Don) plantation showed that fine root regrowth into the root-free soil cores was more abundant from midsummer to late fall than from spring to midsummer ([Fig. 1](#)). This finding contrasted with shoot growth which occurred most rapidly from early to midsummer in this stand. Surprisingly, the amounts of very fine roots (less than 1 mm in diameter) in the ingrowth core were considerably larger (more than double) than those in the original soil core after a 4-month incubation period from midsummer to late fall. However, the effect of severing roots in installing the cores and the difference in soil texture as a rooting medium should be considered in interpreting the results from this method.

[Fig.1:Amount of roots which regrew into root-free soil cores during 2 periods \$d\$ =diameter of roots. Bars indicate standard errors of the mean.\(21 KB\)](#)

Aber et al. (1985)¹⁾ and Nadelhoffer et al. (1985)²⁾ presented in the same year another approach to estimate FRP, namely, the "nitrogen (N) budget" method. Raich and Nadelhoffer (1989)²⁸⁾ introduced an innovative "soil carbon (C) budget" method. These 2 methods can be combined and are referred to as the "budget" method. N budget method determines the amount of N mineralized in soil by soil incubation, N uptake by aboveground part of plants, N content in the aboveground litterfall. FRP estimates can then be calculated. Soil carbon budget can only set the upper limits to FRP, but it can verify the overestimation of FRP. The upper limits can be obtained by subtracting the C amount in litterfall from that of soil respiration. The resultant limits are referred to as total root allocation which expresses live root respiration plus belowground detritus production. These authors were able to define the relationship between aboveground litterfall data and FRP from N budget, and they suggested that annual FRP increases with aboveground production²³⁾. Also their analysis showed that FRP values from "sequential coring" exceeded the predicted upper limits by "soil C budget" in some cases, which may suggest overestimation.

"Minirhizotron" experiments were carried out in North American hardwood forests¹¹⁻¹³⁾. This method requires facilities such as glass tubes inserted into the soil, borescopes equipped with a video camera, and the software suitable for processing data to periodically record root images and analyze them. The most striking feature is that it can provide demographic data, though the root growth may perhaps be different on the interfaces between the soil and the glass tube. Hendrick et al. (1993)¹²⁾ converted their data on a mass basis and obtained FRP estimates of 8,000 and 7,300 kg.ha⁻¹.yr⁻¹ at the 2 sites, which illustrated the important role of fine roots in forest production.

Finally the method of "soil micromorphology" is often used in pedogenesis and soil taxonomy. In the next section, I will present an example of this method in a Japanese coniferous forest.

Application of soil micromorphology to fine root dynamics study

[Table 1. Classification of roots in soil thin sections](#)

Root type	Characteristic
Type 1	Showing annual growth ring(s)
Type 2	Both stele and cortex stained(blue)
Type 3	Only stele stained (blue) and cortex suberized (brown)
Type 4	Both stele and cortex suberized
Type 5	Part of stele and/or cortex decomposed (missing)
Type 6	Only epidermis and endodermis remaining

A larger number of root types reflect the status of roots with low activity, except for type 1, which has a thick xylem layer.

The experimental site was a natural Hinoki cypress (*Chamaecyparis obtusa* Endl.) forest. The stand density (larger than 2 cm in diameter at breast height) was 2,700 (no. ha⁻¹) and the basal area was 46.5 m².ha⁻¹. The soil samples were collected in October 1993, and impregnated with polyethylene glycol (molar mass 4,000) at the site and again in the laboratory and cut with a rock slicer. The sampling depth was limited to the organic layer because of the hardness of the resin used. Fine roots were, however, mostly concentrated in the organic layer. Thus the soil thin sections were stained with methylene blue. The detailed description is presented in the reports of Takeda (1987)³⁰⁾ and Kasuya, Takeda & Iwatsubo (1992)¹⁶⁾. The roots that appeared in the soil thin sections were examined under a microscope and classified by the degree of staining, suberization and decomposition ([Table 1](#), [Fig. 2](#)). The diameters of roots of each type are depicted in [Fig. 3](#).

[Fig.2:Photographs of cross-sections of roots in soil thin sections\(28 KB\)](#)

[Fig.3:Frequency distribution of root diameter in soil thin sections\(46 KB\)](#)

As anticipated, type 1 which shows secondary thickening displayed the largest diameter, while other types, which all consisted of absorbing roots, did not exhibit any difference in the pattern of distribution of root diameter values. Type 2 (the most active roots in terms of absorption capacity) was concentrated in the shallowest layer ([Fig.4](#)).

[Fig.4:Number and percentage of roots of each type in soil cross-sections at each soil depth The type with a low number represents the roots with a more vigorous appearance.\(39 KB\)](#)

This layer corresponded to the litter layer of the forest floor (about 1 cm thick), and the fermentation layer was 3 to 4 cm thick. Although the results were recorded at one time and not in a time series, this method enabled to obtain an accurate classification of root activity by observing directly a cross-section of roots and the fine distribution of roots especially in ecosystems showing distinct seasonal changes in growth. Takeda (1987)³⁰⁾ proposed the use of the method in the classification of organic layers of soil. Also the method can be applied to mycorrhizal research and soil biology after improvement of staining or microscopic techniques⁸⁾.

Future research

Since belowground NPP is positively correlated with aboveground NPP based on data obtained by the "budget" method, the most difficult problem is to determine why fine root decomposition is slow (usually less than 30% per year, from data compiled by Vogt et al. (1991)³⁴) though many data indicate the large contribution of fine roots to annual NPP. Bloomfield and Vogt (1996)⁴ reported that the higher lignin content of fine roots than that of senescent foliage may inhibit decomposition in coniferous as well as in other forest ecosystems. Fahey (1994)⁶ attributed the slow decomposition rate of fine roots to the disturbance effect of the litterbag method used for measuring the decomposition, whereas Vogt et al. (1991)³⁴ compared litterbag and other methods such as trenching, and suggested that the former method gave smaller decomposition rates. It is hoped that the discrepancies in the data of rapid turnover rate and slow decomposition rate of fine roots will be resolved. Atkinson (1992)³ also pointed out that root consumption by herbivores should be re-examined. In the current micromorphological study, it appeared that a substantial amount of roots were grazed since many fecal pellets of collembola were found all around the root cross-sections ([Fig. 2](#)). Furthermore, if the amount of fine root biomass is low in high productivity sites³⁵, how can a tree compensate for the decrease in surface area for absorbing water and nutrients? Some researchers have suggested that woody coarse roots must be responsible for these functions^{2, 18}). Hendricks et al. (1993)¹⁴ noted that the pattern of antiherbivore compound allocation and retranslocation along a N availability gradient remained unknown, since 40-70% of the macronutrients were reabsorbed in fine roots prior to senescence in some coniferous forests²¹).

It remains to be determined whether there is a positive or negative correlation between belowground and aboveground NPP not only in forest production studies but also in relation to the global climatic changes in the near future since forests can mitigate the carbon dioxide increase by acting as a sink

Animal Waste Problems and Their Solution from the Technological Point of View in Japan

Kiyonori HAGA

Department of Feeding and the Environment, National Institute of Animal Industry
(Tsukuba, Ibaraki, 305-0901 Japan)

Abstract

Intensive animal raising in limited areas such as in Japan results in a large accumulation of animal wastes which have been causing serious pollution problems. Animal farms are bound by strict regulations to control environmental pollution, especially water pollution and offensive odor evolution. Animal wastes which are taken out from the farm are classified into 3 types; solid, slurry and waste water. Solid wastes are treated by drying or composting. Dried wastes are used not only as fertilizer but also as fuel for combustion to obtain energy. Compost is the main product from animal wastes in Japan. Slurry is treated by liquid composting or methane fermentation to produce biogas. But slurry spreading to the field is almost restricted to regions such as Hokkaido where there is enough space to apply a large amount of slurry. Waste water is treated by the activated sludge process to obtain clean water or simplified aeration method to produce liquid fertilizer. The most appropriate techniques of animal waste management involve proper treatment followed by application of the treated wastes to cropland for agricultural use as organic fertilizer sources.

Background

1) Animal industry in Japan

The animal industry in Japan has expanded rapidly, for the last few decades, with increasing demand for animal products by the Japanese people. The expansion of the animal industry is characterized by a drastic increase in the number of animals per farm. For example, the average number of pigs per farm in 1996 (618.8 head per farm) was about 86 times that in 1966 (7.2 head per farm) ([Table 1](#)). This kind of expansion of animal industry results in the accumulation of wastes in limited areas.

[Table.1 Changes in the number of pigs, farms and the average number of pigs per farm\(16 KB\)](#)

2) Output of animal wastes

The amount of animal wastes excreted in 1996 was estimated at 85,450,000 t per year ([Fig. 1](#)), an amount exceeding Japanese people night soil and domestic wastes. In 1966, cattle wastes accounted for 75% of the total wastes. The amount of pig and poultry wastes steeply increased during the 1970s and now it accounts for about 50% of the total. In recent years, the total amount of animal wastes has remained at around 90,000,000 t due to the small changes in the number of animals.

[Fig.1. Annual changes in animal wastes\(25 KB\)](#)

3) Occurrence of animal waste pollution problems

The number of complaints against animal waste pollution increased steeply until 1973 (11,676 per year) and then gradually decreased ([Fig. 2](#)). The number of complaints in 1996 decreased to 2,576 which is less than one fourth of the number in 1973. Apparently, it appears that the occurrence of pollution problems is on the decrease. However, in the meantime, the decrease in animal farms is much more drastic while the number of complaints per farm has been rather increasing, suggesting that the problems are becoming increasingly more complicated and serious for each farm.

[Fig.2. Annual changes in the number of complaints about pollution problems by animal wastes\(25 KB\)](#)

4) Legislation

(1) Legislation system

Animal farms are controlled by strict regulations ([Fig. 3](#)). Government legislation of environmental pollution control has been developed due to social needs around 1970. The enactment of the Basic Law for Environmental Pollution Control of 1967 was followed by the enactment of many other laws, namely the Water Pollution Control Law in 1970, the Waste Disposal and Public Cleansing Law in 1970, the Offensive Odor Control Law in 1971, etc. Recently, the Basic Law of 1967 has been fully revised into the Environment Basic Law of 1993 which involves the establishment of social systems for environmental conservation and introduces the concept of preservation of the global environment. Animal waste pollution problems are mainly related to water pollution and offensive odor evolution.

[Fig.3. Legal constraints related to animal wastes\(26 KB\)](#)

(2) Water pollution control

Table 2. Criteria of discharged water

<u>Items</u>	<u>Units</u>	<u>Limits</u>
pH	--	5.8~8.6
BOD	mg/L	160(Daily average 120)
COD	mg/L	160(Daily average 120)
SS	mg/L	200(Daily average 150)
Coliform	number/mL	3,000
N	mg/L	120(Daily average 60)
P	mg/L	16(Daily average 8)

[Table 2](#) shows the regulation standards of discharged water closely related to animal wastewater. These criteria are governmental ones. Each prefecture can promulgate much stricter criteria depending on the local conditions, such as the presence of a national park, water catchment area, etc. Nitrogen and phosphorus were newly introduced in 1985 to cope with the eutrophication of lakes and sea. Limits until 2,000 for nitrogen and phosphorus contents in animal waste water are less than 140 mg/L (daily average 70 mg/L) and less than 34 mg/L (daily average 17 mg/L), respectively. In 1994, the concentration of substances with a trihalomethane forming potential (THMFP)¹⁰ which are the precursors of trihalomethanes considered as carcinogens was regulated in various catchment areas. The criteria for animal waste water range from 1.3 to 5.2 mg/L.

(3) Offensive odor control

[Table 3](#) shows the regulation standards of 22 offensive odor substances which correspond to an odor intensity of 2.5 to 3.5. Among them, 9 substances, such as ammonia, methyl mercaptan, hydrogen sulfide, dimethyl sulfide, dimethyl disulfide, propionic acid, n-butyric acid, n-valeric acid, and isovaleric acid are closely related to animal waste odor. Each prefecture can set up an initial criterion between the governmental ranges listed in Table 3 depending of the local conditions. In April 1996, a new regulation of odor index between 11 to 20 based on sensory tests was enacted additionally.

(Received for publication, November 12, 1997)

The-state-of-the-art of animal waste management

Animal wastes which are taken out from the farm are classified into 3 types; solid, slurry and waste water ([Fig. 4](#)). Solid wastes are treated by drying or composting. Dried wastes are used not only as fertilizer but also as fuel for combustion to obtain energy. Slurry is treated by liquid composting or methane fermentation. Waste water is treated by the activated sludge process to obtain clean water or simplified aeration method to produce liquid fertilizer. The most appropriate techniques of animal waste management should involve proper treatment prior to the application to land. Drying, composting, energy production and waste water treatment are popular and well-studied in Japan.

[Fig.4. Methods generally used for animal waste management in farms\(25 KB\)](#)

Drying

Raw wastes with a high water content are dirty, offensive, putrescible and troublesome in handling. Reduction of water content is necessary for convenience in handling of animal wastes. Drying in a greenhouse with solar heating is superior to that with oil heating, because expenses can be reduced and energy saved. The evaporation power by the greenhouse system is 4.5~5 L/m² in summer and 1.5~2 L/m² in winter in Japan⁴). The area of greenhouse required for construction can be easily estimated based on the evaporation power and the amount and water content of animal wastes to be dried.

Composting

Compost is the main product from animal wastes in Japan. The objectives in composting are to stabilize the biodegradable organic matter (BOD) in raw wastes, to reduce offensive odors, to kill weed seeds and pathogenic organisms, and finally, to produce a uniform organic fertilizer suitable for land application.

1) Conditions for composting

Controlled conditions are important for composting, to distinguish it from other natural biological decomposition processes such as rotting and putrefaction²). Animal wastes contain a sufficient amount of nutrients (biodegradable organic matter) for microorganisms and an adequate number of microorganisms to enhance the composting process. However, the water content of raw wastes is too high to supply oxygen to the microorganisms. Moisture control of the raw wastes at around 65% by the addition of dry materials such as sawdust, rice hull and dried compost or by pre-drying in greenhouses is necessary to achieve suitable composting. The active degradation of organic matter by the microorganisms under controlled conditions leads to heat generation during composting. The high temperature (higher than 60) contributes to the killing of weed seeds and pathogenic organisms, to the evaporation of water and production of sanitary compost for convenience in handling. With occasional turning of the compost pile, the complete composting process requires a few months.

2) Facilities of composting

Various types of composting facilities are available in Japanese farms and compost centers jointly used by several farms²). Facilities can be classified into 5 types; the pile type, the box type, the rotary kiln type, the enclosed vertical type and the open elongated type with turning device ([Fig. 5](#)). For cattle wastes, the pile type and the open elongated type are generally used. For swine and poultry wastes, the open elongated type and the enclosed vertical type are popular

[Fig.5. Composting facilities for animal wastes\(27 KB\)](#)

3) Quality of compost

Chemical nutrients in composts vary with the type of animals producing manure and the type of additional materials used⁴). Many methods have been proposed to estimate the degree of maturity of composts from animal wastes⁶). Only a few methods, however, are easy to use and reliable. Recommended quality index of animal waste composts was temporarily presented as shown in Table 4 in 1993.

[Table.4 Recommended quality index of animal waste compost](#)

A. Items to be indicated

<u>Items</u>	<u>Standard</u>
Organic matter	More than 60% DW
Carbon-nitrogen ratio	less than 30%
Total N	more than 1% DW
P ₂ O ₅	more than 1% DW
K ₂ O	more than 1% DW

B. Items not to be indicated

<u>Items</u>	<u>Standard</u>
Moisture	less than 70% FW
Electric conductivity	less than 5 mS/cm

1)As, Cd and Hg contents should be less than 50, 5 and 2 mg/kg DW, respectively.

2)Abnormal growth should not be observed for the Komatsuna (*Brassica rapa*) seedling test.

3)Cu and Zn contents should be less than 600 and 1,800 mg/kg DW, respectively.

4)DW: Dry weight, FW weight.

Energy production

Animal feces contain a large amount of organic matter (around 80% of dry matter) and have a high value as energy source. Five methods of energy recovery from animal wastes³⁾, such as combustion, pyrolysis gas, oil conversion, heat recovery from compost and biogas can be applied.

1) Heat of combustion

Dried wastes have a fuel value of about 3,000 kcal/kg. For example, broiler litter taken out from a farm has been dried to a moisture content of about 30%. Since broiler farms need energy for floor heating with hot water, it is effective to recycle this dried litter as fuel for a broiler litter boiler and use it for heating purposes. This method enables to save 70 to 80% of the conventional energy consumption³⁾. The residual ash can be used as inorganic fertilizer rich in phosphorus and calcium.

2) Biogas

Biogas can be produced from animal waste slurry by the action of microorganisms in a methane fermenter¹⁾. To achieve efficient methane fermentation, it is necessary to provide favorable conditions to these microorganisms in the fermenter. These conditions include anaerobic conditions, mesophilic temperature (about 35), neutral pH (6 to 8), appropriate organic matter loading (about 3 kg of organic matter/m³ d) and proper retention time (10 to 20 days). For example, 150 to 250 L of biogas are produced from one head of pig per day, and the capacity of a fermenter required for a pig is about 150 L³⁾. The biogas produced contains 60% of methane and 40% of carbon dioxide, and has a fuel value of about 5,500 kcal/m³. It can be used not only as domestic fuel but also for many other purposes, such as agriculture and power generation.

Waste water treatment

[Fig.6. Time chart of conventional, limited aeration and intermittent aeration methods\(22 KB\)](#)

Activated sludge process is one of the typical treatments of animal waste water to secure strict regulations of the effluent⁵⁾. The process consists of a 4-stage cycle, namely sedimentation, discharge, charge and aeration. [Fig. 6](#) shows the time chart of conventional, limited and intermittent aeration methods. The shortcoming of the conventional activated sludge process is the low capacity to remove nitrogen and phosphorus. In the limited aeration method, aeration stops just after charge for several hours⁸⁾. Although most of the nitrogen remains as nitrate nitrogen in the conventional aeration method, most of nitrate nitrogen is removed under anaerobic conditions in the limited aeration method.

The intermittent aeration method⁹⁾ is considered to be more effective to remove nitrogen, because in the intermittent method the limited process is repeated several times a day. [Fig. 7](#) shows the changes in pH, DO (dissolved oxygen) and TOC (total organic carbon) values by the intermittent aeration process. Intermittent increase and decrease of DO values were observed. Nitrification and denitrification occurred intermittently and the efficiency of nitrogen removal increased ([Fig. 8](#)). Phosphorus was also removed and accumulated in the microorganism body. In conclusion, limited and intermittent aeration methods were found to be effective in removing not only nitrogen but also phosphorus. These methods could be performed with minimal improvement of conventional facilities and may enable to achieve the objective at a low cost and with a high efficiency.

[Fig.7. Changes in pH, DO \(dissolved oxygen\) and TOC \(total organic carbon\) values by the intermittent aeration process\(13 KB\)](#)

[Fig.8. Changes in nitrogen forms during intermittent aeration process\(11KB\)](#)

Conclusion

Agricultural use of animal wastes as compost is presently mainly recommended in Japan. Total amounts of nitrogen (N), phosphorus (P₂O₅) and potassium (K₂O) contained in animal wastes are estimated to be 680,000, 450,000 and 550,000 t per year, respectively. These amounts of nutrients are nearly equal to those of chemical fertilizers applied to arable land in Japan. Environmentally friendly use of both animal wastes and chemical fertilizer is recommended. It is difficult to use slurry (liquid wastes) in Japan, except for a part of Hokkaido. Insufficient treatment and/or illegal dumping of excess animal wastes cause serious pollution problems. Then, recycling of animal wastes without any environmental pollution will be closely related to the development of sustainable agriculture with organic fertilizer in Japan.

Abstract

In this study, we attempted to combine a biological treatment process which used Bi-Act SCBA system (SCBA) and chemical treatment process to remove chemical impurities such as COD, BOD₅ and nutrients as well as colored substances from the molasses waste water (MWW). In the pilot plant experiment, SCBA unit A (SCBA-A) was used for the pre-aeration and uniformity of the MWW before biological treatment. The sludge volume (SV₃₀) was about 50 ml/l in the aeration unit of the SCBA-A. The COD and colored substances could not be removed in this step. However, in both SCBA-B and SCBA-C, SV₃₀ increased up to 350-400 ml/l. At the same time, approximately 44.0% and 22.9% of COD of the effluents from SCBA-B and SCBA-C were removed, respectively. On the other hand, the removal of colored substances in SCBA-B and SCBA-C (about 25.0 and 13.3%) was not appreciable. However, the colored substances in the MWW passing through SCBA-B and SCBA-C could be easily precipitated by chemical agents compared with the original MWW. About 93% of the colored substances of the effluent from SCBA-C could be removed in the chemical precipitation step, while the colored substances in the original MWW could not be precipitated.

Introduction

Many by-products such as molasses, bagasses and fiber cake are produced from cane sugar factories. Among them, molasses is the most important product^{4,10}) because molasses has a high commercial value due to its use as a carbon source for fermentation industries, biofertilizer and feed for domestic animals⁵). However, the use of molasses as a raw material for fermentation industries is associated with the presence of a large amount of colored substances which remain in the fermentation residue after recovery of the products. The main colored substance, melanoidin, can hardly be decomposed by usual biological treatment processes^{1,11}) and accounts for the high COD value, which is a major problem for pollution control⁵).

In Thailand, all the alcohol-producing factories use molasses as raw materials and discharge molasses waste water (MWW) accounting for about 10 times the amount of alcohol produced. Several processes⁷⁻⁹) were used for treating the MWW. The use of MWW as feed for aquatic organisms is not suitable economically due to the small volume used. For biofertilizer use, the quality is not as high as that of other biofertilizers or chemical fertilizers (it may be similar to that of soil conditioners). Several alcohol factories have attempted to treat MWW by anaerobic methods such as methane fermentation, anaerobic pond or facultative anaerobic pond, followed by aerobic treatment such as activated sludge, aerated lagoon or oxidation pond^{3,6}). However in these treatment processes, the colored substances of MWW still remained and the COD content in the treated waste water was higher than the standard value authorized by the Ministry of Industry, Thailand. Presently, treatment processes such as chemical precipitation, chemical adsorption or carbon adsorption are used for the removal of the colored substances. However, color removal by the above processes still has disadvantages due to the high operation cost, high consumption of chemicals, fluctuation of the color removal efficiency and the high volume of solid waste produced.

Against this background, we applied biological and chemical processes to MWW from the anaerobic pond of the alcohol factory to remove colored substances, COD

and BOD₅ with high efficiency and at a low cost. The experiments on the biological process were carried out on a pilot plant scale, using the Bi-Act SCBA system¹²) which is characterized by low energy consumption and high efficiencies for aeration and mixing in the aeration tank. In this paper, we report the results of the experiments.

Materials and methods

Bi-Act SCBA unit: Three units of Bi-Act SCBA (SCBA)¹²) supplied by Uni San Pol. Co. Ltd. were used in these experiments. The scheme of the processes shown in [Fig. 1](#) was as follows: 1 unit of 10 m³ storage tank, 2 units of 10 m³ SCBA (unit A and unit B), 1 unit of 4 m³ SCBA (unit C) and 2-tanks for 1 m³ of nutrient supply.

This pilot plant was installed in the waste water treatment plant of Sang Som Distillery Co. Ltd., Nakhon Pathom Province, Thailand.

[Fig.1.Scheme of the pilot plant of Bi-Act SCBA system\(22 KB\)](#)

MWW: The MWW used in this experiment was collected from the anaerobic pond of Sang Som Distillery Co. Ltd.

Supply of nutrients: Cassava flour was supplied as a nutrient for increasing the BOD₅ content in the MWW. Twenty kg of cassava flour was fermented for 1 week in the S1 tank as shown in Fig. 1. The supernatant from S1 tank was transferred to S2 tank before being fed to the SCBA system.

Start-up procedure and operation of the pilot plant unit: The concentrated sludge suspension (MLVSS=10,000 mg/l) from the central waste water treatment plant of BANG-PA-IN Industrial Estate, Ayuthaya, Thailand, was used as the inoculum for starting this pilot plant. The start-up procedure was performed as follows: First, 4, 4 and 2 m³ of concentrated sludge suspensions were put in SCBA-A, SCBA-B and SCBA-C (aeration tank), respectively. Second, water (softened water) was added in all 3 units up to the optimum level and the system was operated without influent feeding overnight. Thereafter, the MWW from the storage tank was fed into the SCBA system at the flow rate of 2 m³ /day. At the same time, the nutrients from tank S2 were fed into SCBA-B at the flow rate of 2 m³/day. The system reached the steady state after 2 weeks' operation. The flow rate of the influent from the storage tank slowly increased up to 4 m³/day within 1 week. Also the flow rate of water (underground water or river water) used instead of the nutrient solution increased up to 4 m³/day within 1 week. The MLSS, SV₃₀ and pH of the system were monitored until the system became steady. The effluent from the clarifier of each SCBA unit was taken for the analysis of BOD₅, COD, SS, TKN, TP, pH and color intensity. Also the mixed liquid from the aeration section of each SCBA unit was collected for measuring the pH and SV₃₀ during the period February-December 1996.

Color removal by chemical precipitation: The effluent from the clarifier of SCBA-C was collected and used for the determination of optimum concentrations of chemical agents to remove the colored substances. The chemical agents used for precipitation of the colored substances were FeCl₃, Al₂(SO₄)₃ and sodium hydroxide. The effluents from each SCBA unit were used to determine the optimum color removal efficiency. All the experiments were performed on a laboratory scale. A certain amount of FeCl₃ (range of 1 to 8 g) or Al₂(SO₄)₃ (range of 4 to 32 g) was added into 1,000 ml of the effluent from SCBA-C. Thereafter, the mixtures were adjusted to pH 7 by the addition of sodium hydroxide solution. The supernatants were collected for the determination of the color intensity, pH and COD.

Assay of chemical composition of the waste water: The BOD₅, COD, TKN, TP and SV₃₀ were determined by a standard method of analysis²⁾.

Estimation of color intensity of the waste water and removal yield: The sample was diluted with 0.1 M acetate buffer solution (pH 6.0) after centrifugation at 6,000×g for 15 min and the color intensity of the diluted solution was measured at 475 nm with a spectrophotometer (LKB, model Biochrom Ultra-space 2, England). The percentage of color removal was expressed as the color intensity of the waste water treated against that of original waste water. The removal yield was expressed as the degree of decrease in the absorbance at 475 nm against the initial absorbance at the same wavelength.

Results

Chemical properties of the MWW: The MWW collected from the anaerobic pond of the waste water treatment plant of Sang Som Distillery Co. Ltd. for this experiment still contained a high level of chemicals and showed a high color intensity as indicated in [Table 1](#). Chemical properties such as COD, BOD₅, contents of total solids and total volatile solids were 33,643, 3,500, 42,250 and 23,180 mg/l, respectively. The color intensity was about 33-35 (optical density at 475 nm).

[Table.1. Chemical properties of MWW from anaerobic pond of Sang Som Distillery Co. Ltd., Thailand\(26 KB\)](#)

Start-up of the SCBA system: By using the concentrated sludge solution from the central waste water treatment plant of BANG-PA-IN Industrial Estate, the microorganisms in both SCBA-B and SCBA-C could easily grow. The SV30 in the aeration tanks of SCBA-B and SCBA-C reached values of 300 and 350 ml/l, respectively within 2-3 weeks, while the level of SV30 was low ((50 ml/l) in the aeration tank of SCBA-A. The SV30 in the aeration tank of both SCBA-B and SCBA-C remained at the levels of 300 and 350 ml/l during the treatment as shown in [Fig. 2](#).

[Fig.2. SV30 profiles in the aeration tank of each SCBA unit in the start-up of the system\(16 KB\)](#)

Continuous treatment by SCBA system: At 3 weeks after the start-up step, the system reached a steady state with an influent flow rate of 4 m³/day and diluted water was fed into the SCBA-B at the rate of 4 m³/day. The removal percentage of the impurities of the waste water (COD, BOD₅, SS and TKN) was high in effluents from SCBA-B and SCBA-C as shown in [Table 2](#), while in the SCBA-A system, the impurities could not be removed effectively. The COD content in the effluent from both SCBA-B and SCBA-C decreased to 44.0 and 22.9%, respectively. Other impurities such as SS, TKN and total phosphate were also removed. For color removal, in SCBA-A the level was only 4.0%, while in the SCBA-B and SCBA-C systems, the removal of the colored substances reached values of 25.0 and 13.3%, respectively, as shown in [Table 2](#). The system could be operated smoothly with a constant COD concentration of the effluents from each SCBA unit up to 36 days, as shown in [Fig. 3](#).

[Table.2. Cheical properties of influent and effluent of each SCBA unit\(49KB\)](#)

[Fig.3. COD profiles of the influents and effluents of each SCBA unit during the continuous operation\(20KB\)](#)

Color removal by chemicals: The effluent from the clarifier of SCBA-C was used as the color solution in the chemical precipitation step. Various concentrations of FeCl₃ in the range of 0-12% were added to the effluent and the mixed solution was adjusted to pH 7.0. The results are shown in [Fig. 4](#). Addition of FeCl₃ at a concentration of 6% in the solution resulted in the highest color removal efficiency. Various concentrations of Al₂(SO₄)₃ solution in the range of 8-30% were also added to the effluent and the

mixed solution was adjusted to pH 7.0. The results are shown in [Fig. 5](#). Addition of $\text{Al}_2(\text{SO}_4)_3$ at a concentration of 20% in the solution was adequate for color removal.

On the other hand, 3 effluents from SCBA-A, SCBA-B and SCBA-C were tested for the removal of color by the addition of FeCl_3 (6%) or $\text{Al}_2(\text{SO}_4)_3$ (20%). After adjustment of the pH to 7.0, the colored substances in the effluents from SCBA-B and SCBA-C were easily removed at the rates of about 28 and 93%, respectively, while those from SCBA-A could not be removed as shown in [Table 3](#). The removal rate by the addition of FeCl_3 and $\text{Al}_2(\text{SO}_4)_3$ was almost the same.

[Fig.4. Removal of colored substances from the effluent of SCBA system by the addition of various concentrations of \$\text{FeCl}_3\$ solutions \(11 KB\)](#)

[Fig.5. Removal of colored substances from the effluent of SCBA system by the addition of various concentrations of \$\text{Al}_2\(\text{SO}_4\)_3\$ solutions \(9 KB\)](#)

Discussion

We carried out experiments to remove chemicals such as COD, BOD₅, TKN, total phosphorus and colored substances by using the SCBA system combined with the chemical treatment process. The SCBA system, which is a kind of activated sludge system, consisted of a new compact unit for biological treatment used in both domestic and industrial waste water treatment plants in Thailand. The rotary drum in the aeration tank of the system was specially designed, and the mixed liquid in the aeration tank was fully supplied with air and completely mixed.

Actually, each unit of SCBA displayed several characteristics. The chemical properties of the effluent from SCBA-A were not different from those of the influent. Sludge (MLSS) generation in the aeration tank was minimal and there was a high concentration of toxic substances in the waste water⁹). The effluent from SCBA-A was diluted with water and transferred to SCBA-B. In SCBA-B, the BOD₅ and COD were removed easily as shown in [Table 2](#). The sludge concentration in the aeration tank (SV₃₀) increased up to 400-500 mg/l, reflecting normal conditions of activated sludge process^{3,6}). In SCBA-C, the results were the same as in SCBA-B. By the SCBA system, the colored substances in the influents of SCBA-B and SCBA-C could be removed at percentages of 25.0 and 13.3%, respectively.

For color removal by the chemical treatment process, the effluent from SCBA-A was hardly precipitated by FeCl_3 and $\text{Al}_2(\text{SO}_4)_3$ even when a high concentration of chemicals was used. However, the color of effluents from both SCBA-B and SCBA-C could be easily removed and the percentages of color removal were 28 and 93%, respectively, as shown in [Table 3](#).

Based on the results obtained, the SCBA system was found to be suitable for the treatment of MWW as well as the hitherto known activated sludge system^{3,6,8}). Furthermore, the SCBA system enabled to remove colored substances in comparison with the activated sludge system. Namely, the colored substances could be removed at a percentage of about 10% by this system directly and about 90% of the

colored substances remaining in the effluent from the system were easily precipitated by treatment with 6% FeCl_3 or 20% $\text{Al}_2(\text{SO}_4)_3$. The reason for easy precipitation could not be determined. It is suggested that the colored substances may have changed or that their structure may have been modified during the passage through the SCBA system.

Postmortem Changes in Skeletal Muscle Connectin (titin) and Its Structure

Ryoichi TANABE

Department of Animal Products, National Institute of Animal Industry (Tsukuba, Ibaraki, 305-0901 Japan)

Abstract

The splitting of the connectin (titin) molecule during meat conditioning and its primary structure were analyzed. Using immunofluorescence microscopy and immunoelectron microscopy, it was shown that the connectin molecule split into β -connectin and a 1,200 kDa-subfragment at a point $0.34 \mu\text{m}$ apart from the Z-disc during meat conditioning. Differences in molecular weight and partial amino acid sequences of connectin were determined for cattle, pig and chicken skeletal muscles. Results of peptide mapping analysis differed according to animal species. Amino acid sequences deduced from partial nucleotide sequences of connectin also differed according to animal species at immunoglobulin-like (Ig) and fibronectin type 3 (FN3) domains. In chicken, the molecular weight of connectin from leg muscles differed from the value recorded in pectoral muscles. It is suggested that meat texture and conditioning may be related to the splitting of the connectin molecule and its structure.

Discipline: Animal industry

Additional key words: splitting of connectin, localization of 1,200 kDa-subfragment, primary structure, meat conditioning, meat texture

Introduction

Connectin is an elastic protein of striated muscle initially reported by Maruyama et al.¹⁶⁾, and also called titin³⁰⁾. The apparent molecular mass of connectin is 3,000 kDa^{14,28)}. Each connectin molecule extends as a long ($\sim 1.2 \mu\text{m}$) filament from the Z disc to the M line in a sarcomere and comprises an elastic segment at the level of the I band and an inelastic segment at the level of the A band. Connectin filaments keep the thick filaments centered within the sarcomere during force generation⁶⁾.

During meat conditioning, the connectin molecule splits into 2 polypeptides. The molecular mass of one peptide is 1,200 kDa (1,200 kDa-subfragment); the other peptide is called β -connectin. This splitting occurred nonenzymatically when myofibrils were treated with a solution containing 0.1 mM CaCl_2 and 30 μg of leupeptin/ml²²⁾. This splitting is very important for meat texture, because it reduces the elasticity of meat during conditioning²³⁾. Connectin filaments split more rapidly in more tender meat^{1,8)}. However, Fritz et al.³⁾ concluded that the connectin content did not enable to distinguish "tough" from "tender" beef. The time required for conditioning varies according to animal species. Within meat conditioned quickly, splitting is also rapid^{1,8,18)}. Differences in molecular structures of connectin may thus be a determinant of meat texture.

Labeit and Kolmerer¹²⁾ determined the complete cDNA sequence of human cardiac connectin and showed that its structure consisted primarily of 2 main types of repeating domains (an immunoglobulin-like (Ig), a fibronectin type 3 (FN3)) and a PEVK domain. They suggested that the PEVK domain primarily accounted for the elasticity of the connectin molecule. They indicated that after the extensibility of the PEVK domain had been exhausted, the stable fold of the Ig domains would resist further extension. These domains may thus determine the meat texture. The molecular structures of connectin in humans, rabbit and experimental animals have been studied extensively^{4,9,10,12,15,17,21)}. However, there are few reports on the molecular structure of connectin in domestic animals.

In this report, it was revealed that the splitting of the connectin molecule occurs at a point $0.34 \mu\text{m}$ apart from the Z-disc during meat conditioning^{25,26}). The differences in the molecular weight of connectin and amino acid sequences of Ig, FN3 and PEVK domains in cattle, pig, chicken and muscle types were described²⁴).

Materials and methods

1) Preparation and Ca treatment of myofibrils

Myofibrils were prepared according to the method of Perry and Grey¹⁹) from cattle, pig and chicken. To induce the splitting of connectin into a 1,200 kDa-subfragment and β -connectin in vitro, freshly prepared myofibrils were treated with 0.1 mM CaCl_2 as described by Takahashi et al.²²).

2) Electrophoresis

Myofibrillar proteins were separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) according to the method of Tatsumi and Hattori²⁷).

3) Preparation of antiserum and immunohistochemical observation

Antiserum against the 1,200-kDa subfragment of the connectin molecule was prepared as previously described²⁶). Indirect immunofluorescence microscopy and immunoelectron microscopy observation using that antiserum was carried out as previously described²⁶).

4) Peptide mapping

Connectin was digested by V8 protease as described previously²⁴). The peptides produced by V8 protease digestion were separated by SDS-PAGE.

5) PCR amplification and sequencing of segments from the connectin gene

Sequences of the oligonucleotide primers were based on the sequences of pig connectin reported by Fritz et al.⁴). The connectin molecule has Ig and FN3 domains. The sense primer for amplification of the Ig domain was 5'-CAGGTGGCTCCTTAAGGTTATTTGTTCC-3' and the antisense primer for the Ig domain was 5'-CAAAGGCAGACTTTGTTCCACTGCTGTT-3'. The sense primer for amplification of the FN3 domain was 5'-CCAGGACCTCCAAACAATCCCAAAGT-3' and the antisense primer was 5'-AGCACAGATACGGAAGTTGTATTTCATG-3'. The positions of these primers on the sequence determined by Fritz et al.⁴) were 509-536, 691-718, 154-179 and 361-387, respectively. Genomic DNA was extracted from cattle, pig and chicken. PCR amplification was conducted according to the method of Chikuni et al.²). Both strands of amplified DNA were sequenced. From the nucleotide sequence, the amino acid sequence was deduced.

(Received for publication, November 12, 1997)

Results and discussion

[Fig. 1-A](#) shows the postmortem changes of myofibrillar proteins in chicken M. tensor fasciae latae stored at 4(25 KB). With increasing postmortem time, the band of connectin became weaker, while the band of β -connectin became stronger. Furthermore, the 1,200 kDa-subfragment appeared during storage. The densitometric analysis suggested that these changes continued until about 4 days postmortem, and β -connectin and the 1,200 kDa peptide were produced stoichiometrically from the entire connectin molecule (data not shown). The same changes were observed in chicken M. semimembranosus and M. adductor 25). These data suggest that the connectin molecule is degraded to-connectin and the 1,200 kDa-subfragment until about 4 days postmortem in chicken leg muscles. [Fig. 1-B](#) shows the changes of myofibrillar proteins of chicken leg muscles during the Ca treatment. Basically, the changes of connectin during the Ca treatment were the same as those occurring in stored muscles. However, the band of the 1,200 kDa-subfragment was stronger and sharper than in the stored muscles. It was confirmed immunologically that the 1,200 kDa-subfragment was derived from the connectin molecule and not from- β connectin by immunoblot analysis using the antiserum against the 1,200 kDa-subfragment26). Takahashi et al.22) demonstrated that connectin is not degraded in a Ca treatment solution containing 5 mM EDTA. Therefore, they concluded that these changes are nonenzymatically induced reactions caused by 0.1 mM Ca ion.

[Fig. 1-A. Postmortem changes of connectin in chicken M. tensor fasciae latae stored at 4](#)

[Fig. 1-B. Changes of connectin during Ca treatment of chicken leg myofibrils\(25KB\)](#)

Localization of the 1,200 kDa-subfragment in a sarcomere was revealed by indirect immunofluorescence microscopy ([Fig. 2-A](#)). When myofibrils were treated with antiserum against the 1,200 kDa-subfragment, Z-disks were strongly fluorescent, the regions of both sides of the Z-disks were fairly fluorescent, and the A-band was absent. Immunoelectron microscopy revealed a heavy deposition of antibodies on the Z-disk and the formation of a stripe in each I-band, which was about 0.34 μ m apart from the Z-disk for a sarcomere length of 2.6 μ m ([Fig. 2-B](#)). The other deposits were scattered and not common to both I-bands. These results indicate that the 1,200-kDa subfragment is a portion of connectin filaments that may become attached to the Z-disk. A single connectin molecule forms an elastic filament connecting a thick filament with a Z-disk, extending its distal end nearly to the M-line. The distance between the Z-disk and the stripe in the I-band, 0.34 μ m, was in good agreement with the difference between the length of a connectin molecule (approximately 1.30 μ m, which is half the length of the sarcomeres we observed) and β -connectin (approximately 0.90 μ m). Therefore, we estimated that the length of the 1,200 kDa-subfragment was about 0.34 μ m for a sarcomere length of 2.6 μ m.

[Fig. 2-A. Immunofluorescence staining of myofibrils with antiserum against the 1,200 kDa-subfragment](#)

[Fig. 2-B. Immunoelectron micrographs showing the localization of the 1,200 kDa-subfragment \(32 KB\)](#)

These results indicate that the splitting of connectin filaments occurs at a point 0.34 μ m apart from the Z-disc in a sarcomere during meat conditioning. [Fig. 3](#) gives a schematic diagram of that splitting.

[**Fig. 3. Splitting of connectin molecule in a sarcomere during meat conditioning\(14 KB\)**](#)

Locker and Wild¹³) reported that the molecular weight of connectin was essentially the same in vertebrate skeletal muscle. However, Hu et al.⁷) observed differences in the molecular weight depending on animal species and muscle types after analyzing many sources of vertebrate striated connectin and non-vertebrate connectin-like protein. Tatsumi and Hattori²⁷) noted that the molecular weight differed between chicken leg, rabbit leg and rabbit back muscles using the same SDS-PAGE conditions as those applied in this study. Molecular weight was found to differ according to the muscle type in chicken ([Fig. 4](#)). The molecular weights in *M. pectoralis profundus* and *M. pectoralis superficialis* were lower than in *M. semitendinosus*, *M. semimembranosus*, *M. sartorius* or *M. biceps femoris* ([Fig. 4, lane 1-6](#)). The sample, which consisted of a mixture of 2 types of pectoral muscles, produced a single band of connectin ([Fig. 4, lane 7](#)). On the other hand, the sample which consisted of a mixture of a pectoral muscle and leg muscles produced 2 bands of connectin ([Fig. 2, lane 8](#)). Thus, it was confirmed that the molecular weight of connectin differed according to the muscle types in chicken. Many muscle proteins are present in different isoforms²⁰). Connectin in rabbit fast muscles showed a higher mobility on SDS-PAGE than connectin in slow muscles and this difference was correlated with the resting tension of muscle fibers^{5,29}). Differences in the molecular weight of connectin in chicken depending on skeletal muscles would thus appear to be derived from physiological differences between fast and slow muscles.

[**Fig. 4. SDS-PAGE analysis of connectin from various muscle types in chicken \(14 KB\)**](#)

By peptide mapping analysis using V8 protease, SDS-PAGE patterns of cattle, pig and chicken were clarified. They indicated that the primary structure of the entire connectin molecule differed according to animal species ([Fig. 5](#)). V8 protease specifically cleaved peptide bonds on the carboxyl side of aspartic and glutamic acid residues. Due to the large molecular mass and the existence of repeating domains in a connectin molecule, V8 protease digestion produced many bands with varying intensities. The patterns of peptide mapping were reproducible. Arrowheads indicate typical bands, which differed from those in other animal species (a, b: cattle; c: pig; d: chicken). Although the 'b' and 'c' bands were close in mobility, the 'c' band was distinctly lower than the 'b' band.

[**Fig. 5. Digestion patterns of connectin in *M. semimembranosus* by *S. aureus* V8 protease \(17 KB\)**](#)

To reveal differences in the primary structure of connectin according to animal species more clearly, partial nucleotide sequences encoding connectin were determined. The connectin molecule contains the Ig and FN3 domains^{10,12}). Most of the connectin molecule consists of repeats of these domains in succession. Partial nucleotide sequences encoding single Ig and FN3 domains of pig, cattle and chicken muscle connectin were determined, on the basis of which, the amino acid sequences were identified ([Fig. 6](#)). Amino acid sequences of pig domains were the same as those indicated by Fritz et al.⁴). The amino acid sequences of the Ig domain in cattle and chicken differed from those of the pig at 1 and 6 points, respectively. Amino acid sequence of the FN3 domain in cattle was different from that of the pig at 2

points. The Ig and FN3 domains of connectin were thus found to display amino acid sequences that differed according to animal species. These results indicate that the primary structure of connectin is completely different in cattle, pig and chicken.

[Fig. 6. Comparison of the corresponding amino acid sequences of connectin Identity of amino acids is indicated by a single dot.\(23 KB\)](#)

Labeit and Kolmerer¹²) determined the complete cDNA sequence of human cardiac muscle connectin. The partial sequences of skeletal muscle connectin of several animal species such as humans, rabbit and chicken have been elucidated^{11,12,15}). It was suggested that tissue-specific connectin was expressed by alternative splicing. Those studies showed that the primary structure of connectin differed according to animal species and muscle types. These findings were confirmed by our data for cattle, pig and chicken.

Connectin is an elastic filament whose splitting results in changes in the meat texture during conditioning²³). The primary structure of connectin was different in cattle, pig and chicken. And the Ig and FN3 domains have been shown to interact with F-actin and myosin^{9,11}). The connectin molecule is anchored to the Z-disc by the binding of the 1,200 kDa-subfragment to α -actinin, which is the major protein constituent of the Z-disc²⁵). Although the sequence changes were mostly conservative (T for S; D for E; Y for F), the interactions between connectin and myofibrillar proteins such as actin, myosin and α -actinin may not be equally strong in different animal species. In many studies, conditioning changes in meat are considered to result from endogenous protease concentration or levels of activation. However, conditioning of meat may be related to the structure of myofibrillar proteins such as connectin.

In this paper, it was revealed that the connectin molecule split at a point 0.34 μ m apart from the Z-disc during the conditioning of meat, and that this site corresponded to the N2-line of a sarcomere. The region of connectin molecules, which is situated near the N2-line, is called the PEVK region and is comprised predominantly of 4 amino acid residues. The sequence of this region differs from those of the Ig and FN3 domains¹²). The PEVK region may also account for the capacity of connectin filament extension¹²), and thus may also be a factor of meat texture and rate of conditioning. Primers for the amplification of the PEVK region of the connectin gene were synthesized, based on sequences that would not include introns and would be conserved in human skeletal and cardiac muscle connectin. These primers, however, failed to amplify the sequence of the PEVK region in cattle, pig and chicken (data not shown). The primary structure of the PEVK region thus appears to differ in those species. It was suggested that the PEVK domain primarily accounted for the elasticity of the connectin molecule³). Therefore, meat texture may be related to differences in the PEVK domain of connectin.

Abstract

We investigated the relationships between the serum γ -globulin concentration and the pathological characteristics in 4 types of bovine lymphosarcoma including the adult, calf, thymic and skin forms. In 5 cases of the adult form, there were extensive neoplastic proliferations in the lymph nodes and the γ -globulin concentration was low. Four cases of the calf form showed systemic lymph node involvement, and the concentration was low in one case and much lower in 3 cases. IgM was absent in 3 cases. In the thymic form, one case showed a slightly high concentration with systemic neoplastic lesions in the lymph nodes, whereas in the other the concentration was normal and lesions were localized. In a cow with the skin form, the concentration was low in the tumor stage but markedly increased in the regressive stage.

Discipline: Animal health

Introduction

Bovine leukosis has been classified into enzootic and sporadic forms²). The former is almost invariably seen in bovine leukaemia virus (BLV)-infected adult cattle, and is referred to as the adult form⁵). The latter consists of 3 clinicopathological types; the calf, thymic and skin forms¹⁴). These neoplasms are malignancies of the lymphoid system²), which is closely related to immunological functions. It is likely that generalized immunological disorders occur in cattle with the lymphoid malignancies. Abnormal electrophoretic patterns of serum proteins are recognized in some of the human lymphomas¹⁶). Although serum protein concentrations have been determined in some cattle with lymphosarcoma^{1,9,10,15}), few studies have dealt with the relations between serum protein concentration and pathological characteristics. The purpose of the present study was to analyze the relationships between the serum γ -globulin concentration and pathological characteristics in 4 types of bovine lymphosarcoma.

Materials and methods

1) Animals

Leukosis in cattle was classified into 4 groups: (1) the adult form including 5 cases, (2) the calf form consisting of 4 cases in which 3 cases older than the age of calves were included, due to the presence of characteristic calf form lesions^{21,24}), (3) the thymic form including 2 cases and (4) the skin form in a cow¹¹). A 2-year-old healthy heifer, which was negative for BLV antibodies, was used as a control animal.

2) Hematological, serological and serum protein analyses

Number of peripheral lymphocytes was calculated based on leukocyte counts and the percentage of differential leukocytes in blood smears stained with Giemsa solution. The agar gel immunodiffusion test was applied to serum samples for the demonstration of antibodies to BLV(13).

The total serum protein concentrations were determined by the biuret method according to the method of Coles(3). The serum protein patterns were examined by electrophoresis on a cellulose-acetate membrane(4,8) and the electrophoretic graphs were analyzed using a spectrophotometer DU-8 (Beckman Co., U.S.A.). Agar gel immunoelectrophoresis was carried out on microscope slides using anti-bovine γ -globulin rabbit serum (Miles Lab., U.S.A.) and anti-bovine IgM rabbit serum (μ -chain specific, Miles Lab., U.S.A.)(8).

3) Cell surface markers

Mononuclear cells were isolated from the peripheral blood and neoplastic tissues of cattle with lymphosarcoma, and also from the peripheral blood, lymph nodes and thymus of a healthy heifer by the sodium metrizoate/Ficoll procedure (Lymphoprep, Nyegaard Co., Norway). The erythrocyte rosette-forming (RF) test for the demonstration of T-cells was performed by Paul's method(17). Aliquots of 1×10^6 mononuclear cells suspended in 100 μ l of RPMI-1640 medium were mixed with 200 μ l of 1% sheep erythrocytes (SRBC). The suspension was incubated at 37°C for 10 min and later at 4°C overnight. A drop of 0.5% trypan blue was added and 200 live cells were counted. When each cell adhered to more than 3 SRBC, the reaction was considered to be positive. For the surface membrane immunoglobulin (sIg), a marker of B-cells, 1×10^6 cells were resuspended in 50 μ l of 1:20 dilution of fluoresceinated anti-bovine IgM rabbit serum (μ -chain specific, EY Lab., U.S.A.) and incubated at 4°C for 30 min. Then 200 live cells were counted under a Zeiss Axiophoto microscope equipped with an epifluorescent apparatus. The standard deviation (SD) of mean was calculated from the results of RF and sIg tests.

4) Pathological examination

Tissue samples were fixed in 10% neutral buffered formalin and processed by a routine paraffin wax sectioning method. Thin sections were stained with haematoxylin and eosin (HE) or by silver impregnation.

Small blocks of neoplastic tissues were fixed in 2.5% glutaraldehyde, postfixed in 1% osmium tetroxide, and embedded in Epon. Ultrathin sections were stained with uranyl acetate and lead citrate, and then examined under an electron microscope (JEOL 100CX).

The immunoperoxidase method was applied to paraffin sections. After deparaffinization, sections were incubated with primary antibodies; rabbit anti-bovine IgM (μ -chain specific, Miles Lab., U.S.A.), rabbit anti-bovine IgG (Fc specific, EY Lab., U.S.A.) or rabbit anti-bovine IgA (α -chain specific, Miles Lab., U.S.A.). A biotin-streptavidin system (BioGenex Lab., U.S.A.) was used in the subsequent processes.

(Received for publication, November 4, 1997)

Results

1) Hematological, serological and serum protein analyses

The lymphocyte counts, antibodies to BLV, serum protein concentrations and the results of the immunodiffusion test are presented in [Table 1](#). A marked increase of the number of peripheral lymphocytes was noted in 2 cases of the adult form (Nos. 1 and 3) and 2 cases of the calf form (Nos. 6 and 9). Antibodies to BLV were detected in all the cases of the adult form.

[Table.1. Results of hematological and serum protein analyses\(41 KB\)](#)

The albumin concentration was low in some animals and there were slight variations in α - and β -globulin concentrations among the cases.

The γ -globulin concentration markedly decreased to 1.1-1.5 g/dl in 3 cases of the adult form (Nos. 1 to 3), and moderately to 1.7 g/dl in 2 cases of the same form (Nos. 4 and 5). In 3 cases of the calf form (Nos. 6 to 8), the γ -globulin concentration was 0.3-0.5 g/dl and much lower than that of the adult form. The other case (No. 9) showed a moderate hypogammaglobulinemia and the concentration of γ -globulin was 1.7 g/dl. In one case of the thymic form (No. 10), the γ -globulin concentration slightly increased to 2.9 g/dl. In the other case (No. 11), a normal value of 2.4 g/dl was recorded. In a cow with the skin form (No. 12), the concentration of γ -globulin decreased to 0.8 g/dl in the tumor stage, but increased to 3.4 g/dl in the regressive stage.

[Fig. 1. Electrophoresis of sera from a healthy heifer \(A\) and leukotic cattle \(No. 8\) with calf form \(B\)\(19 KB\)](#)

Immunoelectrophoresis revealed the absence of IgM lines in 3 out of 4 cases of the calf form (Nos. 6, 7 and 9) ([Figs. 1A and 1B](#)). The remaining one (No. 8) had a weak IgM line.

2) Cell surface markers

The mean value of sIg-positive cells in the adult form markedly increased to 82.8% (SD \pm 6.4) and that of RF-positive cells significantly decreased to 5.7% (SD \pm 2.5) in peripheral lymphocytes ([Table 2](#)). In the lymph nodes with extensive neoplastic involvement of one case, the percentage of sIg-positive cells increased to 66.4% and that of RF-positive cells decreased to 6.4% (No. 2), though the moderately involved lymph nodes in 2 cases contained sIg-positive cells and RF-positive cells with percentages of 51.0 and 28.4% in one case (No. 4), and 54.4 and 27.9% in the other case (No. 5), respectively. Most of the neoplastic cells in the adult form were considered to harbor B-cell markers. In the calf form, the levels of sIg-positive cells and RF-positive cells were, respectively, only 7.6% (SD \pm 2.2) and 7.1% (SD \pm 5.9) in the peripheral lymphocytes, and 6.2% (SD \pm 2.4) and 4.7% (SD \pm 4.1) in the neoplastic lymph nodes. The neoplastic cells were considered to have neither a B- nor T-cell marker. In the thymic form, the percentages of sIg-positive cells and RF-positive cells in peripheral lymphocytes were different in each case. Although one case (No. 10) showed 31.9% of RF-positive cells, a similar value to that of a normal control, the percentage of sIg-positive cells decreased to 3.4%. In the other case (No. 11), the level of RF-positive cells increased moderately to 52.3%, while that of sIg-positive ones decreased slightly to 27.6%. In the neoplastic thymus, the mean values of sIg- positive cells and RF-positive cells were 3.5% (SD \pm 1.5) and 3.8% (SD \pm 1.6), respectively. The neoplastic cells in the thymic form were considered to have neither a B- nor T-cell maker. Surface markers of neoplastic cells in the skin form were not examined.

[Table.2. Results of surface marker and intracytoplasmic immunoglobulin examinations\(50 KB\)](#)

In a healthy heifer, sIg-positive cells and RF-positive cells amounted to 36.9 and 35.8% in the peripheral blood, 52.5 and 38.6% in the lymph nodes, and 4.6 and 62.2% in the thymus, respectively.

3) Pathological findings

Adult form: In 3 cases (Nos. 1 to 3), there was an almost generalized neoplastic involvement of the lymph nodes, which consisted of extensive proliferation of neoplastic cells. The original structure of many lymph nodes was almost completely absent except for one case (No. 3). In the moderately involved lymph nodes, the neoplastic cells tended to proliferate in the sinuses. The other 2 cases (Nos. 4 and 5) showed a localized neoplastic involvement of the lymph nodes. The various extra-nodal tissues were also invaded ([Table 3](#)). Ultrastructurally, neoplastic cells varied in size from small cells with scanty cytoplasm to large cells with abundant cytoplasm. The nuclei showed irregular contours with indentations, and contained coarse chromatin and large nucleoli ([Fig. 2](#)). The rough-surfaced endoplasmic reticulum (RER) was poorly developed. There were a few mitochondria and small areas of Golgi apparatus in the cytoplasm, and free ribosomes were abundant, especially in the large cells.

[Tabel.3. Results of pathological examination of neoplastic lesions\(43 KB\)](#)

[Fig. 2. Electron micrograph of neoplastic cell in adult form \(No. 2\)\(35 KB\)](#)

Calf form: In all the cases, systemic neoplastic involvement was observed in the lymph nodes, and also characteristic involvement was observed in the Glisson capsule of the liver and in the bone marrow²⁴). The neoplastic tissues were also present in other sites (Table 3). In 3 cases (Nos. 6 to 8), the lymphatic parenchyma was crowded with neoplastic cells, and normal lymphatic structures were absent. The other case (No. 9) showed very small areas of normal lymphatic tissue surviving among severe neoplastic proliferation. Ultrastructurally, the size of the neoplastic cells differed in each case ranging from small to medium. Small cells had scanty cytoplasm with poorly developed RER and a few mitochondria, and their nuclei were oval and chromatin was coarse. Medium-sized cells displayed oval nuclei and abundant cytoplasm, in which organelles similar to those of small cells were observed ([Fig. 3](#)).

[Fig. 3. Electron micrograph of neoplastic cell in calf form \(No. 9\)\(35 KB\)](#)

Thymic form: One case (No. 10) showed a large mass of neoplastic thymus and systemic neoplastic lesions, which resembled those of the calf form. In the other case (No. 11), neoplastic lesions were localized in the thymus and a few lymph nodes surrounding it. Ultrastructurally, the neoplastic cells were small with round or slightly indented nuclei with condensed chromatin and inconspicuous nucleoli. The organelles were poorly developed like those in the calf form ([Fig. 4](#)).

[Fig. 4. Electron micrograph of neoplastic cell in thymic form \(No. 10\)\(35 KB\)](#)

Skin form: In addition to the neoplastic lymphoid-cell proliferation in the skin, there were palpable swellings of the superficial and pelvic lymph nodes in the tumor stage. In the regressive stage, the neoplastic cells disappeared from the dermis, and most of the neoplastic cells in the lymph nodes and kidneys degenerated with infiltration of normal lymphocytes and macrophages¹¹). Numerous plasma cells infiltrated many lymph nodes without neoplastic involvement. Ultrastructurally, neoplastic cells were polygonal in shape, and the organelles consisted of poorly developed RER, a few mitochondria and numerous ribosomes. The nuclei were round to oval in shape, and contained a small amount of chromatin and distinct nucleoli. Nuclear convolution was not observed ([Fig. 5](#)).

[Fig. 5. Electron micrograph of neoplastic cell in skin form \(No. 12\)\(35 KB\)](#)

Intracytoplasmic IgM, IgG and IgA were not detected in the neoplastic cells of the 4 types of bovine lymphosarcomas ([Table 3](#)). In contrast, the lymph nodes of a healthy heifer contained plasma cells and immunoblasts, which gave a positive reaction for IgM, IgG or IgA.

Discussion

Human lymphomas are frequently accompanied by abnormalities of serum γ -globulin, such as hypergammaglobulinemia with M-component and hypogammaglobulinemia^{7,16,18,19,23}). Electrophoretic patterns for serum γ -globulin have revealed normal, increased or decreased concentrations in bovine lymphosarcomas¹). In the present study, animals in the adult form had antibodies to BLV and typical lymphosarcoma as described previously²⁴). The values of serum protein suggest that an increase of involved lymph nodes causes a decrease of the level of serum γ -globulin. Since the neoplastic cells gave a positive reaction for sIg, they were presumably derived from the B-cell series²⁰). However, these neoplastic cells showed a poorly developed RER and lacked intracytoplasmic immunoglobulins. It is considered that the neoplastic cells could not differentiate into immunoglobulin-producing cells, and extensive proliferation of these cells in the lymph nodes may cause a decrease of the concentration of

serum γ -globulin.

The characteristic lesions of the calf form consisted of systemic involvement of the lymph nodes and neoplastic proliferation in the bone marrow and in the Glisson capsule of the liver^{21,24}). Although the calf form is most common in calves younger than 6 months of age, similar lesions may be observed in adolescent or adult cattle without antibodies to BLV²⁴), as in the 3 cases in the present study. Neither a B- nor T-cell marker was present in our cases, and the inability to produce immunoglobulins was demonstrated by the absence of intracytoplasmic immunoglobulins and poorly developed RER. Severe hypogammaglobulinemia in 3 cases (Nos. 6 to 8) was probably due to the absence of normal tissue in the lymph nodes, which was replaced by neoplastic proliferation. The moderate decrease of the concentration of serum γ -globulin in one case (No. 9) was presumably associated with the small area of residual lymphatic tissues in the lymph nodes.

The thymic form showed typical involvement in the thymus and the neoplastic cells had neither a B- nor T-cell marker. These cells may originate from thymocytes lacking a T-cell marker due to malignant transformation. In one case, the γ -globulin concentration slightly increased despite the generalized involvement of the lymph nodes, which may be associated with the activation of remaining B-cells by the stimulation of neoplastic cells. It is suggested that the normal value in the other case was due to the fact that in the various lymph nodes without neoplastic lesions normal immunological functions were maintained.

In the skin form, the neoplastic lesions were formed in the lymph nodes and various organs as well as in the skin. These lesions may regress within a few months after the initial recognition of the tumor¹¹). In a study of cutaneous lymphosarcoma, the neoplastic cells gave a negative reaction for the RF test¹¹), while another study showed that the neoplastic cells had a marker for helper/inducer T-cells²⁵). In our study, hypogammaglobulinemia in the tumor stage may be associated with the proliferation of neoplastic cells in the lymph nodes, and hypergammaglobulinemia in the regressive stage may be due to the presence of numerous plasma cells in the lymph nodes.

A lower level of IgM fraction in the sera was observed in BLV-positive cattle with persistent lymphocytosis⁶). In cattle with lymphosarcoma, the absence of IgM was pointed out²²), although the level of IgM did not decrease significantly in other studies¹⁵). Ichijo described a decrease of IgM level in the adult form and IgG in the calf form⁹). No IgM line was detected in our 3 cases with the calf form. It was reported that the immunoblasts, which correspond to one stage of B-cell differentiation, produced initially IgM during differentiation to plasma cells¹²). When the lymphoid tissues are damaged rapidly by malignant growth, the IgM-producing cells may be affected first. In the remaining case of the calf form, with a weak IgM line, it is possible that IgM-producing cells may remain elsewhere including the extra-nodal lymphoid tissues or that IgM which had already been produced may keep a detectable concentration in the serum.

The authors thank Professor Emeritus Dr. Y. Kono, Tokyo University of Agriculture and Technology for the assay of antibodies against BLV.

JIRCAS Visiting Research Fellowship Program at Tsukuba 2002

Japan International Research Center for Agricultural Sciences (JIRCAS) has implemented the "Visiting Research Fellowship Program at Tsukuba" since 1995.

The fellowship aims at the promotion of collaborative research to address various problems confronting the countries in developing regions on a global scale, including the critical situation of food production, the progression of desertification and the gradual disappearance of genetic resources.

JIRCAS which is located in Tsukuba Science City and is equipped with facilities for advanced research, is inviting young promising researchers from institutes in developing regions who will play a major role in the activities of these institutes in future to carry out collaborative research for the sustainable development or rapid progress of agriculture, forestry and fisheries compatible with the preservation of the natural environment.

Under the Fellowship Program, a total of fourteen (14) researchers will be invited, of which ten (10) will undertake the JIRCAS type programs for a period of one (1) year and the other four (4) researchers will be engaged in the NIAS type programs for a period of five (5) months. The former ten (10) will carry out collaborative research at JIRCAS HQ, while the latter four (4) will conduct research at the National Institute of Agrobiological Sciences (NIAS) at Tsukuba.

Fellowship Qualifications

(1) Applicants should be outstanding researchers who will play a major role in the activities of the respective institutes in future. After the completion of the Fellowship, they should continue to carry out research at the same institute.

- (2) Hold a Master's degree in a field relating to socio-economics and natural sciences and technology or equivalent qualifications in related fields. Be preferably less than 35 years of age.
- (3) Carry out research related to one of the themes listed under "Research Themes".
- (4) Should enjoy a good health.
- (5) Have an adequate command of English or Japanese language.

Tenure

In principle, starting from October 2002, the JIRCAS type program will cover a period of one (1) year and the NIAS type program will cover a period of five (5) months.

Fellowship Conditions

- (1) A round-trip airline ticket (economy class) will be available (except for dependents).
- (2) Living allowance: 260,000yen per month.
(including housing allowance)
- (3) Housing: International Guesthouse
2-1-2, Kan-nondai, Tsukuba
- (4) Fixed-rate insurance package (for injury, sickness and damage) will be offered under the JIRCAS Fellowship Program. (except for dependents)

Application Procedure

Applicants are required to submit the following documents to the President of JIRCAS.

- (1) Application form

[pdf](#)

(2) Copies of the most important articles (Up to 3)

Deadline for Application

March 15, 2002(keep strictly)

Notification

JIRCAS will examine the application documents and notify the results of the selection to the applicants about three months after the deadline date for application.

Further information about the Visiting Research Fellowship Program can be obtained from the International Relation Section, Japan International Research Center for Agricultural Sciences, 1-1, Ohwashi, Tsukuba, Ibaraki, 305-8686 Japan.

HOME

JIRCAS Visiting Research Fellowship Program at Okinawa 2002

Japan International Research Center for Agricultural Sciences (JIRCAS) has implemented the "Visiting Research Fellowship Program at Okinawa" since 1992.

The Fellowship emphasizes presently pioneer research on the conservation of the global environment and optimum utilization of bio-resources in the tropics and subtropics.

The successful candidates, the number of which will be about 10, will undertake relevant research pertaining to one of the five themes listed below. Research will be carried out at the Okinawa Subtropical Station of JIRCAS in Ishigaki City, Okinawa Prefecture which is located in the subtropical zone of Japan and is equipped with advanced facilities for research.

Research Themes

- (1) Efficient use of water and fertilizers
- (2) Evaluation and utilization of heat- and salt-tolerant crops
- (3) Evaluation and characterization of tropical and subtropical fruits
- (4) Evaluation and utilization of useful traits in sugarcane and sweet potato
- (5) Integrated pest management of tropical and subtropical crops

Fellowship Qualifications

- (1) Applicants should be nationals of developing countries, be currently employed in a research organization (institute or university, etc.) and be engaged in research relating to tropical or subtropical agriculture and forestry, in principle.
- (2) Hold a Ph. D. degree in a field relating to natural sciences and technology or equivalent qualifications in related fields.
- (3) Be a researcher who will take up research subjects related to one of the four themes listed in the forementioned "Research Themes".
- (4) Be preferably less than 45 years of age.
- (5) Should enjoy a good health.
- (6) Have an adequate command of English or Japanese language.
- (7) Be committed to pursuing research in fields related to tropical agriculture and forestry after the termination of the Fellowship.

Tenure

In principle, one year, starting from October 2002.

Fellowship Conditions

- (1) A round-trip airline ticket (economy class) will be available (except for dependents).
- (2) Living allowance: 260,000yen per month.
(excluding housing allowance)
- (3) Housing (cost borne by JIRCAS):
Maison ICRS, 874 Maezato,

Ishigaki, Okinawa, 907-0002 JAPAN

(4) Fixed-rate insurance package (for injury, sickness and damage) will be offered under the JIRCAS Fellowship Program. (except for dependents)

Application Procedure

Applicants are required to submit the following documents to the President of JIRCAS.

(1) Application form

[pdf](#)

(2) Copies of the most important articles (Up to 3)

Deadline for Application

March 15, 2002 (keep strictly)

Notification

JIRCAS will examine the application documents and notify the results of the selection to the applicants about three months after the deadline date for application.

Further information about the Visiting Research Fellowship Program can be obtained from the International Relation Section, Japan International Research Center for Agricultural Sciences, 1-1, Ohwashi, Tsukuba, Ibaraki, 305-8686 Japan.

Photographs

Group A

Participants:

Zhu, Z., Inst. of Soils Science, CAS, China (Chair)

Hosen, Y., JIRCAS, Japan (Rapporteur)

Chen, J., Chiba Univ., Japan

Eguchi, S., NIAES, Japan

Hasagawa, H., Tohoku Natl. Agric. Exp. Stn., Japan

Ishikawa, T., JIRCAS, Japan

Katou, H., NIAES, Japan

McTaggart, I., Scottish Agric. College, UK

Minami, K., NIAES, Japan

Mishima, S., NIAES, Japan

Niimi, H., Kyushu Natl. Agric. Exp. Stn., Japan

Wan, Q., Geographical Survey Institute, China

1. There must be a compromise between environment, economy and production.
2. Customers must be prepared to pay more for food produced in environmentally suitable method.
3. We need researchers who observe trees and who observe forest; and they should exchange their opinions.

Group B

Participants:

Mosier, A., USDA-ARS, USA (Chair)

Yan, X., JIRCAS, Japan (Rapporteur)

Abe, K., NARC, Japan

Cai, Z., Inst. of Soils Science, CAS, China

Hojito, M., National Grassland Res. Inst.

Park, Y.-H., NIAST, RDA, Korea

Watanabe, T., JIRCAS, Japan

Xu, M., Inst. of Soils and Fertilizers, CAAS, China

Zhao, L., Inst. of Soils and Fertilizers, CAAS, China

Zhu, J., Inst. of Soils Science, CAS, China

A. Gaps in knowledge

1. The fate of fertilizer N is not clearly known.
2. How much of the environmental problems were resulted from fertilization?

B. Methodology issue

1. There is imbalance between the research advances of different countries. A good method should be developed and distributed to estimate N losses.
2. Many ways of nitrogen losses cause environmental problems, but there exists, sometimes, a trade-off relationship between different losses. There is disagreement in the priority to mitigate losses. Therefore, a comprehensive index is needed to indicate the whole all environmental risks of N fertilization.

C. Mitigation options

1. To replace chemical N supply with natural N supply, to replace dangerous fertilizer with less dangerous fertilizer.
2. To have various land-use systems in a watershed therefore to improve N use efficiency by crop and to reduce loss. The function of paddy field as a biological purifier of excessive N is to be verified.

D. What is changing?

Fortunately, in developed nations such as Japan, high crop yield is no more the top priority. Farmers are considering crop quality and environmental regulations. In developing countries such as China, high crop yield is no more the sole purpose of fertilization. They are considering the best combination of •gthree highs•h, i.e., high crop yield, high crop quality and high fertilizer use efficiency.

Participants:

Ito, O., JIRCAS, Japan (Chair)
Han, Y., Inst. of Soils Science, CAS, China (Rapporteur)
Inagaki, M., JIRCAS, Japan
Kim, S.-C., NIAST, Korea
Minamikawa, K., Tsukuba Univ., Japan
Miyaji, N., Shizuoka Pref. Agric. Exp. Stn., Japan
Roelcke, M., Braunschweig Technical University, Germany
Suzuki, K., NIAES, Japan
Tachibana, M., Chisso Corp., Japan
Woli, K.P., Hokkaido Univ., Japan
Zhao, P., NARC, Japan
Zhang, R., Inst. of Soils and Fertilizers, CAAS, China

A. What is the target of research on nitrogen fertilization and the environment?

Company point of view:

- Consumers (farmers) and environment

Researcher's point of view:

- Farmers, ordinary citizens, all people involved in the system.

B. How large are the environmental impacts?

In China: Becoming more and more serious.

Taihu Region: N fertilizers are not the main (or only) source for groundwater pollution, compared to livestock, human settlements, etc.

But N-China: N-deficiency, water shortage. N uptake by plants is small. High groundwater poll.

In Japan: North (Hokkaido):

Only 8% from human wastes, 92% from animal raising. Impact is increasing. But in the S (Kyushu): Animal wastes, excessive fertilizer appl. Rates, NO₃-N has reached the groundwater.

N₂O and NO pollution from farmland is not being controlled, while urban sources (traffic) is being

controlled.

C. How is the impact changing?

N-China: First goal has to be food production, but the environmental impact will be large. Then gradually improve the environment, according to the development of society's basic needs.

Well water table is falling, nitrogen pollution even in the deep wells.

Japan: Impact will continue to increase, because the scientists are a minority compared to the majority of the people; major scientific breakthrough needed.

In Shizuoka tea gardens: N application rates have been reduced from 1000 to 600 kg N/ha during the past 4 years. Nitrate standard has been lowered 2 years ago, consumers are environment conscious, farmers older, apply less fertilizer. GW pollution dependent on the depth of GW table.

D. How can we mitigate the impact?

- Make best use of compost production.
- Combine with controlled release fertilizers.
- In South China: Reduce fertilizer application rates; fertilizer recommendations by the local officials often only aim at maximum yields. So education of extension services, farmers, etc. has to be improved. Young farmers lack experience.
- Provide suitable models as advisory tools.
- Rules and regulations by the government needed to reduce the environmental impact in sensitive areas (drinking water catchments, etc.).
- Price of controlled-release fertilizers are too high for Chinese farmers at present!
- Reduce the burning of crop residues in the field.
- Organic manure should not be neglected. Prepare new kinds of processed organic manure, user-friendly compost preparation; volume reduced.
- If manure has to be dumped, then at least it should be processed before.
- How can the farmers be motivated to take mitigation options?
- User-friendly techniques for the farmers.
- Profitability has to be considered, for example prices for organic farming products.
- Farmers will react to policy changes, such as the lowering of purchasing prices for poor-quality grain; they will shift to higher quality products.
- Several model-farms can be established through the strong leadership of local governments in Japan.
- Then the positive results can be transferred to others.
- Situation in S-Korea: Introduction and adoption of slow-release fertilizers required.

E. What is the gaps in our knowledge on interpretation of results from experiment and real situation?

- We need to fill the gaps in knowledge on the processes of the N-cycle, needed to make better simulation models, to serve as advisory tools for the farmers.
- A network between prefectures in Japan, carrying out research in different areas, the results must be inter-linked.

Group D

Participants:

Ellis, E.C., Univ. of Maryland, BC, USA (Chair)

Maeda, M., NARC, Japan (Rapporteur)

Hatano, R., Hokkaido Univ., Japan

Kanda, K. JIRCAS, Japan

Liyanage, B., Osaka Univ., Japan

Mori, A. Natl. Grassland Res. Inst., Japan

Nakano, A., NIVOT, Japan

Shoji, S., Tohoku Univ., Japan

Zhang, S., Inst. of Soils and Fertilizers, CAAS, China

Impact mitigation:

1. Technical measures:

- i) Efficient recovery of fertilizer N through cropping system / land use / new types of fertilizer;
- ii) Coordination of crop, soil, and fertilizer;
- iii) Barriers to N losses from agricultural fields / watersheds using land use;
- iv) Efficient use of natural N (Nitrogen fixation);
- v) Recycling of organic wastes.

2. Political measures:

Establishment of environmentally sound agriculture:

- i) Recycling of organic matter;
- ii) Development of controlled fertilizers;
- iii) Financial / technical support by government.

3. Educational measures:

- i) Farmer extension;
- ii) Guidance for students;
- iii) Information on web sites;

- iv) Consciousness of consumers;
- v) Community supported agriculture.

4. Economical measures:

- i) Control of importing / exporting agricultural products / livestock food;
- ii) Display for products enabling consumer choice.

Gaps of knowledge:

1. Are nitrates really toxic?
2. Is it possible that denitrification for reducing nitrates causes other environmental problems?
3. Is production of crops with high yield / quality compatible with conservation of the environment (Zero pollution)?

Group C

Publication

The papers presented at the Workshop will be published in a special issue of *Nutrient Cycling in Agro-Ecosystems*. Workshop contributors are strongly encouraged to submit full papers to the mailing address indicated in this web page by **March 31, 2001**. Please refer the instructions for manuscript preparation at the web-site of [Kluwer Publishers](#).

Your manuscript will be assigned to a member of editorial committee, who will obtain at least two anonymous reviews [[schedule for publication](#)]. The decision on acceptability for publication will be made by the editorial committee and journal editors.

Editorial Committee:

Dr. Zucong Cai, Institute of Soil Science, Academia Sinica

Dr. Erle C. Ellis, University of Maryland, Baltimore County

Dr. Iain McTaggart, Scottish Agricultural College

International Workshop
on Nitrogen Fertilization
and the Environment
in East Asian Countries

Background

The global cycle of nitrogen has been altered by human activity to a greater extent than that of any other element. The production of nitrogen fertilizer, cultivation of legume, and incidental nitrogen fixation in internal combustion engines together transfer more nitrogen from the atmosphere into biological available forms than is fixed by all natural processes combined. Additionally, biomass burning and land-use change mobilize large quantities of nitrogen from stored into dynamics forms. In the past decade, we do have seen a large increase in global and regional environmental problems attributable to increased nitrogen cycling through the atmosphere and waters of the world.

East Asian countries, including Japan, China, and Korea, are characterized by intensive agriculture with high input of fertilizer, pesticides, and labors due to recent economical development and high population density. The intensive agriculture with introducing new technologies has promised high grain yield in this region. On the other hand, its adverse effects on the environment have recently become apparent and the sustainability of land resources and environment has become a cause of concern. Many of these problems have resulted from use of agricultural land in a manner that overloads nutrients, in particular nitrogen. Indeed, consumption of nitrogen fertilizer in this region has considerably increased during last three decades and accounted for more than 30% of the world in 1995.

We must now address serious issues in this area: How large is the environmental impact of intensive cropping systems? How is the impact changing? What will happen in future? How can we mitigate the impact?

Themes

This workshop will address the following themes:

- (1) Overview of the issues related to nitrogen fertilization and the environment in east Asian countries and the world,
- (2) Effects of nitrogen fertilization on aquatic systems,
- (3) Effects of nitrogen fertilization on the atmosphere,
- (4) Evaluation of nitrogen cycling in agro-ecosystem at field and regional scales, and
- (5) Technologies that minimize the environmental impact of nitrogen fertilization

And will aim;

- (1) to exchange the understanding of the issues related to nitrogen fertilization and the environment in east Asian countries,
- (2) to identify gaps in our knowledge, and
- (3) to discuss future research needs and possible forms of cooperation.

International Workshop
on Nitrogen Fertilization
and the Environment
in East Asian Countries

General Information

Date & Venue	February 5 and 6, 2001: International Symposium At Tsukuba International Congress Center (EPOCHAL TSUKUBA) February 7, 8 and 9, 2001: Japan/China Project Meeting and Field Excursion In Ibaraki, Yamanashi, and Shizuoka Prefectures
Registration (International Symposium)	The International Symposium (Feb. 5&6) is an open meeting. We welcome anybody to participate. However, we suggest to make a registration with accessing the registration form at our home page at the address below and send the completed form to us by email. *Registration form You may also use the following forms that to be send to our secretary by FAX (+81-298-38-6651). <i>*Word for windows (*.doc) style, *PDF style</i> There is no cost but pre-registration is recommended.
Registration (Excursion)	Number of persons for the excursion tour is limited, but there is still some room. Please contact our secretary if you would like to participate the excursion tour. It costs 32,000 Japanese Yen.
Reception	The Symposium Reception will be held from 19:00 to 21:00 p.m. Monday, February 5, in the Myojo-no-Ma Room on the second floor of the Tsukuba Dai-ichi Hotel.
Official Language	The official language of the Workshop will be English. However, voluntary service of simultaneous translation for any East Asian languages is welcome, in particular during the discussion sessions.
Publication	The papers presented at the Workshop will be published in a special issue of Nutrient Cycling in Agro-Ecosystems. Workshop contributors are strongly encouraged to submit full papers to the mailing address indicated below by February 28, 2001 . Please refer the instructions for manuscript preparation at the web-site of Kluwer Publishers .
Workshop Organization Committee	<i>Coordinators:</i> Dr. Kazuyuki Yagi, Japan International Research Center for Agricultural Sciences (JIRCAS) Dr. Zucong Cai, Institute of Soil Science, Academia Sinica <i>Members:</i> Dr. Yasukazu Hosen, Japan International Research Center for Agricultural Sciences (JIRCAS) Dr. Hidetaka Katou, National Institute of Agro-Environmental Sciences (NIAES) Dr. Morihiro Maeda, National Agricultural Research Center (NARC) Dr. Naomichi Miyaji, Shizuoka Agricultural Experiment Station Dr. Hideshige Toda, Shinshu University Dr. Minggang Xu, Institute of Soils and Fertilizers, Chinese Academy of Agricultural Sciences Dr. Jianguo Zhu, Institute of Soil Science, Academia Sinica (in alphabetical order)

Sponsors	Japan International Research Center for Agricultural Sciences (JIRCAS), Ministry of Agriculture, Forestry and Fisheries Ministry of Education, Culture, Sports, Science and Technology

BACK

**International Workshop
on Nitrogen Fertilization
and the Environment
in East Asian Countries**

Program

Date: 5 and 6 February 2001

Venue: Tsukuba International Congress Center:
Epochal Tsukuba

Monday, February 5, at Epochal Tsukuba, Room 101

0800 *Registration*

Opening Session

Chair: Yagi, K. & Cai, Z.C.

0900 Opening Address Inoue, T. (JIRCAS, Director General)

Keynote Lectures

Chair: Yagi, K. & Cai, Z.C.

0910 Essential Nitrogen: Environmental Challenges Associated with Increased Global Nitrogen Fixation
Mosier, A. (USDA-ARS)

0955 Nitrogen Fertilization: Contribution to the Development of Agriculture and Impact on Environment in
China

Zhu, Z.L. (Institute of Soil Science)

1040 Nitrogen Fertilization Nitrate Pollution in Groundwater in Japan
Kumazawa, K. (The Univ. of Tokyo)

1125 Technologies Using Controlled Release Fertilizers to Improve the Environmental Impacts of Nitrogen
Fertilization

Shoji, S. (Tohoku Univ.)

1210 *Lunch*

Nitrogen Cycling in Agro-Ecosystems Chair: Toda, H.

1330 Nitrogen Fertilizing Management for Rice Cultivation in Korea
Park, Y.-H. and Kim, P.-J. (NIAST)

1350 Nitrogen Budgets in Farm-Systems in Large-Scale Karst Region of Qibainong, Southern China
Hatano, R. (Hokkaido Univ.) et al.

1410 Estimating the Long-Term Impacts of Nitrogen Fertilizers Across Village Landscapes

Ellis, E.C. (Univ. of Maryland)

1430 Recent Trend of Nitrogen Fertilizers Use in Japan and Mitigation Plan

Mishima, S. (NIAES)

Environmental Impact on Water Systems Chair: Roelcke, M.

1450 Evaluating Impact of Land Use and Nitrogen Budgets at Community Scale on Stream Water Quality in Hokkaido, Japan

Woli, K.P. (Hokkaido Univ.) et al.

1510 Effect of Different Chemical Fertilizer Combination on Yield and Nitrate Distribution in Chao Soil Profile

Zhang, S.X. (ISF) et al.

1530 *Tea Break*

1600 Nitrogen Leaching and Balance in Volcanic Ash Soil Affected by Different Fertilizers

Maeda, M. (NARC) et al.

1620 Reduction in Nitrogen Load from Tea Garden by Fallow Paddy Fields at Shizuoka Prefecture, Central Japan

Miyaji, N. (Shizuoka Pref. AES) et al.

1640 Denitrification in Shallow Groundwater in a Coastal Agricultural Area of Japan

Toda, H. (Shinshu Univ.) et al.

Nitrogen Dynamics in Upland Soils Chair: Xu, M.

1700 The Effect of Soil Moisture on Mineral Nitrogen, Soil Electrical Conductivity and pH

Zhang, R. (ISF) and Wienhold, B.J. (Univ. of Nebraska)

1720 Studies on Interaction between Nitrogen and NaCl in Winter Wheat Growth and Yield

Pang, H.C. (ISF) et al.

1740 Dynamics of Nitrogen in Upland Field Applied with a Large Amount of Slurry Barnyard Manure in Southern Kyushu

Niimi, H. (Kyushu AES)

1800 *Adjourn*

1900 *Workshop Reception*

 **Tuesday, February 6**, at Epochal Tsukuba, Room 101

Environmental Impact on the Atmosphere Chair: Watanabe, T.

0900 Ammonia Volatilization from Fertilizers Applied to Rice, Maize and Wheat in China

Cai, G.X. (ISS) et al.

0920 Effects of Deep Application of Nitrogen Fertilizer on NO and N₂O Emissions from an Andisol

Hosen, Y. (JIRCAS) et al.

0940 Mitigating Environmental Impacts Resulted from N Fertilization to a Japanese Andisol Field: Effects of Controlled Release Fertilizer and Deep Application of Urea

Yan, X.Y. (JIRCAS) et al.

1000 Influence of Soil Physical Conditions and Fertiliser Type on N₂O and NO Emissions from Nearly Saturated Japanese Soils

McTaggart, I. (Scottish Agric. College) et al.

1020 *Tea Break*

1040 Major Factors Controlling N₂O and NO Emissions from Fertilised Soils

Tsuruta, H. (NIAES)

Nitrogen Dynamics in Paddy Soils Chair: Park, Y.-H.

1100 Nitrogen Balance during Rice Cultivation in Sandy Soil affected by the Fertilizer Management

Roh, K.A. (NIASST)

1120 Effect of Nitrogen Application Scheme on Growth of Rice

Zhu, J.G. (ISS)

1140 Nitrogen Mineralization in Paddy Soils of the Chinese Taihu Region under Aerobic Conditions

Roelcke, M. (Brawnschweig Tech. Univ.) et al.

1200 *Lunch*

1300 Ammonium Transformation in Paddy Soils affected by the Presence of Nitrate

Cai, Z.C. (ISS)

1320 Transformation and Balance of Nitrogen in Paddy Soil under Different Chemical Fertilizers Combining with Manure Applied in Double-Rice Regions of Southern China

Xu, M.G. (ISF) et al.

Mitigation Technologies Chair: Zhu, J.G.

1340 Increasing Nitrogen Efficiency by Slow Release Fertilizers in Paddy Soils

Kim, S.-C. and Kim, P.-J.(NIASST)

1400 Effects of Low Sulfate Slow Releasing Fertilizer (LSR) on the Growth and Fruits Yield of Tomato Plant (*Lycopersicon esculentum* Mill. Saturn)

Nakano, A. (NIVOT) et al.

1420 Recoveries of MEISTER N by Crops in Japan

Tachibana, M. (Chisso Corp.) et al.

1440 *Tea Break*

Group and General Discussion Chair: Yagi, K. & Cai, Z.C.

1500 Objectives of the discussion

1515 Group discussion (at Epochal Tsukuba, Room 202)

4 break-out groups will discuss and work on draft plan

Chairs: Zhu, Z.L.

Mosier, A.

Ito, O.

Ellis, E.C.

Rapporteurs: Han, Y.

Maeda, M.

Hosen, Y.

Yan, X.Y.

1630 Group reports and general discussion

Closing Remarks

1720 The Nitrogen Cycle and the Environment

Minami K. (NIAES, Director General)

1800 *Adjourn*

**International Workshop
on Nitrogen Fertilization
and the Environment
in East Asian Countries**

Japan/China Project Meeting and Field Excursion

Date: 7, 8, and 9 February 2001

Wednesday, February 7

Field Tour I

Visiting JIRCAS experimental field
Having lunch at Asahi Beer Brewery at Moriya town, Ibaraki Prefecture
Then going to the foot of Mt. Fuji
Staying at Hotel Regina Kawaguchi-ko,
5239-1 Funatsu, Kawaguchi-ko-machi, Minami-tsuru-gun, Yamanashi prefecture
Phone: +81-555-20-9000, Fax: +81-555-72-2561

Thursday, February 8, at Hotel Regina Kawaguchi-ko

4th Planning Meeting of Japan/China Project

Activity 1: Cycles of Major Elements in Agro-Ecosystems in Huang-Huai-Hai Plain and their Controls (ISF-JIRCAS)
Activity 2: Evaluation of Nitrogen Losses in Agro-Ecosystems in Jing-Jin-Tang Region (ISF-JIRCAS)
Activity 3: Evaluation of the Environmental Impact of Non-Point Sources in Tai-hu Catchments (ISS-JIRCAS)
Activity 4: Nitrogen Cycling in Agro-Ecosystems in Tai-hu Region and Strategies for Environmental Sound Management (ISS-JIRCAS)
Activity 5: Development of Farming Systems in paddy fields aimed at Environmental Conservation (ISF-JIRCAS)

Friday, February 9

Field Tour II

Visiting Shizuoka Prefecture Tea Experiment Station
And an Experimental Field of Shizuoka Prefecture Agricultural Experiment Station
Having lunch at a Tea Park, Greenpia Makinohara, Sagara-machi, Shizuoka Prefecture
Enjoying Mt. Fuji, then returning to Tsukuba or Narita

Message from the Director General

JIRCAS celebrates its fifth anniversary

Director General
Dr. Nobuyoshi Maeno

Five years have now passed since the Tropical Agricultural Research Center (TARC) was reorganized into the present Japan International Research Center for Agricultural Sciences. This reorganization was not merely a name change but also considerably widened our research activities and the number of partner countries and regions with which we maintain cooperative research programs.

In these past five years JIRCAS has enjoyed numerous achievements in the field of agricultural science through a variety of successful programs. In addition to enlarging and strengthening comprehensive agricultural research, we have also implemented multi-national collaborative research programs and developed domestic research by focusing on problems relevant to our international activities. In addition, our visiting fellow invitation program at our Sub-tropical Research Station in Okinawa and at our main campus in Tsukuba supports these research efforts. New research strategies in conjunction with strong inter-institutional cooperation has also contributed to our outstanding research record. Furthermore, JIRCAS recently established two new overseas offices in Beijing, China and Londrina, Brazil as bases for regional research activities, complementing our existing office in Bangkok, Thailand. All of the above activities have been made possible through the generous allotment of funds from the budgets of various government ministries and agencies and BRAIN (Bio-oriented Technology Research Advancement Institution), a government-affiliated, semi-private research institution.

A [map](#) indicating the comprehensive research projects being conducted by JIRCAS throughout the world as of June 1999.

Through our strong cooperation with international research institutes, such as the Japan International Cooperation Agency (JICA) and those affiliated to the Consultative Group on International Agriculture (CGIAR), JIRCAS has received international prestige and attention for its activities. The success we have enjoyed is owed solely to the efforts of the people and organizations with which we have excellent collaborative relationships.

Though such problems as food supply instability and environmental degradation are major contributing factors to poverty throughout the world, their negative effects are magnified in developing regions. Therefore, international cooperation is urgently needed to solve these and other obstacles confronting developing countries. The aim of JIRCAS is to play a leading role in the achievement of this goal.

Under current Japanese Government administrative and financial reforms national institutions are being reorganized to streamline costs and increase efficiency. Although government-affiliated research institutes, like JIRCAS, will become independent administrative corporations, the resultant changes will not affect Japan's resolve to actively participate in and contribute to the international community. In fact, the reforms have reaffirmed the necessity of such actions. The importance of JIRCAS and similar research institutes was confirmed in a recent national survey concerning basic food and agricultural problems and subsequently delineated in the new law, "The Basic Law on Food, Agriculture and Rural Areas," written by the Ministry of Agriculture, Forestry and Fisheries (MAFF). In the law the Japanese Government ordered the continuation of agricultural assistance to developing countries; and JIRCAS will be one of the major organs providing the aid.

In any organizational form, JIRCAS will not lose focus on its mission to contribute to the international community through agricultural research. As JIRCAS grows over the next 10-15 years, we must continue to play an active role in solving the world's agricultural problems. To do so, we must not simply adhere to current methods of research and management, but develop new ones so that we may most efficiently and most advantageously utilize our existing resources. In the current discussion of reform programs it is said that it may become possible to more independently manage research resources. Therefore, in maximizing this advantage, I hope for even greater cooperative efforts between JIRCAS and our partner institutes.

JIRCAS front entrance

Note About Annual Report 1998

In keeping with our recent efforts to highlight JIRCAS activities in particular regions of the world, Annual Report 1998 will focus on China. In this year's issue, detailed descriptions of research sites at several Chinese universities and institutions can be found in the section entitled "International Research at JIRCAS." When viewed in full, however, JIRCAS activities range widely across the globe. It is our hope that the increasingly international scope of research at JIRCAS will be equally evident within Annual Report 1998.

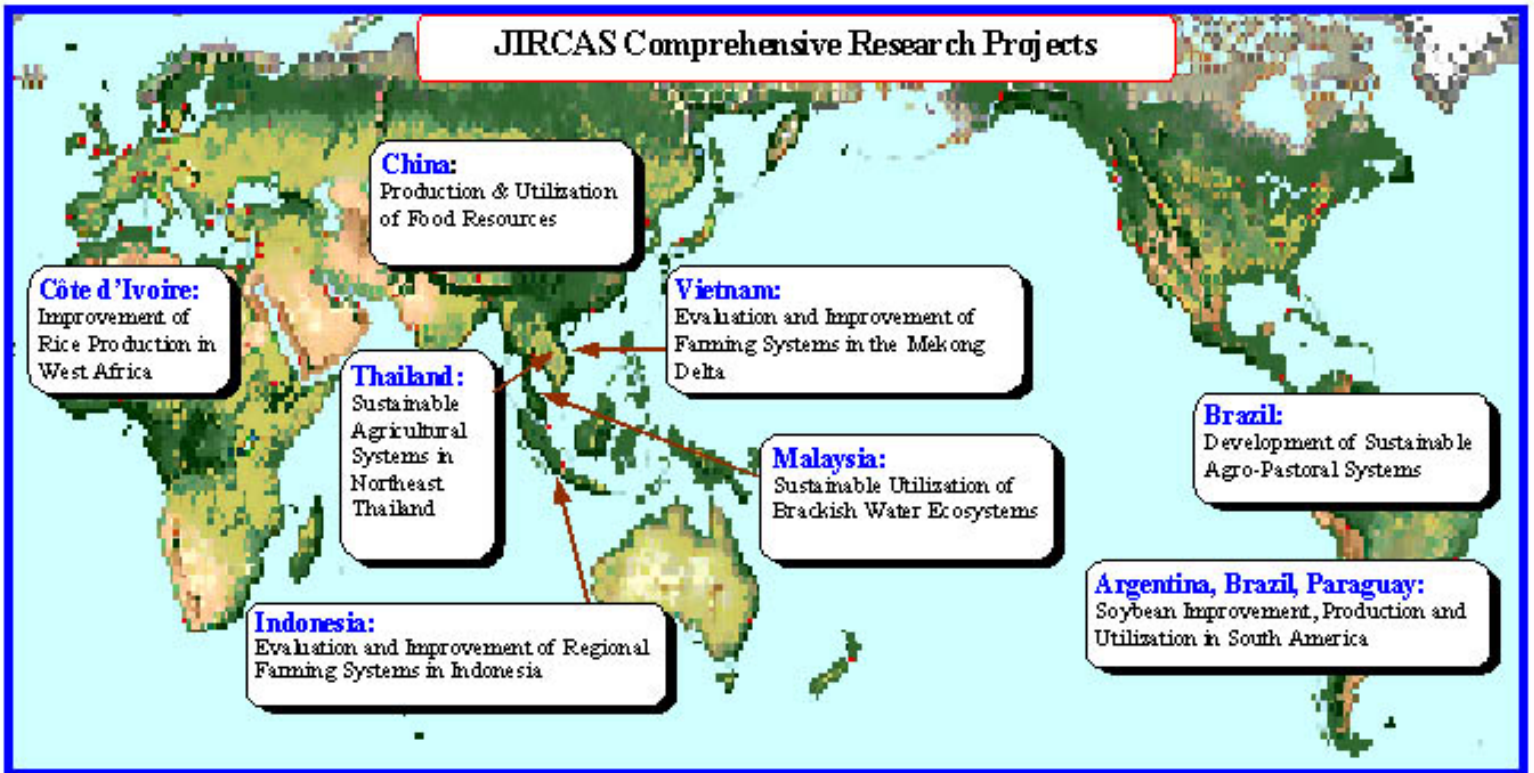

A handwritten signature in black ink, appearing to read 'Maeno'.

Director General Nobuyoshi Maeno

JIRCAS Comprehensive Research Projects

HIGHLIGHTS FROM 1998

@ IMPORTANT NEW DEVELOPMENTS

During Fiscal Year 1998, the Japan International Research Center for Agricultural Sciences (JIRCAS) witnessed a number of noteworthy happenings. One such example is Tanzanian President Benjamin William Mkapa's visit to JIRCAS in December 1998. Others include the production of freshwater fish surimis in China by JIRCAS researchers and the successful development of a heat-tolerant snap bean variety at the Okinawa Subtropical Station. We are pleased to highlight these activities and achievements in greater detail below.

- [Highlight #1](#): Development of Surimi Made from Freshwater Fish in China
- [Highlight #2](#): Inheritance and Physiological Mechanisms of Crop Heat Tolerance and Development of Heat-tolerant Crops
- [Highlight #3](#): Visit of Tanzanian President Benjamin William Mkapa to JIRCAS
- [Highlight #4](#): Research Meetings and Conferences during Fiscal Year 1998

@ NEW RESEARCH COLLABORATION

Since its establishment in 1993, JIRCAS has consistently sought to expand the depth of its collaborative efforts with research organizations and universities in a geographically diverse range of developing countries. In keeping with the JIRCAS mandate, collaborative efforts have become increasingly multidisciplinary in their focus and complex in their approach, often involving formal cooperative agreements between JIRCAS and foreign governmental entities. During Fiscal Year 1998, JIRCAS proudly initiated a new Memoranda of Understanding (MOU) solidifying project ties with the People's Republic of China (PRC).

Highlight #1: Development of Surimi Made from Freshwater Fish in China

Although the level of ocean fisheries resources is presumed to have reached capacity, aquaculture technology is thought to have great potential for expansion and is already serving as a significant source of animal protein. This includes freshwater fisheries resources. China's inland water regions are examples of locations where this technology is being utilized. China's freshwater fisheries catch has increased more than ten times in the last 50 years, reaching more than 10 million tons, equivalent to about 10% of the total world catch. The Food and Agriculture Organization (FAO) has forecasted that the freshwater fisheries catch will account for about 25% of the total world catch in 2010. However, freshwater fisheries resources lack the diversity of consumption when compared to ocean-based resources because the transportation and processing technologies of the freshwater fisheries resources remain behind those of ocean-based resources.

To address postharvest problems, JIRCAS has initiated research on the development of frozen surimi made from freshwater fish with the Shanghai Fisheries University as part of the comprehensive collaborative research project "Development of sustainable production and utilization of major food resources in China." Originally a Japanese term, surimi is an intermediate foodstuff with a high potential for free productivity of texturized products, such as imitation crab, and a long frozen shelf life. Because surimi is manufactured simply by washing, dehydrating, and adding cryoprotectants to minced fish meat, the initial aim of surimi development research was to identify fish species that have a high potential for surimi production.

We carried out studies on the gel-forming properties of surimi made from cultured freshwater fish in China, comparing them with walleye pollack surimis, a typical commercial marine fish surimi that accounts for more than 60% of world surimi production. Consequently, we were able to determine that the main freshwater fish species of China, silver carp, bighead carp, grass carp, and tilapia can be utilized as raw materials for surimi. To appreciate the practical value of these newly developed freshwater fish surimis, we held a tasting party of surimi-based products in a Chinese restaurant in Shanghai, and the foods were very popular with the Chinese people ([Photo](#)).

We presented the results of our collaborative research at the China-Japan joint workshop entitled "Development of utilization technology of freshwater fisheries resources," held at Shanghai Fisheries University, March 25-27, 1999. From our results, the Shanghai Fisheries University is now planning the production of freshwater fish surimis and related products with various Chinese administrative prefectures.

The practical use of fresh water fish surimi will greatly contribute to solving China's food problems. Confronting the problem of a lack of animal protein in their daily diet, developing countries will also be encouraged by this success in China.

Highlight #2: Inheritance and Physiological Mechanisms of Crop Heat Tolerance and Development of Heat-tolerant Crops

Vegetables constitute an important source of human nutrition. In the tropics, however, high temperatures constrain vegetable production leading to serious problems of nutritional imbalance in large parts of the region. In Okinawa, for example, winter and spring are the major seasons for vegetable production whereas only a few vegetables are produced during summer because of high temperatures. As a result, Okinawans are forced to rely on vegetables imported from the Japanese main islands. Development of heat-tolerant vegetables is urgently needed in order to solve this problem

The JIRCAS Okinawa Subtropical Station has been attempting to address the above problem through the development of new heat-tolerant vegetable varieties by evaluating and utilizing crop germplasm collected from tropical countries. We utilized snap bean germplasm from Southeast Asian countries collected and introduced by foreign research institutions including the International Center for Tropical Agriculture (CIAT) and the United States Department of Agriculture (USDA). By screening the germplasm for heat-tolerance (young pod setting under hot conditions), we successfully developed a heat-tolerant snap bean variety, Haibushi (literally southern star in the Okinawan dialect).

This heat-tolerant genotype of Haibushi has spawned further analysis of the heat-tolerance mechanism and comparisons with other heat-sensitive genotypes. In 1998, five crop scientists at the Okinawa Subtropical Station began a collaborative study entitled "Inheritance and physiological mechanisms of crop heat-tolerance during the reproductive process" in collaboration with BRAIN (Bio-oriented Technology Research Advancement Institution). The research program will focus on snap beans and attempt to answer the following questions: 1) which stages are the most sensitive to high temperature during the reproductive process? 2) which organs (or tissues) are damaged by high temperature? 3) how do tolerant genotypes respond to high temperatures? 4) how is tolerance controlled genetically? and 5) how do heat shock proteins function in exhibiting heat tolerance? Through these analyses, we hope to contribute to the further development of heat-tolerant crops.

Highlight #3: Visit of Tanzanian President Benjamin William Mkapa to JIRCAS

The President of the United Republic of Tanzania, Benjamin William Mkapa visited Japan in December, 1998 following the Second Tokyo International Conference on African Development (TICAD II) held in October, 1998. Since gaining its independence, Tanzania has maintained close ties with Japan and continues to receive Japanese technical and economic assistance for development in many areas such as agriculture, health, telecommunications and human resources. During his stay in Japan, President Mkapa visited JIRCAS on December 15. After a welcoming ceremony, Dr. Nobuyoshi Maeno, Director General of JIRCAS, briefed President Mkapa on current JIRCAS research activities, highlighting the collaborative international agricultural research projects which the institute is currently conducting in Asia, Africa and Latin America. President Mkapa showed interest in the advanced state of Japanese agricultural research and possible cooperation between Japanese and Tanzanian institutions to implement such research activities in Tanzania. After the ceremony and discussion, President Mkapa and his group observed the JIRCAS Biotechnology Unit where research on "Improving plant tolerance to environmental stresses by gene transfer" is being carried out by the staff of the Division of Biological Resources.

Photo: President Benjamin William Mkapa of Tanzania visit to JIRCAS in December 1998

The Tanzanian economy depends heavily on the agricultural sector, accounting for about 60% of the GDP, over 61% of export earnings and about 84% of rural employment. The majority of the people (>90%) live in rural areas and are engaged in subsistence farming, with an average of 1.2 hectares per household. Although the national population has grown by about 2.8% per annum in the last 10-15 years, overall agricultural production has thus far been able to match this growth, and the country is nearly self-sufficient in most food crops, excluding drought years. This is a result of horizontal expansion of cultivated area and improvements in productivity of several food and commercial crops, such as maize, rice, cotton and tea. However, due to service and industrial sector expansion, the overall share of the agricultural sector in the national economy, though significant, has continued to decline over the years. The agricultural sector can become more productive by utilizing new technology, taking into consideration the specific agro-ecological and socio-economic environment of various farming communities. The National Agricultural and Livestock Research Project (NALRP), has been attempting to establish an efficient, cost-effective and sustainable research service capable of developing appropriate technologies for the farming communities. Now in phase II, NALRP is initiating prioritized research projects for each agro-ecological zone and crop commodity. Due to the great need for new research, many areas are contending to receive such important projects.

In Africa, JIRCAS is currently carrying out four projects with a variety of international research centers (i.e. ICIPE, ILRI, WARDA and IFDC). Many African nations have requested JIRCAS to increase its efforts to review major issues in African agriculture and examine possible collaborative research projects in the region. Keeping with this request, JIRCAS endeavors to organize missions to African countries whenever the opportunity arises. JIRCAS sent a preliminary mission in March 1999 to Tanzania to clarify its needs and to assess possible areas for future collaboration. President Mkapa's visit may mark the beginning of active communication to explore possible cooperation between Japan and partners African countries.

BACK

Highlight #4: Research meetings and conferences

During FY 1998, JIRCAS played proud host to a great number of research meetings, academic seminars, workshops, and conferences. Discussion topics ranged from postharvest technology in Asia to sustainable agricultural systems in Thailand, and from cryopreservation of tropical plant germplasm to plant signaling. Invited guests included fellow researchers from affiliates of the Consultative Group on International Agricultural Research (CGIAR) and other prominent international research organizations, numerous national universities, and local experts from China, Malaysia, Vietnam, Thailand, India, the Netherlands, the USA, the Philippines, and many other countries.

These gatherings provided an important opportunity for JIRCAS researchers to share the fruits of their ongoing projects with one another and with their counterparts in other institutions. By the same token, contact with researchers most intimately familiar with local conditions enhanced opportunities for learning and influenced the direction of future research. More information on the meetings, seminars, workshops, and conferences sponsored by JIRCAS during the previous year can be found under the "Symposia and Workshops" heading within the section of this Annual Report entitled "Training and Invitation Programs and Information Events."

People's Republic of China

Evaluation of the plant genetic resources, development of novel breeding materials and their effective utilization

Fiscal Year 1998 witnessed a second Memorandum of Understanding (MOU) between JIRCAS and the China National Rice Research Institute (CNRRI). The first, signed August 20, 1997, launched the integrated project "Development of sustainable production and utilization of major food resources in China," a collaborative research program to investigate rice breeding and effective utilization of genetic resources. Before starting the program, it was agreed that genetic resources and breeding materials would be managed by mutual consent in both Japan and China because of their designation as indigenous property.

This agreement was followed by Dr. Cai Hong-Fa's, Director General of CNRRI, visit to JIRCAS during February 21-27, 1999. During the visit, Dr. Cai and his staff met with JIRCAS officials, led by Dr. Nobuyoshi Maeno, JIRCAS Director General. Based on a JIRCAS-CNRRI MOU, the discussions focused generally on the study "Evaluation of plant genetic resources, development of novel breeding materials and their effective utilization," and specifically on rice breeding materials relating to the project. At the conclusion of the Chinese delegation's visit, the timeline for the above project was set for March 1999 to March 2003.

Photo: Ceremony in Fuyan Province, China at which Dr. Nobuyoshi Maeno, Director General of JIRCAS, and Dr. Cai Hong Fa, Director General of CNRRI, signed a Memorandum of Understanding.

The discussion resulted in several other mutual understandings between JIRCAS and CNRRI, including an agreement to mutually supply and utilize breeding materials, to register and mutually utilize breeding materials bred within the project framework, and to protect the intellectual property rights of the researchers who have developed the new varieties of rice. In addition, the two parties consented to research achievements and new breeding materials obtained within the project framework and to resolve any differences in interpretation of the terms included in the Meeting Minutes and related matters. In accordance with the MOU and the Meeting Minutes, a JIRCAS rice breeder has been dispatched to CNRRI to initiate the research project.

The combination of advanced technology in Japan with the abundant genetic resources and high yielding potential of rice varieties in China will likely lead to the establishment of an efficient methodology to develop new, high-yielding, yet environmentally friendly, means of sustainable agricultural production.

Academic Prizes and Awards

JIRCAS is pleased to note that many of its staff members have been the recipients of academic prizes and awards from scientific societies and other organizations. The following is a brief summary of a special achievement received during the previous Fiscal Year. The Institute is proud to include this award in the Highlights of Annual Report 1998.

Dr. Yukiyo Yamamoto, Senior Researcher in the Environmental Resources Division, received the 1998 Research Encouragement Award from the Japanese Society of Grassland Science for "Study of grassland evaluation and planning methods using regional information." The award is given to a researcher as the Society's recognition of the individual's achievement in grassland science and as encouragement for successful career evolution.

JIRCAS AND THE MINISTRY OF AGRICULTURE,

FORESTRY, AND

FISHERIES

Administration of the MAFF Research Institutes

The Japan International Research Center for Agricultural Sciences (JIRCAS) is one of twenty-nine research institutes belonging to the [Ministry of Agriculture, Forestry and Fisheries \(MAFF\)](#), the Government of Japan. In this age, in which we have seen remarkable progress in advanced fields of science and technology including biotechnology, MAFF's research institutes are playing a key role in the development of new technologies to pave the way for further development of the food industry, and promotion of agriculture, forestry and fisheries activities in the twenty-first century. MAFF's institutes work in close collaboration with local governments, universities, and private research organizations and aim to contribute to the overall prosperity of Japan while making significant contributions to the international community.

Nineteen of the twenty-nine institutes including JIRCAS are directly overseen by the [Agriculture, Forestry and Fisheries Research Council \(AFFRC\)](#), which is a special agency attached to MAFF. The main duties of the AFFRC are overall research planning and coordination, liaison and coordination between research and administration, administration and guidance of the institutes, and research assistance to prefectural organizations and the private sector. The AFFRC is headed by a chairman, and its advisory members consist of independent university faculty members and previous MAFF research institute directors and high officials ([Table 1](#)). The remaining ten institutes, which include one institute devoted to forestry and nine fisheries research institutes, are also attached to the AFFRC. However, they are overseen by the Forestry Agency and the Fisheries Agency, administrative agencies under the direct supervision of MAFF. The overall structure of research at MAFF is as shown in [Fig. 1](#).

JIRCAS is unique among the twenty-nine research institutes in that it serves as an international research center but is, at the same time, part of the MAFF infrastructure. Thus, it is involved in active exchange and collaboration with the other twenty-eight institutes. JIRCAS is located in the Tsukuba Science City, which is about 50 km northeast of Tokyo ([Fig. 2](#)). Many other MAFF institutes are also located in Tsukuba, and the AFFRC secretariat maintains a Tsukuba office, forming the Tsukuba Institutional Complex. Tsukuba itself is home to numerous other research institutes and experimental facilities belonging to other ministries and agencies of the Japanese Government, as well as to the private sector.

Administration and Research at JIRCAS

JIRCAS has a current staff of 162, including research scientists and administrators. Thirty-nine of these staff members are located at the JIRCAS Okinawa Subtropical Station on Ishigaki Island. JIRCAS is headed by a Director General. The Research Planning and Coordination Division oversees seven research divisions which are comprised of the Research Information Division, Biological Resources Division, Environmental Resources Division, Crop Production and Post Harvest Technology Division, Animal Production and Grassland Division, Forestry Division, and the Fisheries Division, as well as the Okinawa Subtropical Station. The Administration Division is responsible for general administrative affairs. The structure of research at JIRCAS is delineated in [Fig. 3](#).

● Research Planning and Coordination Division

The Research Planning and Coordination Division in itself does not act as a research division, but rather serves to oversee and support the activities of the Research Divisions and Subtropical Station. The Division consists of four sections which are the Research Planning Section, the Research Coordination Section, the International Relations Section, and the Publication and Documentation Section. In addition, an International Research Coordinator and a Research Information Officer are assigned to the Division.

In order to promote the implementation of research programs both overseas and in Japan, the first three sections are responsible for the overall planning of JIRCAS research projects, dispatching of researchers on long- or short-term bases, implementation of programs for the invitation of researchers and administrators, and liaison and coordination with international and domestic institutions and agencies. The Publication and Documentation Section is responsible for the collection, classification, and supply of bibliographic materials from both overseas and domestic sources, as well as the release of public relations materials. The International Research Coordinator is responsible for overseeing collaborative

work in Southeast Asia while serving as JIRCAS's Thai Office Representative. The Research Information Officer develops computer information networks and coordinates the exchange of data between JIRCAS and related research institutions. Additionally, the Division coordinates the organization of various meetings and workshops including JIRCAS's International Symposia.

● Administration Division

The Administration Division consists of three sections: the General Affairs Section, the Accounting Section, and the Overseas Support Section. The General Affairs Section is responsible for the management of official documents, personnel-related matters, and social affairs pertaining to JIRCAS staff. The Accounting Section handles overall accounting, all budgeting, settlements and wage distribution. Lastly, the Overseas Support Section is in charge of all matters pertaining to JIRCAS's overseas operations, which includes general international affairs, overseas expenditures, and overseas shipments of equipment and materials.

● Other

The Okinawa Subtropical Station has its own General Affairs Section which is independent of the Administration Division. Additionally, JIRCAS has two field management sections which oversee JIRCAS's experimental fields. The Okinawa Section is directly under the Subtropical Station management and the Tsukuba Section is attached to the Crop Production and Postharvest Technology Division.

Domestic institutional support of JIRCAS international collaborative research

JIRCAS's main role is to promote sustainable development of agriculture, forestry and fisheries compatible with the preservation of the environment in developing regions of the world through integrated, collaborative research programs. In performing this role, JIRCAS aims to play an active part in the international community. JIRCAS collaborative projects in developing countries take a multi-disciplinary approach by focusing on each country's socio-economic conditions when evaluating and implementing research programs. JIRCAS and local specialists carry out "comprehensive research" in an effort to address the region's most pressing agricultural problems. Domestic research at JIRCAS facilities in Japan, the JIRCAS visiting fellow invitation program, and strong cooperation with international research institutes all contribute to and support these research efforts abroad.

To orchestrate a project, JIRCAS first systematically collects and analyzes data from a variety of sources including food supply and agricultural research in developing regions and then proposes international collaborative research strategies and policies targeting the specific needs of a country. In this capacity, by devising comprehensive research and policy proposals, JIRCAS essentially functions as a think-tank. Next, JIRCAS utilizes existing technologies, policies, and research to broaden its role into the initiation of research programs to effectively confront such pressing matters as sustainable agricultural development, food security, and environmental problems. At present, JIRCAS is conducting 8 comprehensive projects around the world including ones in Southeast Asia, China, South America, and Africa. Each project is guided and administered by a working group and a project committee, which make on-going adjustments as the project evolves. A JIRCAS staff member directs each project and is supported when necessary on short-term bases by researchers from other agriculture, forestry, and fisheries institutes.

JIRCAS maintains over 100 researchers, 40 of which are on long-term research assignments abroad. Once a topic is decided upon, the details of the research project, such as its parameters, research aim, and length, are presented and the most suitable researchers are selected. When a project requires the long-term assignment of researchers from outside JIRCAS, those scientists participate as JIRCAS staff members for the duration of their assignment. JIRCAS staff members and scientists from other research institutions assist JIRCAS-centered research activities abroad on short-term bases of usually one to two months. Furthermore, about 40 JIRCAS researchers in Tsukuba, Ibaraki Prefecture and Ishigaki Island, Okinawa Prefecture support the international collaborative projects by conducting related domestic research.

In these ways, JIRCAS international collaborative research projects enjoy great support from the Ministry of Agriculture, Forestry and Fisheries' 29 affiliated research organizations and their 2,700 strong research staff. Finally, JIRCAS conducts an Annual Meeting for Review and Promotion of Research for International Collaboration in order to ensure each project proceeds smoothly. In this meeting, the previous year's activities are evaluated and strategies and goals are set for the coming year's research.

JIRCAS ANNUAL REPORT EDITORIAL BOARD

JIRCAS's Annual Report is managed by the Research Planning and Coordination Division and an editorial board formed by staff administrators and researchers. In addition to a Chairman and Vice-Chairman, Editors-in-Chief, Advisory Panel, and Editorial Committee, the Board receives the participation of a graduate student intern from Harvard University's Regional Studies East Asia Program who Serves as a Special Assistant to the Editors -in Chief.

INTERNATIONAL RESEARCH AT JIRCAS

International collaborative projects at JIRCAS encompass all fields of agriculture, forestry and fisheries and are carried out in collaboration with counterpart institutions, including international research centers, national research organizations, and universities. A series of comprehensive projects commenced when the Tropical Agricultural Resource Center (TARC), the predecessor of JIRCAS, was restructured to create the present institution. These projects are focused on answering the difficult agricultural problems, such as developing sustainable agricultural systems, and addressing food supply and environmental problems, which presently confront developing countries. Projects combine research in both the natural and social sciences. Within the scope of a project, JIRCAS dispatches long- and short-term researchers to the target countries and may also sponsor research-related conferences and workshops with the partner country. In addition to comprehensive-type projects, JIRCAS continues to promote specific, focused, unidisciplinary types of projects originally carried out at TARC.

The following section presents recent developments in several ongoing comprehensive projects and, in keeping with this year's focus on the People's Republic of China, spotlights important research sites in China where several collaborative projects are currently being pursued. A [complete listing of comprehensive and unidisciplinary projects](#) undertaken by JIRCAS researchers can be found [here](#).

◆ COMPREHENSIVE PROJECTS

In 1998, JIRCAS was involved in eight comprehensive projects in Vietnam, Thailand, Malaysia, the People's Republic of China, Brazil, Indonesia, South America (Brazil, Argentina and Paraguay), and West Africa. These projects have been divided into three classifications, "Site-specific Comprehensive Projects," "Country-based Comprehensive Projects," and "Multinational Comprehensive Projects."

Site-specific comprehensive projects first systematically analyze the agricultural, forestry, and fisheries issues of a specific region through an understanding of the relationships between various factors such as natural resources, environment, technology, and administration, and then conduct multidisciplinary research addressing the needs of the region. Projects in [Vietnam](#), [Thailand](#), [Malaysia](#), and [Indonesia](#) are examples of site-specific projects. Country-based comprehensive projects identify the most significant food supply and agricultural problems of the partner state and then select several representative research fields and themes in which JIRCAS can best contribute toward the resolution of these problems. In addition, these projects promote comprehensive joint research through collaboration with the government of the partner state. Both the [China](#) and [Brazil](#) projects fall under this classification. Multinational comprehensive projects incorporate researchers in many fields from a wide region covering multiple countries in a cooperative effort to resolve strategically important issues. The projects in [South America](#) (soybeans) and [West Africa](#) (rice) are multinational projects.

Each comprehensive project has a research coordinator in the Research Information Division who assumes the role of project leader, organizing and overseeing collaboration among researchers in participating research divisions. During the planning stages of these comprehensive projects, socio-economic studies are conducted to identify research priorities in counterpart countries.

INTERNATIONAL COLLABORATIVE PROJECTS

Projects are designated as either comprehensive or unidisciplinary. All projects are handled by the JIRCAS Research Divisions.

(A) COMPREHENSIVE

Time Frame	Project Title	Research Site
1994-1998	Evaluation and improvement of farming systems combining agriculture, animal husbandry, and fisheries in the Mekong Delta (Phase I)	Cuu Long Delta Rice Research Institute (CLRRI) and Cantho University (CTU), Vietnam
1999-2003	Development of new technologies and their practice for sustainable farming systems in the Mekong Delta (Phase II)	Cuu Long Delta Rice Research Institute (CLRRI) and Cantho University (CTU), Vietnam
1995-2001	Development of sustainable agricultural technology in northeast Thailand	Department of Agriculture, Department of Livestock Development, Land Development Department, Asian Institute of Technology, Khon Kaen University, Thailand
1995-1999	Productivity and sustainable utilization of tropical and subtropical brackish water ecosystems	Department of Fisheries (DOF), Forestry Research Institute (FRIM), and the Ministry of Agriculture (MOA), University of Malaya, Malaysia
1996-2002	Comprehensive studies on the development of a sustainable agro-pastoral system in the sub-tropical zone of Brazil	Brazilian Agricultural Research Corporation (EMBRAPA), Center for Tropical Agriculture (CIAT), and JATAK International Center for Agriculture Technology, Brazil
1997-2003	Development of sustainable production and utilization of major food resources in China	Institute of Agricultural Economics, Institute of Natural Resources and Regional Planning, Research Center for Rural Economy, China Agricultural University, Institute of Soils and China National Rice Research Institute, and the Shanghai Fisheries University, People's Republic of China
1997-2006	Comprehensive soybean research project in South America (multinational)	Agricultural Technology Center in Paraguay (CETAPAR), Paraguay; Brazilian Agricultural Research Corporation (EMBRAPA), Brazil; and the National Institute for Agricultural Technology (INTA), Argentina
1998-2002	Evaluation and improvement of regional farming systems in Indonesia	Agency for Agricultural Research and Development (AARD), Indonesia
1998-2002	Improving food security in West Africa through increased productivity in rainfed rice systems	West Africa Rice Development Association (WARDA), Côte d'Ivoire

(B) UNIDISCIPLINARY

Time Frame	Project Title	Research Site
1995-1998	Rehabilitation of secondary degraded forest	Forest Research Institute Malaysia (FRIM), Malaysia
1995-1998	Improvement of technologies for raising small livestock in the tropics	Malaysia Agricultural Research and Development Institute (MARDI), Malaysia
1995-1998	Ecology and control of insect pests in reforested areas at Luasong Forestry Center, Tawau	Sabah Forest Research Institute Malaysia (FRIM), Malaysia

1995-1998	Methods of soybean cultivation in cropping systems with low pesticide input in Indonesia	Research Institute for Legumes and Tuber Crops (RILET), CRIFC, and the Agency for Agricultural Research and Development (AARD), Indonesia
1995-1999	Biorational approaches to long term and sustainable management of desert locusts in east and northeast Africa	International Center for Insect Physiology and Ecology (ICIPE), Kenya
1996-1998	An explanation of the ecology and methods for control of weeds in direct seeded rice cultivation in Malaysia	Malaysia Agricultural Research and Development Institute (MARDI), Malaysia
1996-1998	Improvement of logging techniques in hill dipterocarp forests	Forest Research Institute Malaysia (FRIM), Malaysia
1996-1999	Development of effective water management in paddy fields in the dry season	International Irrigation Management Institute (IIMI), Sri Lanka
1996-2000	Development of technology for sustainable management of grasslands in Central Asia.	Kazakh Institute of Agriculture, Republic of Kazakhstan
1996-2000	Afforestation technology for useful tropical tree species and the development of related research	University of the Philippines at Los Baños, Philippines
1997-1998	Early interactions between <i>Theileria parva</i> and bovine immune cell populations	International Livestock Research Institute (ILRI), Kenya
1997-1999	The role of local people in the degradation and rehabilitation of tropical forests	International Center for Research in Agroforestry (ICRAF)-South East Asia, Indonesia
1997-1999	Improvement of high-yielding wheat varieties through biological procedures	International Maize and Wheat Improvement Center (CIMMYT), Mexico
1997-1999	Studies on technology for sustainable production in closed coastal zones	Kasetsart University, Thailand
1997-1999	The development of methods for the use of under-utilized timber resources in the tropics	School of Industrial Technology, Universiti Sains, Malaysia
1997-2001	Development of diagnosis and prevention technology for shrimp viral diseases	Fisheries Research Institute (FRI), Malaysia
1998-2001	Development of technology for water distribution management for large scale paddy fields in tropic monsoon area	Muda Agricultural Development Authority (MADA) and Malaysian Agricultural Research and Development Institute (MARDI), Malaysia

VIETNAM:

Comprehensive Project on the Development of New Technologies and their Practice for Sustainable Farming Systems in the Mekong Delta

Although this project conducted with Vietnamese institutes was JIRCAS's first foray into collaborative research projects, the recently concluded project, "Evaluation and improvement of farming systems combining agriculture, animal husbandry, and fisheries in the Mekong Delta," ran smoothly from its initiation in 1994 owing to the efforts of long- and short-term visiting researchers and counterpart scientists, as well as to strong organizational cooperation. As Phase I of the project, the research provided the foundation for Phase II, entitled, "Development of new technologies and their practice for sustainable farming systems in the Mekong Delta." Results obtained under Phase I of this project relate to the following topics: 1) characterization of the natural and social conditions of typical Mekong Delta agriculture; 2) clarification of primary technological structures of some farming systems; 3) demonstration of possible improvements in rice cropping, pest management, hog raising and aquaculture; 4) clarification of the primary structure of farming households; and 5) presentation of possible directions for future farming system development. Though some of these results had already been obtained by Vietnamese scientists, many were new achievements in this project. Research has been presented not only as individual papers but also as co-published monographs.

Results from this project may be considered as an analytical study of existing farming systems in the Mekong Delta and as a first step in conducting interdisciplinary research. Since the significance of this interdisciplinary project is its role within an overall research framework designed to achieve concrete goals, the next research project will examine and evaluate farming systems with newly developed technologies and regimes in order to achieve sustainability in a variety of ecosystems in the Mekong Delta.

The themes of Phase II of the project are as follows: 1) Development of new technologies for farming systems in the Mekong Delta; three components of farming systems - rice cropping, hog raising, and aquaculture - will be studied in order to increase efficiency, lower costs and reduce pollution in combined farming systems. 2) Farm management and the functions of farmers' organizations; since farming systems are a reflection of natural and social conditions of a region, geographical effects on salt-affected areas and acid-sulfate soil areas, as well as irrigated areas, will be studied. The possibility of establishing farmers' organizations responsible for such services as crediting and delivery of goods will also be studied. 3) Evaluation of sustainability of newly developed farming systems; new farming systems will be proposed and the cycling of nitrogen and other materials in agro-ecosystems will be assessed. General assessment of the agricultural economy and sustainability will be carried out as well.

To be conducted over a 5 year period (1999-2003), the comprehensive research should achieve the following results: 1) new technologies for rice cropping, hog raising and aquaculture will be developed to make farming systems complete as production systems; 2) new farming systems with developed technologies will be proposed for differing ecosystems within the Mekong Delta; 3) new farming systems will be examined and evaluated for their sustainability on the bases of material cycling and agricultural economy. Our Vietnamese counterpart institutes, Cantho University (CTU) and Cuu Long Delta Rice Research Institute (CLRRI), will be responsible for the organization of the new project.

[BACK](#)[NEXT](#)

CHINA:

Comprehensive Project on the Development of Sustainable Production and Utilization of Major Food Resources

JIRCAS officially inaugurated its first comprehensive research project with the national government of the People's Republic of China (PRC) on May 28, 1997, with the signing of a memorandum by representatives from JIRCAS, the Japanese Agriculture, Forestry and Fisheries Research Council (AFFRC), and the Chinese Ministry of Agriculture (MOA). The Memorandum of Understanding commits the institutions to a collaborative research program spanning seven years.

The comprehensive project aims to develop technologies for sustainable production and utilization of major food resources in China. Such resources, including rice, soybeans, corn, and freshwater fish, will become increasingly important as economic development strengthens the purchasing power of ordinary Chinese citizens and enhances their concern for dietary nutrition.

On June 10, 1998, JIRCAS celebrated the opening of its Beijing Office. Composed of a variety of research fields, ranging from the social to the natural sciences, the comprehensive research project involves 10 research institutes of the People's Republic of China, 8 research institutes of MAFF including JIRCAS, and several prefectural research institutes. The newly opened Beijing office will play a pivotal role in facilitating and promoting this and future Japan-China research collaboration.

A report entitled "Who will feed China? Wake-up call for a small planet" (L. Brown, The World Watch Institute, 1995) provided the initial impetus behind concerns about the future of China's food supply. In response, many Chinese and foreign researchers have made analyses and projections regarding food supply problems in China, focusing their studies primarily on the grain sector. These reports reveal little agreement on future scenarios for food production and demand, most likely due to differences in underlying assumptions, data, and estimation processes. Nevertheless, there exists sufficient consensus that food demand will increase continuously during the next three decades and that available supplies will not meet this demand. Consequently, rising demands for imported foodstuffs will likely occur.

The major factors inhibiting agricultural production increases in China include the area of arable land, the poor quality of farmland, the weak response of soils to fertilizer, and the small-holder structure of private Chinese farms. In the process of rapid economic growth, it is inevitable that more farmland will be put toward non-agricultural uses. New efforts to reclaim land and recent increases in crop indices do not seem to have halted the trend toward declining levels of land under cultivation. Moreover, crop yields in China remain significantly lower than in advanced industrial countries.

At the same time, major factors influencing food demand will include the expansion of the population, changes in the structure of Chinese society due to rural-urban migration, the growth of income,

alterations in the prices of agricultural products, and the persistence of poor infrastructure. Due to the inevitable shrinkage of agricultural resources and the natural, structural, financial, and economic constraints on yield potentials, demand for food in China will continue to rise even as agricultural production fails to keep pace.

In light of these trends, this project marks an attempt to develop an effective production and distribution system for food resources in order to cope with changing structures for the supply and demand of agricultural products. Efforts to achieve this objective will require not only an evaluation of the dissemination of new technologies in selected areas and their economic impacts on rural areas and individual farmers, but also modeling for the supply and demand of food resources in selected areas, analysis of the structure of corresponding farming areas and agricultural products, and design of more effective control systems also will be required to improve food supply and demand in selected areas. Joint workshops by JIRCAS, the Institute of Agricultural Economics, and the Chinese Academy of Agricultural Sciences (CAAS) were held on food supply-demand and dissemination of new agricultural technologies in China on November 26, 1998, at JIRCAS. A follow-up workshop was held in Beijing on March 12, 1999, to report the progress of this project and to elucidate and evaluate current research on the dissemination of new agricultural technologies.

In addition, the project seeks to generate technologies for the sustainable and stable production of major food resources. Toward this end, project participants intend to evaluate existing genetic resources, create new species, and develop and evaluate environmentally sensitive agricultural technologies. On the evaluation and development of the methods for sustainable agriculture and environmental conservation, a second planning workshop was held on March 23-25, 1999, in Beijing ([Photo](#)), jointly by JIRCAS, the Institute of Soils and Fertilizers, CAAS, and the Institute of Soil Sciences of the Chinese Academy of Science. Finally, the project aims to develop food technologies that will enhance the utilization and distribution of major food resources. These efforts will include evaluating the quality of major food resources, developing new food ingredients, and improving preservation and distribution technologies for major food resources. The results from the study on the development of new technology to utilize and process freshwater fish meat were presented in the first joint workshop between JIRCAS and Shanghai Fisheries University, March 25-27, 1999, in Shanghai.

BRAZIL:

Comprehensive Project on the Development of Sustainable Agro-pastoral Systems in Sub-tropical Zones

Initiated by JIRCAS in 1996, the project entitled "Comprehensive studies on the development of sustainable agro-pastoral systems in the subtropical zone of Brazil" is another South America-based research program. By emphasizing land utilization through the adoption of crop-pasture rotation systems, this project focuses on the development of highly productive, sustainable farming systems in the environmentally degraded areas of Brazil's sub-tropical zone. Current research involves collaborative efforts from CNPGC (National Research Center for Beef Cattle), [EMBRAPA](#), and JATAK (International Center of Agricultural Technology). In cooperation with JIRCAS, these institutes are conducting research on four themes, including analysis and evaluation of indigenous and traditional land utilization systems for agriculture, multidisciplinary studies on the adoption as sustainable crop-pasture rotation systems, socio-economic evaluation of crop-pasture rotation, and newly developed agro-pastoral systems.

SOUTH AMERICA:

Comprehensive project on Soybean Improvement, Production and Utilization

The soybean, *Glycine max*, is considered to be one of the principal crops for human sustenance. Soybeans provide a major source of food, oil, and protein-rich livestock feed. Production of this valuable crop has increased rapidly in the past three decades in comparison with that of rice, wheat, corn, and other major grains. Encouraging the continuation of this trend may aid efforts to stabilize the world food supply.

At present, Brazil, Argentina, and Paraguay (MERCOSUR countries) account for approximately one-third of global soybean production, placing them among the leading soybean export countries. However, soybean production in South America has often been carried out under environmentally vulnerable conditions in arid, acid soils characterized by low-fertility. Of additional concern, the history of soybean cultivation in these areas is relatively short, giving rise to concerns that continuous cropping, pest and disease outbreaks, and soil erosion may adversely affect future soybean production.

Comprehensive, multinational research efforts focused on the development of sustainable and more efficient systems of soybean production in South America can be considered an important means of addressing these constraints.

The JIRCAS research project entitled "Soybean improvement, production and utilization in South America" marks a new initiative by the institute to promote multi-disciplinary studies on soybean production and utilization in MERCOSUR countries through collaborative research linking Japanese and South American specialists. The project involves collaboration with several South American research institutes, including those affiliated to [EMBRAPA \(The Brazilian Agricultural Research Corporation, Brazil\)](#), MAG (Ministry of Agriculture and Livestock, Paraguay) and INTA (National Institute of Agricultural Technology, Argentina), as well as [JICA/CETAPAR \(Japan International Cooperation Agency - Centro Tecnológico Agropecuario en Paraguay\)](#). This comprehensive project complements earlier efforts in the field by focusing research in five areas: genetics and breeding, soil management and pest control, crop management and production, post harvest technology, and socio-economic factors.

BACK

NEXT

WEST AFRICA:

Comprehensive Project on Improving Food Security through Increased Productivity in Rainfed Rice Systems

Demand for rice in sub-Saharan Africa is growing faster than that for any other major food staple, with consumption broadening across all socio-economic classes, including the poor. Rapid demographic expansion and urbanization in Africa has changed food preferences from traditional food-stuffs to more easily prepared rice and bread. These patterns are especially evident in West Africa where the substitution of rice for coarse grains and traditional root and tuber crops has fueled rice demand at an annual growth rate of 5.6% between 1961 and 1992.

Rice is no longer a luxury food. The poorest urban households in West Africa obtain larger shares of their cereal-based calories from rice than do higher income households, and rice purchases represent a greater share of their total cash expenditures. Rice availability and rice prices directly impact the welfare of the poorest West African consumers who are the least food secure.

Increased rice production in Africa is hampered by a number of constraints, including disease and pests, weed infestation, inadequate water management, soils with low fertility, lack of suitable varieties, and socio-economic factors. To address these problems, JIRCAS initiated a 5-year collaborative research project with the [West Africa Rice Development Association \(WARDA\)](#) in April, 1998. The project aims to develop and distribute rice cultivars which are well suited to local socio-economic conditions, technological levels, and farming practices, with a special focus on resource-poor farmers in the region. Two JIRCAS scientists have been dispatched to the Upland Rice Program and Policy Support Program of WARDA to carry out the following research: 1) genetic and eco-physiological characterization of indigenous rice varieties and inter-specific progenies (*Oryza glaberrima* x *Oryza sativa*), with emphasis placed on tolerance to drought and acid soil conditions, and 2) studies on socio-economic aspects in relation to the sustainability of lowland rice cultivation in West Africa.

BACK

THAILAND:

Comprehensive studies on sustainable agricultural systems in northeast Thailand

The agricultural environment in northeast Thailand is characterized by the alternation of a rainy season followed by a half-year dry season and the wide distribution of infertile sandy and saline soils. Due to these disadvantageous agricultural conditions, the region is not economically blessed. Farmers in the region have been planting rice as a cash crop on rain-fed paddy fields since the 1960s when farmland was extensively expanded through deforestation. Recently, areas used for the harvesting of sugarcane have expanded rapidly as has the breeding of large-sized ruminants. Demands for milk and meat are expected to increase along with the country's recent high economic growth.

Deforestation and the expansion of saline soils have changed the hydrolic environment. In particular, soil erosion and deterioration of soil fertility in cassava fields have resulted in decreased productivity. Cash crop profitability is also waning due to the depression in the market price of agricultural products.

In order to promote agriculture in the region, it is necessary to maintain an environment favorable to reforestation and to utilize water resources effectively. At the same time, it is also necessary to shift the agricultural system from one which is dependent on a few cash crops to a sustainable agricultural system in which local resources are utilized much more effectively. This collaborative project is focused on areas of rain-fed paddy fields in northeast Thailand and is aimed at developing technologies in rice and field crop harvesting, vegetable and fruit cultivation, the livestock industry and sericulture, as well as attaining sustainable agricultural systems that combine farming and animal husbandry.

Photo: Mechanization in crop tending in Thailand

Photo: Non-tillage seeding exhibited an advantage in weed control through pre-seeding herbicide treatment in Thailand

In this project, JIRCAS is focusing on farmers who are eager to diversify agricultural production. Research concerns such topics as: 1) labor reduction through the introduction of direct seeding in dry paddy fields, 2) the introduction of profitable and durable vegetables and forage crops in upland field farming, 3) full utilization of regional resources in order to supply livestock forage on a year-round basis 4) the introduction of small-sized machines in order to improve working efficiency, and 5) the improvement of the hydrolic environment by constructing reservoirs and afforestation. Other research focuses on evaluating the material cycle of organic and inorganic components in crop and livestock production, improving the quality of agricultural and livestock products, and evaluating managerial and economic activities. Complete activities, which comprise 5 main themes are summarized as follows:

I. Evaluation and effective utilization of environmental and biological resources in the area

1. To evaluate characteristics of agricultural conditions based on topography, water and soils and apply the information obtained to proper utilization of land.
2. To clarify the circulation nutrients in the use of organic and inorganic components and to indicate guidelines for the effective use of organic compounds.
3. To evaluate the durability of circulation of materials under the proposed "sustainable agricultural system"

II. Development of sustainable crop production systems

1. Profitable rice cropping: reduction of labor and mechanization by direct sowing on dry paddy fields and subsequent efficient utilization of materials for production purposes.
2. New utilization of sugarcane: development of various technologies including cultivation of sugarcane for use as whole forage crop and cultivation with minimum inputs of nitrogen fertilizer.
3. Profitable cultivation of vegetables: clarification of the effectiveness of silviculture in farmland and alley cropping and to development of water-saving technology for the cultivation of marketable vegetables as well as legumes and potatoes.
4. Development of practical utilization methods of organic fertilizer using livestock excreta.

III. Improvement of feeding management using locally available feed resources

1. To develop technology for animal feed production by making use of local resources.

2. To develop technology for breeding cows for dairy or meat production using local fodder resources.

IV. Development of postharvest technologies for local agricultural products

1. Improvement of rice quality/development of preservation technology

2. Establishment of quality evaluation procedures for dairy and meat products and improvement of conditions for distribution.

V. Economic evaluation of multi-cropping and livestock farming

1. To evaluate energy conservation and profitability in rice production.

2. To evaluate profitability by clarifying external conditions for introduction of highly productive agricultural products such as vegetables.

3. To evaluate profitability of dairy products along with introduction of new forage crops.

4. To evaluate managerial and economic aspects of multiple farming systems based on the introduction of new crops and improvement of cropping systems.

This project has thus far achieved a number of beneficial results. In the field of biological resources, the usefulness of newly introduced cow-pea and sweet potato varieties were evaluated. Sugarcane genes, including those of wild sugarcane, collected from various regions in Thailand were studied in order to improve yield. It was determined that sugarcane and pineapple fix atmospheric nitrogen and that future cultivation of these crops can be accomplished by decreasing the amount of nitrogen. The above findings are useful for the establishment of sustainable agricultural systems in this region.

In an effort to develop a sustainable agricultural production system, the proper interval of planting leguminous trees for alley cropping was determined and a mechanized working system suitable for the region was also investigated. Moreover, the possibility of introducing direct sowing of rice on dried paddy fields was studied. By studying drought-resistant tropical pastures, developing methods for silage preparation, and evaluating the nutritional characteristics of grass pasture, leguminous pasture, feed trees and sugarcane, considerable progress was made in this project from the point of view of improving the utilization of animal resources. We also clarified the metabolizable energy and protein requirements for the maintenance of locally utilized ruminants.

On the postharvest technology research front, the flavor component of Khao Dawk Mali, one of the most important rice varieties in northeast Thailand, was quantitatively analyzed using a 0.5 g rice sample. By developing a process to identify rice varieties using DNA it became possible to determine rice mixing rates.

MALAYSIA:

Comprehensive Project on Productivity and Sustainable Utilization of Brackish Water Mangrove Ecosystems

There is presently wide public and scientific concern to achieve a fuller and more effective understanding of all of Earth's natural ecosystems. For that objective to be realized with tropical mangrove systems will require undiminished effort throughout the present decade and probably well into the next century, because our understanding of mangrove forests lags behind that of many other ecosystems. Nevertheless, as will be seen from the several reports, great advancements have been made during the last decade, particularly in understanding the structure and function of mangrove ecosystems in the Indo-Pacific region.

Many human communities have a traditional dependence on mangroves for their subsistence and a wide range of natural products from mangroves is presently utilized. For some time, however, there has also been exploitation of mangrove resources for broader economic objectives, e.g. forestry. Harvests of that kind, when well-managed, are probably sustainable in the long term as evidenced by the continued high yield of timber products and charcoal from the Matang Mangrove Forest in Malaysia. On the other hand, some other forms of exploitation, often for short-term gain, can be irreversibly destructive. Clear felling of virgin forests for wood chips and paper pulp is a notable example. The conversion of mangrove forests for mariculture ponds on large scale, notwithstanding the recovery of fishery products, is also, of course destructive of the native forests and, at least in practical terms, irreversible. Reclamation of mangrove forests for agricultural, industrial, urban and other forms of land-based development is also increasing and causing irreversible damage in coastal regions throughout the tropics. Such impacts, not to mention the additional burdens of pollution and changes in hydrological regimes caused by freshwater diversion projects, have adverse effects not only on subsistence dwellers in and near mangrove habitats, but also on other members of society, who depend indirectly on intact coastal resources. A consequence of this has been greater public concern for coastal lands, including mangrove forests, and increased research and management effort throughout the tropics.

In order to better understand the functions of these valuable ecosystems, JIRCAS has initiated a collaborative research project on the productivity and sustainable utilization of brackish water mangrove ecosystems in cooperative with leading Malaysian scientists. The project covers a five-year period from 1995-2000 and prioritizes four principal research topics, including production and decomposition processes in differential brackish water mangrove ecosystems, nutrient flux from rivers to coastal ecosystems, energy flow and carrying capacity in differential brackish water mangrove ecosystems, and socio-economic evaluations of brackish water mangrove ecosystems. Research touching upon issues in fisheries is now being conducted in collaboration with the Fisheries Research Institute (FRI) and the [University of Malaya \(UM\)](#).

At present, three research sites in Peninsular Malaysia have been selected for the project. The Matang Mangrove Forest in Perak State is located within a forest reserve measuring 40,711 hectares. The area consists of numerous islands and adjacent water ways and is populated primarily by *Rhizophora apiculata* trees. Under sustainable management since the early part of the century, Matang Mangrove Forest is reputed to be the world's best managed mangrove forest. As such, it will provide a valuable location for analyzing the role of fish populations in mangrove ecosystems. In contrast, disturbance through partial deforestation characterizes Merbok Mangrove

Forest Reserve in Kedah State. The loss of mangroves continues due to the persistence of destructive land uses, especially the conversion of mangrove areas into shrimp culture ponds. The third site, the Lumut Mangrove Forest has experienced much more extensive deforestation. Surveys conducted between 1997 and 1998 in the Selinsing River of the Matang Mangrove indicate the presence of a certain C-N isotopic ratio gradient. This finding suggests the presence of a food pathway that begins with leaf-based detritus in the mangrove, continues upwards to herbivorous shrimp and crab species, and culminates in carnivorous fish and squid. In other words, series of trophic relationships is fulfilled in the Matang brackish water mangrove ecosystem.

Additional research comparing populations of larval and juvenile anchovies, *Stolephorus* spp., at the research sites indicates population densities at least 1.5 times greater in the intact brackish water mangrove ecosystem at Matang than those in the disturbed ecosystem at Merbok. Biomass at Matang also measured 4.3 times higher than that in the Merbok Mangrove. These results confirm our assumptions that the undisturbed nature of Matang Mangrove would generate much higher levels of productivity for larval and juvenile anchovy, when measured as the product of biomass and daily growth rates calculated through otolith ring analysis.

Photo: *Oyster cage culture in a mangrove estuary in Malaysia.*

We have presented the results of these and other studies conducted during the past four years in an annual seminar held under the auspices of the comprehensive project. Two seminar proceedings have already been published. As a result of these studies, integrated criteria on tree and aquatic production under suitable forest management can now be standardized. Information obtained in this project will be useful to scientists in many fields in their efforts to improve techniques for the sustainable utilization of brackish water mangrove ecosystems, benefiting local residents as well as policy makers.

INDONESIA:

Comprehensive Project on the Evaluation and Improvement of Regional Farming Systems

Agricultural production in Indonesia varies greatly from location to location, depending on the natural environmental and socio-economic conditions of each locale. For instance, rapid economic growth, industrialization, and urbanization on Java Island has exacerbated gaps between cities and villages and fundamentally altered the social and economic conditions of rural areas. On the outer islands, generally poor living conditions reflect the slow pace of economic development and the lack of suitable technologies with which to overcome the difficulties of resource exploitation.

Most agricultural research in Indonesia has been focused on lowland farming systems based on the cultivation of rice. This focus, when combined with the effects of other governmental programs to aid rice farmers, allowed Indonesia to achieve its national goal of self-sufficiency in rice by 1984. However, upland crop areas have benefited little from new agricultural techniques in spite of the many research projects that have targeted upland or rainfed lands. Consequently, upland agriculture remains much less developed than lowland agriculture throughout the country. Thus, in addition to the recent shortfalls in rice production in these areas, food crop production enhancement in both lowland and upland areas has become the principal target of agricultural research and development in Indonesia.

Photo: A sampling of vegetables grown locally in Indonesia.

The comprehensive research project entitled "Evaluation and improvement of regional farming systems in Indonesia" aims to shed light on socio-economic and technical evaluations of past and present farming systems research practices and extension in Indonesia. A bottom-up participatory process and an emphasis on multi-disciplinary approaches to problems characterize a "farming systems research approach." The project commenced in April, 1998 and is scheduled to last for five years. The collaborating research institutes of Indonesia include the Center for Agro-Socio Economic Research (CASER), the Research Institute for Legume and Tuber Crops (RILET) of the Central Research Institute for Food Crops (CRIFC), and other organizations under the Agency for Agricultural Research and Development (AARD) of the Ministry of Agriculture of the Republic of Indonesia.

Current research activities include 1) a study on the farmer-state linkages in upland farm development, 2) evaluation of Indonesian soybean varieties for the processing and improvement of traditional fermented foods, and 3) analysis of physical environmental resources using remotely sensed data and GIS for the evaluation and improvement of regional farming systems. JIRCAS recently initiated the third project in collaboration with CASER and the Center for Agroclimate Research (CSAR).

Attempting to deepen the understanding of past and present farming systems research activities, JIRCAS-CASER held an international workshop titled "Learning from farming systems research experiences in Indonesia" in Bogor, Indonesia, March 3-4, 1999. The workshop emphasized the importance of the newly established Assessment Institute for Agricultural Technology (AIAT) in its role to develop and apply new agricultural technologies suitable to farmers engaging in upland agriculture.

JIRCAS Opens China Office

On June 10, 1998, the JIRCAS Beijing Office was officially opened in the Beijing Friendship Hotel, located in the northwestern district of Beijing and near the Chinese Academy of Agricultural Sciences (CAAS).

Photo: *Dr. Ikegami, Head of JIRCAS's China Office.*

The opening ceremony was held in the hotel's Friendship Palace room. Sixteen Japanese guests, including Mr. Sakue Matsumoto, Chairman of the Agriculture, Forestry and Fisheries Research Council (AFFRC), Ministry of Agriculture, Forestry and Fisheries (MAFF), Mr. Toshiaki Namba, Director of the International Research Division, Secretariat for AFFRC, MAFF, Dr. Nobuyoshi Maeno, Director General of JIRCAS, and members of the Embassy of Japan and the [Japan International Cooperation Agency \(JICA\)](#), attended the ceremony. The Chinese delegation included Mr. Lu Ming, Vice-Minister of the Ministry of Agriculture (MOF), Prof. Lu Feijie, President of CAAS, Prof. Mao Daru, President of China Agricultural University, Mr. Wang Wenzhe, President of the China National Food Industry Association and Mr. Gan Zuofu, Minister-Counselor of the Embassy of the People's Republic of China.

The Office plays an important role in coordinating collaborative research projects between JIRCAS and China. It has established close connections with MOF, CAAS and other research organizations in China and has received over 100 guests from JIRCAS, other research institutes of MAFF and other organizations in the first year of its establishment. The Office will contribute to further promotion of Japan-China agricultural cooperation.

China National Rice Research Institute:

A national research center for rice sciences and technologies

A Chinese proverb states "Food is God for the people." Rice is the most important staple food crop in China, with approximately 19.5 billion tons of rice being harvested in roughly 30 million ha of paddy fields each year. China accounts for 37% of world rice production, and 23% of the world's rice land. Inaugurated in 1989 as a national research center for rice sciences and technologies to contribute to rice self-sufficiency, the China National Rice Research Institute (CNRRI) was authorized by the Chinese State Council in 1981 under the financial and academic support of the World Bank, UNDP, the Rockefeller Foundation and the International Rice Research Institute (IRRI). One of China's largest agricultural research institutions, the CNRRI is directly affiliated to the Ministry of Agriculture, but is also partially under the control of Zhejiang Province. The Chinese Academy of Agricultural Sciences in Beijing has supervised CNRRI research activities since 1996. Since its inception, CNRRI has maintained its principle of "Basing the foothold in Zhejiang Province, keeping in mind the whole country and in view the whole world." CNRRI is located in Fuyang Basin, about 40 km southwest of Hangzhou City, Zhejiang Province. Lying along the Fuchunjiang River, the Fuyang Basin is a rice-dominated agricultural area, where both indica and japonica rice are planted under sub-tropical monsoon climatic conditions.

An integrated research institution, CNRRI projects are multi-disciplinary incorporating rice science and technology and are supported by the administrative and farm operation sections. Four Deputy Directors, each under the CNRRI Director General, head these two sections, along with CNRRI's enterprise and research sections. CNRRI is supervised and evaluated by a Board of Trustees and Academic Advisory Committee. The major tasks of CNRRI are summarized as follows:

1. Collection, conservation, evaluation and utilization of rice germplasm resources.
2. Improvement of rice varieties and high-yielding technologies, and increase of profitability of rice agriculture.
3. Planning and coordination of national rice research projects, and promotion of international research collaborations.
4. Exchange and extension of scientific and technological information on rice agriculture, training and education of research personnel, and publication of rice research articles.

Two hundred-fifteen research staff including about 70 senior researchers (with doctoral and master degrees or the equivalent) work at CNRRI supported by about 45 post-graduate research fellows from universities and other institutions. There are 7 research departments: 1) Breeding and Genetics, 2)

Germplasm Resources, 3) Biotechnology, 4) Plant Protection, 5) Agronomy, 6) Plant Physiology and Soil Chemistry, and 7) Agricultural Economy and Information. Each department consists of 3 to 5 research groups, with each group containing one senior and several junior researchers.

At present, JIRCAS is the only foreign institute that dispatches scientists to CNRRI for long-term research collaboration. This collaboration was initiated in 1992 based on an agreement established at the 10th Meeting (1991) of the Japan-China Agricultural Science and Technology Exchange Group. The Tropical Agriculture Research Center (TARC: forerunner to JIRCAS) and the General Station of Plant Protection (currently the National Agro-Technical Extension and Service Center, GSPP) agreed to a collaborative research project on "Long range migration of rice plant hoppers in the monsoon area of East Asia" with the Chinese Ministry of Agriculture and CNRRI. Ending in January 1997, TARC (JIRCAS) and CNRRI entomologists from the project clarified basic patterns of monsoon-dependent migrations of rice planthoppers from northern Vietnam to Japan through China.

Diagram: *CNRRI-JIRCAS Cooperative Research Unit*

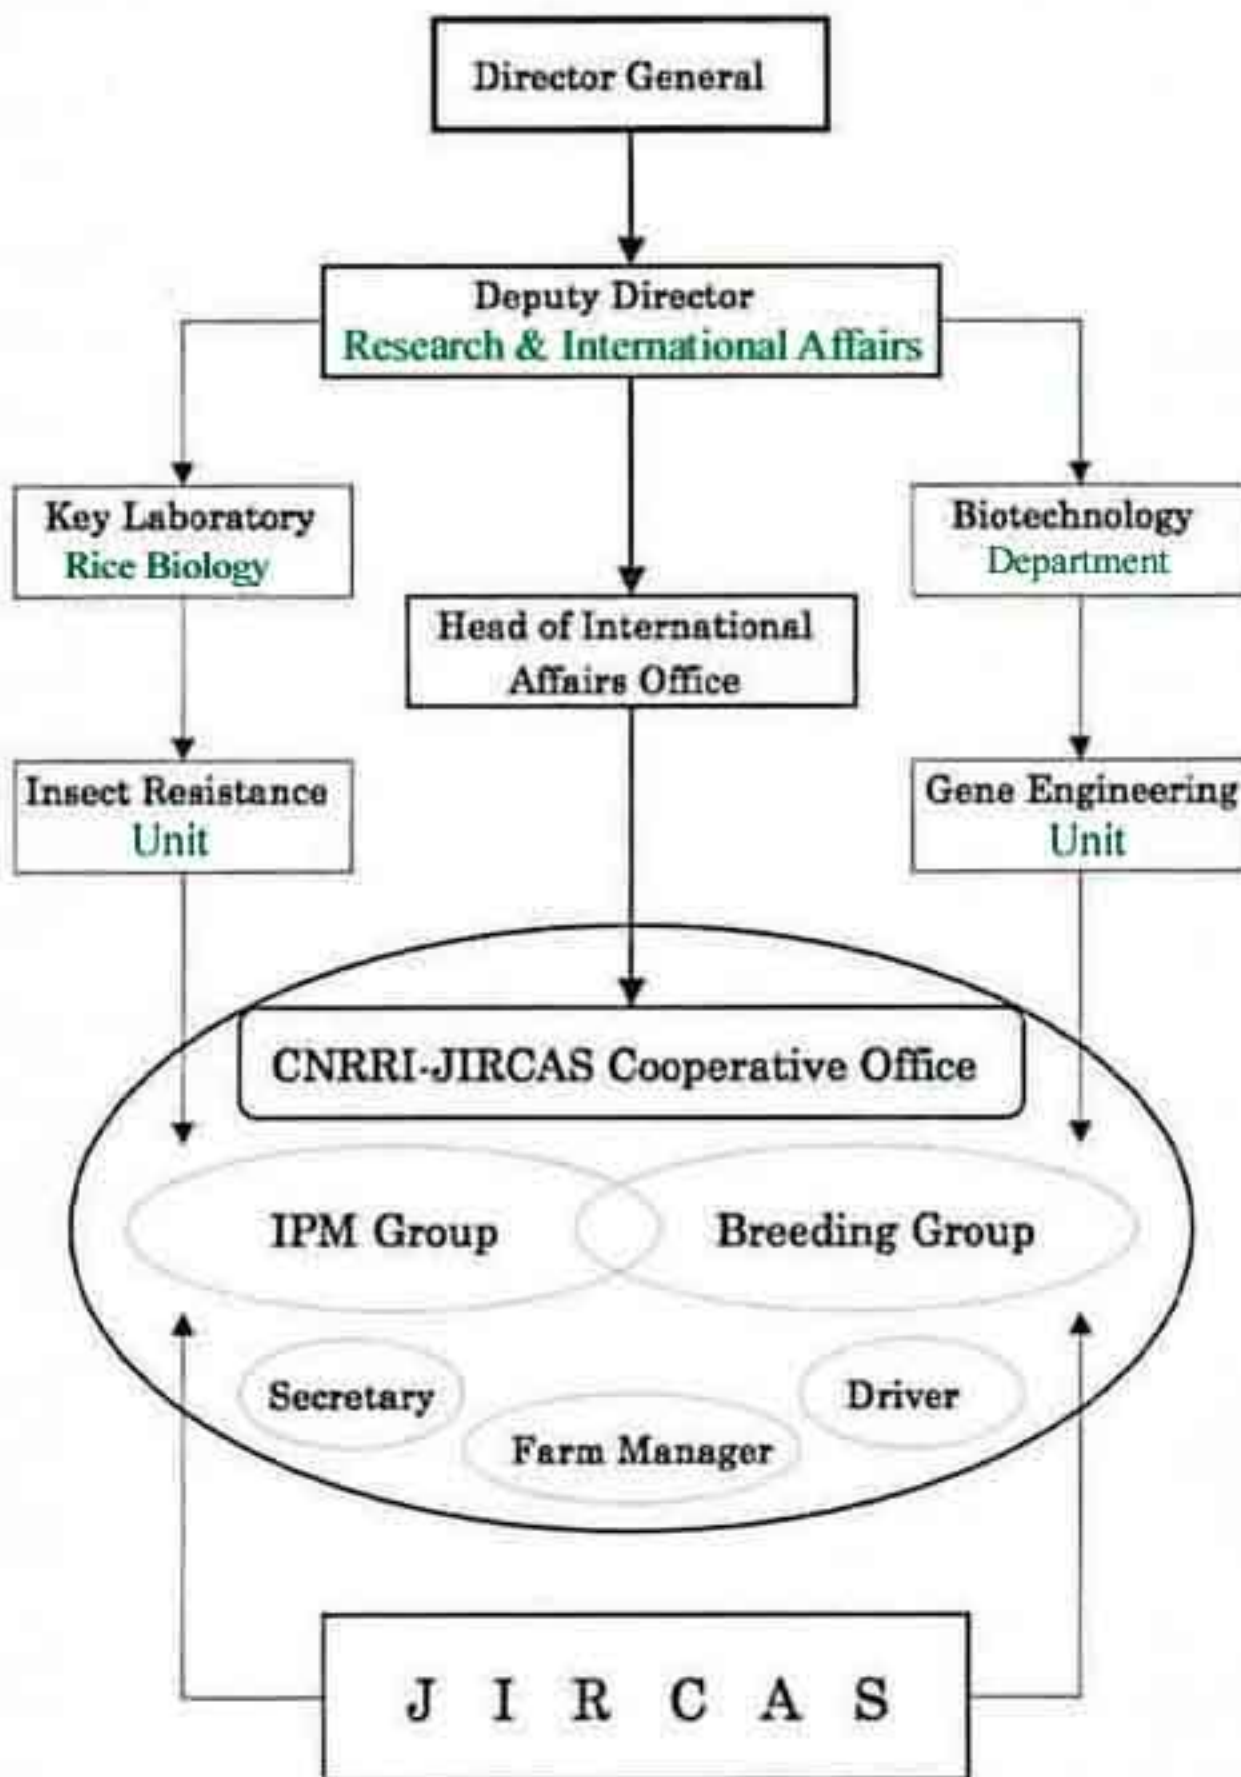

At the 16th Meeting of Japan-China Agricultural Science and Technology Exchange Group, the Ministries of Agriculture of both countries signed a comprehensive agreement for a new project entitled "Development of sustainable production and utilization of major food resources in China" on May 28, 1997. This was followed by a MOU signed on August 20, 1997 by JIRCAS and CNRRI in which the two institutes agreed to conduct 2 new projects on rice breeding and plant protection. "Evaluation of plant genetic resources, development of novel breeding materials and their effective utilization (1997-2003)" and "Integrated management for migratory insect pests of rice (1997-2001)" are the working titles of the 2 collaborative sub-projects, which have been incorporated into the overarching comprehensive project.

CNRRI has made special arrangements to promote collaboration by establishing a cooperative research unit for JIRCAS scientists and their CNRRI counterparts, which is independent from existing CNRRI research departments. This is important to maintain the independence and priority of JIRCAS-CNRRI cooperative research at CNRRI, as well as to avoid unnecessary conflicts due to different fiscal systems between the two institutes. CNRRI provides an office, laboratories, paddy fields, and greenhouse space to the CNRRI-JIRCAS cooperative unit. The cooperative unit is directly supervised by the Director General and administered by the International Cooperation Section, whose chief is concurrently assigned as the Chief Manager of the unit. In addition, CNRRI also collaborated with the Japanese Ministry of Agriculture, Forestry and Fisheries in the joint surveillance of bio-diversity in Chinese rice paddy ecosystems from 1996 to 1998.

The sustainable development of agriculture for food security will continue to be the most fundamental problem facing China. Future JIRCAS-CNRRI collaboration will play an important role in addressing this problem.

Collaborative research to develop postharvest technology at China Agricultural University

Formed following the merger of Beijing Agricultural University (the present West Campus) and Beijing Agricultural Engineering University (the present East Campus) in 1995, China Agricultural University (CAU) is a leading agricultural education and research institution in China. Now under the auspices of the Ministry of Agriculture, the University's roots are in the College of Agriculture established in 1905 in the Capital University (the present Peking University), the oldest university in China.

CAU consists of two campuses, the West and East, about 10 kilometers apart. It boasts 6 academicians from the Chinese Academy of Sciences, 5 academicians from the Chinese Academy of Engineering Sciences, 223 professors, and 617 associate professors. With a constant rise in student population over the past few years, the university is currently home to 1,050 graduate and 7,100 undergraduate students enrolled in 16 colleges. The Food College, founded in 1983, has 4 departments: Food Science and Technology, Food Nutrition and Biotechnology (West Campus), Food Engineering, and Biochemical Engineering (East Campus). Ten professors, seven doctoral supervisors, and twenty-three associate professors serve in the college faculty.

Photo: *Main entrance of China Agricultural University (CAU: East Campus).*

In collaboration with CAU, JIRCAS has been conducting research entitled "Development of technologies for food processing and distribution." Initiated in November 1997, this research aims to develop food technologies for better utilization and distribution of major food resources such as rice, soybean, and freshwater fishes. More specific objectives include quality evaluation of major food resources and development of new food ingredients, and improved preservation and distribution technologies for major food resources.

As purchasing power has increased with the drastic development of the Chinese economy so has the demand for a high-quality diet. While this is certainly true in urban areas, rural Chinese do not have direct access to the benefits of economic development. Indeed, the income differential between rural and urban workers has been steadily rising, a factor contributing to rural-urban migration, thereby altering the structure of the Chinese population. In an effort to reverse this trend and maintain economic development, the Chinese government put the industrialization of farming systems at the forefront of its national policy. The development of food processing technology is one way China hopes to execute the above national policy.

To solve the multiple problems the Chinese face on the food processing front, the government has developed extensive cooperative relationships with domestic food research organizations and the food industry, as well as with JIRCAS. Because almost all foods are manufactured using conventional procedures and techniques, without the benefits of modern science, one of the most pressing problems

for the food industry is the mechanization of traditional food processing.

As an important source of protein, the soybean, specifically tofu, is found readily throughout China. Chinese momen-tofu (cotton tofu), kinugoshi (silken tofu), and packed tofu, similar to their Japanese counterparts, are currently being mass-produced in some factories by Japanese mechanized equipment. However, unlike the tofu mentioned above, products peculiar to China, such as "tofu-skin" (sheet-like tofu), a kind of momen-tofu but with a relatively low water content (about 70%), are produced by the traditional methods and equipment. Since, under traditional methods, the product is manufactured at midnight and then sold the following morning due to its short shelflife, researchers are now attempting develop technology for processing mechanization and for shelf-life extension. To this end, CAU researchers are currently collaborating with JIRCAS, the National Food Research Institute, the Akita Research Institute of Food and Brewing, the Niigata Food Research Center, and other Japanese research organizations.

RESEARCH INFORMATION DIVISION

The Research Information Division fulfills three main responsibilities relating to research operations at JIRCAS. First, the Division collects and analyzes information pertaining to socio-economic conditions and the state of agricultural sciences in developing countries. Second, it attempts to formulate and coordinate collaborative research projects with public and private organizations in developing countries. In recent years, this role has grown in relative importance as JIRCAS has become increasingly involved in large-scale, comprehensive research projects with countries throughout the world. Finally, in an effort to coordinate rising flows of data to and from partner countries, the Division has assumed the responsibility of developing and operating information systems at JIRCAS.

The Division's research coordinators and senior scientists undertake these tasks from two distinct perspectives. The first is a strategic perspective focusing on critically important world regions, including China, other monsoonal areas of Asia, arid and semi-arid Asian areas, Africa, and Latin America. The second perspective focuses on particular issues, with an emphasis on global problems generated by environmental degradation, food insecurity, and imbalanced patterns of rural development. Combining these two perspectives, research coordinators in the Research Information Division conduct studies on agriculture in specific regions and consider the prospects for collaborative studies. They design and coordinate comprehensive projects in which scientists representing different disciplinary backgrounds can work together toward common goals. Thus far, eight major comprehensive projects have been implemented since the establishment of JIRCAS.

In 1994, JIRCAS launched its first comprehensive research project in Vietnam in an effort to promote improved efficiency in the combined farming systems currently used in the Mekong Delta region. Following the conclusion of Phase I of this project in 1998, JIRCAS initiated preparation for the implementation of Phase II to begin in FY 1999. The Division launched comprehensive projects on tropical brackish water ecosystems in Malaysia and sustainable agricultural technologies in northeast Thailand during 1995, and another comprehensive project on sustainable agro-pastoral rotation systems in subtropical Brazil during 1996. In FY 1997, two new comprehensive projects began, one targeting sustainable production and processing of major food resources in China and the other investigating new technological developments for soybean production and utilization in South American countries. Additionally, the Division has launched comprehensive projects on rice development in West Africa and farming systems in Indonesia in FY 1998.

The Research Information Division is also involved in analyzing global issues. In collaboration with the Food and Agriculture Organization (FAO) and other international agencies, the Division helped to develop a sophisticated world food model that can be used to project world food supply and demand and to simulate the effects of proposed policy changes. At the same time, findings derived from ongoing collaborative research projects at JIRCAS are often incorporated into forecast simulations. Currently, researchers are attempting to elaborate the model so that the impact of environmental changes and resource constraints can also be analyzed. In addition, researchers within the Division are studying rural development strategies, with particular emphasis on farming systems research, by reviewing recent development strategies and assisting researchers in the natural sciences who are involved in integrated rural development projects.

Another important task of the Division is to develop and operate the computer-based JIRCAS information system. Since 1996, the Division has been operating a comprehensive statistical database on agriculture, forestry and fisheries, containing data from many international agencies. The Division is currently developing a database of geographical datasets which can be used as basic materials for GIS-related studies. In addition, the Division maintains bibliographic and photo (slides) databases on tropical agriculture and other institutional information systems.

Photo: Crop market in Mosi, Tanzania

Finally, the Division works as the secretariat for the numerous international seminars and workshops that JIRCAS researchers conduct throughout the year. The largest is the JIRCAS International Symposium, which addresses a topic of central importance in agricultural research. In FY 1998, the International Symposium concerned "Postharvest Technology in Asia" and was attended by 230 participants from over twenty countries (see "Symposia and Workshops" section for additional details).

RESEARCH INFORMATION DIVISION TOPIC NO.1

Farming Systems Combining Agriculture, Animal Husbandry, and Fisheries in the Mekong Delta

It is essential for nations to produce sufficient amounts of agricultural commodities in order to achieve food security. In the Mekong Delta region of Vietnam, the economic policy Doi Moi has contributed to rapid economic growth through a unique agricultural system which combines rice cultivation, animal husbandry, aquaculture, and horticulture. JIRCAS implemented a five-year research project starting in 1994 that aimed to clarify the technological and socioeconomic structures of the farming systems and to specify and develop new technology necessary for higher productivity.

The Mekong Delta was formed about 10 thousand years ago at the mouth of the Mekong River. Covering roughly 4 million hectares, the region, except for small hills near the Cambodian border, is less than 1 m above sea level. Large scale flooding follows the rainy season and washes away damaging salt and acid sulfate, providing fresh fertile soil and fish. Depending on the topography, the Delta's soils range from alluvial to acid sulfate to saline. Houses line the banks of the well-developed canal network due to the high elevation and the convenience of waterway transportation. In addition, ponds are also dug for stocking fish and as a source of soil with which to expand farm areas.

The market-oriented economy under the Doi Moi policy has brought about a rapid increase in agricultural production, particularly in rice harvesting. The farming system, a type of compound agriculture, is based on rice cultivation but also includes livestock breeding, aquaculture and horticulture. These systems operate by cycling agricultural products through several stages of production in order to minimize waste, maximize benefits, and contribute to sustainable management. In one model, swine are fed with broken rice and rice bran produced locally. Waste products from the swine are then washed into fish ponds, raising fertility levels in the water and enhancing growth in cultured fish. To complete the cycle, water from the fish ponds is then diverted back into paddy fields, where the abundance of nitrogen and other elements contributes to more fruitful rice production.

The project was successful in obtaining practical information that will increase farming system efficiency and production. Researchers discovered that rice yields can be stabilized at high levels if logging is prevented by nitrogen dressing at the booting stage and by draining water for several days during the cropping period. Moreover, sheath blight, bacterial blight, blast, and red stripe were determined to be the main diseases constraining rice production in the Delta. To combat these diseases, researchers specified bacterial blight and blast resistance genes in rice and succeeded in transferring the genes to other varieties of rice. In addition, scientists eliminated swine parasites and thus decreased the time necessary for pigs to reach shipping weight. Finally, researchers clarified the physiological processes of growth and maturation in the giant freshwater prawn (*Macrobrachium rosenbergii*) so that seed production may be improved.

Photo: Example of an integrated farming system which combines rice cultivation, animal husbandry, aquaculture and horticulture (S. Matsui).

Mekong Delta farms average about 1 ha in size, larger than that of any other region in Vietnam. Since settlement of people to this area is relatively recent, there is not as strong a community structure as the Red River Delta in northern Vietnam, which has been settled for a comparatively longer period of time. Consequently, people in the Mekong Delta are not experienced in organizing themselves for infrastructure management, crediting, marketing, and so forth. Although the number of smaller sized or land less farmers is increasing as one negative effect of the Doi Moi policy, farmers utilizing farming systems maintain stable management of their farms.

To further develop Mekong Delta farming systems, JIRCAS research will focus on such areas as the stable production of better quality rice, the extension of integrated pest management of crops and fruit trees and the improvement of feed and hygiene for hog raising. In addition, a more advanced hog waste treatment system, a stable supply of prawn and fish seeds for aquaculture, and disease control in aquaculture will also be studied. Finally, communal cooperation in trade, water management, and crediting will be fostered. (S. Matsui)

RESEARCH INFORMATION DIVISION TOPIC NO.2

Coordinating multidisciplinary research on agriculture in the Mekong Delta

The first phase of international collaborative research on Mekong Delta farming systems with Cantho University (CTU) and Cuu Long Delta Rice Research Institute (CLRRI), Vietnam was recently completed. JIRCAS's first venture into international collaborative research, much of the project's success is owed to the cooperation of Vietnamese organizations as well as to the efforts of participants dispatched to the Mekong Delta.

The project originated with a visit to the Delta in 1991 by Tropical Agriculture Research Center (TARC) staff members, who were interested in the unique agriculture systems utilized in the region. Although individual farms were as small as 1 ha in area, farmers seemed to make good use of available resources through systems which consisted of rice cultivation, animal husbandry, fisheries and horticulture. In 1994 JIRCAS and the AFFRC initiated a research project entitled "Evaluation and improvement of farming systems combining agriculture, animal husbandry, and fisheries in the Mekong Delta." Since the project targeted crop, animal, fishery and socio-economic disciplines, researchers in these fields were dispatched on both long- and short-term assignments to Vietnamese counterpart institutes. It was decided that the entire project would be steered by a working group (WG) consisting of the directors of the relevant research divisions and the international research coordinator.

The role of working group is as follows:

1. The WG should always be aware that it is indispensable for the whole project to have a concrete objective that is aimed at by all participants from different fields of research. With the support of division directors, individual subjects should have clear targets that are compatible with the overall project objectives.
 - . project objectives
 - . implementation, dispatching and budget plans
 - . periodical review and evaluation
 - . public relation activities
2. Division directors should draft implementation and dispatching plans for specific research subjects and the budget should be proposed by the research coordinator, who is not associated with a specific research field. The proposal and the evaluation of research activities should be discussed openly.
3. Public relations are critically important for the development of the project. The WG must be responsible for such activities.
4. The research coordinator should always correspond with the dispatched researchers and collect and report important information to the WG and Director General. Discussions in the WG should also be announced to the dispatched researchers and the Director General .

Under the guidance of the working group, the project had the objective to clarify the technological and socio-economic structure of farming systems in the Mekong Delta and develop new technologies to improve the systems. To this end, JIRCAS dispatched 6 long-term and 47 short-term researchers in the fields of crop science, plant pathology, animal science, socio-economic science, and fisheries science during the project's 5-year duration. In return, JIRCAS received 23 counterpart researchers including administrators and workshop participants during the same period. Research results have been published by JIRCAS in 50 scientific reports and 16 articles. Some of these are contained in a book entitled "Development of farming systems in the Mekong Delta of Vietnam." (Vo-Tong Xuan and Shigeo Matsui, eds., H.M.C. Publishing House, Ho Chi Minh City, Vietnam).

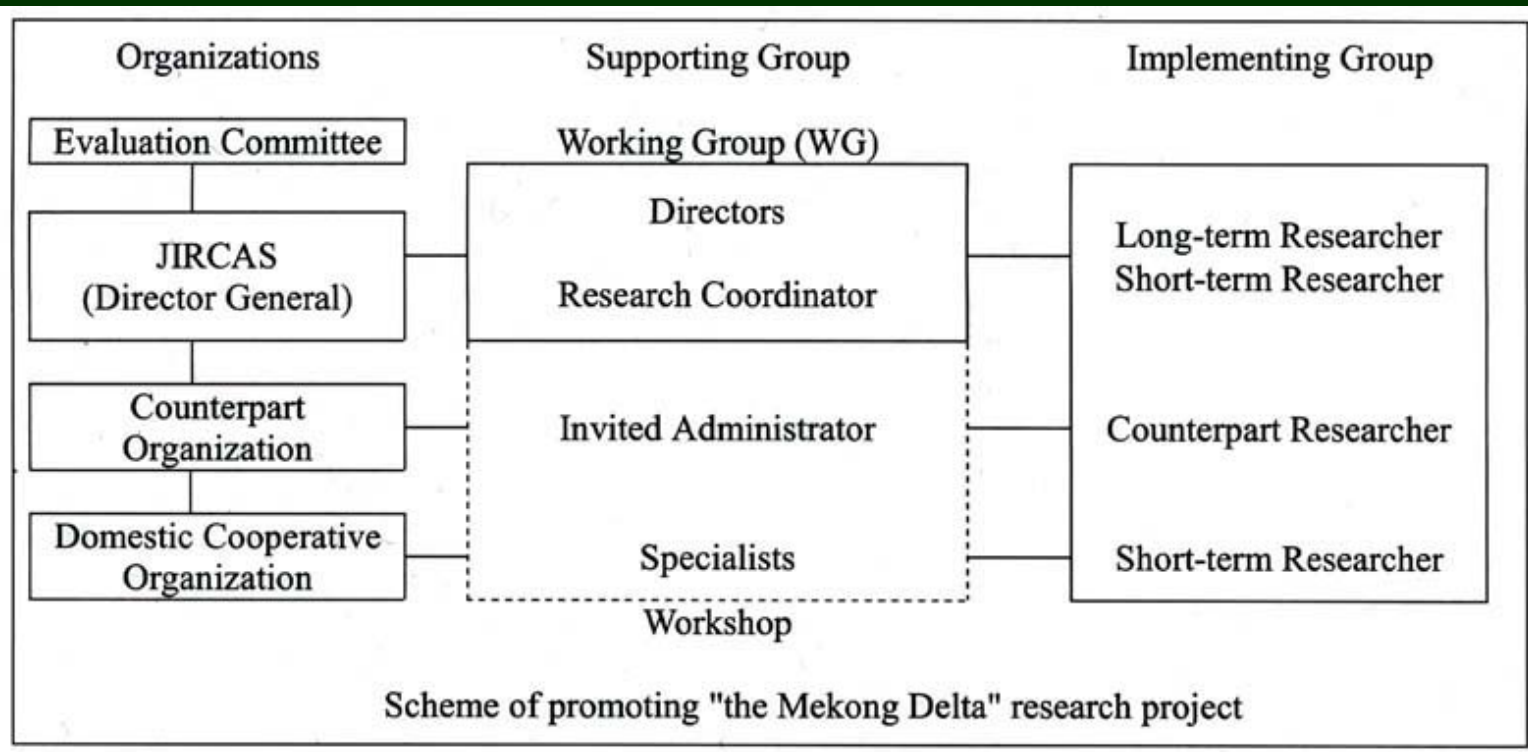

Following the successful completion of the first phase in March 1999, the second phase, entitled "Development of new technologies and their practice for sustainable farming systems in the Mekong Delta" was initiated and will run until 2003 .

No-tillage cultivation of soybean in South America

The soybean is an important crop serving human life, especially as a source of oil for human consumption, and as a protein source for livestock feed. Increases in soybean production have been very rapid compared with those of other major crops during the past three decades, and continuous growth is very important for the stabilization of the world food supply. Soybean production in South America, mainly in the MERCOSUR countries (Brazil, Argentine and Paraguay), amounts to approximately one-third of total world production, and thus the MERCOSUR countries play a major role as leading soybean export countries. However, it is generally recognized that disease and pest outbreak due to continuous cropping and soil erosion are adversely affecting soybean production in this region. In order to address these problems, JIRCAS has initiated a new research project entitled "Comprehensive studies on soybean improvement, production and utilization in South America." In this project, we place emphasis on multinational collaboration among South American countries through the exchange of scientists, joint organization of seminars and conferences, as well as the exchange of samples, materials and information. The project will run until 2006.

To commemorate the initiation of this project, a seminar entitled "No-tillage cultivation of soybean and future research needs" was held March 5-6, 1998 in Foz do Iguassu, Brazil and Yguazu, Paraguay under the joint organization of JIRCAS and the Centro Tecnológico Agropecuario en Paraguay (CETAPAR-JICA). This was the first JIRCAS seminar on soybean research held in South America. This seminar focused on no-tillage systems of soybean production, as this type of cultivation system, which may aid the alleviation of soil erosion, is rapidly expanding in major soybean producing areas in South America and is contributing to a stabilized yield of soybeans. Sixty scientists from 6 countries participated and exchanged views concerning the current situation and future prospects of no-tillage cultivation systems and discussed the potential demands and uses of soybeans. As pointed out by the contributors, many problems remain to be solved in order to achieve further successful application of this cultivation method. Among the problems which should be addressed by future research efforts are physical and chemical deterioration of soil, increased incidence of soil-borne diseases, increased dependence on herbicides and limited variation of crop combinations, all of these tend to be accelerated under no-tillage systems.

The proceedings of the seminar was published by JIRCAS in December 1998. The proceedings contains 11 papers as follows;

- 1) Historical review of no-tillage cultivation of crops (Rolf Derpsch);
- 2) Effects of no-tillage system on chemical and physical characteristics of soil in Paraguay (Cantalicio Paredes Benegas);
- 3) Effect of no-tillage on physical and chemical characteristics of soil in Argentina (Rodolfo C. Gil); 4) Disease management in no-tillage soybean systems (Silvia Vallone);
- 5) Control of weeds in no-tillage cultivation (Dionisio Luiz Pisa Gazziero);
- 6) Establishment of no-tillage system of soybeans in Paraguay (Yoshiro Seki, Wataru Asada and Ken Hoshiba);
- 7) Cropping systems in no-tillage cultivation (Jose Eloir Denardin and R. A. Kochhann);
- 8) An innovative cropping system of soybean: agro-pastoral system in Brazilian Savannas (Manuel Macedo, Jose Bono, Armindo Kichel, Ademir Zimmer and Tsutomu Kanno);
- 9) Role of soybean with reference to global food supply and demand (Hideki Ozeki and Yoshihiko Sugai);
- 10) Potential uses of soybean as food in South America (Mercedes C. Carrao-Panizzi);
- 11) Potentialities for industrial utilization of soybean (John P. Cherry).

BIOLOGICAL RESOURCES DIVISION

Many developing regions of the world are now faced with the need to increase and stabilize agricultural production through methods compatible with the preservation of the environment. Agricultural technologies that optimize the use of biological resources will play an important role in determining whether or not this objective can be met. In response to these concerns, the Biological Resources Division has placed considerable emphasis on collaborative on-site breeding projects in foreign countries and on biotechnology in Tsukuba. The objective of such projects is to utilize available genetic resources and biotechnological procedures to develop new crop varieties.

We have carried out collaborative projects with two centers supported by the Consultative Group on International Agricultural Research (CGIAR). In cooperation with the International Rice Research Institute (IRRI) in the Philippines, the Division has been studying rice blast resistance. We have clarified the rice blast resistant genes in IR varieties that are being used worldwide without the information of resistant genes. This information is prerequisite for the development of all types of durable resistance, for example the pyramiding of major genes and the accumulation of minor genes. We have developed isogenic lines with a few rice blast resistant gene isogenic lines that have several genetic backgrounds and dozens of resistant genes, with more soon to be completed. Among them IR49830-7-1-2-2 and IR24 background isogenic lines can be put into practical use to reduce the usage of fungicide and the damage of blast for long periods. Working with the International Maize and Wheat Improvement Center (CIMMYT) in Mexico, the Division has a project on marker-assisted selection, which may contribute to gene-pyramiding and increased breeding efficiency. In addition, different sources of resistance genes to *Fusarium* head blight (FHB) are being mapped using RFLP and SSR markers.

Under the guidance of JIRCAS integrated projects, our researchers helped develop soybean varieties resistant to viral diseases and nematode pests at the Soybean Institute of the Jilinan Academy of Agricultural Sciences in the People's Republic of China (PRC). The soybean mosaic virus and cucumber mosaic virus (soybean stunt strains) were isolated from soybean plants in the northeast region of China, Inoculation tests suggested that the B strain of the soybean mosaic virus was a dominant soybean virus disease in this region. In the rice program, several researchers have been working with the Yunnan Academy of Agricultural Sciences to analyze genes that provide resistance to blast, bacterial leaf blight and rice stripe virus diseases, and cool-weather tolerance at the booting stage in rice strains. Together with visiting scientists, researchers have also attempted to screen genetic resources that may provide salt tolerance among local varieties of rice from Vietnam.

In the field of soybean production in tropical and subtropical areas, one of the most severe problems is damage caused by insects. As highly resistant germplasms have not been found except for some moderate level resistant ones, the pyramiding of moderate level resistance to *Spodoptera litura* (the most important foliage feeder of soybean in Indonesia) by back-cross was carried out in cooperation with the Research Institute for Legume and Tuber Crops (RILET) in Indonesia. As a result, higher resistant soybean lines to *S. litura* were selected from progeny of the hybrids between moderate resistant germplasms.

Photo: *Damage caused by Fusarium head blight in wheat spikes (Photo: T. Ban).*

The molecular biology group of the Division, including several visiting scientists, has recently utilized biotechnological methods to study tolerance to environmental stresses such as drought, salinity, and freezing in higher plants. In particular, the researchers are examining how to use genes and regulatory factors in the production of environmental stress tolerant transgenic crops. They isolated a number of genes that function in stress tolerance using *Arabidopsis* and cowpea plants and analyzed the regulatory transcription factors of these genes in the stress response. Many genes encoding the transcription factors have been isolated that control the expression of the stress tolerance genes. They also identified regulatory elements in promoters that control stress-responsive gene expression. Using the gene's encoding transcription factors and the stress-responsive promoters, they have succeeded in improving multi-stress tolerance to freezing, drought, and salinity in transgenic *Arabidopsis* as a model. The existence of similar regulatory systems has been reported in other crop plants such as rice, tobacco, and cowpea. These observations suggest that both the gene for the transcription factor and the stress-responsive promoter can be used to improve the stress tolerance of agriculturally important crops by gene transfer. Their research will contribute to the development of commercial crops capable of withstanding potentially damaging environmental stresses, perhaps thereby helping to mitigate problems relating to the food crisis and environmental degradation in developing countries.

Evaluation of doubled haploid breeding Scheme in Wheat improvement

Practical breeding programs for self-pollinating crops, such as wheat (*Triticum aestivum* L.), must include a process of genetic fixation for uniformity of agronomic traits after genetic recombination to increase variations. Pedigree selection (PS) is the conventional method of achieving genetic recombination in each generation. Repeated pedigree selection of heterozygous materials can increase uniformity, but many generations are required to reach homozygosity in loci associated with agronomic traits ([Photo.1](#)). The artificial production of haploid plants followed by chromosome doubling offers the quickest method for developing homozygous breeding lines from heterozygous parental genotypes in a single generation. The doubled haploid (DH) method has an obvious advantage in that yield evaluation can begin earlier and varietal development is speeded up. This method also has the great advantage of increasing the efficiency of selection because DH lines do not express dominance variation and segregation within lines.

A technique for producing wheat haploids using ultra-wide crosses followed by embryo rescue has been developed over the last two decades. Significant technical advances have been achieved familial species and applying plant growth regulators. Efficient crossing procedures were developed using stored pollen and detached-tiller culture. They enabled scientists to avoid having to synchronize flowering times of both parents and resulted in considerable savings in terms of labor and space required for growing parent plants.

In this study, field performance of wheat lines selected by the DH and PS methods from three F1 crosses were compared with the aim of evaluating the doubled haploid method in wheat breeding programs ([Fig. 1](#)). Yield evaluation of each group of the top ten wheat lines selected by DH and PS methods was performed at the F6 generation of PS lines along with DH lines in a two-year field experiment. It took only two years from the planting of wheat materials for DH production to the planting of selected DH lines for yield evaluation. There was no significant difference in grain yield between DH lines and PS lines selected from an F1 cross whose parental varieties were closely related in their pedigrees. In two crosses with low coefficients of parentage and large variation in their progenies, grain yield of selected DH lines was significantly lower than those of selected PS lines. These results confirm that the DH method has the advantage of saving time in obtaining recombinant inbred lines ready for yield evaluation and of increasing selection efficiency. However, a larger DH population is required to achieve the same level of genetic advance with the PS method in crosses containing greater genetic variation.

The application of a doubled haploid breeding scheme with selected breeding objectives can thus complement conventional breeding programs and accelerate the release of new varieties in developed countries, as well as in developing countries where rapid varietal development is critical for sustainable wheat production systems.

ENVIRONMENTAL RESOURCES DIVISION

A recent estimate suggests that the world population could reach 6.3 billion by the year 2000 and 10 billion by 2050. To feed this ever-increasing population, existing agricultural land is likely to be subjected to a higher intensity of cultivation in populous areas, and farmland development is likely to be extended to areas marginally suited for agriculture. Trade liberalization in recent years has led to a sharp increase in commercial crop importation and is stimulating production in exporting countries. This may result in excessive load to farmland soils as well as the continuation of single cropping and deforestation in many countries. Past experience has shown us that these practices accelerate farmland degradation and desertification on a global-scale. Such drastic changes in land use would cause climatic transformation over extended regions and bring about unpredictable constraints to existing agricultural and forest ecosystems.

From the middle of this century, patterns of land utilization have been changing due to population expansion. These changes, along with a rapid increase in fossil fuel consumption, have had tremendous impact on the atmosphere through intensified emission of carbon, nitrogen, and sulfur gases. If the present level of consumption continues, CO₂ concentration will increase by 0.5 percent per year and double by the middle of the next century. The 1995 International Panel on Climate Change (IPCC) report suggests that a two-fold increase in CO₂ concentrations could cause an increase in mean global surface temperature by about 2^oC by the year 2100. Furthermore, research has shown that the atmospheric concentrations of other greenhouse gases such as methane and nitrous oxide have also increased greatly within the past two decades. If the effects of these trace gases are jointly taken into account, global warming is estimated to take place more rapidly than in the case where the effects of CO₂ are considered alone.

To address these problems, the Environmental Resources Division is organizing research to identify and develop technologies for the improvement of agricultural activities compatible with the environment and the ecosystems, such as arid lands, wetlands, sloped lands and degraded lands. Other projects are aimed at developing technologies for sustainable agriculture through analyzing mechanisms of nutrient cycling within agro-ecosystems and for reduction of polluting substances to conserve the global environment.

Suppression of nitrification and nitrous oxide emission by a tropical grass

Nitrification is the reaction in which ammonium-N is changed into nitrite-N and nitrite-N is changed into nitrate-N in soil by microorganisms. By controlling nitrification, it is possible not only to increase the nitrogen absorption efficiency of plants but also to minimize the nitrogen loss by leaching and volatilization. It was reported that the amount of nitrate-N accumulated in the soil where a tropical grass grew seemed to be smaller than that in the soil where other tropical grasses grew. The objective of this study was to demonstrate the ability of this tropical grass to suppress nitrification in soil and nitrous oxide emission to the atmosphere.

Three tropical grasses (*Brachiaria decumbens* (Bd), *B. humidicola* (Bh), and *Melinis minutiflora* (Mm)) supplied by CIAT were grown for 8 weeks in Wagner pots and soils were sampled. Ammonium-N was applied to the sampled soils and the nitrification process was observed. In soils with Bd and Mm treatments, the content of ammonium-N started to decrease 4 days after ammonium-N application and nitrification started rapidly. However, the content of ammonium-N in the soil with Bh treatment did not change until the 12th day and there was a lag period before the onset of nitrification. The results indicate that only *B. humidicola* suppressed nitrification in soil.

Simultaneously, nitrous oxide emission from soil was measured. From soils with Bd and Mm treatments, nitrous oxide emission was observed remarkably. However, nitrous oxide emission from the soil with the Bh treatment was low throughout the experimental period. The amount of nitrous oxide emitted from the soil with the Bd and Mm treatments were 31.0 and [29.3¼g-N/m²-hr](#), respectively. However, that from the Bh treatment was [5.0¼g-N/m²-hr](#) and 1/6 smaller than that from the Bd and Mm treatments. If cannotread [Click here](#)

In another experiment, it appeared that *B. humidicola* suppressing the multiplication of ammonium-oxidizing bacteria specifically but had no effect on the nitrite-oxidizing bacteria. Of the two nitrification processes, it is assumed that the process in which ammonium-N is changed into nitrite-N is a rate-determining process. By suppression of the multiplication of ammonium-oxidizing bacteria, *B. humidicola* suppresses nitrification in soil and nitrous oxide emission to the atmosphere (*Fig. 1*). Generally it is considered that tropical grasses preferentially use nitrate-N compared to ammonium-N. Among the *Brachiaria* species, it is assumed that only *B. humidicola* can utilize both forms of nitrate-N and ammonium-N and that this function of *B. humidicola* may lead to an efficient use of nitrogen in soil.

Native pastures are widely distributed in various countries of the tropical zone but their productivity is very low. In order to increase livestock production, if *B. humidicola* could be introduced, it would be possible to decrease the nitrogen input for agriculture in addition to preserving the environment and ecosystems.

Effects of depth on the site of NO and N₂O production in upland Soil on emission rates to the atmosphere

Driven by the necessity of increased food production, the rate of chemical fertilizer application to arable land is increasing rapidly in developing countries. With this increase comes the heightened possibility of harmful effects on the environment. Two chemical compounds commonly found in fertilizer and possessing potential negative side-effects for the environment and atmosphere are nitric oxide (NO) and nitrous oxide (N₂O). NO is known to be a cause of photochemical atmospheric pollution, acid rain, and is linked to increased tropospheric ozone, one of the green house effect gases. N₂O is a substance that causes global warming and stratospheric ozone layer destruction. Because its damaging influence is estimated to be at a level equal to that of fossil fuel combustion, arable land should not be overlooked as a source of these gases.

Using numerical model analysis and a laboratory experiment, we focused on the effects of depth on fertilizer placement in an attempt to develop a method for mitigating the emissions of these gases from upland fields. The simulation model was prepared based on pre-existing survey data of NO and N₂O soil concentration profiles in the upland fields of Andosol, a volcanic ash soil. It was assumed that the soil conditions are uniform in the horizontal direction; gas diffusion in soil was considered as a one-dimensional vertical flow, fundamentally following Fick's law. In this model, the effects of the depth of gaseous production in soil on concentration profiles and emission rates were estimated.

The estimated results were verified in the laboratory experiment with soil columns. Each soil column, 1 m in height and 0.194 m in diameter, was made of topsoil from Andosol and fertilized with ammonium sulfate at a rate of 20 gNm⁻² at a specific depth (0-10, 5-15 or 10-20 cm). The soil was filled at the bulk density of 0.60 and 0.75 g cm⁻³ at the depth of 0-20 cm and 20-100 cm, respectively. Then content in the soil was set at 49 (q0,9) o/o and the soil columns were then put in a thermostatic chamber (22.2 q 0.6 °C) without a water supply. After two weeks, the ground water level was set and kept at a depth of 100 cm. Soil gas was sampled from PVC tubes in the soil and the gas emission rate was measured using a closed-chamber method.

In the model analysis, we obtained the results that (1) the NO concentration gradient near the soil surface became gentler and the rate of NO emission became lower with the production depth, while (2) the depth of N₂O production had less effect on the emission rate (Fig.1). Results supporting (1) and (2) were obtained by the laboratory experiment. The rate of NO emission from columns fertilized at 10-20 cm depth was reduced to almost the same rate as that of the unfertilized column and to 0.9-20 % of that from the fertilized at the depth of 0-10 cm (Fig.2). However, a remarkable effect of the production depth was not observed in N₂O.

Our findings demonstrate that there is a strong possibility that NO emission from arable land can be mitigated by applying fertilizer deeper into the soil. Because the depth at which the NO emission was mitigated corresponds to the depth utilized in some conventional deep fertilizer applications, the practical application of our findings does not seem difficult. The deep application of fertilizer should be reconsidered not only because of its high efficiency of fertilizer utilization, but also because of its potential for mitigating NO emission.

The phenomena of gaseous production and consumption depend on various soil conditions. We obtained the results mentioned above using Andosol soil, which has a comparatively high gaseous conductance under ideal conditions for NO production, especially in deeper soil. It is our contention that the same or even more considerable effects may be expected under other conditions.

At present, our knowledge regarding possible reductions of NO and N₂O emissions are too uncertain to justify quantification and implementation of strategies designed to mitigate emissions, such as the use of inhibitors, and changing cultivation or land use. This is because the mechanism and factors affecting production and consumption of NO and N₂O in soil during nitrification and denitrification are not clear. In the future we will address the problem of quantifying the effects of each factor on NO and N₂O production and consumption.

CROP PRODUCTION AND POSRHARVEST TECHNOLOGY DIVISION

Although world population growth rates have declined steadily since 1970, the global population will continue to increase by 90 to 100 million people annually for the next several years. Some 95 percent of the growth will occur in developing regions, where food deficits are already severe, and where alternative employment opportunities and economic growth are limited. Clearly, population growth will provide the primary impetus behind growing demands for food. Yet, food markets will also be influenced by shifts in the purchasing power of local consumers. As development proceeds, changing patterns of consumption may dramatically increase demand for greater varieties of vegetables, fruits, and meats.

For these reasons, self-reliance in food, rather than complete economic self-sufficiency, will become an increasingly important objective in developing regions. There are no definitive models for achieving this goal. However, various methods exist for ensuring self-reliance within the particular natural and environmental constraints of each country.

The Crop Production and Postharvest Technology Division promotes research projects on topics ranging from production and storage to the processing and marketing of agricultural products. Our research activities encompass a variety of disciplines including agronomy, plant protection (pest, disease and weed control), agricultural mechanization, irrigation, drainage, cropping systems, food storage, post harvest technology, farm management and agricultural economics.

Because the total area of arable land in the world is limited, we believe that sustainable production of agricultural products can be achieved only by increasing overall productivity. While various technological problems must be resolved, productivity growth must be pursued in ways compatible with the preservation of the natural environment. Therefore, it is necessary to reduce as much as possible the amount of chemical inputs in agricultural endeavors. To achieve this, research should address the need for integrated pest management through biological control systems and better utilization of information. Topics requiring additional attention include ecological studies of insect pests and their natural enemies and the development of predictive methodologies for outbreaks of insects and diseases.

Far too often the problems of feeding the world's hungry is conceived in terms of producing sufficient food. Equally pressing problems related to preservation and distribution, issues which affect food products between harvest and consumption, are frequently neglected. Post-production operations of agricultural and horticultural products include a wide range of functions necessary for supplying good quality food, reducing transaction costs, and raising domestic welfare. It is necessary to stress postharvest studies of agricultural products, such as quality improvement, safety, the extension of shelf life, and the control of the presence of insects and microorganisms in foodstuffs. These constitute important objectives of this Division.

Finally, sustainable production of agricultural commodities can only be supported by the development of sustainable markets. Technology for enhancing the value of agricultural products is being developed with the goal of increasing incentives for farmers to promote sustainable production. Economic studies are requisite in furthering the development of target countries.

Pathogenicity of *Xanthomonas oryzae* pv. *oryzae* strains in Vietnam

Bacterial leaf blight (BLB) of rice caused by *Xanthomonas oryzae* pv. *oryzae* (Xoo) is one of the major constraints on rice production in Vietnam, especially in the rainy season. Although BLB is very severe in the northern part of Vietnam as well as in the Mekong River Delta (MRD), the pathogenic variability of Xoo and varietal resistance have not yet been investigated in detail.

Because the cultivation of resistant varieties is the most promising method to control BLB, characterizing the virulence of the causal bacterium Xoo and surveying the distribution of each race are essential. Therefore, we collected 52 isolates of Xoo throughout Vietnam and examined their variability in virulence based on the reactions of the 18 differential varieties. As a result, 52 isolates were divided into six groups (races) (Table 1). Among the races, Race A predominated with more than 80% of the isolates classified into this race, one which was distributed throughout Vietnam. Although the other nine isolates, belonging to Races B to F, were minor races, the pathogenic characteristics of these six races were relatively similar. Therefore, the diversity in the pathogenicity of the Vietnamese BLB strains may be low based on their virulence to differential varieties.

Almost all the Vietnamese rice varieties were susceptible to the predominant Race A. However, some Race A isolates showed different reactions to varieties cultivated in Vietnam. Furthermore, the pathogenicity of the isolates tested differed slightly depending on the sampling location.

Although Races B and D were avirulent to IR 20, Race D was virulent to IR-BB4, which carried the resistance gene Xa-4 as in the case of IR20 (Table 1), thus exhibiting that IR20 may harbor a resistance gene or genes to Race D. The rice cultivar IR36 may also harbor an additional resistance gene or genes to Race B, though the genetic background of IR36 to BLB has not been studied yet. Furthermore, some local varieties and wild rices may also harbor unknown resistance gene(s). Based on these results, the pathogenic diversity of the isolates in Vietnam seems to be complex despite their simple pathogenic characteristics to the differential varieties.

Most of the local varieties tested were generally susceptible to the Vietnamese isolates. Before the introduction of agronomically improved but susceptible rice varieties, BLB was not a serious disease under traditional cultivation practices even though the local varieties were susceptible. Recently, BLB has been severe in some areas, mainly because of the recent adoption of intensive cultural practices, such as high-density direct seeding (more than 200 kg/ha), the utilization of nitrogen-saturated fertilizers, and the cultivation of three crops per year - a practice introduced after modern, improved rice varieties increased the area cultivated.

In this study, we observed that some differential varieties, IR-BB5 (Xa-5), IR-BB7 (Xa-7) and Asominori (Xa-17), were resistant to all the isolates tested, while IR-BB3 (Xa-3) and IR-BB21 (Xa-21) were susceptible only to four and one isolates, respectively. Therefore, a breeding program should be initiated to transfer these resistance genes from differential varieties to high quality Vietnamese rice varieties to control the disease effectively.

Antioxidant and antimutagenic properties of local agricultural products in Thailand

A wide variety of indigenous plant species are utilized for agriculture and daily consumption in Thailand. Many of these species maintain a long tradition of use in folk remedies. Tropical plant species are known to be rich in phytochemicals that exhibit various biological functions, such as vitamins, terpenoids, flavonoids, alkaloids, organosulfur compounds, and pigments. It has been suggested that many local Thai agricultural products may play an important role in the prevention and/or cure of human chronic diseases as well as cancer. Studies on the biological functions of edible plants in Thailand may be able to elucidate their role in a natural, functional diet. Moreover, information on plant biological functions may contribute to the improvement of public health in Thailand and other tropical countries. In addition, the widespread consumption of such local agricultural products would most likely elevate and stabilize local Thai farmer incomes. In this research, a number of local agricultural products were examined for two important biological functions, antioxidant activity and antimutagenic activity, mainly under the JIRCAS Visiting Research Fellowship Program at Tsukuba from October 1996 to September 1998.

After collecting forty-eight samples of edible plants from several local markets in Thailand, the edible portions were immediately freeze dried and extracted with 80% methanol (methanolic extract). The antioxidant activity of the methanolic extracts was measured by the beta-carotene bleaching method, which is based on the inhibition of discoloration of beta-carotene coupled with the peroxidation of linoleic acid. Butylated hydroxyanisole (BHA) was used as a standard antioxidant. More than 70% Thai plant species showed high antioxidant activity, while only one-third of common edible plants in Japan exhibited high activity ([Photo 1](#)). In particular, three plant species (4 samples) showed significantly potent activity. Pak kra doon (*Careya sphaerica* Roxb.), a leafy vegetable, exhibited the highest activity (121.0 mg BHA equivalent/g), and the leaf of Pak sa meg (*Syzygium gratum* Wall.) and the fruit and the leaf of Kra thin (*Leucaena leucocephala* de wit) showed high activity (40.2, 38.8 and 44.7 mg BHA equivalent/g, respectively), as well.

The antimutagenic activity of the methanolic extracts was determined by an Ames test in the presence of the methanolic extracts, and performed with *Salmonella typhimurium* TA98 (frameshift mutant) as a tester strain and 3-amino-1, 4 dimethyl-5H-pyrido-[4,3-b]indole (Trp-P-I) as an indirect-acting mutagen. The number of *his*⁺ revertant colonies were counted and expressed into a percentage of antimutagenic activity, after subtracting spontaneous revertants. Several plant extracts have a potent inhibitory effect on the mutagenicity of Trp-P-I. The methanolic extracts from 1.25 mg of freeze-dried Pak pai (fragrant knotweed; *Polygonum odoratum* Lour.), a common condiment in Thailand and Vietnam, suppressed 96% of the mutagenicity of 50 ng Trp-P-I, followed by Pak chee (coriander; *Coriandrum sativum*; 94%), Hoom yae (*Trachyspermum roxburghianum* Craib; 92%) and Pegah (Indian trumpet flower; *Oroxylum indicum* Vent.; 90%).

The antimutagenic properties of two Thai gingers, fingerroot and galanga ([Photo 2](#)), were also investigated. These gingers are commonly consumed in Thailand as spices or condiments. The methanolic extracts of fingerroot and galanga showed substantially potent inhibitory effects to the mutagenesis induced by Trp-P-I of 97 to 98% at a concentration of 0.3 mg/plate. Four active compounds from fingerroot and two active compounds from galanga were then isolated to determine their chemical structure. The compounds obtained from fingerroot were identified as chalcone derivatives and flavanone derivatives and exhibited high mutagenic inhibition in a range of 90% to 95% at a concentration of 25 mg/plate. Compounds from galanga were identified as phenyl propanoid derivatives and showed less antimutagenic activity than the fingerroot compounds, 21% and 51%, respectively, at a concentration of 25 mg/plate. All the isolated compounds remained active as antimutagens after heat treatment at 105°C for 15 min, which is considered to be important for food ingredients. Fingerroot and galanga, both important edible plant spices, may play a role in cancer chemoprevention, and, may have potential as effective functional foods.

CROP PRODUCTION AND POSTHARVEST TECHNOLOGY DIVISION Topic3
Quality evaluation of Khao Dawk Mali 105, an aromatic variety of rice from northeast Thailand

Since world rice production exceeds demand, rice farmers must produce rice that follows global consumption trends. With a stronger aroma than ordinary rice, aromatic rice has been very popular in Southeast Asia and has recently gained wider acceptance in Europe and the United States. One such variety, Khao Dawk Mali 105 (KDML105), is mainly produced in northeast Thailand and is increasingly in demand in both domestic and international markets due to widespread consumer appreciation of its high quality. Although there is an urgent need for increased production, infertile and drought-stricken sandy soil has hampered such efforts. Unstable rainfall at the beginning of the rainy season and transplanting labor shortages are other factors destabilizing the production of KDML 105. In addition, since an objective evaluation for this variety of aromatic rice does not currently exist, trade of counterfeit KDML 105 has been rampant.

In Japan, rice is distributed as brown rice, which can be germinated, thus presenting adequate information about its variety. Yet, in Southeast Asia, mostrice is distributed as milled rice, which cannot germinate. Though evaluating similar varieties of milled rice with conventional methods, such as the length-width ratio, are inadequate, DNA based cultivar identification methods like microsatellite analysis (e.g. RAPD and AFLP) could be very useful rice variety evaluations. Thus, there was a need to develop a rapid and simple DNA extraction method for milled rice. We developed such a method to remove starch and protein, the main components of milled rice, by a freeze-thaw cycle. The method uses a single grain for checking the adulterate and, from that grain, recovers 200 ng of DNA. Taking 3 hours and lacking any harmful reagents, this rapid DNA extraction method called the "freeze-thaw" method was combined with a PCR-based microsatellite analysis of KDML 105 (Fig.1). This is a more reliable method for identifying rice varieties than the observation of morphological characteristics.

Furthermore, the potent volatile and aromatic compound in the aromatic rice was identified as 2-acetyl-1-pyrroline (AcPy; Fig.2), and the concentration of AcPy was correlated to aroma quality of the aromatic rice. While conventional quantitative analysis of AcPy was carried out by utilizing a large sample, by applying the GC/MS/SIM method, the sample is reduced by an amount of 0.5g. (Fig.2) Although it is commonly maintained that the aroma quality of KDML 105 depends on growth conditions, especially growth area, there is no direct information proving this conclusion. Accordingly, much more work is urgently needed concerning the objective evaluation of KDML 105. As the main variety of rice under production in northeast Thailand's most important industry, more research is required to improve the quality of KDML 105.

CROP PRODUCTION AND POSTHARVEST TECHNOLOGY DIVISION Topic4
Multiple herbicide-resistant *Limnocharis flava* (L.) Buchenau in Malaysia

2,4-D and sulfonylurea herbicides, such as bensulfuron-methyl, are widely used by farmers in Malaysia to control broad-leaved weeds in paddy fields. In the Muda area, the largest granary area in Malaysia, the former has been widely used since the early 1970s and is still popular today. The latter was introduced to Muda farmers in 1988.

Acetolactate-synthase (ALS) inhibitors, including sulfonylurea herbicides, are used widely because of their high control efficacy on broad-leaved weeds, low mammalian toxicity, and low herbicide injury in many crops. In recent years, however, ALS-inhibitor-resistant biotypes have been reported in many weed species in numerous countries .

At the Malaysia Agricultural Research and Development Institute Seberang Perai Station (MARDI S.P.), a rice breeder observed that *Limnocharis flava* in his experimental field was not killed by the application of 2,4-D and bensulfuron-methyl, a kind of sulfonylurea herbicide. This study was conducted to evaluate the susceptibility to 2,4-D and bensulfuron-methyl in *L. flava* collected from MARDI S.P. and other locations on the west coast of Peninsular Malaysia, and to develop effective control methods against the weed.

MARDI plants were not killed by 2,4-D at the recommended application rate. On the other hand, susceptible plants collected from an abandoned paddy field in Lahar Ikan Mati were completely killed by 2,4-D even at 1/16th the recommended rate. To determine I50 (50% inhibition dose) values, we utilized a logistic curve described by

equation (1):
$$Y = C + \frac{D + C - f \times x}{1 + e^{(x-a)}}$$

Equation(1) was fitted to the relationship between dry weight of the weed and 2,4-D dosage by the non-linear least square method. The I50value in MARDI plants was 0.94 times the recommended rate, while it was 0.02 times in Lahar Ikan Mati ramets (Fig.1). An approximate difference of 50 times in I50 value was observed between the two collections. Similarly, the I50 value for bensulfuron-methyl in the MARDI collection was calculated at 28. 1 times the recommended rate. These results confirmed the development of a multiple herbicide-resistant biotype (resistant to 2,4-D and bensulfuron-methyl) of *L. flava* in the weed population in MARDI S.P. The discovery of bensulfuron-methyl resistance in this study is expected to be the first report on an ALS-inhibitor-resistant biotype in paddy weeds in tropical Asia.

In a field study utilizing various seedling rates of cultivated rice, it was determined that the density of rice seedlings strongly affected the growth of multiple herbicide-resistant *L. flava*. The study established a linear relationship between the density of rice seedling in a logarithmic scale and the dry weight of the weed in an ordinary scale. Moreover, the results suggest that an adequate density of rice seedlings can be an effective means of control for this multiple herbicide-resistant weed in an integrated weed management system.

Except for the MARDI collection, only the Seberang Perak Rice Estate collection was resistant to 2,4-D and not one of the 12 collections from the west coast of Peninsular Malaysia was resistant to bensulfuron-methyl. Conditions where herbicides represent the only form of selection pressure, however, are favorable to the development of herbicide-resistant biotypes. Such conditions are often observed in unmanaged fields in Malaysia, that is, in vacant areas in fields caused by poor rice germination (Photo.1). Therefore, extensive infestation of herbicide-resistant weeds would become unavoidable if vacant areas in fields were left untreated.

As there are few or no alternative herbicides to control resistant biotypes, multiple resistant weeds are of great concern to farmers. If the multiple resistant *L. flava* were to go unchecked, the economic impact would be great. Fortunately, bentazone was able to effectively control this multiple herbicide-resistant biotype. The use of a single type of herbicide, however, may give rise to the risk of additional herbicide resistance. Therefore, integrated weed management becomes much more important in the control of herbicide-resistant weeds.

ANIMAL PRODUCTION AND GRASSLAND DIVISION

In developing countries, domesticated animals contribute to the betterment of people's lives. Animals not only produce meat milk and hide, which are essential in daily life and are an important source of income, but also generate draft power for tillage and transportation and produce wastes for use as fertilizer and fuel. Despite these benefits, livestock production remains at low levels throughout the developing world due to constraints such as low genetic potentials, poor quality feeds, disease prevalence, harsh climatic conditions, and management inexperience.

The Animal Production and Grassland Division carries out research aimed at achieving sustainable increases in animal production without generating adverse environmental consequences. In order to reach this goal, the Division seeks to enhance the productive capacity of natural resources, manage grasslands to secure feed resources, enhance the utilization of agro-industrial by-products, control invasive animal diseases, and improve management practices in developing regions of the world.

During Fiscal Year (FY) 1998, one overseas collaborative research project and two supporting projects in Tsukuba moved toward successful conclusion. The first project involved cooperation between Division researchers and scientists from the Malaysian Agriculture Research and Development Institute (MARDI) to improve local raising methods of small livestock. The two domestic research projects were carried out to identify endophytic fungi in pasture plants in tropical regions and their utilization in plants via biotechnological methods. Moreover, a Division researcher dispatched to Cantho University in Vietnam until the end of FY 1997 completed research concerning the *Ascaris* infection in swine in the Mekong Delta and the application of anthelmintic.

In addition to these projects, four long-term international research projects lasting from two to five years are currently underway. Division researchers are working with the Thai Department of Livestock Development (DLD) to improve cattle production with the feed resources available in northeastern Thailand. The cooperative research on agro-pastoral systems being carried out with the National Center for Research on Beef Cattle (CNPGC-EMBRAPA) and the National Center for Soybean Research (CNPSo) in Brazil focuses on the sustainable management and utilization of grasslands and the analysis of raising technology of small livestock, respectively. Finally, collaborative research on the role of the [TNF- \$\alpha\$](#) gene in trypanosomiasis began in 1998 with the International Livestock Research Institute (ILRI) in Kenya.

In addition to long-term projects, the following studies were carried out by researchers on short-term assignments of one to three months: 1) studies on the nutritive requirements of tropical ruminant and evaluation of nutritive value in ruminant feeds in Thailand with the Khon Kaen Animal Nutrition Research Center and DLD; 2) studies with Cantho University in Vietnam on environmental pollution caused by hog production in farming systems in the Mekong Delta; 3) research on the physiological characteristics of forage grasses in agropastoral systems in Brazil at CNPGC; 4) an evaluation of the feed value of corn stalk and agricultural by-products with the Chinese Agricultural University in northern China; 5) studies on the acute phase response in [TNF- \$\alpha\$](#) deficient mice after *Trypanosome congolense* infection conducted with ILRI in Kenya; 6) studies on the relationship between fertility and grassland vegetation in the steppe soils of central Asia with the Kazakh Institute of Agriculture (KIA); 7) investigation of the production of cloned sheep in central China; and 8) studies of methods for sustaining pasture plants in South America in collaboration with the International Center for Tropical Agriculture (CIAT) in Colombia.

The Division receives numerous requests from developing countries to pursue collaborative research, primarily concerning the incorporation of biotechnological applications and enhancement of overall levels of research. In order to address such needs, the Division has been promoting basic research on JIRCAS's Tsukuba premises in support of overseas activities. Beginning in 1999, one domestic project will investigate nitrogen-fixing endophytic bacteria in pastures.

[Division Topic1: Analysis of chitinolytic enzyme genes of a mycoparasitic bacterium *Flexibacter* sp. FL824A](#)

[BACK](#)

[HOME](#)

TNF- α

Analysis of chitinolytic enzyme genes of a mycoparasitic bacterium *Flexibacter* sp. FL824A

The purpose of this study was to develop a means of disease control in plants by utilizing lytic microorganisms. We detected lytic activity in mycoparasite *Flexibacter* sp. FL824A toward several plant pathogenic fungi. This lytic activity consisted of the secretion of lytic enzymes, chitinolytic enzymes (chitinases and N-acetylglucosaminidases), β -1,3-glucanases and proteases. Because chitin, poly- β -1,4-N-acetylglucosamine [(GlcNAc)_n], is a major structural component of the cell walls of fungi, chitinolytic enzymes are considered to play an important role in the mycoparasitic process. In the first step of our study, we analyzed the genes of chitinolytic enzymes from *Flexibacter* sp. FL824A.

We first constructed a genomic library of *Flexibacter* sp. FL824A using pUC19 and *Escherichia coli*. Hydrolysis activity of the crude protein of the transformants was determined by using analogs of chitin derivatives, 4-methylumbelliferyl- β -D-N,N'-diacetylchitobioside [4-MU-(GlcNAc)₂] or 4-methylumbelliferyl- β -D-N,N''-triacetylchitotriose [4-MU-(GlcNAc)₃] as substrates. Among 6,000 transformants tested, four clones showed positive activity and fell into two groups according to their specificity to the substrates (Table 1). We selected two clones CHF 1149 and CHF 1351, based on activity level, specificity to the substrates, size of DNA-inserted fragments, and digestion pattern of the inserts using restriction endonucleases.

An open reading frame (ORF) of 4236 bp was found to code for a chitinase with 1412 amino acids based on the nucleotide sequence and deduced amino acid sequencing of an 8.7-kbp insert of pCHF 1149. Homology analysis of the deduced amino acid sequence of this protein revealed that the enzyme had a multiple domain structure consisting of at least seven domains (Fig. 1). The most interesting property of the enzyme was that it had two catalytic domains, one homologous to the catalytic domain of chitinase A1 of *Bacillus circulans* WL-12 on the N-terminal side of the protein, and the other homologous to that of chitinase D of the same bacterium on the C-terminal side.

The DNA sequence of 5.0 kbp of the DNA-inserted fragment of pCHF 1351 was determined after subcloning. An open reading frame (ORF) of 1962 bp was found to code for a putative protein with 654 amino acids. The protein shared a 25% homology with endo- β -N-acetylglucosaminidase of *Clostridium perfringens*.

Strong lytic activity of *Flexibacter* sp. FL824A may be due to the presence of a unique chitinase with two catalytic domains. Further studies on the chitinase should be carried out in order to analyze the chitin degradation of this mycoparasitic bacterium.

***Ascaris suum* infection in the Mekong Delta Vietnam and the application of anthelmintic**

The Mekong Delta is an important region for the pig production industry in Vietnam. Pig production is conducted on small farms in integrated farming systems or in the Vuon-Ao-Chung (VAC: Vietnamese for garden-pond-livestock) system that combines agriculture, animal husbandry and fisheries for feed from agricultural by-products. Both the economic efficiency of these farms and the income of the farmers are very low. In order to increase pig productivity and thus farmer income, it is important to prevent the occurrence of various problems relating to feeds and diseases. Helminthic diseases are considered to be associated with low productivity in the VAC

system, the main cause of economic hardship of the farmers. One of the aims of the present study was to survey the actual conditions of nematode infection in the Mekong Delta area. An attempt was also made to investigate the effects of the application of anthelmintic on pig growth.

Eighty-seven fecal samples were collected from pigs from 38 farms in VAC systems in the Mekong Delta area (four provinces). The Watanabe sedimentation method was then applied to detect nematode eggs. Counts of eggs per gram (EPG) were carried out to demonstrate the effect of anthelmintics on *Ascaris suum* using a McMaster EPG counting plate, if necessary.

Eggs of *A. suum* were detected in 51% (44) of 87 pigs, *Metastrongylus* spp. in 14% (12), *Trichuris suis* in 26% (23), *Oesophagostomum* spp. in 14% (12), and *Strongyloides ransomi* in 5% (4). Results of the investigation also showed that the infective rate of lung worms (*Metastrongylus* spp.) was low. However, swine metastrongylosis is a leading cause of swine pneumonia and disturbs their growth in the Mekong Delta. There were distinct differences between the regions surveyed in the infective rate of *A. suum*. For example, the rate of this nematode in the pigs from 12 farms near Cantho University was 100%, whereas it was about 30% in other regions.

Since the morbidity rate of the *A. suum* infection is very high, the effect of the *Ascaris* infection on pig growth was investigated. Each positive for the *A. suum* eggs, six littermates and crossbreeds of Ba Xuyen and Yorkshire weighing approximately 40 kg from the Experimental Animal Farm of Cantho University were used in the experiment. Group 1 consisted of 3 pigs treated with 1 ml per 15 kg of Polystrongle (injectable form tetramizole hydrochloride, France). Group 2 consisted of 3 untreated pigs. Their body weight was checked biweekly for 12 weeks and an EPG count was taken every day for 10 days after treatment. The presence of *A. suum* eggs was also checked by the sedimentation method every week. All the animals were raised under the standard management system utilized by the university's animal farm. In the 3 pigs of the treated group, *A. suum* worms were eliminated within a few days after treatment, and the EPG of this nematode reached a value of zero. However, since *A. suum* eggs were found again 6 weeks later, treatment was resumed. After ingestion of *A. suum* eggs, about 9 weeks were required for adult stage development ([Table 1](#)). Therefore, it is considered that the presence of this anthelmintic in the intestine was effective against nematodes in the adult stages, but not against those in the immature stages.

While the growth rate of the untreated pigs was low, the growth rate of the treated pigs improved ([Photo 1](#)). In the untreated group, the small intestine of an emaciated animal contained 12 *Ascaris* worms ([Photo 2](#)). The growth of the untreated pigs, which reached a weight of 80 kg, was delayed by 2 weeks compared with the treated pigs. Anorexia and diarrhea were not observed in pigs of either group during the examination.

Comparison of treated and untreated pigs showed that the growth rate of the untreated pigs was very low and that this nematode infection might be a cause of heavy economic losses for farmers. Calculations showed that the economic loss was about 25,000 Vietnam dong (about US\$ 2.00) per head on an experimental farm. Low nutrition levels including protein and vitamin A deficiency may exert more deleterious effects on the infected hosts. If farmers use anthelmintic therapy for their pigs, the growth period of the pigs may be shortened by at least 2 weeks. The total cost for the treatment was about 5,000 Vietnam dong. It may be necessary for farmers to use anthelmintic in order to increase productivity and produce high quality meat.

FORESTRY DIVISION

As increasing demands for food compel farmers to exploit ever greater levels of arable land, natural forest cover has declined sharply, particularly in developing areas of the world. In turn, forest degradation has generated serious economic and environmental problems, not only at local levels but also on a global scale. Providing for rehabilitation and sustainable management of forest areas therefore remains an urgent issue, and improving forest production systems and post harvest technologies in local communities can be viewed as an essential means of stanching forest decline.

The Forestry Division conducts a wide range of research in developing countries, addressing issues from production to end-use. Projects undertaken by the Division generally fall under one of two categories, consisting of silvicultural and forest management technologies and processing technologies for forest products. These projects involve our researchers in disciplines such as silviculture, plant ecology and eco-physiology, soil science, entomology, mycology, forest mechanization, socio-economics, and wood technology.

Enrichment and rehabilitation of degraded forests are the first steps in the development of sustainable management in forest reserves. In an effort to make these initial goals attainable, the Forestry Division has concentrated its research on developing relevant technologies in silviculture, site evaluation and pest control, while paying due consideration to natural environmental conditions.

At the same time, the Division has recently initiated studies on species behavior, systems for natural forest regeneration, enrichment planting methods, and harvesting systems. These are designed to support sustainable production of forest products, which constitute a principal trading commodity in thirty-three developing countries around the world. If achieved, sustainable production will help to stabilize levels of exploitation, both in natural forests and plantations .

Finally, the Forestry Division has focused research on problems of shifting cultivation, which remains a leading cause of forest degradation in some areas. Such problems require the development of forest production and planning systems for stimulating local economies. As rapid deforestation continues, the disappearance of various lesser-known tree species and the loss of potential forestry products associated with them also grows. For these reasons, the Division believes that evaluative studies are urgently needed, while efforts to upgrade wood processing technologies currently available in developing regions should be given greater priority.

Vegetation and litter fall in the Matang Forest Reserve, Malaysia

A JIRCAS comprehensive research project entitled "Productivity and sustainable utilization of tropical and subtropical brackish water ecosystems" is currently underway in 40,711 ha of the Matang Mangrove Forest Reserve near Taiping City, 200 km north of Kuala Lumpur. This project has been jointly implemented by the Forestry and Fisheries Divisions of JIRCAS, the Forest Research Institute Malaysia, the University of Malaya, and the Fisheries Research Institute of Malaysia. Through studies on mangroves, crabs, plankton, fish, and human activities, researchers are evaluating the concept of sustainable management of mangrove forests. This area is particularly well known as an example of sustainable management. Under a 30-year rotation system, *Rhizophora apiculata* (a major species of tree in the mangroves) is simultaneously harvested for charcoal and re-planted.

As part of this project, the Forestry Division of JIRCAS is investigating litter fall (any material that falls from mangrove trees) in three different types of mangrove forest. Common types of mangrove forest in this area are a) a mixture of *Avicennia* spp. and *Sonneratia* spp., b) *Rhizophora* spp., and c) *Bruguiera* spp. The distance separating type A from the sea is the shortest of the three, followed by types B and C. During the spring tide, the maximum water level of types A and B is 90 and 70 cm above land, respectively. Type A is under water 16 hours a day during the spring tide and 10 hours a day during neap tide. In comparison, type B is under water 11 hours and 8 hours respectively, while, even during the spring tide, type C is slightly above water level during the majority of the year. The variety in vegetation of the mangroves is a result of the difference in water level.

Litter fall for each type throughout the year is shown in [Fig. 1](#). The total mass of litter fall in types B and C is nearly equivalent ([Fig. 1](#)), while that of type A is roughly half. Despite the difference in total mass, the percentage of leaf weight is similar in all forest types. Leaves account for 56-58% of the total litter fall mass, implying that leaves are the major components of litter fall in all the forest types.

The mangrove tree is unique not only for its shape but also for the movement of its fallen leaves. In lowland and hill forests, which are also present in Peninsular Malaysia, most fallen leaves decompose on the forest floor. In contrast, in type A mangrove forests most fallen leaves are washed out to sea during both spring and neap tides. In a type B forest, fallen leaves are washed out during the spring tide, although most of the leaves remain during the neap tide. Finally, most leaves remain in the spring and during neap tides in a type C forest. Leaf movement determines the fertility of the soil and the food chain of the mangrove ecosystem.

Although the flora of mangrove forests is relatively simple compared to that of the other forest types in Malaysia, it prevents the land from sinking and protects the sea from becoming polluted with sewerage output. Unfortunately, mangroves are disappearing rapidly due to the development of fish and prawn ponds and other human activities. The Matang Forest Reserve offers an excellent example of sustainable forest management.

Chlorine-free bleaching of kraft pulp from oil palm empty fruit bunches

Empty fruit bunches (EFB, [Photo 1](#)) are lignocellulosic residues from palm oil production in Malaysia and other tropical countries. Recent attempts to produce pulp for paper-making from EFB by mechanical and chemical pulping mark the first efforts to utilize this potential resource. However, little work has been done on bleaching EFB pulp, especially utilizing the more environmentally friendly chlorine-free bleaching method.

In this study, we carried out chlorine-free bleaching on EFB kraft pulp. The bleaching process employed the application of oxygen (O_2), sulfuric acid (H_2SO_4), ozone (O_3), and hydrogen peroxide (H_2O_2). After bleaching, the

k-number (indicator of lignin content) of the pulp became negligible ([Table 1](#)), indicating that most of the lignin contained in the pulp can be removed without using chlorine compounds as bleaching agents. Both chlorine-bleached and unbleached handsheets of the EFB pulp were produced and the paper properties were determined as shown in the table. The brightness, a measure of the whiteness of paper, of the bleached pulp handsheets was about 75%. Though this figure is slightly lower than the required brightness of 80% for bleached kraft paper, this result shows a strong possibility of achieving the requisite brightness through chlorine-free bleaching of EFB pulp. Opacity is the ability of paper to hide or mask a color or object. The figure obtained for the bleached handsheet in this study was found to be comparable to that of commercial paper.

Handsheets paper strength, which is indicated by tensile index, stretch, tear index, and burst index, did not change significantly from before and after the bleaching process. Thus, the effects of the bleaching process on handsheet properties are negligible. Moreover, the EFB bleached pulp displayed comparable strength to some hardwood pulps, indicating that EFB has potential to serve as a raw material for chemical pulp through chlorine-free bleaching.

FISHERIES DIVISION

As an initial phase (1994-1998) in international collaborative activity in the field of fisheries, the Fisheries Division has initiated five major research projects in Asian countries, including efforts to improve the management of fisheries resources and the coastal environment in Malaysia and Indonesia, aquaculture in Thailand and Vietnam, and fisheries product processing in China. In addition to these studies, the Division has also endeavored to secure the participation of Southeast Asian countries in a research project targeting prawn viral diseases.

In 1995, the Division initiated its first international collaborative research project on fisheries resource management in Malaysia with the Fisheries Research Institute (FRI) and the University of Malaya (UM). This multidisciplinary project, which examines the productivity and sustainable utilization of brackish water mangrove ecosystems, involves the integration of studies in fisheries, forestry, agriculture, and socio-economics. JIRCAS has successively dispatched two senior researchers to Penang and Kuala Lumpur, Malaysia, to provide long-term oversight for the project, and several short-term scientists specializing in fish larval ecology, crustacean ecology, and marine chemistry have also participated. In December 1998, members of the project team conducted an international seminar on brackish water mangrove ecosystems that brought together researchers from FRI, UM, and the Forest Research Institute Malaysia (FRIM).

At the same time, the Division remains involved in several other ongoing projects. These include collaborative studies on the environmental management of coastal water in Indonesia based on ecological and chemical analyses now being conducted in Maros, South Sulawesi, Indonesia, in conjunction with the Research Institute for Coastal Fisheries (RICF) under the jurisdiction of the Central Research Institute for Fisheries (CRIFI). The project aims to deepen understanding of the ecology of plankton and related environmental factors in ways that may improve marine resource management methods. One researcher has been dispatched to Maros as a long-term residing scientist.

The Division's collaborative work on the development of sustainable aquaculture technology in Southeast Asia also continued at Kasetsart University in Bangkok, Thailand. In addition, the Division has been participating in a comprehensive project entitled "Evaluation and improvement of farming systems combining agriculture, animal husbandry, and fisheries in the Mekong Delta" with the College of Agriculture at Cantho University in Vietnam. This project involves multidisciplinary studies of integrated farming systems to address problems in rice production, animal husbandry, freshwater aquaculture, and socio-economics. Research in fisheries and freshwater aquaculture comprises an important part of the project, in particular as it relates to technologies for the production of prawn and fish fry, the prevention of disease among prawn and fish, and the utilization of new feed resources for freshwater aquaculture. To oversee components of the project which relate to fisheries management, JIRCAS has dispatched on short-term bases one researcher specializing in crustacean endocrinology and two Fisheries Agency scientists specializing in fish disease and fisheries nutrition.

Concerning the processing of fisheries products, the Division has continued collaborative research on postharvest and processing of freshwater fish in China with the Faculty of Food Science and Technology at the Shanghai Fisheries University. One senior researcher has been dispatched successively to Shanghai, and short-term scientists specializing in postharvest technology have visited to lend support to the project.

Finally, under the auspices of the JIRCAS Visiting Research Fellowship Program, one counterpart scientist from Cantho University in Vietnam currently resides in Tsukuba and is undertaking cooperative studies on aquatic animal physiology over a two-year period. Past and future fellows are expected to become core scientists in JIRCAS's counterpart institutions and to contribute to the continued development of collaborative studies.

[BACK](#)

[HOME](#)

Gel formation properties of surimis made from freshwater fish in China

Despite the fact that freshwater fish resources in China have expanded rapidly, their distribution sphere and storage period are very limited since most freshwater fish are transported as live fish without treatment, such as freezing and processing. As an animal protein resource, freshwater fish have not been fully utilized, as in the case of marine fisheries.

In order to address the above problem, JIRCAS has promoted the development of frozen surimi made from freshwater fish meat in cooperation with Shanghai Fisheries University. Frozen surimi is an intermediate foodstuff with high potential for longer shelf life, wider distribution area, and diversification of products. In an effort to identify fish species harboring high potential for surimi production, we carried out studies on the forming properties and its mechanism of cultured freshwater fish in China.

Gel forming properties depended on the heating temperature and heating time of different species of freshwater fish. The configuration of contour maps was classified into two types ([Fig.1](#)). That is, the surimi gels of the left line in Fig.1 showed the shape of a U character, since the gels tends to collapse by heating at an intermediate temperature zone (around 60°C). The surimi gels of the right line showed the shape of a plateau, since the gels degradation phenomena was small at an intermediate temperature. Surimis made from tilapia and grass carp showed a stable gel forming ability at high heating temperatures (around 85°C) and a high resistance of gel degradation at intermediate heating temperatures (around 60°C). However, in the two-step heating process, these species of fish did not form a strong gel under low temperatures (around 30°C) and a subsequent heating at high temperatures (around 85°C). Therefore, it was determined that tilapia and grass carp surimis form a gel in a wide range of heating temperatures and times. Surimis of silver carp and bighead carp showed an enhanced efficiency in gel strength under a two-step heating process, although the gels of both surimis demonstrated degradation under heating at intermediate temperatures. It was determined that, although silver and bighead carp surimis form a strong gel, their optimum heating temperatures and time zone is narrow. Consequently, these four species have a high potential for surimi production.

In contrast, surimis made from blunt snout bream, common carp, and Chinese snake head have little surimi potential, since the gel forming ability at high temperatures was unstable, and gel enhancing ability under the two-step heating was almost non-existent.

This collaborative research on gel formation properties has led to the production of high quality surimi-based foodstuffs from freshwater fish in China. The ultimate goal of this collaborative research is the widespread distribution and consumption of surimi-based products in China.

Characterization of vitellogenin from the giant freshwater prawn *Macrobrachium rosenbergii*

The giant freshwater prawn, *Macrobrachium rosenbergii* (Photo 1), is a commercially important crustacean species cultured extensively throughout Southeast Asia. In Vietnam, where JIRCAS is currently implementing a comprehensive project entitled "Evaluation and improvement of farming systems combining agriculture, animal husbandry and fisheries in the Mekong Delta," *M. rosenbergii* is considered to be an important target species by the Vietnamese Government, and its aquaculture is being actively promoted. Farmers have traditionally depended on wild sources to obtain seed for aquaculture but are now faced with dwindling resources and a shortage of natural spawners. Development of improved means of artificial seed production for *M. rosenbergii* in the Mekong Delta is essential.

JIRCAS is currently implementing basic studies on the reproductive endocrinology of *M. rosenbergii* as part of the Mekong Delta project. Biochemical and molecular biological research is being conducted both at the project site, Cantho University's College of Agriculture, in Cantho Province, Vietnam in collaboration with Vietnam counterparts, and on JIRCAS's Tsukuba premises. In addition, although not directly related to the project, some of these studies have been carried out under the JIRCAS Visiting Fellowship Program at Tsukuba.

In *M. rosenbergii* and most other species of decapod Crustacea, reproduction is thought to be under the control of various hormones, including vitellogenesis inhibiting hormone (VIH) and vitellogenesis stimulating hormone (VSH). The presence of VIH in the eyestalk has been well-established, but less is known about VSH which is thought to originate in the brain and thoracic ganglia. Furthermore, regulatory mechanisms of vitellogenesis in Crustacean remain unclassified; this is due in great part to the fact that the biochemical nature of vitellogenin (yolk protein) is not fully known. Thus, the chemical characterization of vitellogenin and the elucidation of regulatory hormones responsible for reproduction are highly urgent.

In most crustacean species, vitellogenin exists as the precursor of yolk protein and has a molecular mass of more than 200 KDa. In *M. rosenbergii*, vitellogenin is thought to be first synthesized in the hepatopancreas and thereafter secreted into the hemolymph. Then, during vitellogenesis, vitellogenin is taken into the ovary and processed into several subunits to serve as an important source of nutrients during the processes of ovarian and embryonic development. These subunits are known as vitellin.

In this research, vitellin was first extracted from a mature ovary. After filtering the extracts with microconcentrators to cut off low molecular weight proteins, the filtrate was subjected to reversed-phase high pressure liquid chromatography (HPLC). Four major proteins (fractions A, B, C and D) were separated using a linear gradient of acetonitrile/trifluoroacetic acid (TFA) (Fig. 1). The results of Western blotting suggested that the 4 fractions were vitellins. Using TOF (time-of-flight) mass spectrometry, it was observed that the 4 fractions recovered from HPLC exhibited protonated molecular ion peaks at m/z 89560.7, 88721.1, 88963.6, and 88900.9, respectively, indicating molecular weights of approximately 90 KDa for all vitellins. The four fractions were initially subjected to N-terminal amino acid sequence analysis, and we were able to identify more than 30 amino acid residues. To obtain more information about the amino acid sequences, the four fractions were digested with lysyl endopeptidase and the digested fragments were separated by reversed-phase HPLC on an ODP-50 column with a linear gradient of acetonitrile/TFA. A total of 48, 53, 57 and 46 fragments (for fractions A, B, C and D, respectively) were thus obtained and amino acid sequences for several of these fragments were determined.

In order to clone the four cDNA-encoding fractions (fractions A, B, C and D), total RNA isolated from the ovary and hepatopancreas was subjected to reverse transcription (RT) reaction in order to synthesize cDNA. Then, the resultant cDNA were subjected to polymerase chain reaction (PCR) using degenerate oligonucleotide primers. The PCR products were subcloned into a plasmid vector and analyzed to determine the DNA sequences. The complete DNA sequences of the four vitellin cDNAs were determined and the conceptually translated amino acid sequences were identical to those of the N-terminal and lysyl endopeptidase fragment sequences. In subsequent research, this will enable us to determine the DNA sequences of the four vitellins by constructing cDNA libraries from the ovary and hepatopancreas. The genes encoding the four vitellins will then be screened from the cDNA libraries using probes and their sequences will be determined using a DNA sequencer.

In addition, in order to identify the synthetic site of vitellogenin, specific expression of mRNA is being analyzed by Northern-hybridization. The site of expression of mRNA for fractions C and D has already been identified as the hepatopancreas. Furthermore, in order to obtain a complete picture of the dynamics of vitellogenin synthesis, expression of mRNA in various tissues (hepatopancreas, ovary, hemocytes, subepidermal adipose tissue and muscle) are being analyzed at different stages of reproduction.

The expression of the four vitellin mRNAs will serve as a basic tool for developing a bioassay system which will enable us to identify VIH and VSH. Using such a bioassay system, the role of VIH and VSH, as well as of other factors in regulating vitellogenesis, may be examined.

This research will contribute to a further understanding of the endocrine regulation of vitellogenesis in Crustacea and this knowledge will be useful not only from the point of view of basic research but will also have practical applications in commercial culture of *M. rosenbergii*.

This research is expected to be especially relevant in controlling female reproduction in captivity and improving seed production technology.

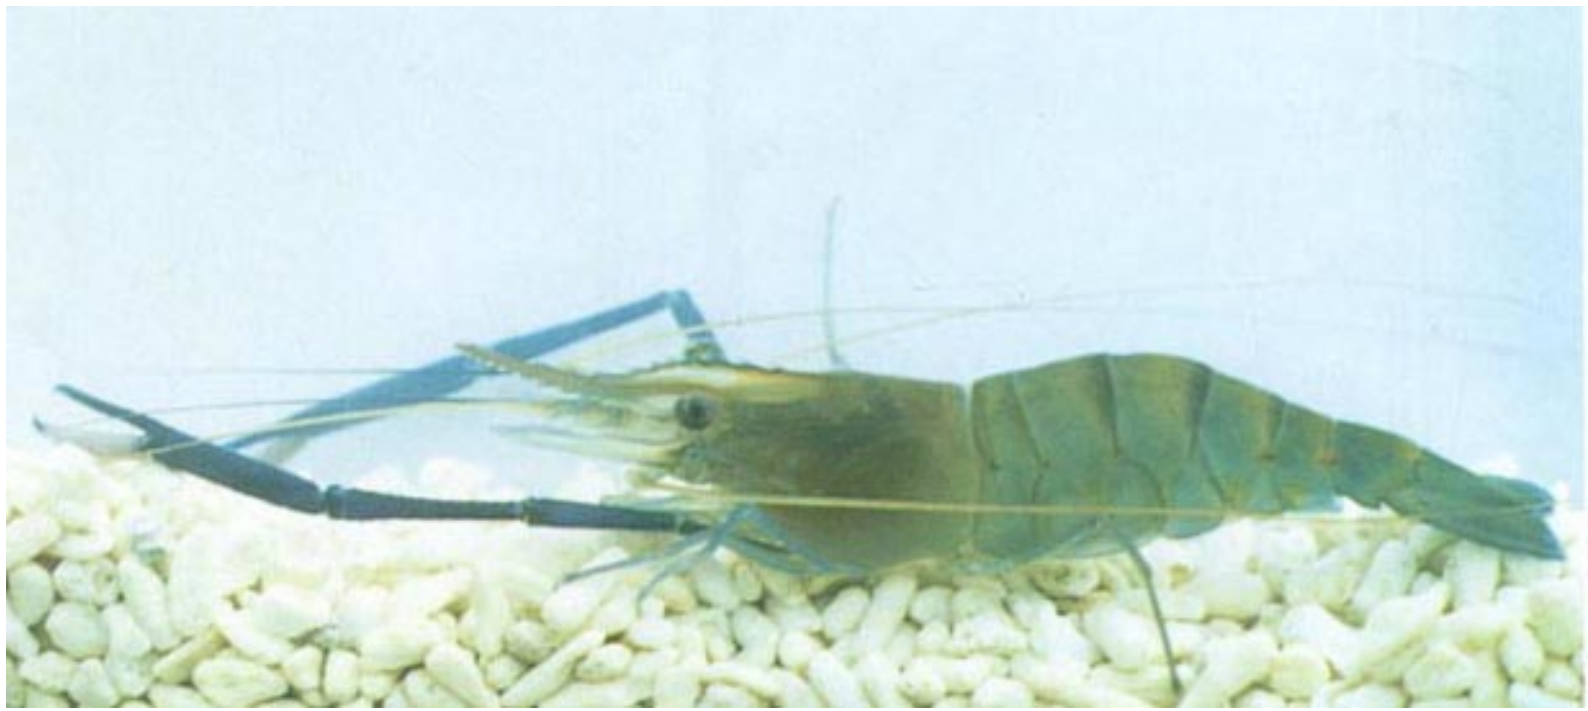

(M.N. Wilder and Y-J. Yang)

OKINAWA SUBTROPICAL STATION

The Okinawa Subtropical Station was established in 1970 as a field experiment station for the Tropical Agriculture Research Center (TARC), which was reorganized into JIRCAS in 1993. It is located on Ishigaki Island, nearly 2,100 km southwest of Tokyo. As annual temperatures on the island average 24°C, the Station provides the most suitable location in Japan for research concerning subtropical and tropical agriculture and the development of techniques and technologies appropriate for the constraints of warm climates.

During Fiscal Year 1998, Station personnel consisted of 24 researchers divided among 7 research sections involved in projects relating to genetic resources, biotechnology, plant physiology, plant breeding, plant protection, and soil science. In addition to the permanent research staff, 9 scientists were invited from Bangladesh, China, Cuba, Ecuador, India, and Thailand under the auspices of the Visiting Research Fellowship Program at Okinawa overseen by the International Research Section.

One notable achievement of the researchers and visiting fellows was the development and official release of a heat-tolerant vegetable variety in 1998. Named "Haibushi," this snap bean can attain great yields of more than 2 tons/ha/season, even during the very warm mid-summer of Ishigaki Island. The success of the bean prompted the Station to initiate research on the physiological and genetic analysis of heat-tolerance in crops and on the practical development of successful varieties. Having commenced

in 1998, this five-year research program will be done in cooperation with Ryukyu University, Nagoya University, and the Tokyo University of Agriculture and is sponsored by the Bio-oriented Technology Research Advancement Institution's (BRAIN) grant of approximately 100 million yen per year.

Partial male sterility observed in some Japanese varieties of rice caused by short day-length conditions on Ishigaki Island

A low degree of seed fertility has been observed in some varieties of Japanese rice when cultivated under short day-length conditions on Ishigaki Island. In this study, the seed sterility of Shinrei, a Japanese cultivar, under shorter day-length conditions was 30% (sown on July 15) and 61 % (sown on August 28) as compared with a seed sterility of 4% when it was cultivated under longer day-length conditions (sown on March 4). In the three plots cited above (July 15, August 28, and March 4), the average day-length of the 20 days before heading was 12 hours and 51 minutes, 11 hours and 53 minutes and 13 hours and 4 minutes, respectively. The average temperature of the 2 weeks before heading was 27.4°C, 25.6°C and 23.0°C, respectively. A similar tendency in seed sterility was observed in the varieties of Nipponbare, Akenohoshi, and Hinohikari, which were adapted mainly to the region west of the Kanto plain.

On the other hand, there were some varieties that showed no difference in the degree of seed sterility among the three plots. The seed sterility of Koshihikari was 8%, 7%, and 9% for plots sown on July 15, August 28 and March 4, respectively. This tendency was observed in the varieties of Akitakomachi, Sasanishiki, and Hitomebore, which were adapted mainly in the Tohoku and Hokuriku areas.

When Shinrei was cultivated under short-day treatment (9 hours day-length), we observed a decrease in the length of the anthers at the flowering stage ([Fig. 1](#)), however the length of the palea was not affected. The number of pollen grains per anther was 320 and the seed sterility was 280/0 under short-day treatment, while 820 pollen grains per anther and 3% seed sterility were observed under long-day treatment (14 hours day-length). The seed fertility of Shinrei grown under short day-length was restored to the normal level by cross-pollinating with Koshihikari. When long-day treatment (14 hours day-length) was given to Shinrei after flower bud formation, partial restoration of anther length, number of pollen grains per anther, and seed fertility were observed.

It was concluded that the partial male sterility observed in some Japanese varieties of rice with underdeveloped anthers and reduced pollen grains per anther was caused by both the extremely accelerated flower bud formation and rapid reproductive growth under short day-length conditions on Ishigaki Island.

(O. Ideta and M. Okamoto)

[Fig. 1. Underdeveloped anthers at flowering stage observed in Shinrei. Underdeveloped anthers caused by the short-day treatment are shown in the center and on the right. A normal type of anther developed under the long-day treatment is shown on the left.](#)

OKINAWA SUBTROPICAL STATION Topic2

Detection of bruchid-resistant strains in wild relatives of the azuki bean

The azuki bean, *Vigna angularis* var. *angularis* ($2n=22, 2x$) is one of the most familiar legumes to Japanese people. It is known that several related wild species of azuki bean occur in Asia. Wild relatives (germplasm) are the primary and secondary gene pools for breeding of the cultigens. Wild germplasm, however, is now confronted with gradual extinction due to natural habitat disturbance. Against this background, we have collected wild azuki bean germplasm in Southeast Asian countries.

The azuki bean weevil (*Callosobruchus chinensis*) causes serious damages to azuki bean, mungbean and cowpea seeds during storage. One accession of wild progenitor species of mungbean (*V. radiata* var. *sublobata*), TC1966, is known to exhibit a complete resistance against *C. chinensis*. However, since reproductive isolation exists between the azuki bean and mungbean, it was impossible to incorporate the resistance from TC 1966 to the azuki bean through conventional crossing procedures. Therefore, we examined wild azuki bean germplasm, including *V. angularis* var. *nipponensis* (wild progenitor of azuki bean), *V. nakashimae*, *V. nepalensis*, *V. minima* var. *minor*, *V. hirtella*, *V. umbellata* and *V. trinervia*, etc., to detect within them the occurrence of bruchid-resistant strains.

In feeding tests of the azuki bean weevil, *V. hirtella*, *V. umbellata* and *V. trinervia*, exhibited resistance against the infestation by *C. chinensis*, although other species were highly susceptible. *V. hirtella* is distributed in India (Assam, Bengal), Myaumar, Thailand, Indo-China, South China and Malaysia. The

strains examined here were collected from northern Thailand by JIRCAS. Cross-compatibility of *V. hirtella* with the azuki bean was high and we successfully obtained fertile F₁ hybrids between them ([Photo 1](#)). At present, we are backcrossing the F₁ hybrids with the azuki bean to develop bruchid-resistant lines. The wild form of *V. umbellata* is distributed widely in northern Thailand and several accessions have been collected by JIRCAS. Hybridization between the azuki bean and *V. umbellata* was impossible. *V. minima* var. *minor* was, however, cross-compatible with both the azuki bean and *V. umbellata* and could be useful as a bridging species for gene flow between them. To develop a resistant line of the azuki bean, we will transfer the resistance gene(s) of *V. umbellata* first to *V. minima* var. *minor* by backcrossing this species recurrently to a hybrid of *V. umbellata* and *V. minima* var. *minor*, and will then incorporate the resistance to the azuki bean from *V. minima* var. *minor*. Geographical distribution of *V. trinervia* ranges from Madagascar, through South India, Sri Lanka, Myaumar and Indonesia, to New Guinea. We have successfully collected a sufficient amount of accessions from peninsular Malaysia. Cross-compatibility of *V. trinervia* with the azuki bean has yet to be analysed.

(Y. Egawa and K. Kohno)

[Photo 1 : Cross-compatibility of *V. hirtella* with the azuki bean was high and we successfully obtained fertile F₁ hybrids between them](#)

A fungal epiphyte(*Ephelis* sp.)of grasses on Ishigaki island and its effect on the feeding of two insect pests

Ephelis sp., a fungus belonging to the family Clavicipitaceae, was found on fifteen species of grasses on Ishigaki island, Okinawa; *Brachiaria mutica* (Forsk.) Stpf, *Chloris barbata* Swarzt, *C. divaricata* R. Br., *Chrysopogon aciculatus* (Retz.) Trin, *Cynodon Dactylon* (L.) Pers., *C. pletostachyus* (K. Schm.) Pilger, *Digitaria decumbens* var. *koenigii* (Retz.) Durand et Schinz, *Leptochloa panica* (Retz.) Ohwi, *Panicum Crus-galli*, Beauv. var. *praticola* Ohwi, *P repens* L., *Paspalum scrobiculatum* G. Forst, *P urvillei* Steud. and *Erichloa procera* C. H. Hubb. Sites with the *Ephelis* infection were most commonly wet areas that had remained undisturbed for many years. The relationship of the *Ephelis* fungus to grasses was essentially that of an epiphyte.

Insect feeding deterrence associated with the presence of the *Ephelis* sp. was detected in choice tests involving infected and uninfected leaves. Larvae of the Japanese army worm, *Pseudaletia separata*, and the adult grasshopper, *Aiolopus thalassimus*, preferred the uninfected leaves of *Digitaria decumbens* to infected ones. The life-span of adult grasshoppers *A. thalassimus* that fed on *Ephelis*-infected *Digitaria decumbens* leaves was shorter than those that fed on *Ephelis*-free leaves.

MISCELLANEOUS PROJECTS OUTLINE

In addition to international collaborative projects, JIRCAS conducts a variety of miscellaneous projects: domestic projects in cooperation with other MAFF institutes; commissioned research, principally in cooperation with universities; cross-ministry and cross-agency projects currently involving the Science and Technology Agency and the Environment Agency; and special allotment projects .

DOMESTIC PROJECTS

In close cooperation with other related Japanese research institutes, JIRCAS conducts domestic research at its main premises in Tsukuba and at its Okinawa Subtropical Station in an effort to support its international collaborative projects. JIRCAS further complements its comprehensive projects through its Tsukuba and Okinawa research fellowship programs in which foreign researchers from JIRCAS counterpart organizations are invited to carry out studies in support of on-going collaborative projects abroad.

In addition, these programs also promote positive relationships between JIRCAS and foreign institutions and facilitate future exchanges of individual research staff. JIRCAS domestic research has produced a variety of significant results, especially in the areas of drought-resistant crop development and world food supply and demand analysis. By focusing on fields where it can effectively utilize its relative superiority in research management and coordination, JIRCAS is able to effectively utilize its limited budget and personnel in resolving critical agricultural and food supply problems in developing countries. Current domestic research focuses on 1) world food supply analysis; 2) development of sustainable agriculture; 3) technology development for the utilization of animal resources; 4) crop tolerance to drought, blight, and low temperatures; 5) circulation of nitrogen in soil; 6) the utilization of remote sensing technology for evaluating environmental resources; 7) technology for the preservation and utilization of environmental resources; 8) evaluation of foodstuff quality in developing countries; and 9) cultivation and practical application of fisheries resources.

DOMESTIC PROJECTS

Simulation analysis of world food policies

(Research Information Division, 1994 - 1998)

A comprehensive evaluation of the effects of international trade fluctuation on resources and the environment

(Research Information Division, 1996 - 2000)

Analysis and settlement of macro indicators (MI) for water resource changes, affected by changes in agricultural production and industrial structure

(Research Information Division, 1996 - 2000)

Development of tools for agricultural information analysis using GIS

(Research Information Division, 1997 - 2002)

Development of remote sensing methods to evaluate major food crops in Asia

(Research Information Division, 1998 - 2001)

Analysis of genes that are induced by dehydration stress in higher plants

(Biological Resources Division, 1993 - 1999)

Effect of cold stress on the phenological development of plants and the analysis of mechanisms for acquiring tolerance to cold stress

(Biological Resources Division, 1998 - 2007)

Development of wheat lines highly resistant to *fusarium* head blight by utilizing rice DNA markers

(Biological Resources Division, 1998 - 2000)

Genetic analysis of pathogenic microorganisms and the development of its application techniques

(Biological Resources Division, 1995 - 2000)

Rice-genome analysis and related projects

(Biological Resources Division and Okinawa Subtropical Station, 1998 - 2008)

Development of a predictive MI method for salt accumulation in semiarid areas

(Crop Production and Postharvest Technology Division, 1996 - 1998)

Search for possible natural enemies of the golden apple snail and evaluation of their efficacy

(Crop Production and Postharvest Technology Division, 1997 - 2000)

Search for endophytes from tropical grasses

(Animal Production and Grassland Division, 1996 - 1998)

Elucidation of antagonistic mechanisms of lytic microorganisms against plant pathogenic fungi and development of a means of disease control

(Animal Production and Grassland Division, 1996 - 1998)

Establishment of highly profitable agricultural technologies in subtropical ,regions through the introduction of vegetables and flowers

(Okinawa Subtropical Station, 1998 - 2002)

Primary characterization of rice genetic resources

(Okinawa Subtropical Station, 1993 - 2000)

Rapid generation advance breeding of high quality wheat for blend usage

(Okinawa Subtropical Station, 1996 - 1998)

Development of the experimental rice Nipponbare

(Okinawa Subtropical Station, 1998 - 2000)

Rapid generation advance breeding of rice with adaptability to direct seeding and combined tolerance

(Okinawa Subtropical Station, 1995 - 2000)

Evaluation of genetic resources in sugarcane

(Okinawa Subtropical Station, 1992 - 1998)

COMMISSIONED RESEARCH

Evaluation of salinity tolerance in wild species of rice and elucidation of tolerance mechanisms

(Okinawa Subtropical Station in cooperation with the University of the Ryukyus, 1996 - 1999)

Mapping of genes related to drought tolerance

(Biological Resources Division in cooperation with the Institute of Physical and Chemical Research (RIKEN), 1997 - 1999)

Climatic changes in cool, dry areas and accompanying environmental changes for cattle raising
(Environmental Resources Division in cooperation with Tsukuba University, 1998 -2000)

RESEARCH PROJECTS WITH OTHER GOVERNMENT AGENCIES AND MINISTRIES

In cooperation with the Science and Technology Agency

Oceanographic investigations: Fluctuations in tropical mangrove forests and evaluation of possible influences
(Forestry Division, 1990 - 1999)

Studies on occurrence mechanism of physiological injury in legumes and vegetables
(Okinawa Subtropical Station, 1998)

Improvements in postharvest quality and safety of tropical agricultural products
(Crop Production and Postharvest Technology Division, 1998)

Efficiency of controlled availability of fertilizers on controlling nitrogen cycling in East Asian cropland
(Environmental Resources Division, 1998)

Control of reproduction in shrimps and prawns under artificial conditions
(Fisheries Division, 1998)

In cooperation with the Environment Agency

Studies on the development of technology for soil rehabilitation with salt accumulation in Central Asia
(Research Information Division, 1996 - 1998)

**In cooperation with BRAIN
(Bio-oriented Technology Research Advancement Institution)**

Molecular analysis of drought and salt stress tolerant mechanisms and its application to breeding

(Biological Resources Division, 1996 - 2000)

Physiological and genetic studies of heat-tolerance of crops and development of tolerant crops

(Okinawa Subtropical Station, 1998 - 2002)

MAFF SPECIAL RESEARCH ALLOTMENTS

Stabilization of rice culture under water stress in the tropics utilizing a broader spectrum of genetic resources

(JIRCAS in cooperation with the International Rice Research Institute (IRRI), 1994 - 1999)

Sustainable cultivation of upland crops in the semiarid tropics

(JIRCAS in cooperation with International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), 1994-1999)

INVITATION PROGRAMS AT JIRCAS

In keeping with its role as an international research center, JIRCAS has implemented several programs for the invitation of foreign researchers and administrators at counterpart organizations. These programs serve to facilitate the exchange of information and opinion concerning agriculture, forestry and fisheries administration and to strengthen international research ties with scientists and administrators in other countries. Current programs are described in greater detail below.

1) Administrative Invitation

Under the Administrative Invitation program, JIRCAS invites administrators from counterpart organizations to the Tsukuba premises to engage in discussions and to review ongoing research in order to ensure the smooth running of collaborative projects. Additionally, the program introduces administrators to current activities at JIRCAS and related MAFF research organizations. Finally, the program provides opportunities for the exchange of information and opinion at the administrative level concerning policy-making and project design, thereby contributing to deeper mutual understanding and international cooperation.

Fifty-seven individual visits to JIRCAS were made during FY 1998 under the Administrative Invitation program, including sixteen invitations to the International Symposium and twenty-one invitations to the International Workshop. Invited administrators and their home institutions are [listed here](#).

2) Counterpart Researcher Invitation

The Counterpart Researcher Invitation program provides invitations for periods of up to six months to researchers engaged in collaborative work with members of the JIRCAS research staff. Counterparts conduct in-depth research at JIRCAS, at other MAFF research institutes, at prefectural research institutes, or at national universities. This invitation program aims both to enhance the quality of research conducted in foreign countries and to facilitate exchanges between individual research staff. Thirty researchers were invited under the Counterpart Researcher Invitation program during FY 1998. Invited researchers, their affiliated research organizations, and their research activities are [summarized here](#).

3) JIRCAS Visiting Research Fellowship Program at Okinawa

The Okinawa Visiting Research Fellowship Program was initiated in FY 1992, prior to the reorganization of the Tropical Agricultural Research Center (TARC) into JIRCAS. The program invites post-doctoral scientists to conduct research for a period of one year at the Okinawa Subtropical Station. Researchers must focus on important topics relating to tropical agriculture in developing countries within one of several broad categories: the development of techniques for environmental control utilizing plants and microorganisms specific to the tropics and subtropics, studies on heat-tolerance mechanisms in tropical and subtropical crops, the identification and evaluation of salt-tolerant crops, or the evaluation and development of long-term conservation techniques of the genetic resources of vegetatively propagated crops in the tropics and subtropics. Ten fellows are chosen each year, beginning their terms on October 1 and ending on September 30 of the following year. Recent invitees and their research activities are [summarized here](#).

More information on the Okinawa Visiting Research Fellowship Program can be obtained by contacting the International Relations Section, Japan International Research Center for Agricultural Sciences, 1-2, Ohwashi, Tsukuba, Ibaraki, 305-8686, Japan. (Tel.: +81-298-38-6335 Fax: +81-298-38-6337; e-mail: irs@jircas.affrc.go.jp).

4) JIRCAS Visiting Research Fellowship Program at Tsukuba

A program similar to the Okinawa Visiting Research Fellowship Program has been implemented on the Tsukuba premises since October 1995. The Tsukuba Visiting Research Fellowship Program aims to promote collaborative research to address various problems confronting countries in developing regions. The program allows for the invitation of six to eight researchers per year. Four researchers engage in two-year projects at JIRCAS and two to four researchers conduct short five-month projects at the National Institute for Agrobiological Resources (NIAR). Recent invitees and their research activities are [listed here](#).

More information on the Tsukuba Visiting Research Fellowship Program can be obtained by contacting the International Relations Section, Japan International Research Center for Agricultural Sciences, 1-2, Ohwashi, Tsukuba, Ibaraki, 305-8686. Japan. (Tel. : +81-298-38-6335 Fax: +81-298-38-6337; e-mail: irs@jircas.affrc.go.jp).

5) Other fellowships for visiting scientists

The Government of Japan sponsors a post-doctoral fellowship program for both Japanese and foreign scientists through the Science and Technology Agency (STA). The program places post-doctoral fellows in national research institutes throughout Japan according to research theme and prior arrangement with a host scientist for a term of generally 1-3 years. Fellowships can be undertaken in any of the ministries and many fellows are currently working at the various institutes of the Ministry of Agriculture, Forestry and Fisheries (MAFF). In 1998, the following visiting scientists resided at JIRCAS: Dr. Chien Hsiaoping (People's Republic of China), Research Information Division; Dr. Park Kwang-Lai (Korea), Environmental Resources Division; Dr. Wei-Jun Yang (People's Republic of China), Fisheries Division; Dr. Harvinder Singh Talwar (India), Okinawa Subtropical Station; Dr. Yan Xiaoyuan (People's Republic of China), Environmental Resources Division; and Mr. Michael J. Christensen (New Zealand), Okinawa Subtropical Station. In addition, three Japanese fellows, Dr. N. Aoki, Biological Resources Division; Dr. T. Kitamado, Fisheries Division; and Dr. M. Sakagawa, Environmental Resources Division, also conducted research at JIRCAS. The Environment Agency of Japan also sponsors a post-doctoral fellowship program for foreign scientists. Dr. Yao Heng (People's Republic of China) resided at the Environmental Resources Division, JIRCAS.

Administrative Invitation Program Invitees

Under the Administrative Invitation program, JIRCAS invites administrators from counterpart organizations to the Tsukuba premises to engage in discussions and to review ongoing research in order to ensure the smooth running of collaborative projects. Additionally, the program introduces administrators to current activities at JIRCAS and related MAFF research organizations. Finally, the program provides opportunities for the exchange of information and opinion at the administrative level concerning policy-making and project design, thereby contributing to deeper mutual understanding and international cooperation.

Fifty-seven individual visits to JIRCAS were made during FY 1998 under the Administrative Invitation program, including sixteen invitations to the International Symposium and twenty-one invitations to the International Workshop Invited administrators and their home institutions are listed below.

FY 1998		
Dr. Akke van der Zijpp	Deputy Director General International Center of Insect and Physiology and Ecology (ICIPE) Kenya	Jul 5-7, 1998
Mr. Panus Songserm	Director Khon Kaen Field Crop Research Center Thailand	Sep. 3-12, 1998
Dr. H. Suyamto	Director Research Institute for Legume and Tuber Crops (RILET) Indonesia	Sep. 8-15, 1998
Dr. Monty Patrick Jones	Leader of Rainfed Program, Principal Rice Breeder West Africa Rice Development Association (WARDA) Cote d'Ivoire	Oct. 5-15, 1998
Dr. Ronald P. Cantrell	Director General International Rice Research Institute (IRRI) The Philippines	Nov. 17-20, 1998
Dr. Zhu Xigang	Director General Institute of Agricultural Economy, Chinese Academy of Agricultural Sciences People's Republic of China	Nov. 23-Dec. 4, 1998
Dr. Ananta Dalodom	Director General Department of Agriculture Thailand	Dec.7-12, 1998
Mr. Paiwit Watanavitawas	Director International Training Center for Agricultural Development (ITCAD) Thailand	Dec.7-12, 1998
Dr. Abdul Razak bin Mohd Ali	Director General Forest Research Institute Malaysia Malaysia	Feb.7-14, 1999
Dr. Mohd. Azemi Mohd. Noor	Dean School of Industrial Technology, University Sains Malaysia Malaysia	Feb. 12-19, 1999
Mr. Pan Honggen	Sub-leader Support Group of Sino & Japan Collaborative Research, Shanghai Fisheries University People's Republic of China	Feb. 17-24, 1999

Mr. Cai Hong fa	Director General China National Rice Research Institute People 's Republic of China	Feb. 21-27, 1999
Mr. Lu Yong liang	Section Chief China National Rice Research Institute People 's Republic of China	Feb. 21-27, 1999
Ms. Xu Qing	Deputy Section Chief China National Rice Research Institute People's Republic of China	Feb. 21-27, 1999
Mr. Ismail bin Awang Kechik	Director Fisheries Research Institute, Department of Fisheries Malaysia Malaysia	Mar. 8-17, 1999
Dr. Henk Breman	Director General International Fertilizer Development Center (IFDC)-Africa Togo	Mar. 13-20, 1999
Dr. Stella Zerbino	Entomologist Instituto Nacional de Investigacion Agropecuaria, La Estanzuela Uruguay	Mar. 22-27, 1999
Dr. Azmi Man	Senior Research Officer Food and Industrial Crop Center Malaysian Agricultural Research and Development Institute (MARDI) Malaysia	Mar. 22-27, 1999
Mr. Ho Nai Kirl	Senior Agricultural Officer Agricultural Division, Muda Agricultural Development Authority (MADA) Malaysia	Mar. 22-27, 1999
Dr. Pham Sy Tan	Head of Agronomy Division Cuu Long Delta Rice Research Institute (CLRRI) Vietnam	Mar. 25-31, 1999
Dr. Vo-tong Xuan	Director Mekong Delta Farming System Research and Development Institute, Cantho University Vietnam	Mar. 26-31, 1999
International Symposium Invitees, FY 1998		
Dr. Le Van To	Director Post-Harvest Technology Institute Vietnam	Sep. 8-12, 1998
Dr. Silvesta C. Andales	Executive Director Bureau of Postharvest Research and Extension The Philippines	Sep. 7-12, 1998
Dr. Jingtair Siriphanich	Associate Professor Kasetsart University Thailand	Sep. 8-12, 1998
Dr . Feng Shuangqing	Director Department of Food Service, China Agricultural University People's Republic of China	Sep. 8-12, 1998
Dr. Ananthaswamyao Ramesh	Head of Food Engineering Department Central Food Technological Research Institute India	Sep. 8-12, 1998
Dr. Bruce R. Champ	Former Consultant Australian Center for International Agricultural Research Australia	Sep. 8-12, 1998

Dr. Filipinas Caliboso	Director Bureau of Postharvest Research and Extension The Philippines	Sep. 8-12, 1998
Dr. Prisnar Siriacha	Researcher Kasetsart Agricultural and Agro-industrial Product Improvement Institute, Kasetsart University Thailand	Sep. 8-11, 1998
Dr. Mulyo Sidik	Assistant to Ministry of Food and Horticulture Indonesia	Sep. 8-12, 1998
Dr. Greg Johnson	Program Manager Australian Center for International Agricultural Research Australia	Sep. 8-12, 1998
Dr. Saipin Maneepun	Director Institute of Food Research and Product Development, Kasetsart University Thailand	Sep. 8-12, 1998
Dr. Josue S. Falla	Director Bureau of Postharvest Research and Extension The Philippines	Sep. 8-12, 1998
Dr. Deng Yong	Director Department of Food Engineering, China Agricultural University People's Republic of China	Sep. 8-12, 1998
Dr. Aman Wirakartakusumah	Vice Rector for Academic Affairs Department of Food Science and Technology, Inter University Indonesia	Sep. 8-12, 1998
Dr. Liu Tin-Yin	Director Food Industry Research & Development Institute Taiwan	Sep. 8-12, 1998
Dr. Cherl-Ho Lee	Professor Center for Advanced Food Science & Technology, Graduate School of Biotechnology, Korea University Korea	Sep. 7-11, 1998

JIRCAS/IPGRI Joint International Workshop invitees, FY 1998

Dr. Bart Panis	Research Scientist Catholic University of Leuvan Belgium	Oct. 19-25, 1998
Dr. David Cyr	Research Scientist BC Research/Silvagen Inc. Canada	Oct. 18-24, 1998
Mr. Yongjie Wu	Research Scientist Changli Pomology Institute People's Republic of China	Oct. 19-24, 1998
Dr. Roosevelt Escobar	Research Scientist Centro Internacional de Agricultura Tropical (CIAT) Colombia	Oct. 19-25, 1998
Dr. Dominique Dumet	Research Scientist University of Abertay Dundee England	Oct. 18-24, 1998
Dr. Poula Reinhoud	Research Scientist Leiden University Holland	Oct. 19-24, 1998

Dr. B.B. Mandal	Research Scientist National Bureau of Plant Genetic Resources India	Oct. 18-24, 1998
Dr. Enny Sudamonowati	Research Scientist R&D Center for Biotechnology, Indonesian Institute of Sciences Indonesia	Oct. 19-24, 1998
Prof. N. Normah	Professor University Kebangsaan Malaysia Malaysia	Oct. 19-24, 1998
Dr. S.Y. Choy Ng	Research Scientist International Institute of Tropical Agriculture Nigeria	Oct. 19-25, 1998
Dr. P.M. Kyesmu	Senior Lecturer Jos University Nigeria	Oct. 19-24, 1998
Dr. Ali Golmirzaie	Research Scientist International Potato Center (CIP) Peru	Oct. 19-25, 1998
Ms. Alfinetta B. Zamora	Laboratory Chief Institute of Plant Breeding, University of the Philippines at Los Banos The Philippines	Oct. 19-24, 1998
Prof. Patricia Berjak	Research Scientist University of Natal South Africa	Oct. 20-25, 1998
Dr. Chalernpol Kirdmanee	Research Scientist National Center for Genetic Engineering and Biotechnology Thailand	Oct. 19-23, 1998
Dr. Barbara Reed	Research Scientist United States Department of Agriculture-Agriculture Research Station (USDA-ARS) National Clonal Germplasm Repository USA	Oct. 18-25, 1998
Dr. Darren Touchell	Research Scientist United States Department of Agriculture-Agriculture Research Station (USDA-ARS) National Clonal Germplasm Repository USA	Oct. 19-24, 1998
Dr. Tien Thinh Nguyen	Research Scientist Nuclear Research Institute Vietnam	Oct. 19-24, 1998
Dr. Maria Elena Aguilar	Research Scientist Centro Agronomico Tropical de Investigation Ensenanza Costa Rica	Oct. 19-24, 1998
Ms. Ana Abdelnour Esquivel	Professor Costa Rica Institute of Technology Costa Rica	Oct. 19-24, 1998

Counterpart Researcher Invitation

The Counterpart Researcher Invitation program provides invitations for periods of up to six months to researchers engaged in collaborative work with members of the JIRCAS research staff. Counterparts conduct in-depth research at JIRCAS, at other MAFF research institutes, at prefectural research institutes, or at national universities. This invitation program aims both to enhance the quality of research conducted in foreign countries and to facilitate exchanges between individual research staff. Thirty researchers were invited under the Counterpart Researcher Invitation program during FY 1998. Invited researchers, their affiliated research organizations, and their research activities are summarized below.

FY 1998

(At Japan International Research Center for Agricultural Sciences, Apr. 1-12, 1998)

Ms. Zhou Li-pin	Shanghai Fisheries University People's Republic of China	Gel formation in freshwater fish meat by ohmic heating
-----------------	--	--

(At Japan International Research Center for Agricultural Sciences and National Institute of Sericultural and Entomological Science, Apr. 1-29, 1998)

Ms. Anchalee Chuaboonmee	Sisaket Sericultural Research Center Thailand	Studies on the physical properties of Thai poly voltine raw silk for warp yarn
--------------------------	---	--

(At Japan International Research Center for Agricultural Sciences and National Food Research Institute, Apr 1-May 1, 1998)

Dr. Vipapom Na Thalang	Department of Research, Kasetsart University Thailand	Study on antioxidant activity of various vegetables
------------------------	---	---

(At Japan International Research Center for Agricultural Sciences, June 27-Sept. 30, 1998)

Mr. Anrullo Gesite	Bureau of Soils and Water Management The Philippines	Introduction of a low cost runoff under sugarcane with various cover crops for erosion control
